Apart from the ordinaries and those other charges that have been mentioned incidentally, there are some peculiarities of heraldic charges that need to be noted. Mythical birds and animals are much used, the product of ancient and medieval natural history-or the lack of it. Such are the dragon, griffin, wyvern, harpy, phoenix, and martlet. In addition, there are some creatures bearing the names of real animals but not resembling them in all respects. The heraldic tiger is more like a lion or a wolf in some features. When the real tiger became known to heraldry, it was described as a Bengal tiger. The heraldic description of animals is very important. Rampant means on the hindlegs, while rampant guardant is the same posture but full faced. Reguardant means looking back; passant, walking. Combattant signifies two animals fighting on hindlegs, Couchant is lying down; dormant, sleeping; and sejant, sitting. A beast of the hunt is called at gaze when looking full face, trippant when at trot with one foot raised, and statant when standing. Parts of an animal may be a charge; e.g., a demilion or demiwolf, a lion's or bear's gamb or foreleg. Heads are described as erased when cut off by a jagged line, couped when cut by a straight line, and caboshed when the severed head looks straight forward. A bird shown with wings expanded is said to be displayed. Creatures placed back to back are addorsed. A fabulous bird, the phoenix, is known to heraldry; also known was the legendary pelican that fed her young on her own blood and was called "in her piety," then being considered an emblem of Jesus Christ, who fed or redeemed his flock with his own blood. The martlet is another fabulous bird widely known outside heraldry, owing to John Milton's reference to the herald's martlet, which has no legs. It is a frequent charge, resembling a swallow, and is used in cadency to denote the fourth son. Other terms have special heraldic significance. Armed is used of the horns, teeth, or . claws of a beast, or the beak or talons of a bird, and of the human being when in armour. The term slipped applies to flowers and fruit when the stalk is seen. Counterchanged refers to the field when it has two tinctures, a metal and a colour, and when one is the background for the other on one side of the shield but the relationship is reversed on the other side. An example is the Warner arms: "per bend argent and gules two bendlets between six roses all counterchanged," where the three roses on argent will be

gules and the three on the gules will be argent. The field is

separated by a partition line and the charge or charges of the arms are said to be countercharged when the charge or portion of a charge that lies on the metal is of the colour and vice versa.

THE READING OF HERALDRY

A method has been devised to indicate heraldic colours in black-and-white illustrations. Known as the system of Sylvester Petra-Sancta, an Italian herald, it makes use of the following equivalents: or is denoted by dots or points, azure by horizontal lines, vert by lines from dexter chief to sinister base, purpure by lines from sinister chief to dexter base, argent by a plain field, gules by perpendicular lines, and sable by cross lines horizontal and perpendicular. Furs are depicted with black or white spots on the appropriate ground; vair and countervair are shown by alternate lines and plain surfaces

Describing, or blazoning, of arms must always begin with an identification of the ground of the shield, such as argent or gules or ermine. For a woman who is not married, the arms normally appear on a lozenge, not a shield, but the field or ground in this instance, too, must be the start of the blazon. Then come the charges. A typical blazon is thus: "sable [ground of shield] a chevron ermine between three lions rampant argent crowned or" (arms ascribed to a family of Hinstoke). The chevron is a fur; the lions are silver, appear on the sides of the chevron and its base, and have gold crowns. One important feature in heraldic writing is economy of words. Technically, it should be possible to avoid punctuation marks, thus: "azure a fess between three stags trippant or" (Hind). Here both fess and stags are in gold. When three beasts are depicted, they

are shown in the most convenient way around the main charge; that is to say, two in the upper part of the shield Drawing by Wm. A. Norr An engrailed figure is scooped out along its edges, leaving a series of points. An invected figure is scalloped, leaving similar series of a fess extending inward engrailed embattled dancetté nebulé (deep) nebulé (shallow)

A line described as flory, or flory counterflory, employs a series of small fleurs-de-lis that have substance of their own beyond the two areas being divided. Rayonny (or rayonné) may alternate straight points with curved points.

and one below. A straightforward coat with only one charge on the field is that of the Italian Segni family of Agnani, which gave to the church the popes Innocent III, Gregory IX, and Alexander IV: "gules an eagle displayed chequy sable and or." Economy, however, can be carried too far as in the following: "azure a lion rampant double queued barry of ten argent and gules armed and langued of the last crowned or, within a bordure of the second and third" (Mountbatten). Here is an example of a usage that grew up in past centuries and was designed to avoid repetition of the name of a tincture but in reality served to create confusion. "Of the last" means that the lion's claws and tongue are in red or gules. "Of the second and third" means simply argent and gules. There is no real economy since more words actually are used and reference has been made to the earlier parts of the blazon. This type of blazon is used when a large amount of heraldic insignia has to be described, but it makes such long blazons unnecessarily complicated. Anyone who is writing a blazon should not use this jargon of last, first, second, and so on.

Conventional representations of tinctures used by engravers and others when actual colours are not practicable.

The helmet is the next item to be characterized, although in blazons it is usually taken for granted and left undescribed. When it is mentioned, it is said to be "befitting his degree." Although the helmet need not appear in written descriptions, it always should be depicted in illustrations. It is a bad feature of many drawings that the helmet is absent, showing the crest as if it were airborne above the shield and thus unsupported. The crest must always be mentioned when, as in the vast majority of cases, one exists. In formal blazons, the wreath (also called the torse) is given as well; thus, crest-"on a wreath of the colours, a wolf passant proper" (Trelawny). The wreath is not usually mentioned, however, because like the helmet it is always assumed to be there. The term colours refers to the two chief colours of the ground of the shield. As with the shield, the older the crest, the simpler it will be. Most people can envisage on a knight's helmet the figure of a wolf walking, but it is difficult to picture someone in armour wearing as his head crest "the stern of a Spanish man-of-war on waves of the sea all proper thereon inscribed 'San Josef' with the motto above, 'Faith and Works' " (Nelson). This latter example belongs to the period of decadent heraldry in the late 18th century and 19th century in England.

The mantling, or lambrequin, is mentioned in formal descriptions but not in general usage. The supporters and compartment pertain only to a few classes of arms bearers, and in descriptions the supporters are blazoned after the crest (or crests). The compartment is not usually described

but sometimes has to be, as in the arms of the earl of Perth: supporters (two savages = two ancient Caledonians) stand on "a compartment strewn with caltraps" (from "caltrops," iron instruments designed to maim horses' feet and used by the Scots with great effect at the Battle of Bannockburn, 1314).

The motto comes at the end of the description, not being part of the arms. The badge is rarely found, except among very historic families (and by a strange inversion in some 20th-century grants), but when it occurs it, too, comes at the end of the blazon. It can be very simple, as with that of Lord Mowbray, Segrave, and Stourton-"a sledge or." It may be very elaborate, as with Constantine-"a hurt [i.e., a roundel in azure] charged with a leopard's face and surmounted upon the edge with two fleurs-de-lis in pale or, and as many roses in fess, argent, barbed and seeded proper." In this example the roses are silver but the leaves are proper. Coronets of rank are not usually mentioned in English or Scottish heraldry, but caps of maintenance and crest coronets must be blazoned with the crest. Banners and standards are not as a rule mentioned in blazons. though they may be when they occur in a modern grant.

MANIPULATION OF HERALDIC DESIGN

It is clear that the vast majority of heraldic charges are without the foundation of legend often assigned to them, though in many instances the real origin of the charge is lost. A Jacobean dramatist could write of a family as old as the first virtue that merited an escutcheon—a nice poetic flourish that should remain in poetic realms. In modern grants the heralds try to give some allusion to the grantee's work and achievements and his place of origin, and canting arms still appear. Many arms are recondite, however, in their significance, and much has to be learned before the significance of the charges is known.

Cadency. The rules evolved over the centuries to denote particular distinctions in heraldry are fairly straightforward. Cadency is the use of various devices designed to show a man's position in a family, with the aforementioned basic aim of reserving the entire arms to the head of the family and to differentiate the arms of the rest, who are the cadets, or younger members. Heraldic works in the 16th century refer to cadency marks as: a label for the eldest son during his father's lifetime; a crescent for the second son; a mullet (five-pointed star) for the third; a martlet (a mythical bird), the fourth; an annulet (a small rug), the fifth, a fleur-de-lis, the sixth; a rose, the seventh; and so forth. These marks were not always used in the Middle Ages. Differences might be shown instead by a

Marks of cadency, used to difference the arms of cadets of the same family. The label, the mark of the eldest male heir, is a notable feature of the arms of the prince of Wales, the heir to the throne The second cadet displays a crescent, the third a mullet, and so on. These symbols may be of any tincture and may be used otherwise than as signs of cadency.

wing by Wm. A. Norm

change of tincture, by adding small charges to the field, and the like. Both on the Continent and in England, rules of cadency have long ceased to be used. It is customary for all members of a family to use the entire arms of the head. There are, however, two exceptions. Very occasionally, a crescent is used for difference by a noble family showing descent from a second son. The other exception occurs in the arms of the British royal family, in which the cadency system exists in rigour. The reason is that the royal arms are arms of sovereignty and cannot be shared. The sovereign alone can have the whole undifferenced arms. Nor does any member of the royal family-not even the prince of Wales-have any right to the use of arms until they have been granted to him by the sovereign. A label of difference with marks is placed on the arms; a threepronged label for the children of the sovereign, a fivepronged label for grandchildren. The Duke of Windsor after his abdication as Edward VIII in 1936, was granted arms with a label

In Scotland the position on cadency is very different. Since heraldry is regulated in Scotland by acts of the Scots Parliament before the Union in 1707 with England, and confirmed by the British Parliament, the regulation of arms is very precise. The strict observance of cadency is probably because the Celtic clans formed the original social system in Scotland before the advent of feudalism. Thus only the chief of the name can have the entire arms. He matriculates, or enters his arms, in the registers of the Lord Lyon King of Arms (whose court has jurisdiction over armorial bearings in Scotland). This registration also applies to his eldest son (subject to suitable differencing of the arms) who inherits them in due course. The younger sons must petition for a matriculation of the paternal arms with a suitable difference indicating the position of each in the family. As families from the descendants of the original grantee continue to be established, so there is matriculation and rematriculation, in a carefully prescribed manner.

Arms of women

A woman adopts the undifferenced arms of her father. An unmarried woman: the arms of her father are displayed on a lozenge; a true lover's knot signifies unmarried status. A married woman: the wife's arms, to the sinister, impale those of the husband, to the dexter; the husband displays the combined arms as head of the family, and the wife shares his escutcheon. A widow: the woman's arms revert to the lozenge, retaining the deceased husband's impaled arms.

Arms of women. Arms of women are shown during spinsterhood or widowhood on a lozenge, not on a shield. without a crest (except in Scotland, where a woman who is chief of a clan and head of the name, such as MacLeod of MacLeod, is allowed a crest). A woman divorced and not remarried also uses a lozenge. The arms of a married woman are shown in conjunction with her husband's by impalement, the division of the shield into two equal portions, the husband's arms on the dexter and the wife's on the sinister. Should she be a heraldic heiress, the arms of her family are placed upon an inescutcheon (originally inner escutcheon) or "escutcheon of pretence" (a small shield whose position in the fess point of the husband's shield gives it precedence over all of the other parts of the shield). The only exception to these rules for women is that of a queen regnant like Elizabeth II, who, being sovereign and thus considered in heraldic terms to be heaself the source of honour for all her subjects, possesses the full arms of sovereignty of her royal house and kingdom. In the Middle Ages, arms for women were often shown on shields, and those like Joan of Arc who bore arms in battle may have used crests.

Royal arms of England as used from Henry V's time, quarterly France and England, first used by Edward III but by him with the French quarter showing strewn fleurs-de-lis. Roof boss from St. George's Chapel, Windsor Castle, 1483-1528

Quarterings and marshalling. In the quarterings and the marshalling arrangement of more than one coat of arms in the same shield, the position of heiresses must be considered first. The children of a heraldic heiress are entitled on her death to quarter her arms with their father's (the arrangement is to show the shield divided into four quarters so that quarters 1 and 4 are the father's arms, 2 and 3 the mother's). This positioning of the quarterings is also used in England when an additional surname and arms are taken, almost always in obedience to a will. This is the "name and arms" clause peculiar to English law. Its operation over the last 200 years is responsible for the double- or treble-barrelled surname common in England and also found in Scotland. Thus in Salusbury-Trelawny, the original Trelawny arms appear in quarters 1 and 4 and the assumed additional arms for Salusbury in 2 and 3. A famous historical case is that of King Edward III of England, who in 1340 claimed the throne of France in right of his mother, a French princess. He then quartered the lilies of France (the fleurs-de-lis) with the lions (leopards) of England. England should have been placed in 1 and 4, but Edward gave this position to France, probably because of the greater size and resources of France at that time. In this form, the royal arms continued until 1800, when the empty title of king of France was dropped and the lilies went out with it.

When quarterings are inherited from a woman, no crest is transmitted with them, because a woman cannot pass

Heirship through the female lines.

marshal-

coats in

one shield

ling several

on a crest. The matter alters, however, when additional arms are taken in obedience to a will; then a double crest is likely. There is no reason why a further assumption may not occur, so that triple or quadruple hyphenated names are found: for example, the English county family Sawbridge-Erle-Drax has quarterly arms, 1 and 4 Drax, 2 Erle, and 3 Sawbridge. This type of quartering is not difficult to follow, but a real problem in marshalling several Problem of coats in one shield arises when more than one heraldic heiress occurs in the same family. Some families of long descent have often married heraldic heiresses, acquiring many quarterings. Sometimes several hundred quarterings are attributed to the head of a great family. A splendid instance of quartering occurred in the achievement of the empress Maria Theresa. Before her accession to the imperial throne she was queen of Hungary and Bohemia and by marriage grand duchess of Tuscany. As a sovereign in her own right she bore a shield on which there were 29 quarterings. The dukes of Rohan-Chabot in France bore a quartered shield with Navarre, Scotland, Brittany, and Flanders; overall was an escutcheon of Rohan quartering Chabot

Even without such large numbers of arms to deal with, the marshalling of quarterings is still a problem. Various methods have been tried, often with results as difficult to decipher. An interesting illustration of the marshalling of several coats of arms is that of the baronet Cameron-Ramsay-Fairfax-Lucy. The arms are said to be quarterly with the arms of Lucy in 1 and 4. Then in 2, the description runs, grand quarter counterquartered. This means that quarter 2 is itself a quarterly coat, 1 and 4 of which are for Fairfax, 2 for Ramsay, with the third quarter counterquartered; i.e., itself quartered, showing two coats of arms. The third quarter is that for Cameron.

Arms of bastardy. The heraldic illustration of bastardy was achieved in several ways in the older days of chivalry. Little social or moral obloquy attended the status of bastardy, possibly because of the late marriages of the upper classes and their arranged unions. Thus the arms of a

bastard were merely differentiated as perhaps those of a distant cadet line would be. From early times the bend or bendlet sinister was used. The erroneous use of bar sinister might have come about because the French for bend sinister was une barre. In the arms of British royal bastards like the dukes of St. Albans, of Buccleuch, of Grafton, and others, a baton sinister is used to denote bastardy. The royal arms of these illegitimate scions are said to be "debruised" (crossed or partly covered) by the baton sinister. English heralds in the last 150 years have

often signified bastardy by the use of the bordure.

Nonfamilial heraldry. The arms of grantees other than families or individuals are often encountered. In modern times the granting of arms to private persons has ceased in some countries where grants of corporate arms are frequent. In Sweden, for example, grant of neither title nor arms occurs, but grant of arms to public bodies, such as local administrative units, is frequent, Historically, it was an easy passage from the arms of individuals to those of corporate bodies. This is particularly evident in the military sphere, where the great crusading orders led to the many important orders of chivalry in the principal European countries. The Elephant of Denmark, the Golden Fleece of Spain and of Austria, the Holy Spirit of France, the Garter of England, and the Thistle of Scotland were all preceded by the orders of military monks, and all have insignia that contain heraldic features and that occur in many arms illustrations. Most of the older bishops' sees have official arms; in the Anglican Church the missionary bishops as well as the diocesan bishops have arms. In the Roman Catholic Church the episcopal sees all have arms; and new arms are granted by the pope, who, as head of the Vatican state, is a temporal sovereign as well as spiritual head of the church. The arms of the popes often contain charges that are added to their individual arms after their election to the papacy or to earlier ecclesiastical office.

Dominion and colonial arms are necessarily interconnected with royal arms, since the British crown in each country is or was the source of honour and must have granted arms to its various territories. Because of the vast extent of the former British Empire, the richest collection

of arms of dominion is to be found in the numerous members of the Commonwealth, Canada, for instance, has arms for the sovereign of Canada as authorized by George V in 1921, and the 12 provinces of Canada have similar arms approved by the sovereign. Much the same is true of the former French colonies, though there was no sovereign to grant the arms. The arms of political units are used throughout the Western world. The cities and boroughs of the United Kingdom, for example, have their heraldry, as do the U.S. states.

The blazoning of these nonfamilial arms is conducted on the same principles as for family arms, except that the explanation of the charges is usually forthcoming.

The arms of Canada, derived from the royal arms. The three maple leaves in the base, originally green, were altered to red to conform to the new national flag adopted in 1964. French traditions and ties are represented by the gold fleurs-de-lis and the white lilies in the compartment.

Historical development of heraldry

The exact date or place of origin of the heraldic system in western Europe in the 12th century is not known; neither are the precise reasons for its introduction. But limits can be drawn to indicate generally when heraldry began, and probable reasons for its emergence can be deduced. The Bayeux Tapestry, produced in the last quarter of the 11th century in Bayeux, France, is a pictorial record that shows conditions in everyday life and in warfare at the time of the Norman Conquest of England. The English and Norman soldiers are armed alike. None of the Englishmen has a design of any kind on his shield or armour. In a few scenes, Normans or Frenchmen have designs on their shields that have a rough heraldic resemblance. In scene VIII of the tapestry, four of the followers of Guy, count of Ponthieu, have shields with these devices: some kind of creature holding what appears to be a fish in its mouth, a rough design emerging from the left side of the shield, a cross, and an animal resembling a sheep. In scene XII the messenger of William the Conqueror bears a winged creature on his shield, and this reappears in scenes XIII and XV. In scene XVIII a cross or a variant of it is seen on a shield, but this was probably a boss (metal protuberance) to strengthen it. Scene LXXV has a Norman knight with a design of a birdlike creature on the shield, but generally the Normans shields have only bosses in the middle.

In 1066, at the time of the Conquest, heraldry clearly did not exist. The most that can be said is that possibly some of the rudiments out of which it emerged were present. Even at the time of the First Crusade (1095-99), there is evidence that heraldry was not yet in use. The Alexiad, the history of the Emperor Alexius (reigned 1081-1118) written by his daughter, the princess Anna Comnena, contains a vivid description of the Frankish barbarians-as the Crusaders appeared in the eyes of the civilized Byzantines. The Princess gave a careful account of the Crusaders' armour. She said that Alexius exhorted his archers to shoot at the Franks' horses rather than their riders, whose armour rendered them almost invulnerable. "For the Frankish weapon of defence is this coat of mail, ring plaited into ring, and the iron fabric is such excellent iron that it repels arrows and keeps the wearer's skin unhurt. An additional weapon of defence is a shield which is not round, but a long shield, very broad at the top and running out to a point, hollowed out slightly inside, but externally smooth and gleaming with a brilliant boss of molten brass." The shields in her description, therefore, are similar to those depicted in the Bayeux Tapestry, Thus, all the pictures from later times of King Alfred the Great, William the Conqueror, or Charlemagne bearing coat armour can be disregarded as anachronisms.

EARLY ROOTS OF HERALDRY

Not until a generation after the First Crusade does unmistakable evidence of heraldic designs appear. The earliest evidence is in an enamel (Musée de Tessé, Le Mans, France) made not later than 1151 showing Geoffrey, count of Aniou, bearing a shield azure with possibly four rampant golden lions (the exact number is not discernible because of the position in which the shield was depicted). The count was the son-in-law of King Henry I of England (reigned 1100-35), and, according to a chronicle, Henry in knighting Geoffrey bestowed upon him a shield that bore painted lions. In addition, from 1136, heraldic devices appear on seals. It is possible that the insignia were used first on seals and later on warriors' shields. Simultaneously, body armour was becoming all-enveloping, and some means of distinguishing men in full armour became necessary. The heavy barrel-type helmet closed in the wearer's face except for the opening of his visor, and a mixture of plate and ring mail enclosed the whole body. Another factor was the Crusades, in which men from different lands had to be distinguished from one another.

Within a few years heraldry was found throughout all of western Christendom. The first English king to bear arms was the crusader Richard I the Lion-Heart (1157-99). The three gold leopards or lions of England have been used by every dynasty since his time.

Bayeux Tapestry record of

The first unmistakable evidence of heraldic designs

Plaque from the tomb of Geoffrey Plantagenet, count of Anjou, enamel, Limoges school, c. 1151–60. The stylized pattern of blue and white liming the figure's cloak represents a series of squirrel skins, called vair, frequently mentioned in blazons. In the Musée de Tessé, Le Mans, France.

Seals. The earliest body of evidence of heraldic insignia is found in seals, large numbers of which have been preserved in England, France, and Germany, with fewer surviving in Spain and Italy. For the first century of heraldry, seals supply the bulk of information. It is from seals that the rise and development of the English royal arms can be traced. Seals from the first years of Richard I's reign show the design of a lion rampant to the left side. Some scholars think that two lions were used, since only half of the shield can be seen. Seals from the end of Richard's reign bear the three lions or leopards that have been used by all subsequent English sovereigns. The adoption of the same coat of arms by subsequent dynasties is also found in the royal arms of Sweden and of Denmark; but unlike the English, those royal families place their family arms on an inescutcheon in the middle of the shield.

Roll of arms. Next to seals as evidence of heraldic usage come the rolls of arms, which in England date from about 1250. These are lists of arms, often with pictures drawn ("tricked") on the rolls, of persons who were present on a particular occasion, such as at a tournament or on a military expedition. England and Belgium (Flanders) are rich in the rolls of arms. France, Spain, and Scotland have fewer surviving examples. In place of the rolls, collections of painted books of arms have been preserved in Germany. A notable roll is the Armoral de Berry, dating about 1445, the work of a French herald, Gilles le Bouvier, who travelled widely and recorded arms borne in France, England, Scotland, Germany, Italy, and other European countries.

Records in stone and glass. Another very important source of information is to be found in representations on stone, wood, glass, and in books and engravings. Over the gateway of Bodiam Castle in Sussex can be seen the arms cut in stone of three owners of the castle, the families of Bodiam (who took their name from the place), Wardedieux, and Dalyngrygge. Of such arms nothing would be known without these centuries-old memorials. In Rome, many examples occur of the arms of various popes in their palaces and other buildings, for instance the bees of the Barbarini pope Urban VIII in the Palazzo Venezia. Heraldic glass is usually much more recent in origin but of immense value in supplying information as it is always in colour, while other memorials often are not. Very few churches of any great age in western Europe are without armorial illustration. Switzerland in particular has splendid memorials in stained glass; for example, the Dom, or main Protestant church in Berne, has windows that are aflame with glorious heraldic colours. Sweden has a fine collection of coloured plaques of arms in the House of Nobles in Stockholm; in the Frederiksborg Slot (castle) at Hillerød, Denmark, may be seen the shields of the Knights of the Order of the Elephant, in which can be read the history of heraldry over several centuries.

Church brasses: Brasses in churches are an important source of heraldic information. It was formerly the custom to put a brass tablet over the grave slab, and on this would be shown a figure of the deceased with his armorial bearings. Many fine examples of this are found in old English churches. A very fine collection of floor brasses is in the small church of Stopham in Sussex, which has been the memorial place of the local Barttellot family for many centuries. Also found in churches are hatchments, heraldic paintings on wood that were made for deceased persons and hung over their house doors, being later set up in the local church where they have often been preserved.

iousts and

tourneys

As for written material-such as official enactments, grants of arms, and books-nothing is dated earlier than the 14th century.

GROWTH OF HERALDRY AFTER THE 13TH CENTURY

The initial meaning of the term herald is uncertain. Some authorities derive the word from two German words-Heer, "a host," and Held, "a champion"-not a very obvious etymology. It is clear that heralds were in existence from the 13th century, if not earlier. In their beginnings they were more or less menials, ranked with the jugglers and the minstrels. First used as messengers who wore Messengers livery, they later were used in the jousts and tourneys to announce the contenders. To identify the knights, they had to know the arms on the shields, and from this grew their knowledge and skill in heraldry.

Heraldic colleges and offices. From this lowly origin have come the colourful figures of the English College of Arms, who now alone, save for the Scottish heralds, possess a high position in the modern world. The Lord Lyon, the head of the Scottish heralds, derives his office from a much higher source than do the heralds in other parts of Europe. The Sennachie, or official bard of the Scots' king, was the record keeper of the old Celtic kingdom of Scotland, and from the Sennachie is derived the Lord Lyon, a great officer of state in Scotland.

The older statements found in many books that the medieval heralds were either identical, or in some way connected, with the old Greek kervx or Latin fetialis need only be stated to be dismissed. Since ancient times men have been found who, because their persons were accepted as sacred, were able to carry messages and other communications between nations either hostile or strange to one another. These ambassadors bore several names before the development of a diplomatic corps. In the earlier Middle Ages, for instance, churchmen, monks, or priests were used for this type of service. When William I the Conqueror sent a messenger to Harold II of England, it was a monk who carried William's denunciation of Harold Heralds were not then in existence.

As they ascended the social scale, heralds began to serve as ambassadors between the different courts, a function that was still theirs in the first half of the 17th century. In 1627, for example, Sir Henry St. George was joined in a commission with Lord Spencer and Peter Young to present the insignia of the Order of the Garter to Gustavus II Adolphus, king of Sweden, who then knighted Sir Henry and granted him an augmentation to his arms showing the royal arms of Sweden.

At first every great noble had his herald, and the royal heralds were distinguished from the others by the greater importance of their masters. Gradually, it came about that a king would form his heralds into a college or corporation. The King of France did so in 1407: it was not until 1484 that the King of England followed by establishing the College of Arms, which has been housed for 300 years in the same building in London. The English College, sometimes called the Heralds' College, has outlived all similar elaborate establishments in Europe, except that in Scotland. Outside Great Britain, heraldic offices are found in the 20th century in Sweden, Denmark, the Republic of Ireland and Spain

The English College is under the control of the earl marshal, an office that has been hereditary in the family of the duke of Norfolk since the 1660s. The holder of the dukedom is always earl marshal. Under him are 13 officers of arms; three kings of arms (Garter, Norroy and Ulster, and Clarenceux); six heralds (Windsor, Richmond, York, Lancaster, Chester, and Somerset); and four pursuivants (Rouge Dragon, Rouge Croix, Bluemantle, and Portcullis). These medieval names are derived from sources connected with royalty, titles, badges, or orders of knighthood. Pursuivants are "followers," or junior heralds. In Scotland the Lord Lyon is the head of the heraldic officers, of whom there are three heralds (Albany, Marchmont, and Rothesay) and four pursuivants (Carrick, Kintyre, Unicorn, and Ormond). In England and Scotland the officers are not civil servants but members of the sovereign's household. In both countries there are also heralds extraordinary, who

are appointed at times for special reasons or functions. Records and grants. In England an important development came with the Heraldic Visitations. From 1530 in the reign of Henry VIII to 1686 in the reign of James II, commissions were issued by the sovereign to the heralds directing them to proceed to a county in England or Wales and to inspect the arms in use there. The records of the Visitations have been preserved and constitute a valuable body of genealogy as well as of heraldry. From the period of the Visitations the heralds built up huge collections of

family history and began to record pedigrees. From about a half century before the foundation of the College of Arms, the English heralds are found to be issuing grants of arms on behalf of the sovereign. This is some 300 years after the first appearance of heraldry, which obviously much antedated not only royal colleges or corporations of heralds but even the existence of heralds themselves. From this evidence, it seems clear that in the early days of heraldry men assumed arms to suit themselves without reference to any authority. A very simple coat of arms would not be difficult to invent. That three unrelated persons from three different counties could bear these same arms is not only not surprising but proof that the arms were self-chosen. When disputes over ownership among the three came up, the matter was referred to the king. His judgment was final, but it is noteworthy that one of the defeated, compelled to give up his arms, then consoled himself with a new coat that was also self-derived and self-assumed. Unquestionably, the great majority of ancient coats of arms, borne before 1500, were never granted but were taken by the owners.

Writers on heraldry. The earliest writing on heraldry extant is a short treatise by Bartolo da Sassolerrato, whose Tractatus de insigniis et armis ("Treatise on Insignia and Arms") was published about 1356. In his small book Bartolo describes the various categories of arms bearing and how they have been assumed. He refers specifically to arms granted by a prince and gives reasons for their value but asks why one man may not bear arms identical with those of another.

In 1355 Bartolo had been sent to Pisa from Perugia as an envoy to the Holy Roman emperor, Charles IV, from whom he received many privileges, including a grant of arms, which were the same as those of the Emperor as king of Bohemia but with changed incuture: "or a lion rampant with two tails gules." An American scholar, L.M. Mladen, remarked of this grant and others made by Charles IV at the same time: "Charles was in all probability the first ruler ever to grant arms. To my knowledge, no earlier occurrence has been found."

The first English heraldic writer was John of Guildford, or Johannes de Bado Aureo, whose Tractatus de armis ("Treatise on Arms") was produced about 1394. Then came a Welsh treatise, the Llyfr arfau ("Book of Arms"). Nicholas Upton, a canno of Salishury Cathedral, about 1440 wrote De studio militari ("On Military Studies"). John of Guildford's treatise was printed in 1654 with Upton's work and the Aspilogia of Sir Henry Spelman by Sir Edward Byshe, Garter king of arms, who edited and annotated all three works. The whole was in Latin; no complete English version of Upton's book has been published.

These books are by authorities who were concerned with the realities of heraldry in their own day. A tendency away from actuality and toward the fanciful and absurd manifested itself from the end of the 15th century. Some of these farfetched conceits showed themselves in *The*

Boke of St. Albans (1486). Yet by comparison with the vast mass of nonsense contained in the folios of the 16th century, those conceits were reasonable. The works of Sir John Ferne, Blazon of Gentrie (1586), Gerard Leph, The Accedens of Armorie (1562), and John Guillim, A Display of Heraldrie (1610) not only perpetuate the nonsensical natural history of olden days but are largely responsible for the belief that heraldic charges have a definite symbolic meaning and that they were granted as the reward of valorous deeds.

Continental versus British heraldry. Much greater significance was attached in former times to heraldic insignia, though the attitude varied from country to country. Heraldry has become more widespread than at any other time, but as a sign of rank it has hardly any remaining value.

A distinction can be made between the Continent and Great Britain regarding medieval and later heraldry. The doctrine of the Seize Quartiers (16 quarterings) prevailed over most of the Continent but not in Britain. This theory required that, in order for a person to claim nobility, all of his 16 ancestors (16 great-great-grandparents) should have been entitled to bear arms. This is known as the "Proof of the Seize Quartiers" and was the reason why Frederick II the Great of Prussia, though professing the views of the Enlightenment in the Age of Reason, diligently scrutinized his courtiers' quarterings. The theory is based on the rigidity of a noble caste that married only with its own kind. On the Continent, every member of a noble family is noble; hence the enormous numbers of titles. Similarly, the continental royalty tended to marry only with other royal families. As a result both royal and noble families formed a class apart from the bulk of the people.

Continental heraldic insignia, therefore, from their origins until the late 18th century, provided symbols to indicate a higher caste and, in fact, were signs of nobility. Yet, strangely, in several countries heraldry was in wide general use as a means of identification, serving in the same way as a surmane. In France, for example, it is abundantly clear that from the 13th century, not only the bourgeoisie of the towns but also the peasant born heraldic arms. The usage had percolated down from the noble class. The carliest example of the use of arms by a peasant is that of Jaquier te Bretoit in 1369, whose arms show a punning allusion to his name (brebis, 'sheep'—three sheep held by a girl), in other European lands—Hungary and the Low Countries—burgher or peasant arms were also found, but neither in these lands nor in France were the possessors

regarded as noble. In France the regulations of arms followed a quite different course from those in England, Although King Charles VI had in 1407 led the way in creating a college of arms, his heralds lost influence over the next two centuries. They had no power, unlike their Scottish and English counterparts, to grant arms and they gradually faded into insignificance. To overcome the loss, Louis XIII in 1615 appointed a juge géneral d'armes ("general judge of arms"), an official whose powers resembled those of the Lord Lyon. The French royal government showed itself very broad-minded on the possession of arms. A decree of Louis XIV in 1696, designed to raise money, ordered all persons who bore arms to register them. Even those who were not part of the arms-bearing population were forced to buy arms. Later, in 1760, an ordinance was framed by which the lesser townsfolk, artisans, and peasants were to be excluded from the use of arms-after these classes had used them for 400 years. But the Parlement of Paris refused to allow the ordinance to be implemented. Later, during the French Revolution (1789), arms were suppressed as signs of feudalism.

The view of arms held in England was and is quite different. No such thing as a noble caste has ever existed in England. Only the reigning peer and his wife are regarded as noble; the rest of the family are commoners, and only a few of them bear what are called courtesy tiles. Moreover, except for the Hanoverian (1714–1837) and Victorian (1837–1901) peochs, the royal house has not necessarily married royalty but much more often the nobility, a practice to which it has returned in the present century. As a result, the Continental doctrine of Seize Quartiers does a result, the Continental doctrine of Seize Quartiers does Seize Quartiers

Peasant and bourgeois

The trend to the nonsensical after the 15th century A matter of clan and family in Scotland

Ireland

Herald of

not apply in England. It cannot, since noble and nonnoble are so mixed. Nor are there any such things as nonnoble arms. All arms are on the same basis; all are signs of gentility-nobility, in fact. Arms then have long had a high social significance in England; those who possess them have social prestige. The situation is somewhat different in Scotland where arms are bound up with clanship and family solidarity. To the Scotsman, arms are not so much a matter of social status as of family or clan, and he proves his right to them by process of law in Lyon Court.

20TH-CENTURY HERALDRY

France and Italy. Without a monarchy, heraldry can still flourish, but it does not normally do so. The French Revolution abolished arms, which returned with the monarchy, and now, although France is a republic, a person assuming arms to which he is not entitled may be prosecuted. In the same way, it is not permissible to assume a name of a great family. In England, however, the assumption of the name Windsor (the name of the British royal family) is possible for anyone. There is, however, no recognized heraldic authority in France, nor for that matter in other European countries that have abolished their monarchies. Most such republican states have associations that seek to maintain heraldic standards. Thus in Italy the Collegio Araldico (Heraldic College) consists of experts whose main object is to promote heraldic and genealogical studies. An association of nobles was formed as the National Heraldic Council of the Italian nobility. under the authority of former king Umberto II; it tries to regulate the use of arms and titles.

Many changes in heraldry have taken place since 1945, as it is not a static subject.

Communist countries. In communist European countries, the study of genealogy and heraldry had been generally suppressed. Since about 1956 it had been possible to obtain much more statistical information from the U.S.S.R. (until its dissolution in 1991) than formerly, but no heraldic data were supplied. Much the same was true of the other communist countries in Europe. Under communist regimes, heraldry was viewed as it was by the French revolutionaries, as part of the feudal past, although there is reason to believe that heraldic archives were in many cases carefully preserved.

Ireland. A different development occurred in two of the republics that have emerged from the British Empire-Ireland and South Africa-both of which have set up their own heraldic offices. As early as 1382, there was an Ireland King of Arms who was responsible for all matters armorial in that country. The last holder of the office died in 1487, and in 1553 Edward VI created a new armorial king under the title of Ulster, to control bearings throughout Ireland. His place of business was in Dublin Castle. When the Irish Free State, or Eire (now the Republic of Ireland), was established in 1921-22, the Ulster Office was reserved as an appointment of the British crown with the thencurrent Ulster to hold office for life. After his death in 1940, an arrangement was made between the British and Irish governments by which the heraldic office in Dublin Castle with its records was taken over by the Irish authorities. Photostat copies were made of the records and sent to the College of Arms, London. The Irish government appointed a Chief Herald of Ireland, and the Ulster Office became known as the Genealogical Office. A civil servant was then appointed as Chief Herald of Ireland. The office of Ulster King has now been united with that of Norroy King in the College of Arms, London. The Irish Herald carries out the duties formerly performed by Ulster in the 26 counties of the Republic of Ireland; Norroy and *Ulster has jurisdiction over the six counties of Northern

Ireland (Ulster). South Africa. In South Africa an act was passed in 1962 under which was established a Bureau of Heraldry and a Heraldry Council for the grants, registration, and protection of coats of arms, badges, and other emblems. A state herald is appointed as head of the Bureau of Heraldry. The Heraldry Council consists of the state herald and at least seven other members appointed by the government minister responsible.

The United States. There has been a remarkable evolution of heraldry in the United States. Ever since the American Revolution, the use of arms, especially of arms of English families with whom the users were related or whose surname they bore, has continued. The English College of Arms claims heraldic jurisdiction over persons of English and Welsh descent (Wales has been reckoned with England in this and all other administrative matters since the union of England and Wales, 1542). The Lord Lyon of Scotland claims jurisdiction likewise over persons of Scottish descent throughout the world. In addition, the English College at one time claimed a worldwide imperial jurisdiction over anyone who could be brought within the definition of British subject. Under this jurisdiction even the Indian princes were occasionally granted arms by the College of Arms, although they were not British subjects but independent rulers who had entered into treaty relations with the British crown. Many Americans have been granted arms by the college by virtue of their descent from English or Welsh forebears or by the Lord Lyon if they are of Scottish descent. Irish Americans often were granted arms from Dublin, from either the Ulster King or his successor. Americans of Northern Irish descent have been granted arms by Norroy and Ulster. In addition, there are several states of the United States that were formerly Spanish territory, and the Spanish Kings of Arms, the equivalent of the English and Scottish heralds, exercised a heraldic authority over persons of Spanish descent in the old Spanish Empire. By extension, they have recently granted arms to Americans who are resident in those formerly Spanish states but who are not of Spanish descent.

To these classes of arms obtained by Americans from overseas must be added such instances as the award of arms to Pres. Dwight D. Eisenhower in Denmark. Also, Americans of French, German, Italian, Polish, and other European origins have inherited from their immigrant ancestors arms once granted or recorded by heraldic authorities no longer in existence. All these classes of arms share one feature whatever their origin; they are hereditary honours granted to American citizens by other countries. As they do not carry titles, they do not contravene the principle of the American Constitution on this subject. An American who receives a knighthood of some foreign state possesses only an honorary knighthood; he is not "Sir." But for the citizen of an independent sovereign power to approach and receive from another power a hereditary honour has seemed to many Americans an undesirable procedure. There have been and still are thousands of assumptions of arms by Americans on consideration of mere mail-order salesmanship; arms in these transactions are, at the best, supposed to be those "of the name" (that is, belonging to a name rather than a person), a view for

which no justification exists. Endeavours have been made to set up American authorities who would not only record but also grant arms. The New England Historic Genealogical Society of Boston appointed a Committee on Heraldry that since 1928 has issued rolls of arms, in which have been entered the names and arms of those who have submitted their claims to its judgment. The use of this method of issuing or publicizing arms recalls the usage previously referred to, which has not been practiced in Europe for more than 400 years. In the introduction to the second roll (1932) it is stated: "There is certainly no legal reason, perhaps no reason at all, why an American gentleman should not assume in more majorum any new coat that pleases his fancy, but he should not assume an old coat, for if he does, he is very likely denying his own forefathers and he surely is affirming what he has no sufficient reason to be true." Not only British-derived arms but also continental European arms have been registered. In addition, the committee has assisted inquirers in devising new coats of arms, not only for schools, colleges, and other institutions but also for individuals. In the introduction to the first roll a very reasonable view toward heraldry was expressed: "Taking into consideration the early history of coat armour there seems to be no reason in this country at least, why anyone provided he observes the simple rules of blazon and does not appropriate the arms of another, may not assume and use

Heraldry in states from the old Spanish Empire

Revival of England's ancient Court of Chivalry England. Heraldic development has also occurred in England, where in 1934 the ancient Court of Chivalry was revived. This was once the court of the lord high constable and the earl marshal, and it dealt with matters relating to knights and gentlemen. Although it was concerned also with matters of military discipline, it was not the forerunner of the modern court-martial in the armed forces. The court gradually declined in the 17th and 18th centuries and had not sat from 1735 until its revival.

The office of lord high constable has long ceased to be hereditary or of permanent status in England. During coronations, however, a constable is appointed for the occasion. Therefore, in the revived court that sat in 1954 to deal with a test case, Manchester Corporation v. Manchester Palace of Varieties, the earl marshal (the duke of Norfolk) presided with a surrogate, who was the lord chief justice of England appearing in his capacity as a doctor of civil law. As a result of the stiting, the jurisdiction of the court was confirmed, and the City of London recorded its crest and supporters.

The unorganized condition of heraldry in many European countries has spurred private attempts to bring some order into the field. The movement known as the International Congress of Heraldry and Genealogy began in 1928 with a meeting in Barcelona, Spain. A second Congress was held in Rome and Naples in 1953, and from that time regular meetings occurred at two- or three-year intervals. Out of these was established an international organization, El Instituto International de Genealogy at Heraldica (The International Institute of Genealogy and Heraldry), with is headquarters in Madrid.

USES OF HERALDRY FOR STUDY AND VERIFICATION

The uses of heraldry, apart from its general significance in providing distinguished symbols, are considerable. Heraldry illustrates much history and literature that is otheraldry illustrates much history and literature that is otheraldry in buildings, in manuscripts, and in paintings is of immense value for purposes of identification. It serves to link one person with another, to connect families, and to disclose origins of states and of institutions. With the use of heraldry in connection with genealogy, from which it cannot easily be separated, much that is difficult to follow becomes easy to interpret. In every building that contains armorial engravings or other prictures of arms, there is a concise history of the place, which gives a knowledgeable onlooker a useful clue to the background and details of the building.

In law the place of heraldry is sometimes very precise, as in modern Scotland; in England, on the other hand, it is more involved. To understand the latter is to gain an insight into the development of English law. Similarity of arms does not always indicate identity of family; it may merely denote assumption of devices. According to the English laws of inheritance, not only an estate but also a surname and arms can pass by eventual succession to individuals unconnected by blood with the original owner. Thus in the families of Lytton and Carew, and in branches of Trelawny, instances occur in which possession of the name and arms is contrary to blood relationship. Sometimes, however, identity of a name with a puzzling discrepancy in the arms can only be explained by a study of the family sheraldry.

BIBLIOGRAPHY. There are many guides to heraldry; the majority appear to be derived from an old original. Among the most useful for the beginner are: A.C. FOX-DAVIES, Heraldry Explained (1906, repinted 1971), a small, well-illustrated book written by the clearest expositor of heraldry; cHARLES MACKIN-

NON, The Observer's Book of Heraldry (1966), a very useful and clearly written work; and SIR ANTHONY R. WAGNER, Heraldry in England (1946, reprinted 1953), a brief account but with 15 plates in colour, LESLIE G. PINE, Teach Yourself Heraldry and Genealogy, 2nd ed. (1970), designed for the beginner and including a glossary of terms, and The Genealogist's Encyclopaedia (1969, reprinted 1973); and JAMES R. PLANCHE, The Pursuivant of Arms or Heraldry Founded upon Facts (1852, reprinted 1973).

More specialized works include A.C. FOX-DAVIES, A Complete Guide to Heraldry (1909, reprinted 1978), and Armorial Families: A Directory of Gentlemen of Coat Armour, 7th ed., 2 vol. (1929-30, reprinted 1970). GERARD J. BRAULT, Early Blazon: Heraldic Terminology in the Twelfth and Thirteenth Centuries. with Special Reference to Arthurian Literature (1972), illustrates the development of the language of blazon. The writings of oswald barron should be read as a correction to some of Fox-Davies' theories on heraldic history. Some of his best work may be found in the 12 volumes of The Ancestor, which he edited in 1902-05. Two volumes now reprinted in one constitute A Treatise on Heraldry: British and Foreign by JOHN WOODWARD and GEORGE BURNETT (1892, reprinted 1969), which contains some inaccuracies, SIR THOMAS INNES, Scots Heraldry, new ed. (1978), explains much in heraldic practice that may not otherwise be clear. Another good view of heraldry in the international sense is ROBERT GAYRE OF GAYRE AND NIGG, The Nature of Arms (1961). For information on Irish heraldry, see SIR CHRISTOPHER and ADRIAN LYNCH-ROBINSON, Intelligible Heraldry (1948, reprinted 1967), Boutell's Heraldry has been edited many times since its first appearance in the 19th century. The editions of v. wheeler-holohan (1931), C.W. SCOTT-GILES (1958), and JOHN P. BROOKE-LITTLE (1978) are all very useful, as are JOHN P. BROOKE-LITTLE, An Heraldic Alphabet (1973); and OTTFRIED NEUBECKER and JOHN P. BROOKE-LITTLE, Heraldry: Sources, Symbols, and Meaning (1977). JULIAN FRANKLYN, Shield and Crest, 3rd ed. (1971), gives much otherwise not easily obtained information.

Little continental work on heraldry has been translated into English. Perhaps the best course is to consult periodical publications like The Augustan, with articles from a wide variety of sources. Several non-English-language encyclopaedias, such as the Enciclopedia Italiana (1929-37), have excellent articles on heraldry. Many non-English writers transcend their national boundaries in writing on the subject. Rémi Mathieu in Le Système héraldique français (1946) writes of French heraldry, see 1086. ASPINIO Y TORRES, Tratado de heráldica y blasón, 37 ded. rev. (1854, eprinted 1929); and LUCAS DE PALACIO, De Genealogia y heraldica (1946), the latter author being especially interested in the connection between totemism and heraldry; the Japanese mon is exhaustively dealt with by CaRROLL PARISH in The

Augustan, vol. 11, no. 1 (1968).

Other works that will help the student after he has acquired a sound knowledge of this subject are: SIR ANTHONY

R. WAONER, Heralds and Heraldsy in the Middle Ages, and ed. (1996, reprinted 1960), and Historic Heraldsy of Britain (1993, reprinted 1972); and LESLIE O, PINE, The Yory of Heraldsy (1952, reprinted 1967), an account of much controversial matter, including the present English heraldic position in law, GEORGE D. SQUIBB, The High Court of Chivalry: A Study of the Civil Law in England (1959); c. PAMA, Lions and Virgins (1965), which discusses the history of arms in South Africa; and LESLIE G. PINE, International Heraldry (1970), and Amal LESLIE G. PINE, International Heraldry (1970), and Amount of the World.

Reference works in English are easily available, SIR JOHN B. BURKE, The General Armory of England, Scotland, Ireland, and Wales (1883, reprinted 1976), gives the description under alphabetical order of surnames of thousands of coats of arms. JOHN WOODY PAPWORTH, An Alphabetical Dictionary of Coats of Arms Belonging to Families in Great Britain and Ireland (1858-74, reprinted 1977), the counterpart of Burke's General Armory, enables the seeker to trace a coat of arms without knowing the owner's name. Both books contain inaccuracies. JAMES PARKER, A Glossary of Terms Used in Heraldry, new ed. (1970), with 1,000 illustrations, is a helpful book, as is LESLIE G. PINE, A Dictionary of Mottoes (1983). Regular editions of JOHN DEBRETT, Peerage, Baronetage, Knightage and Companionage (since 1713); and JOHN B. BURKE, A Genealogical and Heraldic History of the Peerage, Baronetage, and Knightage (since 1826), and Genealogical and Heraldic History of the Landed Gentry (since 1837), abound in illustrations and descriptions of arms. The role of the herald in history and in the contemporary art and science of heraldry is explored in RODNEY DENNYS, The Heraldic Imagination (1976), and Heraldry and the Herald

Hinduism

he term Hinduism refers to the civilization of the Hindus (originally, the inhabitants of the land of the Indus River). Introduced in about 1830 by British writers, it properly denotes the Indian civilization of approximately the last 2,000 years, which evolved from Vedism, the religion of the Indo-European peoples who settled in India in the last centuries of the 2nd millennium BC.

Because it integrates a variety of elements, Hinduism constitutes a complex but largely continuous whole and has religious, social, economic, literary, and artistic aspects. As a religion, Hinduism is a composite of diverse doctrines, cults, and ways of life.

General nature and characteristic features

The spectrum that ranges from the level of popular Hindu belief to that of elaborate ritual technique and philosophical speculation is very broad and is attended by many stages of transition and varieties of coexistence. Magic rites, animal worship, and belief in demons are often combined with the worship of more or less personal gods or with mysticism, asceticism, and abstract and profound theological systems or esoteric doctrines. The worship of local deities does not exclude the belief in pan-Indian higher gods or even in a single high God. Such local deities are also frequently looked upon as manifestations of a high God.

In principle, Hinduism incorporates all forms of belief and worship without necessitating the selection or elimination of any. It is axiomatic that no religious idea in India ever dies or is superseded-it is merely combined with the new ideas that arise in response to it. Hindus are inclined to revere the divine in every manifestation, whatever it may be, and are doctrinally tolerant, allowing others-including both Hindus and non-Hinduswhatever beliefs suit them best. A Hindu may embrace a non-Hindu religion without ceasing to be a Hindu, and because Hindus are disposed to think synthetically and to regard other forms of worship, strange gods, and divergent doctrines as inadequate rather than wrong or objectionable, they tend to believe that the highest divine powers complement one another. Few religious ideas are considered to be irreconcilable. The core of religion does not depend on the existence or nonexistence of God or on whether there is one god or many. Because religious truth is said to transcend all verbal definition, it is not conceived in dogmatic terms. Moreover, the tendency of Hindus to distinguish themselves from others on the basis of practice (orthopraxy) rather than doctrine (orthodoxy) further de-emphasizes doctrinal differences.

Hinduism is both a civilization and a congregation of religions; it has neither a beginning or founder, nor a central authority, hierarchy, or organization. Every attempt at a

specific definition of Hinduism has proved unsatisfactory in one way or another, the more so because the finest scholars of Hinduism, including Hindus themselves, have emphasized different aspects of the whole.

COMMON CHARACTERISTICS OF HINDU BELIEF

Nevertheless, it is possible to discern among the myriad forms of Hinduism several common characteristics of belief and practice.

Authority of the Veda and the Brahman class. Perhaps the defining characteristic of Hindu belief is the recognition of the Veda, the most ancient body of religious literature, as an absolute authority revealing fundamental and unassailable truth. At the same time, however, its content has long been practically unknown to most Hindus, and it is seldom drawn upon for literal information or advice. Still, it is venerated from a distance by every traditional Hindu, and those Indians who reject its authority (such as Buddhists and Jains) are regarded as unfaithful to their tradition. The Veda is also regarded as the basis of all the later Shastraic texts used in Hindu doctrine and practice. Parts of the Veda are still quoted in essential Hindu rituals, and it is the source of many enduring patterns of Hindu thought.

Also characteristic of Hinduism is the belief in the power of the Brahmans, a priestly class possessing spiritual supremacy by birth. As special manifestations of religious power and as bearers and teachers of the Veda, Brahmans are considered to represent the ideal of ritual purity and social prestige

Doctrine of atman-brahman. Hindus believe in an uncreated, eternal, infinite, transcendent, and all-embracing principle, which, "comprising in itself being and nonbeing," is the sole reality, the ultimate cause and foundation, source, and goal of all existence. This ultimate reality is called brahman. As the All, brahman causes the universe and all beings to emanate from itself, transforms itself into the universe, or assumes its appearance. Brahman is in all things and is the Self (atman) of all living beings. Brahman is the creator, preserver, or transformer

(liberation)

and

and reabsorber of everything. Although it is Being in itself, without attributes and qualities and hence impersonal, it may also be conceived of as a personal high God, usually as Vishnu (Visnu) or Siva. This fundamental belief in and the essentially religious search for ultimate reality-i.e., the One that is the All-have continued almost unaltered for more than 30 centuries and have been the central focus of India's spiritual life.

Ahimsa: non-injury. A further characteristic of Hin-duism is the ideal of ahimsa. Ahimsa, "non-injury" or the absence of the desire to harm, is regarded by Indian thinkers as one of the keystones of their ethics. Historically, ahimsa is unrelated to vegetarianism; in ancient India, killing people in war or in capital punishment and killing animals in Vedic sacrifices were acceptable to many people who for other reasons refrained from eating meat. However, the two movements, ahimsa and vegetarianism, reinforced one another through the common concept of the disinclination to kill and eat animals, and together they contributed to the growing importance of the protection and veneration of the cow, which gives food without having to be killed. Neither ahimsa nor vegetarianism ever found full acceptance. Even today, many Hindus eat beef, and nonviolence (as the ideal of ahimsa is often translated) has never been a notable characteristic of Hindu behaviour.

Doctrines of transmigration and karma. Hindus generally accept the doctrine of transmigration and rebirth and the complementary belief in karma, or previous acts as the factor that determines the condition into which a being, after a stay in heaven or hell, is reborn in one form or another. The whole process of rebirths is called samsara. Any earthly process is viewed as cyclic, and all worldly existence is subject to the cycle. Samsara has no beginning and, in most cases, no end; it is not a cycle of progress or a process of purification but a matter of perpetual attachment. Karma, acting like a clockwork that, while running down, always winds itself up, binds the atmans (selves) of beings to the world and compels them to go through an endless series of births and deaths. This belief is indissolubly connected with the traditional Indian views of society and earthly life, and any social interaction (particularly those involving sex or food) results in the mutual exchange of good and bad karma. It has given rise to the belief that any misfortune is the effect of karma, or one's own deeds, and to the conviction that the course of world history is conditioned by collective karma.

Such doctrines encourage the view that mundane life is not true existence and that human endeavour should be directed toward a permanent interruption of the mechanism of karma and transmigration-that is, toward final emancipation (moksha), toward escaping forever from the impermanence that is an inescapable feature of mundane existence. In this view the only goal is the one permanent and eternal principle: the One, God, brahman, which is totally opposite to any phenomenal existence. Anyone who has not fully realized that his being is identical with brahman is thus seen as deluded. The only possible solution consists in the realization that the kernel of human personality (atman) really is brahman and that it is their attachment to worldly objects that prevents people from reaching salvation and eternal peace. (Hindus sometimes use the largely Buddhist term nirvana to describe this

Concepts of istadevată and Trimürti. Although those Hindus who particularly worship either Vishnu or Siva generally consider one or the other as their "favourite god" (iştadevatā) and as the Lord (Īśāna) and Brahman in its personal aspect, Vishnu is often regarded as a special manifestation of the preservative aspect of the Supreme and Siva as that of the destructive function. Another deity, Brahmă, the creator, remains in the background as a demiurge. These three great figures (Brahmā, Vishnu, and Siva) constitute the so-called Hindu Trinity (Trimurti, "the One or Whole with Three Forms"). This conception attempts to synthesize and harmonize the conviction that the Supreme Power is singular with the plurality of gods in daily religious worship. Although the concept of the Trimurti assigns a position of special importance to some

great gods, it never has become a living element in the religion of the people. Moreover, Brahma has had no major cult since ancient times, and many Hindus worship neither Siva nor Vishnu but one or more of the innumerable other Hindu gods.

Ashramas: the four stages of life. In the West, the socalled life-negating aspects of Hinduism have often been overemphasized. The polarity of asceticism and sensuality, which assumed the form of a conflict between the aspiration to liberation and the heartfelt desire to have descendants and continue earthly life, manifested itself in Hindu social life as the tension between the different goals and stages of life. The relative value of an active life and the performance of meritorious works (prayrtti) as opposed to the renunciation of all worldly interests and activity (nivrtti) was a much-debated issue. While one-sided religious and philosophical works, such as the Upanishads, placed emphasis on renunciation, the dharma texts argued that the householder who maintains his sacred fire, procreates children, and performs his ritual duties well also earns religious merit. Nearly 2,000 years ago, these dharma texts elaborated the social doctrine of the four ashramas (stages of life). This concept is an attempt at harmonizing the conflicting tendencies of Hinduism into one system It held that a member of the three higher classes should first become a chaste student (brahmachari); then become a married householder (grihastha), discharging his debts to his ancestors by begetting sons and to the gods by sacrificing; then retire (as a vanaprastha), with or without his wife, to the forest to devote himself to spiritual contemplation; and finally, but not mandatorily, become a homeless wandering ascetic (sannyasin). The situation of the forest dweller was always a delicate compromise that remained problematic on the mythological level and was often omitted or rejected in practical life. Although the status of a householder was often extolled,

and some authorities, regarding studentship as a mere preparation, went so far as to brand the other stages as inferior, there were always people who became wandering ascetics immediately after studentship. Theorists were inclined to reconcile the divergent views and practices by allowing the ascetic way of life to those who are, owing to the effects of restrained conduct in former lives, entirely free from worldly desire, even if they had not gone through the traditional prior stages.

THREE MARGAS: PATHS TO SALVATION

Hindus disagree about the way (marga) to final emancipation (moksha). Three paths to salvation (variously valued but nonexclusive) are presented in an extremely influential religious text, the Bhagavadgītā ("Song of the Lord"; c. 200 BC), according to which it is not acts themselves but the desire for their results that produces karma and thus attachment. These three ways to salvation are (1) the karma-marga ("the path of duties"), the disinterested discharge of ritual and social obligations; (2) the jnanamarga ("the path of knowledge"), the use of meditative concentration preceded by a long and systematic ethical and contemplative training, yoga, to gain a supra-intellectual insight into one's identity with brahman; and (3) the bhakti-marga ("the path of devotion"), the devotion to a personal God. These ways are regarded as suited to various types of people.

Although the search for moksha has never been the goal of more than a small minority of Hindus, liberation was a religious ideal that affected all lives. Moksha determined not only the hierarchical values of Indian social institutions and religious doctrines and practices but also the function of Indian philosophy, which is to discuss what one must do to find true fulfillment and what one has to realize, by direct experience, in order to escape from samsara (bondage) and obtain spiritual freedom. While those who have not been reached by formal Indian philosophy have only vague ideas about the doctrines of karma and moksha, in semipopular milieus these doctrines gave rise to much speculation

For the ordinary Hindu, the main aim of worldly life lies in conforming to social and ritual duties, to the traditional rules of conduct for one's caste, family, and profession.

The holder

Such requirements constitute an individual's dharma (law and duties), one's own part of the broader stability, law, order, and fundamental equilibrium in the cosmos, nature, and society. Sanātana (traditional) dharma-a term used by Hindus to denote their own religion-is a close approximation to "religious practices" in the West. This traditional dharma applies theoretically to all Hindus, but it is superseded by the more particular dharmas that are appropriate to each of the four major varnas, or classes of society: Brahmans (priests), Ksatriyas (warrior kings), Vaisyas (the common people), and Sudras (servants). These four rather abstract categories are further superseded by the more practically applicable dharmas appropriate to each of the thousands of particular castes (jātis). Thus, religion for Hindus is mainly a tradition and a heritage, a way of life and a mode of thought. In practice, it is the right application of methods for securing both welfare in this life and a good condition in the hereafter.

The history of Hinduism

The history of Hinduism began in India about 1500 Bc, Although its literature can be traced only to before 1000 Bc, evidence of Hinduism's earlier antecedents is derived from archaeology, comparative philology, and comparative religion.

SOURCES OF HINDUISM

Indo-European sources. The earliest literary source for the history of Hinduism is the Rigeda (Rgveda), the hymns of which were chiefly composed during the last two or three centuries of the 2nd millennium as C. the religious life reflected in this text is not that of Hinduism but of an earlier sacrificial religious system, generally known as Brahmanism or Vedism, which developed in India among Aryan invaders. This branch of a related group of nomadic and seminomadic tribal peoples originally inhabiting the steppe country of southern Russia and Central Asia brought with them the horse and chariot and the Sanskrit language. Other branches of these peoples penetrated into Europe, bringing with them Indo-European languages that developed into the chief language groups now spoken there.

Before they entered the Indian subcontinent (c. 1500 ac), the Aryans were in close contact with the ancestors of the Iranians, as evidenced by similarities between Sanskrit and the earliest surviving Iranian languages. Thus, the religion of the Rigveda contains elements from three evolutionary strata: an early element common to most of the Indo-European tribes; a later element held in common with the early Iranians; and an element acquired in the Indian subcontinent itself, after the main Aryan migrations. Hinduism arose from the continued accretion of further elements derived from the original non-Aryan inhabitants, from outside sources, and from the geniuses of individual reformers at all periods.

Hinduism has a few direct survivals from its Indo-European heritage. Some of the rituals of the Hindu wedding ceremony, notably the circumambulation of the sacred fire and the cult of the domestic fire itself, have their roots in the remote Indo-European past. The same is probably true of the custom of cremation and some aspects of the ancestor cult. The Rigweda contains many other Indo-European elements, such as the worship of male sky gods with sacrifices and the existence of the old sky god Dyaus, whose name is cognate with those of the classical Zeus of Greece and Jupiter of Rome ("Father Jove"). The Vedic heaven, the "world of the fathers," resembled the Germanic Valhalla and seems also to be an Indo-European inheritance.

annentance. The Indo-Iranian element in later Hinduism is chiefly found in the initiatory ceremony (upa-mayana) performed by boys of the three upper classes, a rite both in Hinduism and in Zoroastrianism that involves the tying of a sacred cord. The Vedie god Varuna, now an unimportant sea god, appears in the Rigveda as sharing many features of the Zoroastrian Ahura Mazda ("Wise Lord"); the hallucinogenic sacred drink soma corresponds to the sacred haoma of Zoroastrianian.

Indigenous sources. Even in the earlier parts of the Rigveda the religion had already acquired numerous specifically Indian features. Some of the chief gods, for example, have no clear Indo-European or Indo-Iranian counterparts. Although some of the new features may have evolved entirely within the Aryan framework, it is generally presumed that many of them stem from the influence of the indigenous inhabitants. The Vedic Aryans may never have been in direct contact with the civilization of the Indus Valley in its prime, but the religion of the valley's culture undoubtedly influenced them.

Non-Indo-European sources. The Dravidian hypothesis. Features of Hinduism that cannot be traced to the Rigveda are sometimes ascribed to the influence of the original inhabitants, who are often vaguely and incorrectly referred to as "Dravidians." The ruling classes of the Harappa culture (c. 2500-1700 BC), or the Indus civilization, may have spoken a Dravidian language, but as long as their script remains undeciphered this cannot be proved. Moreover, the presence of Dravidian speakers throughout the whole subcontinent at any time in history is not attested. The Mediterranean racial type, to which most modern highercaste Dravidian speakers belong, is widespread throughout India; but it cannot be proved that all people of this type originally spoke Dravidian languages or that all followed the same culture. Equally or more widely spread in South and Southeast Asia is the Proto-Australoid racial type, the purest members of which in India are the tribal peoples of the centre and the south, many of whom speak languages of the Austric family. Thus, although many aspects of Hinduism are traceable to non-Arvan influence, not all of these aspects are borrowed from "Dravidians." In the 20th century the term Dravidian generally refers to a family of languages and not to an ethnic group.

Other sources: The Central Asian nomads who entered India in the two centuries before and after the beginning of the Christian Fra might have influenced the growth of devotional Hinduism out of Vedic religion. The classical Western world directly affected Hindu religious art, and several features of Hinduism can be traced to Zoroastrianism. The influence of later Chinese Taoism on Tantic Hinduism (an esoteric system of rituals for spiritual power) has been suggested, though not proved. In more recent centuries, the influence of Islâm and Christianity on Hinduism can be seen.

The process of "Sanskritization." The development of Hinduism can be interpreted as a constant interaction between the religion of the upper social groups, represented by the Brahmans (priests and teachers), and the religion of other groups. From the time of the Arvan invasion (c. 1500 BC) the indigenous inhabitants of the subcontinent have tended to adapt their religious and social life to Brahmanic norms. This has developed from the desire of lower-class groups to rise on the social ladder by adopting the ways and beliefs of the higher castes. This process, sometimes called "Sanskritization," began in Vedic times when non-Arvan chieftains accepted the ministrations of Brahmans and thus achieved social status for themselves and their subjects. It was probably the principal method by which Hinduism spread through the subcontinent and into Southeast Asia. Sanskritization still continues in the form of the conversion of tribal groups, and it is reflected by the persistent tendency of low-caste Hindus to try to raise their status by adopting high-caste customs, such as wearing the sacred cord and becoming vegetarians.

If Sanskritization has been the main means of spreading Hinduism throughout the subcontinent, its converse
process, which has no convenient label, has been one of
the means whereby Hinduism has changed and developed
over the centuries. The Aryan conquerors lived side by
side with the indigenous inhabitants of the subcontinent,
and many features of Hinduism, as distinct from Vedic
religion, may have been adapted from the religions of the
non-Aryan peoples of India. The phallic emblem of the
god Siva arose from a combination of the phallic aspects
of the Vedic god Indra and a non-Vedic icon of early
popular fertility cults. Many features of Hindu mythology
and several of the lesser gods—such as Gapeša, an elephant-headed god, and Hanuman, the monkey god—were

Rigveda

of the

Contributions from non-Aryan religions incorporated into Hinduism and assimilated into the appropriate Vedic gods by this means. Similarly, the worship of many goddesses who are now regarded as the consorts of the great male Hindu gods, as well as the worship of the one great goddess herself, may have originally incorporated the worship of non-Aryan local goddesses. Unorthodox circles on the fringes of Brahmanic culture (probably in southern India) were one of the important sources of the system of ecstatic devotional religion known as bhakti.

Thus, the history of Hinduism can be interpreted as the imposition of orthodox custom upon wider and wider ranges of people and, complementarily, as the survival of features of non-Aryan religions that gained strength steadily until they were adapted by the Brahmans.

THE PREHISTORIC PERIOD (3RD AND 2ND MILLENNIA BC)

Indigenous prehistoric religion. The prehistoric culture of the Indus Valley arose in the latter centuries of the 3rd millennium BC from the metal-using village cultures of the region. There is considerable evidence of the religious life of the Indus people, but until their writing is deciphered its interpretation is speculative. Enough evidence exists, however, to show that several features of later Hinduism had prehistoric origins.

In most of the village cultures, small terra-cotta figurines of women, found in large quantities, have been interpreted as icons of a fertility deity whose cult was widespread in the Mediterranean area and in western Asia from Neolithic times onward. This hypothesis is strengthened by the fact that the goddess was apparently associated with the bulla feature also found in the ancient religions farther west.

Religion in the Indus Valley civilization. The Harappa culture (often called the Indus Valley civilization), located in modern Pakistan, has produced much evidence of the cult of the goddess and the bull. Figurines of both occur, with the goddess being more common than the bull. The bull, however, appears more frequently on the many steatite seals. A horned deity, possibly with three faces, occurs on a few seals, and on one seal he is surrounded by animals. A few male figurines in hieratic (sacerdotal) poses and one apparently in a dancing posture may represent deities. No building has been discovered at any Harappan site that can be positively identified as a temple, but the Great Bath at Mohenjo-daro was almost certainly used for ritual purposes, as were the ghats (bathing steps on riverbanks) attached to later Hindu temples. The presence of bathrooms in most of the houses and the remarkable system of covered drains indicate a strong concern for cleanliness that may have been related to concepts of ritual purity as well as to ideas of hygiene.

Many seals show religious and legendary themes that cannot be interpreted with certainty. There is clear evidence, however, of the worship of sacred trees or of the divinities believed to reside in them. The bull is often depicted standing before a sort of altar, and the horned god has been interpreted, perhaps overconfidently, as a prototype of the Hindu god Siva. Small conical objects appear to be phallic emblems that are also connected with Siva in later Hinduism, although they may have been pieces used in board games. Other interpretations of the remains of the Harappa culture are more speculative and, if accepted, would indicate that many features of later Hinduism were already in existence 4,000 years ago. The fact that Harappans buried their dead with grave deposits, a practice not followed by the later Hindus, suggests that they had some belief in an afterlife.

Survival of archaic religious practices. Some elements of the religious life of current and past folk religionsnotably sacred animals, sacred trees, especially the pipal (Ficus religiosa), and the use of small figurines for cult purposes-are found in all parts of India and may have been borrowed from pre-Aryan civilizations. On the other hand, these figures are also commonly encountered outside of India, and therefore they may have originated independently in Hinduism as well.

THE VEDIC PERIOD (2ND MILLENNIUM-7TH CENTURY BC) The Aryans of the early Vedic period left few material remains, but they left a very important literary record called the Rigyeda. Its 1.028 hymns are distributed throughout 10 books, of which the first and the last are the most recent. A hymn usually consists of three sections: it begins with an exhortation that is followed in the main part by praise of the deity, prayers, and imploration, with frequent references to the deity's mythology, and finishes with a specific request.

The Rieveda ("Wisdom of the Verses") is not a unitary work, and its composition may have taken several centuries. In its form at the time of its final edition it reflects a well-developed religious system. The date commonly given for the final recension of the Rigveda is 1000 BC. During the next two or three centuries the Rigveda was supplemented by three other Vedas and, still later, by Vedic texts called the Brahmanas and the Unanishads (see below Sacred texts: Vedas).

CHALLENGES TO BRAHMANISM (7TH-2ND CENTURY BC)

The century from about 550 BC onward was a period of great change in the religious life of India. This century saw the rise of breakaway sects of ascetics who denied the authority of the Vedas and of the Brahmans and who followed founders claiming to have discovered the secret of obtaining release from transmigration. By far the

Aspects of a soma sacrifice performed in Pune (Poona), India, on behalf of a traditional Brahman, following the same ritual used in 500 BC, an unusual example of the continuance of the Vedic tradition. (Though Vedic rites are still occasionally performed, photographic documentation of a complete and ritually correct ceremony is rare.) (Top) Group of 16 priests (four for each of the four Vedas) swear to the common interest of the sacrificer before the beginning of the ritual, their hands outstretched toward the fire (āhavaniya). (Bottom) Priests bring in fire to light the sacrificial fire in the newly constructed altar, taken from the household fire of the sacrificer, shown with his wife in the middle of the group.

The Harappā culture

Sacred trees

most important of these were Siddhārtha Gautama, called the Buddha, and Vardhamāna, called Mahāvīra ("Great Hero"), the great teacher of Jainism (see also BUDDHISM, THE BUDDHA AND; JAINISM). There were many other heterodox teachers who organized bands of ascetic followers, and each group followed a specific code of conduct. They gained considerable support from ruling families and merchants. The latter were growing in wealth and influence. and many of them were searching for alternative forms of religious activity that would give them a more significant role than did orthodox Brahmanism or that would be less

expensive to support The scriptures of the new religious movements throw some light on the popular religious life of the period. The god Prajapati was widely believed to be the highest god and the creator of the universe, with Indra, known chiefly as Śakra ("the Mighty One"), second to him in importance. The Brahmans were very influential, but opposition had developed to their large-scale animal sacrifices-on both philosophical and economic grounds-and their pretensions to superiority by virtue of their birth were questioned. The doctrine of transmigration was by then generally accepted, although a group of outright materialists denied the survival of the soul after death. The ancestor cult, part of the Indo-European heritage, was retained almost universally, at least by the higher castes. Popular religious life largely centred around the worship of local fertility divinities (yaksha), snake-spirits (naga), and other minor spirits in sacred places and groves (caitya). Although these sacred places were the main centres of popular religious life, there is no evidence of any buildings or images associated with them, and it appears that neither temples nor

large icons existed at the time.

Around 500 BC asceticism became widespread, and increasing numbers of intelligent young men "gave up the world" to search for release from transmigration by achieving a state of psychic security. The orthodox Brahmanical teachers reacted to these tendencies by devising the doctrine of the four ashramas (āśramas, "abodes"), which divided the life of the twice-born after initiation into four stages: the brahmachari (celibate religious student); the grihastha (married householder); the vanaprastha (forest dweller); and the sannyasin (wandering ascetic). This attempt to keep asceticism in check and confine it to men of late middle age was never followed universally, but thereafter Hindu social theory centred on the concept of varnashramadharma, or the duties of the four classes (varna) and the four stages of life (ashramas), which formed the ideal that Hindus were encouraged to follow.

The 3rd century BC was the period of the Mauryan empire, the first great empire of India. Its early rulers were heterodox, and Aśoka (reigned c. 265-238 BC), the third and most famous of the Mauryan rulers, was a professed Buddhist. Although there is no doubt that Aśoka's patronage of Buddhism did much to spread that religion, his inscriptions recognize the Brahmans as worthy of respect. Sentiments in favour of nonviolence (ahimsa) and vegetarianism, much encouraged by the heterodox sects, spread during the Mauryan period and were greatly encouraged by Aśoka. A Brahmanic revival appears to have occurred with the fall of the Mauryas. The orthodox religion itself was undergoing change at this time, however, because of the development of theistic tendencies that centred around

the gods Vishnu and Siva.

Inscriptions, iconographic evidence, and literary references point to the emergence of devotional theism in the 2nd century BC. Several brief votive inscriptions refer to the god Väsudeva, who by this time was widely worshiped in western India. At the end of the 2nd century, Heliodorus, a Greek ambassador from King Antialcidas of Taxila (in Pakistan), erected a large column in honour of Vāsudeva at Besnagar in Madhya Pradesh and recorded that he was a Bhagavata, a term specifically used for the devotees of Vishnu. The identification of Vasudeva with the old Vedic god Vishnu and, later, with Vishnu's incarnation, Krishna (Kṛṣṇa), was quickly accepted.

Near the end of the Mauryan period the first surviving stone images of Hinduism appear. Several large, simply carved figures survive, not representing any of the great

Brahman priest reading the unbound folio manuscript of a sacred text, a śrauta-sūtra, at a Vedic yajňa (sacrifice). The animal skin is the sacrificer's seat, the wooden cups are for drinking the soma.

gods but rather yakshas, or local chthonic divinities connected with water, fertility, and magic. The original locations of these images are uncertain, but they were probably erected in the open air in sacred enclosures. Temples are not clearly attested in this period by either archaeology or literature. A few fragmentary images thought to be those of Vasudeva and Siva, the latter in anthropomorphic form and in the form of a lingam, or phallic emblem, are found on coins of the 2nd and 1st centuries BC.

EARLY HINDUISM (2ND CENTURY BC-4TH CENTURY AD)

The centuries immediately preceding and following the dawn of the Common Era saw the recension of the two great Sanskrit epics, the Rāmāyaņa and the Mahābhārata (the latter incorporating into it the Bhagavadgītā). Although it was the worship of Vishnu, incarnate as Krishna in the Mahābhārata and as Rāma in the Rāmāyana, that developed significantly during this period (see below Sacred texts: Epics and Purāṇas), the god Siva is active in the Mahābhārata, and the cult of Siva developed alongside the cult of Vishnu.

The rise of the major sects: Vaishnavism, Saivism, and Säktism. The Vedic god Rudra gained in importance from the end of the Rigvedic period. In the Svetäśvatara Upanishad, Rudra is for the first time called Siva and is described as the creator, preserver, and destroyer of the universe. His followers are called on to worship him with devotion (bhakti). The tendency for the laity to form themselves into religious guilds, or societies-evident in the case of the yaksha cults, Buddhism, and Jainism-promoted the growth of devotional Vaishnavism and Saivism. These local associations of worshipers appear to have been a principal factor in the spread of the new cults. Theistic ascetics are less in evidence at this time; but a community of Saivite monks, the Pāsupatas, was also in existence by the 2nd or 3rd century AD.

The period between the fall of the Mauryan empire (c. 185 BC) and the rise of the Gupta (c. AD 320) was one of great change, with most of the area of Pakistan and parts of western India being conquered by a succession of invaders. India was opened to influence from the West as never before, not only by its invaders but by way of the sea through the flourishing trade with the Roman Empire. The effects of the new contacts were most obvious in art and architecture. The oldest freestanding stone temple in the subcontinent has been excavated at Taxila, near Rāwalpindi, Pak. During the 1st century BC the Gandhāra school of sculpture arose in the same region and made use of Hellenistic and Roman prototypes, mainly in the service of Buddhism. At that time Hindu temples proba-

Western influences

doctrine

of the four

achramae

The beginning of devotional theism

By the time of the early Gupta empire the new theism had been harmonized with the old Vedic religion, and two of the main branches of Hinduism were fully recognized. The Vaishnavas had the support of the Gupta emperors, who took the title paramabhagavata ("supreme devotee of Vishnu"). Vishnu temples were numerous and the doctrine of Vishnu's avatars (incarnations) was widely accepted. Of the 10 incarnations of later Vaishnavism, however, only two seem to have been much worshiped in the Gupta period. These were Krishna, the hero of the Mahābhārata, who also begins to appear in his pastoral aspect as the cowherd and flute player, and the divine boar (Varāha), of whom several impressive images survive from the Gupta period.

The Saivites were also a growing force in the religious life of India. The sect of Pāsupata ascetics, founded by Lakulīśa (or Nahulīśa), who lived in the 2nd century AD, is attested by inscriptions from the 5th century and is among the earliest of the sectarian religious orders of Hinduism. Representations of the son of Siva, Skanda (also called Kärttikeya, the war god), appeared on Kushan coins as early as AD 100. Siva's other son, the elephantheaded Ganesa, patron deity of commercial and literary enterprises, did not appear until the 5th century. Very important in this period was Sürya, the sun god, who had temples built in his honour, although in modern times he is little regarded by most Hindus. The solar cult had Vedic roots but later may have expanded under Iranian

Rising

impor

tance of

goddesses

Several goddesses began to gain importance in this period. Although goddesses had always been worshiped in local and popular cults, they play comparatively minor roles in Vedic religion. Laksmī or Śrī, goddess of fortune and consort of Vishnu, was worshiped before the beginning of the Christian era, and several lesser goddesses are attested from the Gupta period. But the cult of Durga, the consort of Siva, was only beginning to gain importance in the 4th century, and the large-scale development of Saktism (devotion to the active, creative principle personified as the Mother Goddess) did not take place until medieval times.

The development of temples. The Gupta period (4th-6th century) saw the rapid development of temple architecture. Earlier temples were made of wood, but freestanding stone and brick temples soon appeared in many parts of India. By the 7th century, stone temples, some of considerable dimensions, were found in the Aryanized parts of the country. Originally, the design of the Hindu temple may have borrowed from the Buddhist precedent, for in some of the oldest temples the image was placed in the centre of the shrine, which was surrounded by an ambulatory path resembling the path around the Buddhist stupa (a religious building containing a relic). Nearly all surviving Gupta temples are comparatively small; they consist of a small cella (central chamber), constructed of thick and solid masonry, with a veranda either at the entrance or on all sides of the building. The earliest Gupta temples, such as the Buddhist temples at Sanchi, have flat roofs; however, the sikhara (spire), typical of the north Indian temple, was developed in this period and with time steadily was made taller. The massive and tall tower of the Buddhist temple of Buddh Gaya, which was in existence in the 7th century, represents the culmination of Gupta temple architecture.

The Buddhists and Jains had made use of artificial caves for religious purposes, and these were adapted by the Hindus. Hindu cave-temples, however, are comparatively rare, and none has been discovered from earlier than the Gupta period. In the Pallava site of Mahābalipuram, south of Madras, a number of small temples were carved in the 7th century from outcroppings of rock and represent some of the oldest religious buildings in the Tamil country.

The spread of Hinduism in Southeast Asia and the Pacific. Hinduism and Buddhism had an immense impact on the civilizations of Southeast Asia and contributed greatly to the development of a written tradition in that area. Around the beginning of the Christian era, Indian merchants in comparatively large numbers settled there. bringing Brahmans and Buddhist monks with them. These religious men were patronized by local chiefs, who converted to the new religion. The earliest material evidence of Hinduism in Southeast Asia comes from Borneo, where late 4th-century Sanskrit inscriptions testify to the performance of Vedic sacrifices by Brahmans at the behest of local chiefs. Chinese chronicles attest an Indianized kingdom in Vietnam two centuries earlier. The dominant form of Hinduism exported to Southeast Asia was Saivism. though some Vaishnavism was also known there. Later, from the 9th century onward, Tantrism, both Hindu and Buddhist, spread throughout the region.

The civilizations of Southeast Asia developed forms of Hinduism and Buddhism that had distinctive local features and were attuned to the local cultures, but the framework of their religious life was essentially Indian. Stories from the Rāmāyana and the Mahābhārata became widely known in Southeast Asia and are still popular there in local versions. The people of Bali (in Indonesia) still follow a form of Hinduism adapted to their own genius. Versions of the Manu-smṛṭi ("Laws of Manu") were taken to Southeast Asia and were translated and adapted to indigenous cultures until they lost most of their original content.

Claims of early Hindu contacts farther east are more doubtful. There is little evidence of the influence of Hinduism on China and Japan, except through Buddhism.

Indian religious influence in the Mediterranean world. Nearly as dubious as the question of Hindu influence on the religious life of the Far East is its influence on that of the ancient Mediterranean world. The Greek philosopher Pythagoras may have obtained his doctrine of metempsychosis (transmigration, or passage of the soul from one body to another) from India, mediated by Achaemenian (6th-4th century BC) Persia, but similar ideas were known in Egypt and were certainly present in Greece before the time of Pythagoras. The Pythagorean doctrine of a cyclic universe may also be derived from India, but the Indian theory of cosmic cycles is not attested in the 6th century BC. Nevertheless, it is known that Hindu ascetics occasionally visited Greece. The most striking similarity of Greek and Indian thought is the resemblance between the system of mystical gnosis (esoteric knowledge) described in the Enneads of the Neoplatonic philosopher Plotinus (3rd century AD) and that of the Yoga-sūtras attributed to Patañjali, an Indian religious teacher sometimes dated in the 2nd century AD. The Patañjali text is the older, and influence must be suspected, though the problem of mediation remains difficult because Plotinus gives no direct evidence of having known anything about Indian mysticism. Several Greek (e.g., Clement of Alexandria) and Latin writers show considerable knowledge of the externals of Indian religions, but none gives any intimation of understanding their more recondite aspects.

Certain Vaishnava legends, especially those referring to the infant Krishna, bear some resemblance to those of Christianity, and claims have been made by both Hinduism and Christianity that the one influenced the other. There is, however, no definitive evidence for the priority

of either one.

THE RISE OF DEVOTIONAL HINDUISM (4TH-11TH CENTURY) The medieval period saw the growth of new devotional religious movements centred on hymnodists who taught in the popular languages of the time. The new movements probably began with the appearance of hymns in Tamil associated with two groups of poets, the Nāyaṇārs, worshipers of Siva, and the Alvars, devoted to Vishnu. The oldest of these date from the early 7th century, although passages of devotional character can be found in earlier strata of Tamil literature.

The term bhakti, in the sense of devotion to a personal god, appears in the Bhagavadgītā and the Švetāśvatara Upanishad. In these early sources it represents a devotion still somewhat restrained and unemotional. The new form of bhakti, associated with singing in the languages of the common people, was highly charged with emotion, and the relation of worshiper and divinity was often de-

influences

temples

scribed by the analogy of that of lover and beloved. This devotional poetry is characterized by a mystical fervour not found in the Upanishads and the Bhagavadgitā, in both of which, even when the object of meditation is conceived as a personal God, there is little expression of passion. The Tamil "saints," however, felt an intense love (Tamil: anbu) of a personal kind toward their god. They experienced overwhelming joy in his presence and deep sorrow when he did not reveal himself. Some of them felt a profound sense of guilt or inadequacy in the face of the divine. But the dominant emotion in these poems is one of joy, often expressing itself in song and dance. The poems have a strong ethical content and encourage the virtues of love, humility, and brotherhood. The ideas of these poets, spreading northward, probably were the origin

Antagonism hetween devotional cults and Buddhism

Hinduism

on the eve of the

Muslim

occupation

of the growth of bhakti in northern India The devotional cults further weakened Buddhism, which had long been on the decline. From time to time Hindus, especially Saivites, took aggressive action against Buddhism. At least two Saivite kings-the Hephthalite invader Mihirakula (early 6th century) and the Bengal king Śaśāńka (early 7th century)-are reported to have been active persecutors, destroying monasteries and killing monks. The philosophers Kumarila and Sankara were also strongly opposed to Buddhism. In their journeys throughout India, their biographies claim, they vehemently debated with Buddhists and tried to persuade kings and other influential people to withdraw their support from Buddhist monasteries. Only in Bihar and Bengal, because of the patronage of the Pala dynasty and some lesser kings and chiefs, did Buddhist monasteries continue to flourish Buddhism in eastern India, however, was well on the way to being reabsorbed into Hinduism when the Muslims invaded the Ganges (Ganga) Valley in the 12th century. The great Buddhist shrine of Buddh Gaya, the site of the Buddha's enlightenment, became a Hindu temple and remained as such until recent times.

At the end of its existence in India, Buddhism developed in a way that had some effect on Hinduism. Among the Buddhist Tantrists appeared a new school of preachers often known as siddhas (those who have achieved), who sang their verses in the contemporary languages, early Maithili and Bengali. They taught that giving up the world was not necessary for release from transmigration and that by living a life of simplicity in one's own home one could achieve the highest state. This system, known as Sahajayana ("the Vehicle of the Natural," or "the Easy Vehicle"), influenced both Bengali devotional Vaishnavism, which produced sects called Sahājiyā with similar doctrines, and the Natha yogis (mentioned below), whose teachings influenced Kabir and other later bhakti teachers.

HINDUISM UNDER ISLAM (11TH-19TH CENTURY)

The challenge of Islam and popular religion. The phase of Indian history marked by the domination of the Muslims in most of northern India saw great changes in Indian religion. The advent of Islam in the Ganges Basin at the end of the 12th century resulted in the withdrawal of royal patronage from Hinduism in much of the area. The attitude of the Muslim rulers toward Hinduism varied. Some, like Firuz Tughluq (ruled 1351-88) and Aurangzeb (ruled 1658-1707), were strongly anti-Hindu and enforced payment of jizya, a poll tax on unbelievers. Others, like the Bengali sultan Husayn Shāh 'Alā' ad-Dīn (reigned 1493-1519) and the great Akbar (reigned 1556-1605), were well-disposed toward their Hindu subjects. Many temples, however, were destroyed by the more fanatical rulers. Conversion to Islām was more common in areas where Buddhism had once been strongest-modern Pakistan, Bangladesh, and Kashmir.

On the eve of the Muslim occupation, Hinduism was by no means sterile in northern India, but its vitality was centred in the southern, Dravidian-speaking areas. Throughout the centuries, the system of class and caste had become more rigid; in each region there was a complex hierarchy of castes strictly forbidden to intermarry and interdine, controlled and regulated by secular powers who acted on the advice of the court Brahmans. The largescale Vedic sacrifices had practically vanished, but simple domestic Vedic sacrifices continued, and new forms of animal, and sometimes vegetarian, sacrifice had appeared. especially connected with the cult of the Mother Goddess.

By that time, the main divinities of later Hinduism were worshiped. Rāma, the hero of the epic poem, had become the eighth avatar of Vishnu, and his cult was growing, although it was not yet as prominent as it later became, Similarly, Rāma's monkey helper, Hanumān, now one of the most popular divinities of India and the most ready helper in time of need, was rising in importance. Krishna was worshiped with his adulterous consort. Rādhā. Strange syncretic gods had appeared, such as Harihara, a combination of Vishnu and Siva, and Ardhanārīśvara, a synthesis of Śiva and his shakti Pārvatī or Durgā.

Temple complexes. From the Gupta period onward Hindu temples tended to become larger and more promi- Hindu nent, and their architecture developed in distinctive regional styles. In northern India the best remaining Hindu temples are found in the Orissa region and in the town of Khajurāho in northern Madhya Pradesh. The best example of Orissan temple architecture is the Linearaja temple of Bhubaneswar, built about 1000. The largest temple of the region, however, is the famous Black Pagoda, the Sun Temple (Surya Deula) of Konarak, built in the mid-13th century. Its tower has long since collapsed, and only the assembly hall remains. The most important Khajuraho temples were built during the 11th century. Individual architectural styles also arose in Guiarat and Raiasthan, but their surviving products are less impressive than those of Orissa and Khajurāho. By the end of the 1st millennium AD the South Indian style had reached its apogee in the great Răjarājeśvara temple of Thanjāvūr (Tanjore),

In the temple the god was worshiped by the rites of puia (reverencing a sacred being or object) as though the worshipers were serving a great king. In the important temples a large staff of trained officiants waited on the god. He was awakened in the morning along with his goddess, washed, clothed and fed, placed in his shrine to give audience to his subjects, praised and entertained throughout the day. ceremoniously fed, undressed, and put to bed at night. Worshipers sang, burned lamps, waved lights before the divine image, and performed other acts of homage. The god's dancing girls (devadasis) performed before him at regular intervals, watched by the officiants and lay worshipers, who were his courtiers. These women, either the daughters of devadasis or girls dedicated in childhood, may have also served as prostitutes. The association of dedicated prostitutes with certain Hindu shrines can be traced back to before the Christian era. It became more widespread in post-Gupta times, especially in South India, and aroused the reprobation of 19th-century Europeans. Through the efforts of Hindu reformers the office of the devadasis was discontinued. The role of devadasis is best understood in the context of the analogy between the tem-

Four Priests Doing Puja Before the Image of Śrî Nāthajī, Rajasthani miniature painting from Näthdwära, c. 1830. In the Fogg Art Museum, Cambridge, Mass.

dancing girls, who bestowed their favours on his courtiers. Parallels between the temple and the royal palace also were in evidence in the rathayatras (shrine processions). As on festival days, when the king issued from his palace and paraded around his city, escorted by courtiers, troops, and musicians, so also the god paraded around his city in a splendid procession, together with the lesser gods of the minor shrines. The god rode on a tremendous and ornate moving shrine (ratha), which was often pulled by large bands of devotees. Rathayatras still take place in many cities of India. The best-known is the annual procession of Jagannātha ("Juggernaut"), a form of Vishnu,

The wealth of the great temples

at Puri, Orissa. The great temples were (and still are) wealthy institutions. They were supported by the transfer of the taxes levied by kings on specific areas of the nearby countryside, by donations of the pious, and by the fees of worshipers. Their immense wealth was one of the factors that encouraged the Ghaznavid and Ghurid Turks to invade India after the 11th century. They were controlled by self-perpetuating committees-whose membership was usually a hereditary privilege-and by a large staff of priests and temple servants under a high priest who wielded tremendous power and influence. The great walled temple complexes of South India were (and still are) small cities, containing the central and numerous lesser shrines, bathing tanks, administrative offices, homes of the temple employees, workshops, bazaars, and public buildings of many kinds. Directly and indirectly they played an important part in the economy, as they were among the largest employers and greatest landowners in their areas. They also performed valuable social functions because they served as schools, dispensaries, poorhouses, banks, and concert halls.

The Muslim occupation brought India into close contact with a different, more aggressive, religion. In such circumstances, the absence of a central religious authority in Hinduism was a source of strength. The purchitas, or family priests who performed the domestic rituals and personal sacraments for the lay people, continued to function, as did the thousands of ascetics. In Muslim-occupied territory the temples suffered the most. In the sacred cities of Vārānasi (Benares) and Mathurā, no large temple remains from any period before the 17th century. The same is true of most of the main religious centres of northern India, but not of the regions where the Muslim hold was less firm, such as Orissa, Rājasthān, and South India.

Sectarian movements. Before the time the Muslims invaded the subcontinent, the new forms of South Indian bhakti were spreading beyond the bounds of the Dravidian south. Certain Vaishnava theologians of the Pañcarătra and Bhāgavata schools, including Rāmānuja, a Tamil Brahman who was for a time chief priest of the Vaishnava temple of Srīrangam, near Tiruchchirāppalli (Trichinopoly), taught in the 11th century. They gave the growing Vaishnava bhakti cults a philosophical framework that also influenced some Saivite schools

Two other Vaishnava teachers deserve mention, Nimbarka, a Telugu Brahman of the 12th or 13th century, spread the cult of the divine cowherd and his favourite gopi (cowherdess, especially associated with the legends of Krishna's youth), Rādhā. His sect survives near Mathurā but has made little impact elsewhere. More important was Vallabha (Vallabhācārya; 1479-1531), who took the Vaishnava doctrine of grace and emphasized its erotic imagery. His sect is noteworthy because it stresses absolute obedience to the guru (teacher). Early in its existence it was organized with a hierarchy of senior monks (gosvāmī), many of whom became very rich. The Vallabhācārya sect was once very influential in the western half of North India, but it declined in the 19th century, in part because of a number of lawsuits against the chief guru, the descen-

The Saiva sects also developed from the 10th century onward. In South India there emerged the school of Saivasiddhanta, still one of the most significant religious forces in that region, and one that, unlike the school of Sankara, does not admit the full identity of the soul and God. A completely monistic school of Saivism appeared in Kashmir in the early 9th century. Its doctrines differ from those of Śańkara chiefly because it attributes personality to the absolute spirit, who is the god Siva and not the impersonal brahman.

An important and interesting sect, founded in the 12th century in the Kannada-speaking area of the Deccan, was that of the Lingayats, or Vīraśaivas ("Heroes of the Śaiya Religion"). Its traditional founder, Basaya, taught doctrines and practices of surprising unorthodoxy: he opposed all forms of image worship and accepted only the lingam of Siva as a sacred symbol. Vīrašaivism rejected the Vedas, the Brahman priesthood, and all caste distinction. Several Lingayat practices, now largely abandoned, such as the remarriage of widows and the burial of the dead, are deliberately antinomian.

An important development of Saivism in North India was brought about by Gorakhnäth (Goraksanätha), who in the 13th century became leader of a sect of Saivite ascetics known as Natha ("Lord") from the title of their chief teachers. The Gorakhnāthīs were particularly important as propagators of the practices of hatha-yoga, a form of yoga that requires complex and difficult physical exercises and that has become popular in the West. These vogis, who are still numerous, influenced the teaching of several of the bhakti poets.

Bhakti movements. The poets and "saints" of medieval bhakti appeared throughout India. Although all have their individual genius, the bhakti lyricists share a number of common features whatever their language. The Sanskrit education needed for authors of Sanskrit texts limited them largely to the Brahman class and thus put a definite stamp on them. Because bhakti poets could use any language. they might come from any class. They brought to their poetry a familiarity with folk religion unknown or ignored in the Sanskrit texts. The use of the spoken language, even though it was formalized, made possible the immediate expression of an unmediated vision that needed no further context; thus the lyrics are short, intensely personal, and precise. These works illustrate the localistic and reformist tendency evidenced throughout India in the vernacular literatures, especially in Tamil, Bengali, and Hindi. (See below Vernacular literatures.)

The origin of the new forms of Hinduism has been attributed to the influence of Islam, but the proposition that the rise of popular emotional bhakti was a response to Islam is impossible, for the practice of singing ecstatic hymns in the current local language was well-known in South India even before Muhammad. All the features of this form of bhakti are found in the Bhagavata-Purana and in the commentaries of Rămānuja. The earliest bhakti literature in a living Indo-Aryan language is from Mahārāshtra and was composed before Muslims occupied the area. Thus, passionate bhakti existed long before the Muslim conquest. However, the presence of rulers of alien faith and the withdrawal of royal patronage from the temples and Brahmanic colleges may have encouraged the spread of new, more popular forms of Hinduism. The psychological effect of the Muslim conquest may also have predisposed the people to accept the powerful teachings of the poets, but Islām was only a contributory factor in the spread of the new movements.

Much has been said about the synthesis of Hinduism and Islām in the period of Muslim dominance, but, as far as the Hindus were concerned, this was generally a matter of superficial observances. Thus, purdah (narda), the strict seclusion of women, became commonplace among the Hindu upper classes of northern India, numerous Muslim social customs were adopted, and Persian and Arabic words entered the vocabularies of Indian languages. The fundamental theology of Hinduism, however, was unaffected by Islām, even in the teachings of such men as Basava and Kabir, who may have been somewhat influenced by Muslim observances and social customs.

What synthesis did take place came from the Muslims, most of whom were Indian by blood. In Hindi, Bengali, Gujarati, Punjabi, and Marathi there is much poetic literature, written by Muslims and commencing with the Islāmic invocation of Allāh, which nevertheless betrays strong Hindu influence. Thus, there are texts that proclaim Krishna as being in the line of the prophets of on Islam

The Hindu

Syncretic tendencies were encouraged by tolerant Muslim rulers, and these tendencies reached their zenith in the reign of Akbar (1556-1605), who took a great interest in the religion of his Hindu subjects, favoured vegetarianism. and tried to establish a single, all-embracing religion for his empire. Although the efforts of Akbar failed, they influenced India for more than 50 years after his death. The orthodox Muslim theologians had long been complaining about the growth of heresy, however, and the emperor Aurangzeb (reigned 1658-1707) did all in his power to discourage it. Popular Muslim preachers throughout the 18th and 19th centuries worked to restore orthodoxy. Thus, syncretic tendencies virtually came to an end before the imposition of British power in the mid-18th century. Furthermore, British rule emphasized the distinctions between Hindu and Muslim and did not encourage efforts to harmonize the two religions.

THE MODERN PERIOD (19TH-20TH CENTURY)

From their small coastal settlements in southern India, the Portuguese promoted Roman Catholic missionary activity and made converts, most of whom were of low caste; the majority of caste Hindus were unaffected. Small Protestant missions operated from the Danish factories of Tranquebar in Tamil Nādu and Serampore in Bengal, but they were even less influential. The British East India Company, conscious of the disadvantages of unnecessarily antagonizing its Indian subjects, excluded all Christian missionary activity from its territories. Indeed, the company continued the patronage accorded by indigenous rulers to many Hindu temples and forbade its Indian troops to embrace Christianity. The growing evangelical conscience in England brought this policy to an end with the renewal of the company's charter in 1813. The company's policy then became one of strict impartiality in matters of religion, and missionaries were allowed to work throughout its territory. Thus, Christian ideas began to spread.

Hindu reform movements. Brahmo Samāj. The pioneer of reform was Ram Mohun Roy. His intense belief in strict monotheism and in the evils of image worship began early and probably was derived from Islām, because at first he had no knowledge of Christianity. He later learned English and in 1814 settled in Calcutta, where he was prominent in the movement for encouraging education of a Western type. His final achievement was the foundation of the Brahmo Samaj ("Society of God") in 1828.

Roy outwardly remained a Hindu, wearing the sacred cord and keeping most of the customs of the orthodox Brahman; but his theology was surprisingly un-Indian. He was chiefly inspired by 18th-century Deism (rational belief in a transcendent creator god) and Unitarianism (belief in God's essential oneness), but some of his writing suggests that he was aware of the religious ideas of the Freemasons (a secret fraternity that espouses some Deistic concepts). Several of his friends were members of a Masonic lodge in Calcutta. His ideas of the afterlife are obscure, and it is possible that he did not believe in the doctrine of transmigration. Roy was one of the first higher-class Hindus to visit Europe, where he was much admired by the intelligentisa of Britain and France.

After Ram Mohun Roy's death, Debendranath Tagore became leader of the Brahmo Samaj, and under his guidance a more mystical note was sounded by the society. The third great leader of the Brahmo Samaj, Keshab Chunder Sen, was a vigorous reformer who completely abolished caste in the samaj and admitted women. As his theology

became more syncretistic and eclectic, a schism developed, and the more conservative faction remained under the leadership of Tagore. Keshab's faction, the Brahmo Samaj of India, adopted as its scripture a selection of theistic texts gathered from all the main religions; at the same time, it became more Hindu in its worship, employing the sarpikrtana (hymn-singing session) and nagara-ktrana (street procession) of the Caitanya sect. In 1881 Keshab founded the Church of the New Dispensation (Naba Bidhan) for the purpose of establishing the truth of all the great religions in an institution that he believed would replace them all. When he died in 1884, the Brahmo Samaj began to decline, but it produced the greatest poet of modern India, Rabindranath Tagore (1861–1941), son of the second of its great leaders. Debendranath Tagore of the second of its great leaders. Debendranath Tagore

Arya Samai. A reformer of different character was Dayanand Sarasvati, who was trained as a yogi but steadily lost faith in yoga and many other aspects of Hinduism. After traveling widely as an itinerant preacher, he founded the Arya Samaj in 1875, and it rapidly gained ground in the west of India. Dayanand rejected image worship, sacrifice, and polytheism and claimed to base his doctrines on the four Vedas as the eternal word of God. Later Hindu scriptures were judged critically, and many of them were believed to be completely evil. The Arya Samaj did much to encourage Hindu nationalism, but it did not disparage the knowledge of the West, and it established many schools and colleges. Among its members was the revolutionary Lala Lajapt Raj.

New religious movements. Ramakrishna Mission. The most important developments in Hinduism, however, did not arise primarily from the new samājes. The mystic Ramakrishna, who was a devotee at a temple of Kāil called Daksiņešvar to the north of Calcutta, attracted a band of educated lay followers who spread his doctrines. As a result of his studies and visions, he came to the conclusion that "all religions are true" but that the religion of a person's own time and place was for him the best expression of the truth. Even idolatry met the needs of simple people and was not to be disparaged. Ramakrishna thus gave educated Hindus a basis on which they could justify the less rational aspects of their religion to a con-

sciousness increasingly influenced by Western values. Among the followers of Ramakrishna was Narendranath Datta, who became an ascetic after his master's death and assumed the religious name Vivekananda. In 1893 he attended the World's Parliament of Religions in Chicago, where his powerful personality and stirring oratory deeply impressed the gathering. After lecturing in the United States and England, he returned to India in 1897 with a small band of Western disciples. There he founded the Ramakrishna Mission, the most important modern organization of reformed Hinduism, Vivekananda, more than any earlier Hindu reformer, encouraged social service and the uplift of the downtrodden. Influenced by progressive Western political ideas, he set himself firmly against all forms of caste distinction and fostered a spirit of selfreliance in his followers. The Ramakrishna Mission has done much to spread a knowledge of its version of Hinduism outside India and now has branches in many parts

of the world.

Theosophical Society. Another movement influenced in part by Hinduism is the Theosophical Society, which at one time exerted considerable influence. Founded in New York City in 1875 by Helena Blavatsky of Russia, it had as its original inspiration Kabbala (fewish esoteric mysteism), Gnosticism (esoteric salvatory knowledge), and other forms of Western occultism. When Blavatsky went to India in 1879, her doctrines quickly took on an Indian character, and from her headquarters at Adyar she and her followers established branches in many cities of India.

The society survived serious accusations of charlatanry leveled against its founder and certain other leaders, and it reached the peak of its influence under its next important leader, Annie Besant, a reform-minded Englishwoman. Under her guidance, many Theosophical lodges were founded in Europe and the United States, and these helped to acquaint the West with the principles of Hindussn, if in a rather idiosyncratic form.

Rift between liberal and conservative factions

missionary

Aurobindo Ashram. Another modern teacher whose doctrines have had some influence outside India was Śrī Aurobindo, who began his career as a revolutionary. He later withdrew from politics and settled in Pondicherry, then a French possession. There he established an ashram, or āśrama (a retreat), and achieved a high reputation as a sage. His followers saw him as the first incarnate manifestation of the superbeings whose evolution he prophesied, and apparently he did not discourage this belief. After his death, the leadership of the Aurobindo Ashram was assumed by Mira Richard, a Frenchwoman who had been one of his disciples.

Other reform movements. Numerous other teachers have affected the religious life of modern India. Among them was the great Bengali poet Rabindranath Tagore, who was influenced by many currents of earlier religious thought, both Indian and other. Tagore was particularly popular in Europe and America around the time of World War I, and he did much to disseminate Hindu religious thought in the West.

Less important outside India, but much respected in India itself, especially in the Dravidian south, was Ramana Maharshi, a Tamil mystic who maintained almost complete silence. His powerful personality attracted a large band of devotees.

Swami Śivānanda, who had been a physician, established an ashram and an organization called the Divine Life Society near the sacred site of Rishikesh in the Himalayas. This organization has numerous branches in India and some elsewhere. His movement teaches more or less orthodox Vedănta, combined with both yoga and bhakti, but rejects caste and stresses social service.

Jiddu Krishnamurti represents the most attenuated form of Hinduism. He rejects all religious organization and makes no claim to special revelations or exceptional spiritual development; instead, he teaches self-realization through introspection and the abandonment of personal

ambition.

The struggle for independence. The Hindu revival and reform movements of the 19th and early 20th centuries were closely linked with the growth of Indian nationalism and the struggle for independence. The Arya Samai strongly encouraged nationalism, and even though Swami Vivekananda and the Ramakrishna Mission were always uncompromisingly nonpolitical, their effect in promoting the movement for self-government is quite evident.

Religion and politics were joined in the career of Bal Gangadhar Tilak, an orthodox Mahārāshtrian Brahman who believed that the people of India could be aroused only by appeals couched in religious terms. Tilak used the annual festival of the god Ganeśa (Ganapati) for nationalist propaganda. His interpretation of the Bhagavadgitā as a call to action was also a reflection of his nationalism. and through his mediation the Bhagavadgītā became a stimulus to later leaders, including Mahatma Gandhi.

Hindu religious concepts also were enlisted in the nationalist cause in Bengal. In his historical novel Anandamath, the Bengali novelist Bankim Chandra Chatteriee described a band of martial ascetics at the time of the decline of the Mughal empire, who were pledged to free India from Muslim domination. These had as their anthem a stirring devotional song written in simple Sanskrit-"Bande Mātaram" ("I revere the Mother"). The Mother referred to is both the stern demon-destroying goddess Kālī and a personification of India. This song was soon adopted by the more extreme nationalists. Vivekananda emphasized the need to turn the emotion of bhakti toward the suffering poor of India. During his short career as a young revolutionary leader, Śrī Aurobindo made much use of "Bande Mätaram," and he called on his countrymen to strive for the freedom of India in a spirit of devotion. The bhakti of the medieval poets was thus enlisted in the cause of modern independence

Mahatma Gandhi. Much influenced by the traditional bhakti of his native Gujarāt and fortified by Christian and other religious literature that encouraged similar attitudes, Mahatma Gandhi, the most important leader for independence, appeared to his followers as the quintessence of the Hindu tradition. His austere celibate life was one that the Indian laity had learned to respect implicitly. Gandhi's message reached a wider public than that of any of the earlier reformers.

The Western element in Gandhi's ideology has often been exaggerated. His doctrine of nonviolence can be found in many Hindu sources, although his beliefs were much strengthened by Christian ethical literature and especially by the later writings of Leo Tolstoy. His political technique of passive resistance, satyagraha, also has Indian precedents, although in this he was influenced by Western writers such as the American Henry David Thoreau. The chief innovations in Gandhi's philosophy were his belief in the dignity of manual labour and the equality of women. Precedents for both of these can be found in the writings of some 19th-century reformers, but they have little basis in earlier Indian thought. In many ways Gandhi was a traditionalist. His respect for the cow-which he and other educated Indians rationalized as the representative of Mother Earth-was a factor in the failure of his movement to attract large-scale Muslim support. His insistence on strict vegetarianism and celibacy among his disciples, in keeping with the traditions of Vaishnava ascetic ethics, also caused difficulty among some of his followers. Still, the success of Gandhi represented a political culmination of the movement of popular bhakti begun in South India early in the Christian era.

The mantle of Mahatma Gandhi fell on Vinoba Bhave, one of his most devoted Mahārāshtrian supporters. For some years after independence Vinoba led a campaign of social service that culminated in the bhūdān (landgiving) movement, which persuaded many landowners and wealthy peasants to give fields to landless labourers. This movement had some small success in rural areas, but it gradually lost momentum. Although the memory of Gandhi continues to be revered by most Indians, his policies and principles carry little weight. The great bulk of social service is performed by government agencies rather than by voluntary bodies, whether Gandhian or other.

The religious situation after independence. The increase of nationalism, after the division of India into India and Pakistan in 1947, led to a widening of the gulf between Hindus and Muslims. In the early 1970s it was fashionable in Indian circles to paint the relations of the two religions in earlier centuries as friendly, blaming alien rule for the division of India. In Pakistan the tendency has been to insist that Hindus and Muslims have always been "two nations," even though the Hindus were happy under their Muslim rulers. Neither position is entirely correct. In earlier times there was much mutual influence. But the conservative and rigid moralistic element in Indian Islām gained the upper hand long before British power was consolidated in India, and Islamic influence on Hinduism remained superficial.

Among the pioneers of nationalism, Tilak glorified the Mahārāshtrian hero Šivājī as the liberator of his country from the alien yoke of the Mughals; and Bankim Chandra Chatterjee's militant ascetics, who pledged to conquer and expel the Muslims, sang a battle hymn that no orthodox Muslim could repeat. British rulers of India did little or nothing to lessen Hindu-Muslim tension, and their policy of separate electorates for the two communities worsened the situation. Many leaders of the Indian National Congress movement, such as Jawaharlal Nehru, carried their Hinduism lightly and favoured a secular approach to politics. The majority, however, followed the lead of Gandhi, whose insistence on Hindu values discouraged Muslims from joining his movement, despite the fact that at his prayer meetings he recited passages from the Qur'an as well as from Hindu and Christian scriptures. To the right of the Congress politically, the Hindu Mahasabha was equally nationalistic, but its explicitly Hindu nationalism was not opposed to nonviolence in its drive to establish a Hindu state in India

The transfer of power in 1947 was accompanied by slaughter and pillage of huge proportions. Millions of Hindus left their homes in Pakistan for India, and millions of Muslims migrated in the opposite direction. The tension culminated in the assassination of Gandhi by a Hindu fanatic in January 1948.

The policy of the Indian government was to establish a secular state, and the successive Congress governments have broadly kept to this policy. The governments of the Indian states, however, have not been so restricted by constitutional niceties. Some state governments have

introduced legislation of a specifically Hindu character. On the other hand, the Congress government has passed legislation more offensive to Hindu traditional prejudices than anything that any British Indian government would have dared to enact. All forms of discrimination against "untouchables" (now usually referred to by euphemisms such as "harijans," or "people of God," instead of the British euphemism "scheduled castes") are forbidden, although it has been impossible to enforce the law in every case. A great blow to conservatism was dealt by legislation in 1955 and 1956 that gave full rights of inheritance to widows and daughters, enforced monogamy, and permitted divorce on quite easy terms. The 1961 law forbidding dowries further undermined traditional Hinduism. Although the dowry has long been a tremendous burden to the parents of daughters, the strength of social custom is such that the law cannot be fully enforced.

The social structure of traditional Hinduism is slowly crumbling in the cities. Intercaste and interreligious marriages are becoming more frequent among the educated, although some aspects of the caste system show remarkable vitality, especially in the matter of appointments and elections. The bonds of the tightly knit Hindu joint family are also weakening, a process helped by legislation and the emancipation of women. The professional priests, who perform rituals for lay people in homes or at temples and sacred sites, complain of the lack of custom, and their

numbers are diminishing.

Nevertheless, Hinduism is far from dying, Mythological films, once the most popular form of entertainment, are enjoying a renaissance. Organizations such as the Ramakrishna Mission flourish and expand their activities. New teachers appear from time to time and attract considerable followings. Militant fundamentalist Hindu organizations such as the Society for the Self-Service of the Nation (Rashtriya Svayamsevak Sangh; RSS) are steadily growing. Such movements can be seen as the cause or the result, or both, of persistent outbreaks of communal religious violence involving Hindus and Sikhs in North India, Tamil Hindus and Sri Lankan Buddhists in Sri Lanka, Tamil extremists and moderates in Tamil Nādu, and, still everywhere, Hindus and Muslims,

The adaptability of Hinduism to changing conditions is illustrated by the appearance in the Hindu pantheon of a new divinity, of special utility in an acquisitive society. This is the goddess Santosī Mātā, first worshiped widely by women in many cities of Uttar Pradesh and now worshiped throughout India, largely as the result of a popular mythological film about her birth and the origin of her worship. The new goddess was unheard-of a few years ago and has no basis in any Puranic myth. Propitiated by comparatively simple and inexpensive rites performed in the home without the intervention of a priest, Santosi, it is believed, grants practical and obvious blessings, such as a promotion for a needy, overworked husband, a new radio, or even a refrigerator. News of Santosi's blessings is passed from housewife to housewife, and even moderately well-educated women have become her devotees

On both the intellectual and the popular level, Hinduism is thus in the process of adapting itself to new values and new conditions that have been brought about by mass education and industrialization and is responding to 20th-

century challenges.

Hinduism outside India. Since the latter part of the 19th century large colonies of Hindu migrants have been established in East Africa, Malaysia, the islands of the Pacific and the Indian Ocean, and some of the islands of the West Indies. These migrants have taken their religion with them and have adhered to it faithfully for several generations. In recent years they have been aided by Hindu missionaries, chiefly from the Arya Samaj or the Ramakrishna Mission. Since World War II many Hindus have also settled in the United Kingdom. Most of these migrants, however, are comparatively uneducated, and their religion has made

little impression on the people among whom they live. They also have made no serious attempts to gain converts. Yet, one of the most striking aspects of contemporary Western culture is its readiness to accept Eastern religious ideas in a way that is unprecedented since the days of the Roman Empire. A recent manifestation of the spread of Indian religious attitudes in the Western world is the Hare Krishna cult, officially known as the International Society for Krishna Consciousness, with its principal office in Los Angeles. This is essentially a bhakti movement, broadly following the precedents of Caitanya. Since its foundation by a Hindu sannyasi, A.C. Bhaktivedanta (Swami Prabhupāda), in 1966, its growth has been surprising, and sankirtana (devotional singing and dancing) can be seen in the streets of New York City and London, performed by young men and women from Christian or Jewish homes wearing dhotis and saris. These manifestations are part of a process that began in 1784 with the first English translation of a Hindu religious text, Charles Wilkins' version of the Bhagavadgitā

Hinduism is not by nature a proselytizing religion, however, in part because of its inextricable roots in the social system and the land of India. In recent years, many new gurus, such as Bhagwan Shree Rajneesh and Satva Sai Baba, have been successful in making converts in Europe and the United States. The very success of these gurus, however, has produced material profits that many people regard as incompatible with the ascetic attitude appropriate to a Hindu spiritual leader; in some cases, the profits have led to notoriety and even legal prosecution. In addition, the self-proclaimed conversion to questionable forms of "Hinduism" by popular singers and film stars has tended both to increase the glamour and to diminish the respectability of these new forms of Orientalism. That Hinduism is flourishing in India is obvious; that it has made, and can continue to make, a genuine contribution to Western religious thought is undeniable; that the invasion of the gurus is a part of that contribution is highly dehatable (A.L.B./J.A.B.v.B./W.Do.)

Sacred texts

Importance of the Vedas. The Veda, meaning "Knowledge," is a collective term for the sacred scriptures of the Hindus. Since about the 5th century BC, the Veda has been considered to be the creation of neither human nor god; rather, it is regarded as the eternal Truth that was in ancient times directly revealed to or "heard" by gifted and inspired seers (rishis) who transcribed it into the most perfect human language, Sanskrit. Although most of the religion of the Vedic texts, which revolves around rituals of fire sacrifice, has been eclipsed by Hindu doctrines and practices, the absolute authority and sacredness of the Veda remains a central tenet of virtually all Hindu sects and traditions. Even today, as it has been for several millennia, parts of the Veda are memorized and recited as a religious act of great merit.

The components of the Veda. The Veda is the product of the Aryan invaders of the Indian subcontinent and their descendants, although the original inhabitants (disdainfully called dásyus, or "slaves," in the Veda) may very well have exerted an influence on the final product. The Veda represents the particular interests of two classes of Aryan society, the priests (Brahmans) and the warriorkings (Kşatriyas), who together ruled over the far more

numerous peasants (Vaisyas).

Vedic literature ranges from the Rigveda (Rgveda; c. 1400 BC) to the Upanishads (Upanisads; c. 1000-500 BC). This literature provides the sole documentation for all Indian religion before Buddhism and the early texts of classical Hinduism. Because it is the literature of a ruling class, it probably does not represent all the myths and cults of the early Indo-Aryans, let alone those of the non-Aryans.

The most important texts are the four collections (Samhitās) known as the Veda or Vedas (i.e., "Book[s] of Knowledge"); the Rigveda ("Wisdom of the Verses"), the Yajurveda ("Wisdom of the Sacrificial Formulas"), the Sāmaveda ("Wisdom of the Chants"), and the Athar-

The great of Vedic literature

The soma

sacrifice

Rigveda

in the

vaveda ("Wisdom of the Atharvan Priests"). Of these, the Rioveda is the oldest

In the Vedic texts following these earliest compilations, the Brahmanas (discussions of the ritual), Aranyakas (books studied in the forest), and Upanishads (secret teachings concerning cosmic equations), the interest in the early Rigvedic gods wanes, and they become little more than accessories to the Vedic rite. Polytheism begins to be replaced by a sacrificial pantheism of Prajapati ("Lord of Creatures"), who is the All. In the Upanishads Prajāpati merges with the concept of brahman, the supreme reality and substance of the universe (not to be confused with the Hindu god Brahmā), replacing any specific personification, thus transforming the mythology into abstract philosophy.

Together, the components of each of the four Vedasthe Samhitäs, Brāhmanas, Āranyakas, and Upanishadsconstitute the revealed scripture of Hinduism, or the Sruti (Sruti: "Heard"). All other works-in which the actual doctrines and practices of Hindus are encoded-are recognized as having been composed by human authors and are thus classed as Smriti (Smṛti; "Remembered"). The categorization of Veda, however, is capable of elasticity. First, the Sruti is not exactly closed; Upanishads, for example, have been composed until recent times. Second, the texts categorized as Smriti inevitably claim to be in accord with the authoritative Sruti, and thus worthy of the same respect and sacredness. For Hindus, the Veda is a symbol of unchallenged authority and tradition.

The Rigveda. The religion reflected in the Rigveda is a polytheism mainly concerned with the propitiation of divinities associated with the sky and the atmosphere. Of these, the Indo-European sky father Dyaus was by then little regarded. More important were such gods as Indra, Varuna (guardian of the cosmic order), Agni (the sacrifi-

cial fire), and Sūrya (the Sun).

The main ritual activity referred to in the Rigveda is the soma sacrifice. Soma was a hallucinogenic beverage prepared from a now-unknown plant; recently it has been suggested that the plant was a mushroom and that later another plant was substituted for the agaric fungus, which had become difficult to obtain. The Rigveda contains a few clear references to animal sacrifice, which probably became more widespread later. There is some doubt whether the priests formed a separate class of society at the beginning of the Rigvedic period. If they did so, the prevailingly loose boundaries of class made it possible for a man of nonpriestly parentage to become a priest. By the end of the period, however, they had become a separate class of specialists, the Brahmans (Brāhmanas), who claimed superiority over all the other social classes, including the Rajanyas (later Ksatriyas), the warrior-kings.

The Rigveda contains little about birth rituals, but the rites of marriage and disposal of the dead were basically the same as in later Hinduism. Marriage was an indissoluble bond cemented by a lengthy and solemn ritual centring on the domestic hearth. The funeral rites of the rich included cremation, although other funeral forms were also practiced. An interesting reference in one hymn shows that the wife of the dead man lay down beside him on the funeral pyre but was called upon to return to the land of the living before it was lighted. This may have been a survival from an earlier period when the wife was actually cremated with the husband, a custom that was revived in later times.

Among other features of Rigvedic religious life that were important for later generations were the munis. The muni was apparently a sort of shaman (a religious personage having healing and psychic transformation powers), trained in various magic arts and believed to be capable of supernatural feats, such as levitation. He was particularly associated with the god Rudra, a deity connected with mountains and storm and more feared than loved. Rudra developed into the Hindu god Śiva, and his prestige increased steadily. The same is true of Vishnu, a minor solar deity in the Rigveda, who later became one of the most important and popular divinities of Hinduism.

One of the favourite myths of the Aryans was one that attributed the origin of the cosmos to the god Indra, after he had slain the great dragon Vrtra, a myth very similar to one known in early Mesopotamia. With time, such tales were replaced by more abstract theories that are reflected in several hymns of the late 10th book of the Rigveda. These speculative tendencies were the beginnings of the persistent effort of Indian philosophers to reduce all things to a single basic principle.

Elaborations of text and ritual: the later Vedas. The chronology of later Vedic developments is extremely vague, but it probably encompasses the period from 1000 to 500 BC, which are the dates of the Painted Grayware strata in the archaeological sites of the western Ganges Valley. These excavations reflect a culture still without writing but showing considerable advances in civilization. Nothing, however, has been discovered from sites of this period that throws much light on the religious situation, and historians still must rely on the following texts to describe this phase of the religion.

The Yajurveda and The Yajurveda and Sāmaveda. Sāmaveda are completely subordinate to the liturgy. The Yajurveda contains the lines, usually in brief prose, with which the executive priest (adhvaryu) accompanies his ritual manipulations, addressing the implements he handles and the offering he pours and admonishing other priests to do their invocations. The Samaveda is a collection of verses from the Rigveda (and a few new ones) that were chanted with certain fixed melodies.

The Atharvaveda. The Atharvaveda stands apart from other Vedic texts. It contains both hymns and prose passages and is divided into 20 books. Books 1-7 contain magical prayers for precise purposes; spells for a long life. cures, curses, love charms, prayers for prosperity, charms for kingship and Brahmanhood, and expiations for evil committed. They reflect the magical-religious concerns of everyday life and are on a different level than the Rigveda, which glorifies the great gods and their liturgy. Books 8-12 contain similar texts but also include cosmological hymns that continue those of the Rigveda and provide a transition to the more complex speculations of the Upanishads. Books 13-20 celebrate the cosmic principle (book 13) and present marriage prayers (book 14), funeral formulas (book 18), and other magical and ritual formulas. This text is an extremely important source of knowledge of practical religion and magic, particularly where it com-

Kausika family of priests) of the Atharvaveda. The Brāhmanas and Āranyakas. Attached to each Samhitā was a collection of explanations of the rituals, called a Brahmana, which often relied on mythology to trace the origins and importance of individual ritual acts. Although they were not manuals or handbooks in the manner of the later Śrauta Sutras, the Brāhmaṇas do contain some detail about the performance and meaning of Vedic sacrificial rituals and are invaluable sources of

plements the one-sided picture of the Rigveda. Many rites

are also laid down in the "Kausikasūtra" (manual of the

information about the Vedic religion.

In these texts the sacrifice is the very centre of cosmic processes, all human concerns, and religious desires and goals. It is through the sacrifice that the cosmos continues in its cycles and that human beings obtain the goods of life and a birth in heaven in the next world. The ritual was thought to have such effects on the visible and invisible worlds because of homologies, or connections (bandhus), that were said to lie between the components and phases of the ritual and corresponding parts of the universe. The universalization of the dynamics of the ritual into the dynamics of the cosmos was depicted as the sacrifice of the primordial deity, Prajāpati ("Lord of Creatures"), who was perpetually regenerated by the sacrifice.

The lengthy series of rituals of the royal consecration. the rājasūya, emphasized royal power and endowed the king with a divine charisma, raising him, at least for the duration of the ceremony, to the status of a god. Typical of this period was the elaborate asvamedha, the horse sacrifice, in which a consecrated horse was freed and allowed to wander at will for a year; it was always followed by the king's troops, who defended it from all attack until it was brought back to the royal capital and sacrificed in a very complicated ritual.

Vedic cosmic-sacrificial speculations continued in the

The other Samhitās

Āraņyakas (forest books), which contain materials of two kinds: Brāhmaṇa-like discussions of rites not believed to be suitable for the village (hence the name "forest") and continuing visions of the relationship between sacrifice, universe, and man. The word brahman-the creative power of the ritual utterances, which is used to denote the creativeness of the sacrifice and which underlies ritual and therefore cosmic order-is prominent in these texts.

Vedic religion. Cosmogony and cosmology. In the Vedic literature there are different but not exclusive accounts of the origin of the universe. The simplest is that the creator built the universe with timber, as a carpenter builds a house. Hence there are many references to gods measuring the different worlds as parts of one edifice, atmosphere upon Earth, heaven upon atmosphere. Creation may be viewed as procreation: the personified Heaven, Dyaus (the word is related to the Greek Zeus), impregnates the Earth goddess, Prthivi, with rain, causing crops to grow on her. Quite another myth is recorded in the last (10th) book of the Rigveda: in the "Hymn of the Cosmic Man" ("Purusasukta") it is said that the universe was created out of the parts of the body of a single cosmic man (Purusa) when his body was immolated and dismembered at the primordial sacrifice. There the four classes (varnas) of Indian society are referred to: the priest (Brahman) emerging from the mouth, the warrior (Rājanya) from the arms, the peasant (Vaisya) from the thighs, and the servant (Sūdra) from the legs of the primeval victim. The "Puruşasükta" represents the beginning of a new phase, in which the sacrifice became more important and elaborate as cosmological and social philosophies were constructed around it.

In the same book of the Rigveda, mythology begins to be transformed into philosophy; for example, "in the beginning was the nonexistent, from which the existent arose" (Rigveda 10.72.2). Even the reality of the nonexistent is questioned: "then there was neither the nonexistent nor the existent" (Rigveda 10.129). Such cosmogonic speculations continue, particularly in the older Upanishads. Originally there was nothing at all, or Hunger, which then, to sate itself, creates the world as its food. Alternatively, the creator creates himself in the universe by an act of self-recognition, self-formulation, or self-formation. Or the one creator grows "as big as a man and a woman embracing" (Brhadaranyaka Upanishad I.4.3) and splits into man and woman, and in various transformations the couple create other creatures. In one of the last stages of this line of thought (Chandogya Upanishad 6.2), the following account became fundamental to the ontology of the philosophical schools of Vedanta: in the beginning was the Existent, or brahman, which through heaven, Earth, and atmosphere (the triadic space) and the three seasons of summer, rains, and harvest (the triadic time) produced

the entire universe. The three

The Vedic texts generally regarded the universe as three layers of "worlds" (loka): heaven, atmosphere, and Earth. Heaven is that part of the universe where the sun shines and is correlated with sun, fire, and ether; the atmosphere is that part of the sky between heaven and Earth where the clouds insert themselves in the rainy season and is correlated with water and wind; Earth, a flat disk, like a wheel, is here below as the "holder of treasure" (vasumdharā) and giver of food. In addition to this tripartite pattern, there is also an ancient notion of duality, in which heaven is masculine and father and Earth is feminine and mother. Later texts present the conception that combinations and permutations of five elements (ether-space [ākāśa], wind [vāyu], fire [agni], water [āpas], and earth [bhūmi]) formed the universe.

Theology. Generally speaking, Vedic gods share many characteristics: several of them (Indra, Varuna, Vishnu) are said to have created the universe, set the Sun in the sky, and propped apart heaven and Earth. All of them are bright and shining, and all are susceptible to human praise. Some major gods were clearly personifications of natural phenomena, and for these deities no clearly delineated divine personalities were perceived.

The three most frequently invoked gods are Indra, Agni, and Soma. Indra, the foremost god of the Vedic pantheon, is a god of war and rain. Agni (a cognate of the Latin ignis) is the deified fire, particularly the fire of sacrifice, and Soma is the intoxicating or hallucinogenic drink of the sacrifice, or the plant from which it is pressed; neither is greatly personified.

The principal focus of Vedic literature is the sacrifice. which in its simplest form can be viewed as a ritualized banquet to which a god is invited to partake of a meal shared by the sacrificer and his priest. The invocations mention, often casually, the past exploits of the deity. The offered meal gives strength to the deity to repeat his feat and to aid the sacrificer.

The myth of Indra killing the dragon Vrtra has many levels of meaning. Vrtra prevents the monsoon rains from breaking. Because the monsoon is the greatest single factor in Indian agriculture, the event celebrated in this myth impinges on everyone's life. In the social circles represented in the Rigveda, however, the myth is cast in a warrior mold and the breaking of the monsoon is viewed as a cosmic battle. The entire monsoon complex is involved: Indra is the Lord of the Winds, the gales that accompany the monsoon; his weapons are lightning and thunderbolt. with which he lays Vrtra low. To accomplish this feat he must be strengthened with soma. Simultaneously, he is the god of war and is invoked to defeat the non-Aryan dásyus, the indigenous peoples referred to in the Vedas. These important concerns-the promptness and abundance of the rains, success in warfare, and the Aryan conquest of the land-all find their focus in Indra.

Because the Vedic gods were not fully anthropomorphic, their functions were subject to various applications and interpretations. Thus Indra, the greatest and most anthropomorphic god of the early Veda, was, in the view of the noble patrons of the Vedic poets, primarily a fighter and a warrior god invoked to bring booty and victory. Agriculturalists and hunters emphasized Indra's fecundity, celebrating his festivals to produce fertility, welfare, and happiness. Indra, however, was essentially a representative of useful force in nature and the cosmos and therefore was the great champion of an ordered and habitable world. His repeated victories over the snake-demon Vrtra, the representative of obstruction and chaos, resulted in the separation of heaven and Earth (the support of the former and the stabilization of the latter), the rise of the Sun, and the release of the waters: in short, in the organization of

Although morality is not an issue in Indra's myth, it is in those of the other principal Vedic deities. Central to ancient morality was the notion of rita (rta), the basic meaning of which appears to have been the truthfulness with which the alliance between humans (and between humans and gods) was observed-a quality necessary to maintain the physical and moral order of the universe. Varuna is an older sovereign god, who with Mitra (related to the Persian god Mithra) presides over the observance of the rita. Thus Varuna is a judge before whom a mortal may stand guilty, while Indra is a king who may support a mortal king. Typical requests that are made of Varuna are for forgiveness, for deliverance from evil committed by oneself or others, and for protection; Indra is prayed to for bounty, for aid against enemies, and for leadership

Distinct from both is Agni, the fire, who is observed in all his multifarious manifestations: in the sacrificial fire, in lightning, or hidden in the logs from which fire can be drilled. As the fire of sacrifice, he is the mouth of the gods and the carrier of the oblation, the mediator between the human and the divine orders. Agni is above all the good friend of the Aryans and is prayed to to strike down and to burn their enemies and to mediate between gods and men.

against demons and dásvus.

Among other Vedic gods, only a few stand out. One is Vishnu, important perhaps more in retrospect than in fact. He is famous for his "three strides," with which he traversed the universe, thus creating and possessing it. In his later mythology this pervasiveness, which invites identification with other gods, remains characteristic. His function as helper to the conqueror-god Indra is important.

Impersonality is increased by the prevalence of pairs and groups of gods. Thus Varuna and Mitra are members of the group of Adityas (sons of Aditi, an old progenitrix),

The notion

katheno-

who generally are celestial gods. They are also combined in the double god Mitra-Varuna. Indra and Vishnu are combined as Indra-Vishnu. There is also Rudra, an ambivalent god who is dreaded for his unpredictable attacks but is simultaneously benign insofar as he can restrain his attacks. Although there are many demons (rakshasas), no one god embodies the evil spirit; rather, many gods have their devil within, inspiring fear as well as trust. Among the perpetually beneficent gods are the Aśvins (horsemen), who are helpers and healers and often visit the needy. Almost otiose is the personified heaven, Dyaus, who most often appears literally as the sky, and often as day. As a person, he is coupled with Earth (in the god pair Dyāvā-Prthivi) as a father; Earth by herself is more predominantly known as Mother (Matr). Apart from Earth, the other goddess of importance in the text of the Rigveda is Usas (Dawn), who brings in the day and thus is said to bring forth the Sun.

In the later Vedic period the significance of the Rigvedic gods and their myths began to wane. The peculiar theism of the Rigveda, in which any one of several different gods might be hailed as supreme and attributes of one god could be transferred to another (called kathenotheism by the Vedic scholar F. Max Müller), stressed godhead more than individual gods. In the end this led to a pantheism of Prajapati, the deified sacrifice or ritualized deity; with his consort Vac (i.e., the speech of ritual recitation), he is

said to have begotten the world.

In the course of the Vedic period Purusa fused with the figure Nārāyana ("Scion of Man") and with Prajāpati ("Lord of Creatures"), the patron of procreation in popular belief. In the speculative thought of the ritualists, Prajāpati came to the fore as the creator god and in many respects as the highest divinity, the immortal father even of the gods, whom he transcends, encompasses, and molds into one complex. As the One, the concentrated All, or Totality, Prajāpati was identified with the highest and most general categories. By a process of emanation and selfdifferentiation (by dividing himself), he created all beings and the universe. After this "creation," Prajapati became the disintegrated and differentiated All of the phenomenal world and was exhausted. By means of a rite, he then reintegrated himself to prepare for a new phase of creativity. Because the purpose of the sacred act is the restitution of the organic structural norm, which ensures the ordered functioning of the universe, Prajāpati was identified with the rite. Thus, by identifying himself with Prajapati, a sacrificer may temporarily reintegrate within himself what has been disintegrated, thereby restoring oneness and totality in himself and the universe.

Ethical and social doctrines. In Vedic times, "sin" (énas) or evil (pāpmán) was put on a par with illness, enmity, distress, or malediction; it was conceived of as a sort of pollution that could be neutralized by ritual or devices for averting evil. A man might incur "sin" by any incorrect or improper behaviour, especially improper speech, and thus be guilty of anrta (i.e., any infidelity to fact or departure from what is true, real, and constitutes the established order) whether or not he had deliberately committed a crime. Other transgressions included making mistakes in sacrifices and coming into contact with corpses, ritually impure persons, or persons belonging to the lower classes of society. These acts were only rarely considered to be misdeeds against a god or violations of moral principles of divine origin, and the consciousness of guilt was much rarer than the fear of the evil consequences of sin, such as disease or untimely death. Sometimes, however, a god (Agni, the evil-devouring fire, or Varuna, the god of order, whose role included punishing and fettering the "sinner") was invoked to forgive the neglect or transgression or to release a man from their concrete results. More usually, however, these results were abrogated by means of purifications, such as the ceremonial use of water, and a variety of expiatory rites.

To the pure who earned ritual merits, the prospect of a safe "world" (loka) or condition was held out. The meticulous effort to purify oneself from every kind of evil also involved the observance of various customs regarding the avoidance of inauspicious occurrences-an endeavour called śānti. Ritual purity was the principal concern of the compilers of the manuals of dharma (religious law) that, belonging to the sacred tradition (Smriti; i.e., remembered by human teachers), have contributed much to the special character of Hinduism. According to the authorities on dharma, ritual purity is: the first approach to dharma, the resting place of the Veda (brahman), the abode of prosperity (śrī), the favourite of the gods, and the means of clearing (soothing) the mind and of seeing (realizing) the atman in the body.

The sacred: nature, man, and God. The contact with the unseen or sacred included humankind's contributions by ritual acts to the maintenance of the universe-of which Vedic thinkers felt themselves an indissoluble part-and to the periodic regeneration, through sacrificial practices, of both the powers for good and the cosmic processes that make earthly life and welfare possible. The Vedic poets were deeply convinced that the world is an organized cosmos governed by order and truth (rita) and that it is always in danger of being damaged or destroyed by the powers of chaos (asat). This conviction found mythological expression in the continual conflict between gods (devas) and demoniac antigods (asuras).

Gods were conceived as presiding over certain provinces of the universe or as responsible for important cosmic or social phenomena. Their deeds are timeless and exemplary presentations of mythic events replete with power and universal, eternal significance. To reproduce themselves in time and thus retain their vitality and efficacy, mythical events need to be repeated-that is, celebrated and confirmed by means of the spoken word and ritual acts.

Vedic and Brahmanic rites. Vedic religion is primarily a liturgy differentiated in various types of ritual designed for almost any conceivable purpose. These rites are described in the texts in minute detail; theoretically, no operation, no gesture, no formula is meaningless or left to an officiant's discretion. On the basis of a complicated speculative system, all are explained and shown to be effective in the Brahmanas. The often complicated ritual technique was devised mainly to safeguard human life and survival, to enable people to face the many risks and dangers of existence, to thwart the designs of human and superhuman enemies that cannot be counteracted by ordinary means, to control the unseen powers, and to establish and maintain beneficial relations with the supramundane sacred order. Belief in the efficacy of the rites is the natural consequence of the belief that all things and events are connected with or participate in one another. Hence it is also believed that a close correspondence exists between a sacred place-such as the sacrificial place of many Vedic rites, a place of pilgrimage, or a consecrated area (mandala, "circle")-and a province of the universe or even the universe itself. These places represent, within the reach of the officiants, the universe or as much of it as is relevant. In such places, direct communication with other cosmic regions (heaven or underworld) is possible because they are said to be at the point of contact between this world and the "pillar of the universe," "the navel of the earth." The sacred place is (by virtue of a system of connections) identical with the universe in its various states of emanation from, reabsorption into, integration with, and disintegration from the sacred. This idea has as its corollary the possibility of ritually enacting the cosmic drama and, thus, of influencing, through the same system of connections, those events in the cosmos that continuously affect human weal and woe.

The Vedic ritual system is organized into three main forms. The simplest, and hierarchically inferior, type of Vedic ritualism is the grhya, or domestic ritual, in which the householder himself offers modest oblations into the one sacred household fire. The more ambitious, wealthy, and powerful married householder sets three or five fires and, with the help of professional officiants, engages in the more complex śrauta sacrifices. These require oblations of vegetable substances and, in some instances, of parts of ritually killed animals (mostly goats, but also sheep, cows, horses, and perhaps at one time human beings as well). Finally, at the highest level of Vedic ritualism are the sacrifices of soma, which can continue for days or even years

atman-

and whose intricacies and complexities are truly stunning. In the major srauta rites, requiring three fires and 16 priests or more, "the man who knows"-he who has an insight into the correspondences (bándhu) between the mundane and cosmic phenomena and the eternal transcendent reality beyond them and who knows the meaning of the ritual words and acts-may set great cosmic processes in motion for the sake of human interests. In these rites, Brahman officiants repeat the mythic drama for the benefit of their patron, the "sacrificer," who temporarily becomes its centre and realizes through ritual symbolism his identity with the universe. Whatever magical elements may be involved in this ritual technique, its aim in establishing an efficacious contact with a transcendental order that is the source of all life and power is based on an essentially religious conception. Such officiants are firmly convinced of the efficacy of their rites: "the sun would not rise, were he [the officiant] not to make that offering; this is why he performs it" (Satapatha Brahmana 2.3.1.5). The oblations should not be used to propitiate the gods or to thank them for favours bestowed, since the efficacy of the rites, some of which are still occasionally performed, does not depend on the will of the gods.

The Upanishads. With the last component of the Veda, the mystically oriented and originally esoteric texts known as the Upanishads, Vedic ritualism and the doctrine of the interconnectedness of separate phenomena was superseded by a new emphasis on knowledge alone-primarily knowledge of the ultimate identity of all phenomena, which merely appeared to be separate. The phase of Indian religious life roughly between 700 and 500 BC was the period of the beginnings of philosophy and mysticism marked by the Upanishads ("Sittings Near a Teacher"). Historically, the most important of these are the two oldest, the Brhadaranyaka ("Great Forest Text") and the Chandogva (pertaining to the Chandogas, a class of priests who intone hymns at sacrifices), both of which are compilations that record the traditions of sages (rishis) of the period, notably Yājñavalkya, who was a pioneer of new religious ideas

The primary motive of the Upanishads is a desire for mystical knowledge that would ensure freedom from "redeath." Throughout the later Vedic period, the idea that the world of heaven was not the end-and that even in heaven death was inevitable-had been growing. For Vedic thinkers, the fear of the impermanence of religious merit and its loss in the hereafter, as well as the fearprovoking anticipation of the transience of any form of existence after death, culminating in the much-feared repeated death (punarmṛtyu), assumed the character of an obsession. The means of escaping and conquering death and of attaining integral life devised in the Brahmanas were of a ritual nature, but in one of the oldest Upanishads, the Brhadaranyaka (c. 10th-5th century BC), more emphasis was placed on the knowledge of the cosmic connection underlying ritual. When the doctrine of the identity of atman (the Self) and brahman was established in the Upanishads, the true knowledge of the Self and the realization of this identity was (by those sages who were inclined to meditative thought) substituted for the ritual method.

In the following centuries, the main theories connected with the divine essence underlying the world were harmonized and synthetically combined, and the tendency was to extol one god as the supreme Lord and Originator (Īśvara), who is at the same time Purușa and Prajāpati and brahman and the inner Self (atman) of all beings. For those who worshiped him, he became the goal of identificatory meditation, which leads to complete cessation of phenomenal existence and becomes the refuge of those who seek eternal peace.

The period during which the Upanishads were composed was one of much social, political, and economic upheaval. Rural tribal society was disappearing, and the adjustments of the people to urban living under a monarchy probably provoked many psychological and religious responses. During this period many groups of mystics, world-renouncers, and forest-dwellers appeared in India, and these included the authors of the Upanishads. Among the more important practices and doctrines of these worldrenouncers were asceticism and the concept of rebirth or transmigration.

The Rigveda shows few examples of asceticism, except among the munis (shamans). The Atharvaveda describes another class of religious adepts, or specialists, the vratyas, particularly associated with the region of Magadha (west central Bihār). The vrātya was a wandering hierophant (one who manifested the Holy) who remained outside the regular system of Vedic religion. He traveled from place to place in a bullock cart with an apprentice and with a woman who appears to have been used for ritual prostitution. Flagellation and other forms of self-mortification seem to have been part of his routine. Efforts were made by the orthodox to bring the vrātyas into the Vedic system by special rituals of conversion, and it may be that these people helped to introduce non-Aryan beliefs and practices into Vedic religion. At the same time, the more complex sacrifices of the later Vedic period demanded purificatory rituals, such as fasting and vigil, as part of the preparations for the ceremony. Thus there was a growing tendency toward the mortification of the flesh

The origin and the development of the belief in the transmigration of souls are very obscure. A few passages suggest that this doctrine was known even in the days of the Rigveda, but it was first clearly propounded in the earliest Upanishad-the Brhadaranyaka. There it is stated that normally the soul returns to Earth and is reborn in human or animal form. This doctrine of samsara (reincarnation) is attributed to the sage Uddālaka Āruņi, who is said to have learned it from a Ksatriya chief. In the same text, the doctrine of karma (actions), according to which the soul achieves a happy or unhappy rebirth according to its works in the previous life, also occurs for the first time, attributed to Yājñavalkya. Both doctrines appear to have been new and strange ones, circulating among small groups of ascetics who were disinclined to make them public, perhaps for fear of the orthodox priests. These doctrines must have spread rapidly, for in the later Upanishads and in the earliest Buddhist and Jain scriptures they are common knowledge.

SUTRAS, SHASTRAS, AND SMRITIS

The Vedangas. Toward the end of the Vedic period. and more or less simultaneously with the production of the principal Upanishads, concise, technical, and usually aphoristic texts were composed about various subjects relating to the proper and timely performance of the Vedic sacrificial rituals. These were eventually labeled as Vedāngas ("Studies Accessory to the Veda").

The intense preoccupation with the liturgy gave rise to scholarly disciplines that were part of the Vedic erudition. There were six such fields: (1) śikṣā (instruction), which explains the proper articulation and pronunciation of the Vedic texts. Different branches had different ways of pronouncing the texts, and these variations were recorded in prātišākhyas (literally, "Instructions for the śākhās"branches), four of which are extant; (2) chandas (metre), of which there remains only one late representative; (3) vyākarana (analysis and derivation), in which the language is grammatically described-Panini's famous grammar (c. 400 BC) and the prātiśākhyas are the oldest examples of this discipline; (4) nirukta (lexicon), which discusses and gives meanings for difficult words, represented by the Nirukta of Yāska (c. 600 BC); (5) jyotişa (luminaries), a system of astronomy and astrology used to determine the right times for rituals; and (6) kalpa (mode of performance), which studies the correct ways of performing the ritual.

Of special importance are the texts constituting the Kalpa Sutras (collections of aphorisms on the mode of ritual performance). The composition of these texts was begun around 600 BC by Brahmans belonging to the ritual schools (śākhās), each of which was attached to a particular recension of one of the four Vedas. A complete Kalpa Sutra contains four principal components: (1) a Śrauta Sutra, which establishes the rules for performing the more complex rituals of the Vedic repertoire; (2) a Sulba Sutra, which shows how to make the geometric calculations necessary for the proper construction of the ritual arena; (3) a Grhya Sutra, which explains the rules for performing the

Early scholarly disciplines Society was ritually stratified in the four classes, each of which had its own dharma (law), or eternal norm of conduct. The ideal life was constructed through sacraments in the course of numerous ceremonies, performed by the upper classes, that carried the individual from conception to cremation in a series of complex rites. The Grhya Sutras show that in the popular religion of the time there were many minor divinities who are rarely mentioned in the literature of the large-scale sacrifices but who were probably far more influential on the lives of most people than were the great gods of Vedism.

Dharma Sutra and Dharma Shastra. Among the texts inspired by the Veda are the Dharma Sutras, or manuals on dharma, which contain rules of conduct and rites as they were practiced in a number of branches of the Vedic schools. Their principal contents address the duties of people at various stages of life or ashramas (studenthood, householdership, retirement, and asceticism); dietary regulations; offenses and expiations; and the rights and duties of kings. They also discuss purification rites, funerary ceremonies, forms of hospitality, and daily oblations. Finally, they even mention juridical matters. The more important of these texts are the sutras of Gautama, Baudhayana, and Apastamba. Although the direct relationship is not clear, the contents of these works were further elaborated in the more systematic Dharma Shastras, which in turn became the basis of Hindu law.

First among them stands the Dharma Shastra of Manu. also known as the Manu-smrti ("Tradition of Manu"; c. AD 200), with 2,694 stanzas divided into 12 chapters. It deals with various topics such as cosmogony, definition of dharma, the sacraments, initiation and Vedic study, the eight forms of marriage, hospitality and funerary rites, dietary laws, pollution and purification, rules for women and wives, royal law, 18 categories of juridical matters, and finally more religious matters, including donations, rites of reparation, the doctrine of karma, the soul, and punishment in hell. Law in the juridical sense is thus completely embedded in religious law and practice. The framework is provided by the model of the four-class society. The influence of the Dharma Shastra of Manu has been enormous, as it provided Hindu society with its practical morality. For large parts of the Indian subcontinent, Manu's text-mediated by its commentaries, notably that of Medhātithi (9th century)-has been the law.

Second only to Manu is the Dharma Shastra of Yājnāvalkya; its 1,013 stanzas are distributed under the three headings of good conduct, law, and expiation. Its commentary, Miākṣarā of Vijñāneśvara (11th century), has extended its influence.

Smrtif texts. The shastras are a part of the Smrtif ("Remembered," or traditional) literature which, like the sutra literature that preceded it, stresses the religious merit of gifts to Brahmans. Because kings often transferred the revenues of villages or groups of villages to Brahmans, either singly or in corporate groups, the status and wealth of the priestly class rose steadily. In the agrahdras, as the settlements of Brahmans were called, they were encouraged to devote themselves to the study of the Vedas and the subsidiary studies associated with them; but many Brahmans also developed the sciences of the period, such as mathematics, astronomy, and medicine, while others cultivated literature.

cultivated literature.

The Smnti texts are binding to this day on orthodox Hindus, and until quite recently Hindu family law was based on them. Although there is evidence of divorce in early Indian history, by the Gupta period marriage was solemnized by lengthy sacred rites and was virtually indissoluble. Intercaste marriage was becoming rarer and more difficult, and child marriage and the rite of suttee were already in existence, although less frequent than they later became. One of the earliest definite records of a widow burning herself on her husband's pyre is found in an inscription from Eran, Madhya Pradesh, dated 510, but the custom had been followed sporadically long before this. From the 6th century Ao onward, such occurrences

became frequent in certain parts of India, particularly in Rajasthan.

EPICS AND PURANAS

During the centuries immediately preceding and following the beginning of the Christian era, the recension of the two great Sanskrit epics, the Mahābhārata and the Rā-māyaṇa, took shape out of existing material such as heroic epic stories, mythology, philosophy, and above all the discussion of the problem of dharma. Much of the material of which the epics are composed dates far back into the Vedic period, while the rest continued to be added until well into the medieval period. It is conventional, however, to date the recension of the Sanskrit texts to the period from 300 BC to AD 300 for the Mahābhārata and to the period from 200 BC to AD 200 for the Rāmāyaṇa.

The Mahābhārata. The Mahābhārata ("Great Epic of the Bhārata Dynasty"), a text of some 100,000 verses attributed to the sage Vyasa, was preserved both orally and in manuscript form for centuries. The central plot concerns a great battle between the five sons of Pandu, called the Pandayas (Ariuna, Yudhisthira, Bhīma, and the twins Nakula and Sahadeva), and the sons of Pandu's brother Dhrtarastra. The battle eventually leads to the destruction of the entire race, save for one survivor who continues the dynasty. As each of the heroes is the son of a god (Indra, Dharma, Vayu, and the Aśvins, respectively), the epic is deeply infused with religious implications. There are, moreover, many passages in which dharma is systematically treated, so that Hindus regard the Mahābhārata as one of the Dharma Shastras, Religious practice takes the form of Vedic ritual on official occasions, pilgrimage, and, to some extent, adoration of gods. Apart from the Bhagavadgītā (part of book 6) much of the didactic material is found in the Book of the Forest (book 3), in which sages teach the exiled heroes, and in the Book of Peace (book 12), in which the wise Bhīsma expounds on religious and moral matters.

The Vedic gods have lost importance and survive as figures of folklore. Prajāpati of the Upanishads is popularly personified as the god Brahma, who creates all classes of beings and dispenses boons. Of far greater importance is Krishna. In the epic he is a hero, a leader of his people, and an active helper of his friends. His biography as it is known later is not worked out; still, the text is the source of early Krishnaism. Not everywhere, and certainly not by everyone, is Krishna considered a god, and even as god his stature is superhuman rather than divine. He is occasionally, but not significantly, identified with Vishnu. Later, as one of the most important of the incarnations of Vishnu, Krishna undergoes a complex development as an incarnate god. In the Mahābhārata he is primarily a hero, a chieftain of a tribe, and an ally of the Pandavas, the heroes of the Mahābhārata. He accomplishes heroic feats with the Pandava prince Arjuna. Typically he helps the Pandava brothers to settle in their kingdom and, when the kingdom is taken from them, to regain it. In the process he emerges as a great teacher who reveals the Bhagavadgitā, the most important religious text of Hinduism. In the further development of the Krishna myth, this dharmic aspect recedes and makes way for an idyllic myth about Krishna's boyhood, when he plays with and loves young cowherd women (gopis) in the village while hiding from an uncle who threatens to kill him. The influence of this theme on art has been profound. But there is a shadow side to this idyll. Even in the Mahābhārata, where it is often said that Krishna becomes incarnate in order to sustain dharma when it wanes and to combat adharma (forces contrary to dharma), he himself commits a number of deeds in direct violation of the warrior ethic and is indirectly responsible for the destruction of his entire family. This adharmic shadow is also cast in the Purāṇic idyll because the gopis that he woos are the wives of other men.

Far remoter than the instantly accessible Krishna is Śiva, who also is hailed as the supreme god in several myths recounted of him, notably the Story of the Five Indras, Arjuna's battle with him, and his destruction of the sacrifice of Daksha. The epic is rich in information about sacred places, and it is clear that making pilgrimages and

Krishna in the Mahābhārata

Family law and the Smriti

texts

Hindu

law

bathing in sacred rivers constituted an important part of religious life. Occasionally these sacred places are associated with sanctuaries of gods. More frequent are accounts of mythical events concerning the particular place and enriching its sanctity. Numerous descriptions of pilgrimages (tīrthayātrā) give the authors opportunities to detail local myths and legends. In addition to these, countless edifying stories shed light on the religious and moral concerns of the age. Almost divine are the towering ascetics capable of fantastic feats, whose benevolence is sought and whose curses are feared.

The Rāmāyaṇa. The classical narrative of Rāma is recounted in the Sanskrit epic the Rāmāyana by the sage Vālmīki, who is the traditional author of the epic. Rāma is deprived of the kingdom to which he is heir and is exiled to the forest with his wife Sitā and his brother Laksmaņa. While there, Sītā is abducted by Rāvaṇa, the demon king of Lanka. In their search for Sītā, the brothers ally themselves with a monkey king whose general, Hanuman (who later became a monkey deity), finds Sītā in Lankā. In a cosmic battle, Rāvaņa is defeated and Sītā rescued. When Rama is restored to his kingdom, the populace casts doubt on Sita's chastity while a captive. To reassure them, Rāma banishes Sītā to a hermitage, where she bears him two sons and eventually dies by reentering the earth from which she had been born. Rama's reign becomes the prototype of the harmonious and just kingdom, to which all kings should aspire. Rāma and Sītā set the ideal of conjugal love; Rāma's relationship to his father is the ideal of filial love; and Rāma and Laksmana represent perfect fraternal love. Everything in the myth is designed for harmony, which after being disrupted is at last regained.

Rāma and

Sītā

In all but its oldest form, the Rāmāyana identifies Rāma with Vishnu as another incarnation and remains the principal source for Ramaism (worship of Rama). Though not as long as the Mahābhārata, the text contains a great deal of comparable religious material in the form of myths. stories of great sages, and accounts of exemplary human

Rāma also has a shadow side. His killing of the monkey king Vālin (or Bālin) in violation of all rules of combat and his banishment of the innocent Sitä are troublesome to subsequent tradition. These problems of the "subtlety" of dharma and the inevitability of its violation, central themes in both epics, remained the locus of philosophical argument throughout Indian history. Apart from their influence as Sanskrit texts, the Mahābhārata and the Rāmāyana have made an impact in southern and Southeast Asia, where their stories have been continually retold in vernacular and oral versions, and their influence on Indian and Southeast Asian art has been profound. Even today, the epic stories and tales are part of the early education of all Hindus; a continuous reading of the Rāmāvana is an act of great merit, and a popular enactment of one version is an annual event across northern India

The Bhagavadgita. The Bhagavadgita ("Song of the Lord") is the most influential Indian religious text, although it is not strictly Sruti, or revelation. It is a brief text, 700 verses divided into 18 chapters, in quasi-dialogue form. When the opposing parties in the Mahābhārata war stand ready to begin battle, Arjuna, the hero of the favoured party, despairs at the thought of having to kill his kinsmen and lays down his arms. Krishna, his charioteer, friend, and adviser, thereupon argues against Arjuna's failure to do his duty as a noble. The argument soon becomes elevated into a general discourse on religious and philosophical matters. The text is typical of Hinduism in that it is able to reconcile different viewpoints, however incompatible they seem to be, and yet emerge with an undeniable character of its own. Three different ways of releasing the self from transmigration are set forth. There is the discipline of action (karma-yoga): against the views held by Buddhism, Jainism, and Samkhya philosophy, which hold that all acts bind and that therefore abstention from action is a precondition of release, Krishna argues that it is not the acts that bind but the selfish intentions with which they are performed. He argues for a selfdiscipline in which a person does his duties according to the dictates of prescribed tasks (dharma), but without any

self-interest in the personal consequences of the acts. On the other hand, he does not deny the relevance of the discipline of knowledge (jnana-yoga), in which one seeks release in a yogic (ascetic) course of withdrawal and concentration. Then the tone changes and becomes intensely religious: Krishna reveals himself as the Supreme God and grants Arjuna a vision of himself. The third, and perhaps superior, way of release is through a discipline of devotion to God (bhakti-yoga) in which the self humbly worships the loving God and in release hopes not so much for personal liberation from transmigration but for an eternal vision of God. In response to this devotion, God will extend his grace to his votaries, enabling them to overcome the bonds of this world.

The Bhagavadgītā is not a systematic theological treatise, and it combines many different elements from Samkhya and Vedanta philosophy. In matters of religion, its important contribution was the new emphasis placed on devotion, which has since remained a central path in Hinduism. In addition, the popular theism evidenced elsewhere in the Mahābhārata and the transcendentalism of the Upanishads converge, and a God of personal characteristics is identified with the brahman of the Vedic tradition. In its three disciplines the Bhagavadgītā gives a typology of the three dominant trends of Indian religion: dharmabased Brahmanism, enlightenment-based asceticism, and devotion-based theism.

The influence of the Bhagavadgītā has been profound. It was a popular text, open to all who would listen, and it was fundamental for all later Hinduism. Vedănta philosophy recognizes it, with the Upanishads and the Brahmasūtras (brief doctrinal rules concerning brahman). as the third authoritative text, so that all philosophers wrote commentaries on it. Even in the 20th century, as is evident from the lives of such diverse personalities as the Indian freedom fighters Tilak and Gandhi, who acknowledged its influence, it has continued to shape the attitudes of Hindus.

The Bhagavadgitā, by demanding that God's worshipers fulfill their duties-"better one's own duty ill-done than another's well-performed" (3.35)-and observe the rules of moral conduct, bridged the chasm between ascetic disciplines and the search for emancipation, on the one hand, and the exigencies of daily life, on the other. For those who must lead a normal life in this world, the Bhagavadgītā gave a moral code and a prospect of final liberation. Thus, the work founded, on the basis of the Vaishnava tradition, what may be called a social ethic. Because God is in all beings as their physical and psychical substratum-and as he exists collectively in human society-the wise should not see any difference between their fellow creatures and should love God in them equally. Like God himself, the devotee should be impartial-the same to friend as to foe. The serious endeavour of realizing God's presence in human beings requires humility and a complete unconsciousness of oneself as a corollary of the consciousness of the Presence. It demands the selfless dedication of all actions, duties, and ceremonies to the Lord and obliges a person to promote both individual and social uplift and welfare. Yet, by emphasizing that all humans have not only different propensities for each of the three disciplines of release but also different responsibilities arising out of their births in different castes, the Bhagavadgītā also provided a powerful justification for the caste system.

The Puranas. The period of the Guptas saw the production of the first of the series (traditionally 18) of often voluminous texts that treat in encyclopaedic manner the myths, legends, and genealogies of gods, heroes, and saints. The usual list of the Purāṇas is as follows: the Brāhma-, Brāhmānda-, Brahmavaivarta-, Mārkandeya-, Bhavişya-, and Vāmana-Purāṇas; the Viṣṇu-, Bhāgavata-, Nāradīya-, Gāruda-, Pādma-, and Vārāha-Purānas; and the Śiva-, Linga-, Skanda-, Agni- (or Vāyu-), Mātsya-, and Kūrma-Purāṇas. Many deal with the same or similar materials.

With the epics, with which they are closely linked in origin, the Purāṇas became the scriptures of the common people; they were available to everybody, including women and members of the lowest order of society (Sudras), and were not, like the Vedas, restricted to initiated

Theologies of the Bhagavadeitä

Popular Sanskrit

men of the three higher orders. The origin of much of their contents may be non-Brahmanic, but they were accepted and adapted by the Brahmans, who thus brought new elements into their orthodox religion.

At first sight the discontinuity between Vedic and Purapic mythology appears to be so sharp that they might be considered as being of allogether different traditions. Yet it soon becomes clear that they are in part continuous and that what appears to be discrepancy is merely a difference between the liturgical emphasis of the Vedas and the more eclectic genres of the epics and Purapas. For example, the great god of the Rigveda is Indra, the god of war and monsoon, prototype of the warmior, but for the population as a whole he was more important as the rain god than the war god, and it is as such that he survives in early Purapic mythology. Little is learned in the Veda of goddesses, yet they rose steadily in recognition in Purapic mythology.

Although in the Putājas some of the Vedic gods have an afterlife in which their importance is reduced, other gods, previously of less official significance, arise. The two principal gods of Purafic Hinduism are Vishnu and Rudra-Siva. Both are known in the Vedas, though they play only minor roles: Vishnu is the strider who, with his three strides, established the three worlds (heaven, atmosphere, and Earth) and thus is present in all three orders; and Rudra-Siva is a mysterious god who must be propitiated.

Purapic literature documents the stages of the rise of the two gods as they eventually attract to themselves the identities of other popular gods and heroes: Vishnu assumes the powers of those gods who protect the world and its order, Siva the powers that are outside and beyond Vishnu's. To these two is often added Brahma, creator of the world and teacher of the gods. Although still a cosmic figure, Brahmā appears in the Purāpus primarily to appease overpowerful sages and demons by granting them boons.

In the Puranic literature of AD 500 to 1000, sectarianism creeps into mythology, and one god is extolled above the others. Of prime interest are cosmology, myths of the great ascetics (who in some respects eclipse the old gods), and myths of sacred places, usually rivers and fords, whose powers to reward the pilgrim are often cited and related to local leeends.

Cosmogony. Purăție cosmogony greatly expands upon the already complex cosmogonies of the Brăhmanas, Upanishads, and epics. According to one of many versions of the story of the origin of the universe, in the beginnig the god Nărăyâṇa (dentified with Vishnu) floated on the snake Ananta ("Endless") on the primeral waters. From his navel grew a lotus, in which the god Brahmā was born reciting the four Vedas with his four mouths and creating the "Egg of Brahmā," which contains all the worlds. There are numerous other accounts that refer to other demiurges, or creators, like Manu (the primordial ancestor of humankind).

Although the Vedas do not seem to conceive of an end to the world, Puranic cosmogony accounts for the periodic destruction of the world at the close of an eon, when the Fire of Time will put an end to the universe. Elsewhere the destruction is specifically attributed to the god Siva, who dances the tandava dance of doomsday and destroys the world. Yet this end is not an absolute end but a temporary suspension (pralaya), after which creation begins again in the same fashion.

Cosmology. The Purāṇa texts present an elaborate mythical cosmography. The old tripartite universe persists, but it is modified. There are three levels—heaven, Earth, and the netherworld—but the first and last are further subdivided into vertical layers. Earth consists of seven circular continents, the central one surrounded by the salty ocean and each of the other concentric continents by oceans of other liquids. In the centre of the central main-land stands the cosmic mountain Meru; the southernmost portion of this mainland is Bhāratavarṣa, the old name for India. Above Earth there are seven layers in heaven, at the summit of which is the world of Brahma (brahma-loka), there are also seven layers below Earth, the location of hells inhabited by serpents and demons of various kinds.

Myths of time and eternity. The oldest texts speak little of time and eternity. It is taken for granted that the gods,

though born, are immortal; they are called "sons of Immortality." In the Atharvaveda, Time appears personified as creator and ruler of everything. In the Brähmangas and later Vedic texts there are repeated esoteric speculations concerning the year, which is the unit of creation and thus is identified with the creative and regenerative sacrifice and with Prajāpati ("Lord of Creatures"), the god of the sacrifice. Time is an endless repetition of the year, and thus of creation; this is the starting point of later notions of repeated creations.

Puranic myths develop around the notion of yuga (world age), of which there are four. These four vugas, Krta. Treta, Dvapara, and Kali-they are named after the four throws, from best to worst, in a dice game-constitute a mahāvuga (large vuga), and, like the comparable ages of the world depicted by the Greek poet Hesiod, are periods of increasing deterioration. Time itself also deteriorates, for the ages are successively shorter. Each yuga is preceded by an intermediate "dawn" and "dusk." The Krta Yuga lasts 4,000 years, with a dawn and dusk of 400 years each, or a total of 4,800 years; Tretā a total of 3,600 years; Dvāpara 2,400 years; and Kali (the current one), 1,200 years. A mahāyuga thus lasts 12,000 years and observes the usual coefficient of 12, derived from the 12-month year, the unit of creation. These years are "years of the gods," each lasting 360 human years, 360 being the days in a year. Two thousand mahāyugas form one kalpa (eon), which is itself but one day in the life of Brahmā, whose full life lasts 100 years; the present is the midpoint of his life. Each kalpa is followed by an equally long period of abeyance (pralaya), in which the universe is asleep. Seemingly the universe will come to an end at the end of Brahma's life, but Brahmās too are innumerable, and a new universe is reborn with each new Brahmā.

Another myth lays particular stress on the destructive aspect of time. Everything dies in time: "Time ripens the creatures, Time rots them" (Mahābhārata 1.1.188). "Time" (kāla) is thus another name for the god of death. Yama. The name is associated especially with Siva in his destructive aspect as Mahākāla and is extended to his consort, who may be known as the goddess Käli or Mahākāli. On a mythological level the speculations on time reflect the doctrine of the eternal return in the philosophy of transmigration. The universe returns just as, after death, a soul returns to be born again. In the oldest description of the process (Chandogya Upanishad 5.3.1.-5.3.10), the account is still mythic, but with tendencies to naturalism. The soul on departing may go either of two ways: the Way of the Gods, which brings it through days, bright fortnights, the half year of the northern course of the Sun. to the full year, and eventually to brahman; or the Way of the Ancestors, through nights, dark fortnights, the half year of the southern course of the Sun, and, failing to reach the full year, eventually back to Earth clinging to raindrops. If the soul happens to light on a plant that is subsequently eaten by a man, the man may impregnate a woman and thus the soul is reborn. Once more the significance of the year as a symbol of complete time is clear.

Myths of the gods. According to the epic Mahābhārata (1.1.39), there are 33,333 Hindu deities. In other, later sources, that number is multiplied a thousandfold. Usually, however, the gods are referred to as "The Thirty-Three."

The tendency toward pantheism increased in Purāṇic Hinduism and led to a kind of theism that exalted several supreme gods who were not prominently represented in the Vedic corpus, while many of the Vedic gods disappeared or were greatly diminished in stature. New patterns became apparent: the notion of rita, the basis of the conception of cosmic order, was reshaped into that of dharma, or the religious-social tasks and obligations of humans in society that maintain order in the universe. There also was a broader vision of the universe and the place of divinity.

Three principal moments are envisioned in the life of the cosmos: creation, maintenance, and destruction. Important myths about the gods are tied to these moments. Traditionally, Brahmā is the creator, emanating the universe and simultaneously promulgating the four Vedas from his four mouths. The conception of time as almost

The four yugas of the world

Mythologies of creation and doomsday endlessly repeating itself in kalpas detracts, however, from the uniqueness of the first creation, and Brahmā becomes little more than a demiurge. Far more attention is given to the maintenance and to the destruction of the universe. Maintenance and destruction are symptomatic of order and disorder, and order and disorder in turn are closely associated with society and the realm outside society. The god Vishnu, who became the god of maintenance, is thus also the social god par excellence, while Siva, partly established as the agent of destruction, is in many respects an asocial god. Vishnu is the saviour from lawlessness, destroyer of those who threaten the good order, and king of the harmonious realm. Siva represents untamed wildness; he is the lone hunter and dancer, the yogi (the accomplished practitioner of yoga) withdrawn from society, and the ash-covered ascetic. The distinction between the gods is not between good and evil but rather between two ways in which the divine manifests itself in this worldas both benevolent and fearful, both harmonious and disharmonious.

Bhāgavata-Purāna. South Indian devotionalism produced many works in Sanskrit; the most important was the Bhāgavata-Purāna, which soon became known throughout India. Its 10th book is devoted entirely to Krishna. and there, for the first time, his adventures as a lovable child and as a youth are recounted in great detail. The Bhāgavata-Purāņa may have been written in the 10th century and is certainly a product of the Dravidian south. The doctrine of the avatars of Vishnu was by now in full force, and the Bhagavata recognizes 22 of them.

While all Purāṇas have exerted influence on Hinduismand are in turn reflections of trends in Hinduism-none can compare in popularity with the Bhagavata-Purana ("The Purana of the Devotees of the Blessed Lord Krishna"), the Purāna of the god Krishna par excellence. It differs from the other Puranas in that it is planned as a unit and that far greater care is taken with both metre and style. Its nearly 18,000 stanzas are divided into 12 books. The most popular part of the Purana is the description of the life of Krishna, for which it has since remained the principal authority. In this work far greater emphasis than in other texts is placed on the youth of Krishna: the threats against his life by the tyrant Kamsa, his flight and life among the cowherds at Gokula, and especially his adventures and pranks with the cowherd girls. This treatment has remained classic, and the popularity of the text has led to the survival of many manuscripts, some beautifully illustrated. Much of medieval Indian painting and an enormous amount of vernacular literature draw upon the Bhāgavata-Purāņa for their themes.

The Bhagavata-Purana teaches a quite representative Vaishnava theology: God is transcendent and beyond human understanding; he is the universal causality, creator and substratum; he is time and the bearer of all possibilities that are susceptible of actualization; through his incomprehensible creative ability (maya) or specific power (ātmaśakti) he expands himself into the universe, which he pervades and which is his outward appearance (his immanence). Thus he is the All and everything and the inner Self of all beings. When God is conceived of as brahman, he is immutable and therefore must be the Purusa (cosmic Person) who is not the universe; if, however, his creation is thought to be in him, he is the world.

Accepting the Bhagavata-Purana as a high scriptural authority. Vaishnavism considers God the ground and subsistence of whatever exists, from whom all objects have come, by whom they continue to be, toward whom they move, and into whom they enter at the final dissolution at the end of this world, unless they already came to him in the state of emancipation (moksha). Between God and the world there is a relation of inconceivable difference in identity and identity in difference (acintyabhedābheda; literally, "unthinkable difference and nondifference"). The Lord creates the world merely because he wills to do so. Creation, or rather the process of differentiation and integration, is his sport (līlā). The world is real, but reality has two aspects: the transcendent and eternally real and the reality that is progressively realized and, in the process, bound up with the eternal aspect.

One of the chief purposes of the Bhagavata-Purana is the glorification of an intensely personal and passionate bhakti that gradually develops into a decidedly erotic mysticism, independent of all alternative means of salvation. According to this text, there are nine characteristics of bhakti: listening to the sin-destroying sacred histories; praising God's name; remembering and meditating on his nature and salutary endeavour (resulting in a spiritual fusion of devotee and God); serving his image; adoring him; respectful salutation; servitude; friendship; and self-surrender. Meritorious works are also an element of bhakti

According to the Bhagavata-Purana, the highest Bhagavata-worshiper of the Bhagavat (God: "the Adorable One")-sees himself in all beings and all beings in the Bhagavat; free from hatred and prejudice and knowing God to be present in all beings, he loves him by loving them. Those who cannot reach this level can at least have friendly relations with coreligionists, irrespective of their birth or social status, and take compassion upon the infatuated. The true Vaishnava should worship Vishnu or one of his avatars, construct temples, bathe in holy rivers, study religious texts, serve superiors, and honour cows. In social intercourse with the adherents of other religions he tends to be passively intolerant, avoiding direct contact, without injuring them or prejudicing their rights. He should not neglect other gods but must avoid following the rituals of their followers. Misuse of the advantages of birth is severely condemned, and those who apply themselves mainly to the acquisition and enjoyment of wealth are not well qualified for bhakti. The concept of class divisions is accepted, but the idea that possession of the characteristics of a particular class is the inevitable result of birth is decidedly rejected. Because sin is antithetical to bhakti, a Brahman who is not free from falsehood, hypocrisy, envy, aggression, and pride cannot be the highest of men, and many persons of low social status may have some advantage over him in moral attitude and behaviour. The most desirable behaviour is compatible with bhakti but independent of class

In establishing bhakti religion against any form of opposition and defending the devout irrespective of birth, the Bhagavata religion did not actively propagate social reform; but the attempts to make religion an efficient vehicle of new spiritual and social ideas, especially Caitanya's movement, contributed, to a certain extent, to the emancipation of lowborn followers of Vishnu.

VAISHNAVISM AND ŚAIVISM

Vaishnavism. Vaishnavism is the worship of Vishnu and his various incarnations. During a long and complex development from Vedic times, there arose many Vaishnava groups with differing beliefs and aims. Some of the major Vaishnava groups include the Śrīvaiṣṇavas and Dvaitins "philosophical or religious dualists") of South India, the followers of the teachings of Vallabha in western India, and several Vaishnava groups in Bengal in eastern India, who follow teachings derived from those of the saint Caitanya. The majority of Vaishnava believers, however, take what they like from the various traditions and blend it with various local practices.

In the Veda, Vishnu is the god of far-extending motion and pervasiveness who, for humans in distress, particularly through constrictions, penetrates and traverses the triple spaces to make their existence possible. All beings are said to dwell in his three strides or footsteps (tri-vikrama): his highest step, or abode, is beyond mortal ken in his dear and highest resort, the realm of heaven. So Vishnu is also the god of the pillar of the universe and is identified with the sacrifice. He imparts his all-pervading power to the sacrificer who imitates his strides and so identifies himself with the god, thus conquering the universe and attaining "the goal, the safe foundation, the highest light" (Satapatha

In the centuries preceding the beginning of the Christian era, Vishnu became the Isvara (immanent deity) of his special worshipers, fusing with the Purusa-Prajāpati figure; with Nārāyana, whose cult discloses a prominent influence of ascetics; with Krishna, who in the Bhagavadgītā revealed a popular and universal religion, open to everyBhagavat Bhāgavata

Composite historical nature of Vishnu

childhood of Krishna The 10

Vishnu

avatars of

body desiring to lead a socially normal life while having a prospect of final liberation; and with Vasudeva, adored by a group known as the Pañcaratras.

The extensive mythology attached to Vishnu consists largely of the mythology of his incarnations (avatars). Although the notion of "incarnation" is found elsewhere in Hinduism, it is basic to Vaishnavism. The concept is particularly geared to the social role of Vishnu; whenever dharma (universal law and order) is in danger, Vishnu departs from his heaven, Vaikuntha, and incarnates himself in an earthly form to restore the good order. Each of his incarnations has a particular mythology. The classical number of these incarnations is 10, ascending from theriomorphic (animal form) to fully anthropomorphic manifestations. These are: Fish (Matsya), Tortoise (Kūrma), Boar (Varāha), Man-Lion (Narasimha), Dwarf (Vāmana), Rāma-with-the-Ax (Paraśurāma), King Rāma, Krishna, Buddha, and the future incarnation, Kalkin,

A god thus active for the good of society and the individual inspires love. Vishnu has indeed been the object of devotional religion (bhakti) to a marked degree, but mainly in his incarnations, and among them specially as Krishna and Rāma. The god rewards devotion with his grace, through which the votary may be lifted from transmigration to release. Like most other gods, Vishnu has his especial entourage: his wife is Lakşmī or Śrī, the lotus goddess, granter of beauty, wealth, and good luck, She came forth from the ocean when gods and demons churned it in order to recover from its depths the ambrosia or elixir of immortality, amrta. At the beginning of the commercial year special worship is paid to her for success in personal affairs. Vishnu's mount is the bird Garuda, archenemy of snakes, and his emblems are the lotus, club, discus (as a weapon), and a conch shell, which he carries

in his four hands.

Whatever justification the different Vaishnava groups (e.g., the Śrīvaisnavas of South India or the worshipers of Vishnu Vithobā in Mahārāshtra) offer for their philosophical position, all Vaishnavas believe in God as a person with distinctively high qualities and worship him through his manifestations and representations. Vaishnava faith is essentially monotheistic, whether the object of adoration be Vishnu Nārāyaņa or one of his avatars such as Rāma or Krishna. Preference for any one of these manifestations is largely a matter of tradition. Thus, most South Indian Śrīvaisnavas prefer Vishnu, Rāma, or Śrī (Vishnu's consort); the North Indian groups prefer Krishna. The avatar doctrine, by accommodating the cults of various divine or heroic figures within a monotheistic framework, proved to be a powerful integrating force. Whenever the dharma declines and evil and general disaster threaten, God, the protector and preserver of the world, emanates himself and assumes an earthly form to guard the good, to destroy the wicked, and to confirm the dharma. The benevolence and beneficial activity of these figures (Rāma, Krishna, et al.) is, however, occasionally in doubt. In many mythical tales, Vishnu is depicted as a versatile figure of great adaptability, able, for instance, to disguise himself as a fascinating young woman in order to trick the asuras (antigods) out of the possession of the newly produced amrta. His absorbing, many-sided character was a source of inspiration for various stories in which he often acts deceitfully, selfishly, or helplessly. The scene of his great deeds is usually laid in this world, especially India, in places often mentioned by name. The narratives are full of the miraculous, but their central figures give the impression of human, sometimes all too human, characters whose actions and reactions are within the limits of ordinary understanding.

A pronounced feature of Vaishnavism is the strong tendency to devotion (bhakti), which is generally considered to be "the heart of worship," the sole true religious attitude toward a personal God, and the very foundation of the realization of man's relationship with him. Characterized by a continual consciousness of participating in God's essence, bhakti is the disinterested performance of all deeds for him, a passionate love and adoration of God, and a complete surrender to him. The widespread bhakti movement is a corollary of the Vaishnava ideal of a loving personal God and aversion to a conception of salvation

that puts an end to all consciousness or individuality. Attesting to the superiority of a mystic and emotional attitude to the meditative or preponderantly ritualistic means to the highest goal, the practical and theoretical development of the bhakti idea constitutes one of the main points of difference among the several Vaishnava schools. The belief expressed in the Bhagavadgītā-that those who seek refuge in God with all their being will, by his benevolence and grace (prasada), win peace supreme, the eternal abode-was generally accepted: bhakti will result in divine intercession with regard to the consequences of one's deeds. Among many followers of Rămănuja, however, complete self-surrender (prapatti) came to be distinguished from bhakti as a superior means of spiritual realization.

Saivism. The character and position of the Vedic god Rudra-called Siva, "the Mild or Auspicious One," when this aspect of his ambivalent nature is emphasized-remain clearly perceptible in some of the important features of the great god Siva, who together with Vishnu came to

dominate Hinduism.

During a complex development from ancient, possibly in part from pre-Vedic, times, many different Saiva groups arose. Major groups such as the Lingayats of southern India and the Kashmir Saivas contributed the theological principles of Saivism, and Saiva worship became a complex amalgam of pan-Indian Saiva philosophy and local or folk worship.

In the minds of the ancient Indians Siva must have been primarily the divine representative of the uncultivated. dangerous, unreliable, and much-to-be-feared aspects of nature. Siva's character lent itself to being split into partial manifestations-each said to represent only an aspect of him—as well as to assimilating divine or demoniac powers of a similar nature from other deities. Already in the Rigveda, appeals to him for help in case of disaster-of which he might be the originator-were combined with the confirmation of his great power. In the course of the Vedic period, Siva-originally a ritual and conceptual outsider, yet a mighty god whose benevolent aspects were readily emphasized-gradually gained access to the circle of respectable gods who preside over various spheres of human interest. Many characteristics of the Vedic Prajapati, the creator, of Indra, the god of the phallus, and of the great Vedic god of fire, Agni, have been integrated into the figure of Siva.

In those circles that produced the Svetāśvatara Upanishad (c. 400 BC), Siva rose to the highest rank. Its author uses grandiose terms to show a way of escape from samsara. to proclaim Siva the sole eternal Lord, and to establish Siva's existence. In this description of Siva's nature, some of the most salient features of the later Siva, the Isvara (immanent deity), are clearly discernible: he is the ultimate foundation of all existence and the source and ruler of all life, who, while emanating and withdrawing the universe, is the goal of that identificatory meditation that leads to complete cessation from phenomenal existence. While Vishnu became a friend nearer to man, Rudra-Śiva developed into an ambivalent and many-sided lord and master. His "doubles" or partial manifestations, however, were active among mankind: as Pasupati ("Lord of Cattle"), he took over the fetters of the Vedic Varuna; as Aghora ("To Whom Nothing Is Horrible"), he showed the uncanny traits of his nature (evil, death, punishment) and

also their opposites. It is not always clear in particular cases whether Siva is invoked as a great deva (god) of frightful aspect, capable of conquering demoniac power, or as the boon-giving Lord and protector. The Iśvara idea of a Highest Being demonstrably beyond contingency is rather abstract; hence its propagators needed to use imagery, popular belief, and mythical thought. Siva might be the sole Principle above change and variation, yet he did not sever his connections with innumerable local deities and much-feared powers worshiped by most Hindus, who still continue to invoke him in magical rites. Whereas Vishnu champions the cause of the gods, Siva sometimes sides with the demons. Siva is a typical example of polarity within the Highest Being because he reconciles in his person semantically opposite though complementary aspects: he is both terriPartial manifes. tations of Śiva

The playfulness of the incarnate God ble and mild, creator and agent of reabsorption, eternal rest and ceaseless activity. These seeming contradictions make him a paradoxical figure, transcending humanity and assuming a mysterious sublimity of his own. His character is so complicated and his interests are so widely divergent as to lead him in mythical narratives into conflicting situations. Yet, although Brahman philosophers like to emphasize his ascetic aspects and the ritualists of the Tantric tradition his sexuality, the seemingly opposite strands of his nature are generally accepted as two sides of one character

Power of

sexuality

chastity

and

Siva interrupts his austerity and asceticism (tapas), which is sometimes described as continuous, to marry Parvatihe is even said to perform ascetic acts in order to win her love-and he combines the roles of lover and ascetic to such a degree that his wife must be an ascetic (yogi) when he devotes himself to austerities and a lustful mistress when he is in his erotic mode. This dual character finds its explanation in the ancient double conviction that unrestrained sexual intercourse is conducive to the fertility of nature and that the chastity and continence of the ascetic produce marvelous events and have an uncommon influence upon the unseen. By his very chastity, an ascetic accumulates (sexual) power that can be discharged suddenly and completely so as to produce marvelous results such as the fecundation of the soil. From various mythical tales it is seen that both chastity and the loss of chastity are necessary for fertility and the intermittent process of regeneration in nature. Ascetics engaging in erotic and creative experiences are a familiar feature in Hinduism, and the element of teeming sexuality in mythological thought counterbalances the Hindu bent for asceticism. Such sexuality, while rather idyllic in Krishna, assumes a mystical aspect in Siva, which is why the devotee can see in him the realization of the possibilities of both asceticism and the householder state. His marriage with Parvati is, then, a model of conjugal love, the divine prototype of human marriage, sanctifying the forces that carry on the human race

Siva's myths tend to depict him as the absolutely mighty unique One, who is not responsible to anybody or for anything. His many poses express aspects of his nature: as a dancer, he is the originator of the eternal rhythm of the universe; he also catches the waters of the heavenly Ganges River, which destroy all sin; and he wears in his headdress the crescent moon, which drips the nectar of everlasting life.

Siva represents the unpredictability of divinity. In him

the Vedic Rudra is partly continued, but his mythology has become exceedingly complex. He is the hunter who and his slays and skins his prey and dances a wild dance while consorts covered with the bloody hide. Far from society and the ordered world, he sits on the inaccessible Himalayan plateau of Mount Kailāsa, an austere ascetic, averse to love, who burns Kāma, the god of love, to ashes with a glance from the third eye-the eye of insight beyond duality-in the middle of his forehead. Yet another epiphany is that of the lingam, an upright rounded post, usually of stone, a formalized phallic symbol, in which form he is worshiped throughout India. And at the end of the eon, he will dance the universe to destruction. He is, nevertheless, invoked as Śiva, Śambhu, Śankara (meaning: "the Auspicious One" or "the Peaceful One"), for the god that can strike down can also spare. Snakes seek his company and twine themselves around his body. He wears a necklace of skulls. He sits in meditation, with his hair braided like a hermit's, his body smeared white with ashes. These ashes recall the burning pyres on which the sannyasis (renouncers) take leave of the social order of the world and set out on a lonely course toward release, carrying with them a human skull.

Like so many ascetics-often irascible and dangerous-Siva demands to be seduced. His consort is Pārvatī ("Daughter of the Mountain"), a goddess most unlike the consorts of Vishnu in his various incarnations. She is also personified as the Goddess (Devi "goddess"), Mother (Ambā), black and destructive (Kālī), fierce (Candikā), and well-nigh inaccessible (Durga). As Siva's female counterpart, she inherits some of Siva's more fearful aspects. She comes to be regarded as the power (shakti) of Siva. without which Siva is literally powerless. Sakti is in turn personified in the form of many different goddesses, often said to be aspects of her.

Thus the spheres of the Vishnu complex and the Siva complex are very different ones. In important respects they represent the two different ethics of Hinduism: the dharma ethic, which aims at upholding the dharma and the cosmic and social order based on it, and the moksha (liberation) ethic, which searches for release from an order that perpetuates transmigration.

Myths of culture heroes. A culture hero can easily be assimilated to a god by identifying him with an incarnation of a god. Thus great religious teachers are considered manifestations of the god of their devotional preaching, and their lives become part of mythology. The mythology concerning great ascetics is very rich. Practically gods on Earth, these ascetics have amassed tremendous powers

Paradoxical nature of Siva as indicated by differing representations (Left) Gajantaka, destroyer of the elephant demon, sculpture from Orissa, 8th century. In the Indian Museum, Calcutta. The trial

of kings

that they do not hesitate to use. The sage Kapila, meditating in the netherworld, burned to ashes 60,000 princes who had dug their way to him. Another sage, Bhagiratha, brought the Ganges River down from heaven to sanctify their ashes and, in the process, created the ocean. Agastya, revered as the Brahman who brought Sanskrit civilization to South India, drank and digested the ocean. When the Vindhya mountain range would not stop growing, Agastya crossed it to the south and commanded it to cease growing until his return; he still has not returned. Viśvāmitra, a king who became a Brahman, created a new universe with its own galaxies to spite the gods. It is in such myths that the mythopoeic imagination exults in its sensitivity to the

awesome, mysterious, and marvelous. In myths concerning kings and princes, a prevailing theme is the trial of the son by the father. For example, the ancient king Yayati had five sons to whom he wanted to transfer his own senescence for a stipulated period. All refused except the youngest, Puru. As a reward he became his father's successor, and his descendants became the Pauravas, the line of succession or dynasty in which the heroes of the Mahābhārata were later born. The latter heroes also underwent a trial when they were exiled from their newly won kingdom; similarly, Rama underwent his ordeal in exile. Heroines undergo their own trials, which usually challenge their chastity, as in the case of Sītā in the Rāmāyaṇa and Draupadī, the one wife of all five Pāndava brothers, whose sari became endless when a lustful villain attempted to pull it off.

Moving from myth to legend, there are also stories told of the great teachers, and every founder of a sect is soon deified as an incarnation of a god: the philosopher Śańkara (c. 788-820) as an incarnation of Siva, the religious leader Rāmānuja (d. AD 1137) as that of Nārāyaņa-Vishnu, and the Bengal teacher Caitanya (1485-1533) simultaneously as that of Krishna and his beloved Radha.

Myths of holy rivers and places. Of particular sanctity in India are the perennial rivers, among which the Ganges stands first. This river, personified as a goddess, originally flowed only in heaven until she was brought down by Bhagiratha to purify the ashes of his ancestors. She came down reluctantly, cascading first on the head of Siva, in order to break her fall, which would have shattered the Earth. Confluences are particularly holy, and the Ganges' confluence with the Yamuna at Allahābād is the most sacred spot in India. Another river of importance is the Sarasvatī, which loses itself in desert; it was personified as a goddess of eloquence and learning.

Every major and many minor temples and sanctuaries have their own myths of how they were founded and what miracles were wrought there. The same is true of famous places of pilgrimage, usually at sacred spots near and in rivers; important among these are Vrindavana (Brindaban) on the Yamuna, which is held to be the scene of the youthful adventures of Krishna and the cowherd wives. Another such centre with its own myths is Gaya, especially sacred for the funerary rites that are held there. And there is no spot in Vārānasi (Benares) along the Ganges that is without its own mythical history.

PHILOSOPHICAL TEXTS

Although the details of Indian philosophy, as it was developed by professional philosophers, may be treated as a subject separate from Hinduism (see INDIAN PHILOSOPHY), certain broad philosophical concepts were absorbed into the myths and rituals of Hindus and are best viewed as a component of the religious tradition.

Mysticism. One of the major trends of Indian religious philosophy is a kind of mysticism: the desire for union of the self with something greater than the self, whether that be defined as a principle that pervades the universe or as a personal God. Hindu mysticism includes both these forms and a great many that lie in between. At one extreme is the realization of the identity of the individual self with the impersonal principle called brahman, the position of the Vedanta school of Indian philosophy; and at the other is the intensive devotionalism to a personal God, called by a variety of names, that is found in the bhakti (devotional) sects.

There are four things common to most Hindu mystical thought. First, it is based on experience: the state of realization, whatever it is called, is both knowable and communicable, and the systems are all designed to teach people how to reach it. It is not, in other words, pure speculation. Second, it has as its goal the release of the spirit-substance of the individual from its prison in matter, whether matter be considered real or illusory. Matter is the cause of the suffering of which Buddhism speaks. Third, all the systems recognize the importance or the necessity of the control of the mind and body as a means of realization; sometimes this takes the form of extreme asceticism and mortification, and sometimes, at the other extreme, it takes the form of the cultivation of mind and body in order that their energies may be properly channeled. And, finally, at the core of Hindu mystical thought is the functional principle that knowing is being. Thus, knowledge is something more than analytical categorizing; it is total understanding. This understanding can be purely intellectual, and some schools equate the final goal with omniscience, as does yoga. Knowing can also mean total transformation; if one truly knows something, he is that thing. Thus, in the devotional schools, the goal of the devotee is to transform himself into a being who, in eternity, is in immediate and loving relationship to the deity. But despite the fact that these are both ways of knowing, the difference between them is significant. In the first instance, the individual has the responsibility to train and use his own intellect. The love relationship of the second, on the other hand, is one of dependence, and the deity assists the devotee through grace. The distinction is generally made by the analogy of the cat and the monkey: the cat carries her young in her mouth, and thus the kitten has no responsibility. But the young monkey must cling by its own strength to its mother's back.

It is usual for writers on the subject, following Surendranath Dasgupta, a historian of Indian philosophy, to list five major varieties of Hindu mysticism, the five having arisen in historical order as follows:

1. The sacrificial, based on the Vedas and Brāhmaņas.

2. The Upanishadic, in which are found the beginnings of both monistic (concerned with a unitary principle of reality, immanent in the world) and theistic (concerned with a personal or suprapersonal God) systems.

3. The yogic, relating to physical and mental discipline; the earliest known text of this school is the Yoga-sūtra of Patañjali, dated variously between the 2nd century BC and the 5th century AD. According to yogic mysticism, man realizes union by means of physical and mental control of himself, which in turn leads to control of both natural and divine forces.

4. The Buddhistic, in which enlightenment is the realization of the four Truths-the fact of suffering, the cause of suffering, the cessation of suffering, and the means of arriving at these three truths: the Eightfold Path. The ultimate state, the culmination of one path of the Eightfold Path, is nirvana, "the blowing out," the extinction of desire (see BUDDHISM, THE BUDDHA AND).

5. The devotional, or bhakti, type of mysticism comprises a range of theistic systems, with a conception of absolute dualism between man and God on the one extreme, and a conception of qualified nondualism on the other. Although there are traces of this devotionalism throughout the history of Indian religion, it began to develop in earnest in South India in the 7th through 10th century AD with the hymns of the poet saints called Alvars.

Philosophical sutras and the rise of the six schools of philosophy. From about the beginning of the Christian era through the period of the Gupta empire, the systems of the Six Schools (Saddarsana) of orthodox philosophy were formulated in terse sutras.

The most important of the Six Schools is the Vedanta ("End of the Vedas"), also called Uttara-Mimamsa, or later Mīmāmsā. The most renowned philosopher of this school and, indeed, of all Hinduism was Sankara (traditionally dated c. 788-820, but he probably died about 20 years later). He was born at Kāladi in Kerala and is said to have spent most of his life traveling through India debating with members of other sects. The Sankaran system

Knowledge as being becoming

Sankara and the Vedānta school

has sounded the keynote of intellectual Hinduism down to the present, but later teachers founded sub-schools of Vedanta, which are perhaps equally important.

Śańkara was also responsible for the growth of Hindu monasticism, which had been in existence for more than a millennium in the form of hermit colonies. Inscriptions from Gupta times onward also refer to monklike orders of Saiva ascetics, apparently living according to distinctive disciplines and with distinguishing garments and emblems. Śańkara founded a closely disciplined Śaiva order, perhaps partly modeled on the Buddhist sangha, or order, known as daśnāmī, which is still the most influential orthodox Hindu ascetic group. The order is composed of 10 brotherhoods and hence called daśnāmīs ("those with 10 names"). Orders became an established institution with wider geographic affiliations. Some of these admitted Brahmans only; others were open to all four classes or even to women; some made a practice of nudity. These Saiva communities are more inclined to individual asceticism and are less closely organized than the Vaishnava vairāgins ("the dispassionate") or gosvāmins ("the masters"). Sankara is also said to have founded the four main monasteries (matha) at the four corners of India: Sringeri in Karnataka, Badrīnāth in the Himalayas, Dwārkā in Gujarat, and Puri in Orissa. The abbots of these monasteries control the spiritual lives of many millions of devout Saiva laymen throughout India, and their establishments strive to maintain the traditional philosophical Hinduism of the strict Vedanta. In modern times, certain daśnāmī leaders have incurred criticism for their firm opposition to social change.

Vaishnava theology of Rāmānuia

The theologians had to assume the task of explaining the relation between God, as the unaffected and unchanging cause of all things, and the universe. According to Ramānuja (c. 1017-1137), a great South Indian thinker of Śrīvaisnava persuasion, brahman (i.e., God) is a Person with high attributes, the object of an individual's search for the higher knowledge that is the only entrance to salvation. Because an absolute creation is denied, God is viewed as the sole cause of his own modifications; namely, the emanation, existence, and absorption of the universe. Although unlimitedly expansive, God is conceived to be essentially different from everything material, the absolute opposite of any evil, free from any imperfection, omniscient, omnipotent, possessed of all positive qualities (such as knowledge, bliss, beauty, and truth), of incomparable majesty, the inner soul of all beings, and the ultimate goal of every religious effort. The universe is considered a real transformation of brahman, whose "body" consists of the conscious souls and everything unconscious in their subtle and gross states. The karma doctrine is modified as follows: the Lord, having determined good and bad deeds, provides all individual souls with a body in which they perform deeds, reveals to them the scriptures from which they may learn the dharma, and enters into them as their internal regulator. The individual acts at his own discretion but needs the Lord's assent. If the devotee wishes to please him, God induces him, with infallible justice and loving regard, to intentions and effort to perform good deeds by which the devotee will attain to him; if not, God keeps him from that goal.

The influence of the bhakti movement had earlier led Rāmānuja to admit a twofold possibility of emancipation: in addition to the meditative method of the highest insight (jnana) into the oneness of soul and God, which destroys the residues of karma and propitiates God to win his grace, there is the way of bhakti. Those who prefer the former way will reach a state of isolation, the others an infinitely blissful eternal life in, through, and for God, with whom they are one in nature but not identical. They do not lose their individuality and may even meet Vishnu in his Vaikuntha heaven and enjoy delight beyond description.

An interesting development of Rămānuja's doctrine of qualified monism is found in the philosophy of Madhva (died c. 1276). This Kanarese Brahman taught a doctrine of dualism according to which God and the soul are eternally distinct

Authors of Saiva Puranas established two ingenious and complementary doctrines to explain the nature and omnipotence of God (the force that rules, absorbs, and reproduces the world and that in performing any one of these acts necessarily performs the other two as well), the existence of the world, and the identity of God and the world. A theory of five "faces," or manifestations-each of which is given mythological names and related mantrasis of great ritual significance. It associates Siva's so-called creative function, by which he provokes the evolution of the material cause of the universe, with his first face, or aspect; its maintenance and reabsorption with his second and third faces; his power of obscuration, by which he conceals the souls in the phenomena of samsara, with his fourth face; and his ability to bestow his grace, which leads to final emancipation, with his fifth face. The five functions are an emanation of the unmanifested Siva who is the transcendent brahman.

The faces became the central elements of a comprehensive classification system. They were identified with parts of God's body, regions of the universe, various ontological principles, organs of sense and action, and the elements. The system was used to explain how Siva's being is the All and how the universe is exclusively composed of aspects or manifestations of Šiva. In his fivefold nature, Šiva was shown to be identical with the 25 (five times five) elements or principles assumed by the prominent Samkhyā school of Indian philosophy. The special significance of the number five in Saivism can be understood as a philosophical elaboration of the time-honoured fourfold organization of the universe. (The four quarters of the sky also play a prominent part in religious practice.) According to this conception, a fifth aspect, when added to the four, is considered the most important aspect of the group because it represents each of the four and collectively unites all of their functions in itself. The system finds its complement in the doctrine of the five Sadakhyas (five items that bear the name sat, "is" or "being") representing the five aspects of that state, which may be spoken of as the experience of "there is" (sat) and which have evolved from God's fivefold creative energy (shakti). In these, God "dwells" in his aspect called Sadāsiva ("the Eternal Śiva"), which is regarded sometimes as a manifestation of and sometimes as identical with the Supreme Being.

Another Saiva doctrine posits eight "embodiments" of Siva as the elements of nature (ether, wind, fire, water, earth), Sun, Moon, and the sacrificer, or consecrated worshiper (also called Atman). To each of these eight elements corresponds one of Siva's traditional names or aspectsto the last one, usually Pasupati. The world is a product of these eight forms, consists of them, and can only exist and fulfill its task because the eight embodiments cooperate. Because each individual is also composed of the same eight realities (e.g., the light of man's eyes corresponds to that of the Sun). Siva constitutes the corporeal frame and the psychical organism of every living being. The eighth constituent is the indispensable performer of the rites that sustain the gods who preside over the cosmic processes and are really Siva's faculties.

Although Saivism is a much more coherent whole than Vaishnavism, there evolved, in different parts of India, some branches with peculiarities of their own. According to the pronouncedly idealist monism of Kashmir Saivism, an important religiophilosophic school, Siva manifests himself through a special power as the first cause of creation, and he also manifests himself through a second power as the innumerable individual souls who, because of a veil of impurity, forget that they are the embodiment of the Highest. This veil can be torn off by intense faith and constant meditation on God, by which the soul transmutes itself into a universal soul and eventually attains liberation through a lightninglike, intuitive insight into its own nature. Those Hindus who adhere to this group consider their doctrine a manifestation of the highest Reality, Knowing Consciousness, neither personal nor impersonal; as Siva in the form of the transcendent Word, which is his unspoken Thought, the content of which is the universe.

The Saiva-siddhanta, a prominent religiophilosophic school of Tamil-speaking South India, assumes three eternal principles: God (who is independent existence, unqualified intelligence, and absolute bliss), the universe, and the Regional variations in Śaivism souls. The world, because it is created by God (efficient cause) through his conscious power (instrumental cause) and maya (material cause), is no illusion. The main purpose of its creation is the liberation of the beginningless souls, which are conceived as "cattle" (paśu) bound by the noose (nāśa) of impurity (mala) or spiritual ignorance, which forces them to produce karma. However, they see the karma process as a benefit, for as soon as the soul has sufficiently ripened and reached a state of purity enabling it to strive after the highest insight, God graciously intervenes, appearing in the shape of a fully qualified and liberated spiritual guide (guru), through whose words God permits himself to be realized by the individual soul.

TANTRISM

Tantric traditions and Śāktism. Toward the end of the 5th century, the cult of the Mother Goddess began to achieve a significant place in religious life. Śāktism, the worship of the Sakti, the active power of the godhead conceived in feminine terms, should be distinguished from Tantrism, the search for spiritual power and ultimate release by means of the repetition of sacred syllables and phrases (mantras), symbolic drawings (mandalas), and other secret rites elaborated in the texts known as tantras ("looms").

In many respects the tantras are similar to the Purānas. Theoretically a tantra deals with (1) knowledge, or philosophy, (2) yoga, or concentration techniques, (3) ritual, which includes the formation of icons and the building of temples, and (4) conduct in religious worship and social practice. In general the last two subjects preponderate, while voga tends to centre on the mystique of certain sound-symbols (mantras) that sum up esoteric doctrines. The philosophy tends to be a syncretistic mixture of Sāmkhva and Vedānta philosophical thought, with special and at times exclusive emphasis on the god's power, or shakti. The Tantric texts can be divided into three classes: (1) Saiva Agamas (traditions of the followers of Siva), (2) Vaishnava Samhitās ("Collections of the Vaishnavas, name borrowed from the Vedic Samhitas), and (3) Śakta Tantras ("Looms of the Followers of the Goddess Sakti"). However, they all have the common bond of venerating

Surviving Hindu tantras were written much later than many of those of Tantric Buddhism, and it may be that the Hindus derived much from the Buddhists in this respect. Although there is early evidence of Tantrism and Säktism in other parts of India, the chief centres of both were modern Bengal, Bihar, and Assam,

Saiva Agamas. Like much other Hindu sacred literature, this literature is neither well-cataloged nor thoroughly studied. It is only possible here to summarize classes of texts within the various traditions.

The sects of Agamic Saivas (Siva worshipers who follow their own Agama-"traditional"-texts) encompass both the Sanskritic Saiva-siddhanta-i.e., those who accept the philosophical premises and conclusions of Saivas in the north-and the southern Lingayats or Virasaivas (from vīra, literally "hero"; a lingam is the Siva emblem that is worshiped in lieu of images). The Saiva-siddhanta traditionally has 28 Agamas and 150 sub-Agamas. Their principal texts are hard to date; most probably they do not antedate the 8th century. Their doctrine states that Siva is the conscious principle of the universe, while matter is unconscious. Siva's power, or shakti, personified as a goddess, causes bondage and release. She is also the magic Word, and thus her nature can be sought out and meditated upon in mantras.

Kashmir Saivism begins with the Sivasūtra or "Lines of Doctrine Concerning Siva" (c. 850) as a new revelation of Siva. The system embraces the Sivadṛṣṭi ("A Vision of Śiva") of Somānanda (950), in which emphasis is placed on the continuous recognition of Siva; the world is a manifestation of Siva brought about by his shakti. The system is called trika ("triad"), because it recognizes the three principles of Siva, Sakti, and the individual soul. Vīraśaiva texts begin at about 1150 with the Vācanams "Sayings") of Basava. The sect is puritanical, worships Siva exclusively, rejects the caste system in favour of its

own social organization, and is highly structured with monasteries and gurus.

Vaishnava Samhitās. These consist of two groups of texts: Vaikhānasa Samhitās and Pāñcarātra Samhitās. The latter group is the prevailing one; more than 200 titles are known, though the official number is 108. Vaikhānasa Samhitās (collections of the Vaishnava school of Vaikhānasas, who were originally ascetics) seem to have embodied the original temple manuals for the Bhagavatas (devotees), which by the 11th or 12th century had become supplanted by the Pañcaratra Samhitas (collections of the Vaishnava school of Pañcaratra—"the System of the Five Nights"). The philosophy of the latter is largely a matter of cosmogony, greatly inspired by both the Samkhya and yoga philosophies.

Notion

naviem

of shakti

in Vaish-

Apart from their theology, in which for the first time the notion of shakti is introduced into Vaishnavism, they are important because they give an exposition of Vaishnava temple and cult practices. On the philosophical side it is maintained that the supreme god Krishna Väsudeva manifests himself in four coequal "divisions" (vyūhas), representing levels in creation. These gods emanate as supramundane patrons before the primary creation is started by their shakti (power). In the primary creation Sakti manifests herself as a female creative force inspired by the Sāmkhya philosophy's cosmogony. Practically, stress is laid on a type of incarnation-"iconic incarnation"in which the god is actually present with a portion of himself in a stone or statue, which thus becomes an icon; therefore the icon can be worshiped as God himself.

Sākta Tantras. Sāktism in one form or the other has been known since Bana (c. 650) wrote his Hundred Couplets to Candi (Candi-śataka) and Bhavabhūti his play Mālatī Mādhava (725), both of which refer to Tantric practices. There is no traditional authoritative list of texts, but many texts are extant.

Śāktism is an amalgam of Śaivism and folk mothergoddess cults. The Saiva notion that not Siva himself but his shakti (sexual, creative power) is active is taken to the extreme—that, without Sakti, Siva is a corpse, and simultaneously that Sakti is the creator as well as creation. In yoga, great importance is ascribed to mantras, which conjure up the realities with which they are identified. Another important notion (partly derived from yoga philosophy) is that through the body run subtle canals that carry esoteric powers connected with the spinal cord, at the bottom of which the Goddess is coiled around the lingam as Kundalini; she can be made to rise through the body to the top, whereupon release from samsara takes place. Important among the Sakta Tantras are the Kularnava Tantra ("Ocean of Tantrism"), which gives details on the "left-handed" cult forms of ritual copulation; the Kulacūḍāmaņi ("Crown Jewel of Tantrism"), which embroiders on ritual; and the Saradātilaka ("Beauty Mark of the Goddess Sarada") of Laksmanadesika (11th century), which discusses magic.

A temple was erected in honour of the mother goddesses at Gangdhär, Räjasthän, in AD 423. There, magical rites of a terrifying kind were practiced, for the temple is described as "loud with the shouts of demonesses, crying in the thick darkness," by the playwright Bhavabhūti, whose drama Mālatī Mādhava (about the adventures of the hero Mādhava and his beloved Målati) contains a scene depicting secret rites with human sacrifice and ritual cannibalism. The goddess cults eventually centred around Durga, the

consort of Siva, in her fiercer aspect. Nature of Tantric tradition. Tantrism, which appears both in Buddhism and in Hinduism, is an important component of religion that, though primarily meant for esoteric circles, also influenced, from the 5th century AD, many religious trends and movements. Opinions of what Tantrism is are quite diverse. Generally, Tantrism claims to show in times of religious decadence a new way to the highest goal and bases itself upon mystic speculations concerning divine creative energy (shakti). Tantrism is a method of conquering transcendent powers and realizing oneness with the highest principle by yogic and ritual means-in part magical and orgiastic-which are also supposed to achieve other supranormal goals.

Śaiva, Vaishnava. and Śākta tantras

Vāmācāra:

Tantra

left-handed

Tantrists take for granted that all factors in both the macrocosm and the microcosm are closely connected. The adept (sādhaka) has to perform the relevant rites on his own body, transforming its normal, chaotic state into a "cosmos." The macrocosm is conceived as a complex system of powers that by means of ritual-psychological techniques can be activated and organized within the individual body of the adept. Contrary to the ascetic emancipation methods of other groups, the Tantrists emphasize the activation and sublimation of the possibilities of their own body, without which salvation is believed to be beyond reach.

The Tantrists of the Vāmācāra ("the left-hand practice") sought to intensify their own sense impressions by making enjoyment, or sensuality (bhoga), their principal concern; the adept pursued his spiritual objective through his natural functions and inclinations, which were sublimated and then gratified in rituals in order to disintegrate his normal personality. This implies that cultic life was also largely interiorized and that the whole world, because it became completely ritualized, was given a new and esoteric meaning.

Tantric worship (puja) is complicated and in many respects different from the conventional ceremonies that it has often influenced. Tantric devotees distinguish between an "external" and an esoteric meaning of their texts and interpret their texts by means of an ambiguous "twilight" language. Tantrists describe states of consciousness with erotic terminology and describe physiological processes with cosmological terminology. They proceed from "external" to "internal" worship and adore the Goddess mentally, offering their hearts as her throne and their selfrenunciation as "flowers."

According to Tantrism, concentration is intended to evoke an internal image of the deity and to resuscitate the powers inherent in it so that the symbol changes into mental experience. This "symbolic ambiguity" is also much in evidence in the esoteric interpretation of ritual acts performed in connection with images, flowers, and other cult objects and is intended to bring about a transfiguration in the mind of the adept.

The mantras (sacred utterances, such as hum, hrim, and klam) are an indispensable means of entering into contact with the power they bear and of transcending normal mundane existence. Most potent are the monosyllabic, fundamental, so-called bija ("seed") mantras, which constitute the main element of longer formulas and embody the essence of divine power as the eternal, indestructible prototypes from which anything phenomenal derives its existence. The cosmos itself owes its very structure and harmony to them. Also important is the introduction of spiritual qualities or divine power into the body (nyāsa) by placing a finger on the relevant spot (accompanied by a mantra).

Those Tantrists who follow the "right-hand path" attach much value to the yoga that developed under their influence and to bhakti and aspire to union with the Supreme by emotional-dynamic means, their yoga being a selfabnegation in order to reach a state of ecstatic blissfulness in which the passive soul is lifted up by divine grace.

There is also a Tantric mantra yoga (discipline through spells), which operates with formulas, and a hatha-yoga, (Sanskrit: "union of force"). In addition to normal yogic practices-abstinences, observances, bodily postures. breath control that requires intensive training, withdrawal of the mind from external objects, concentration, contemplation, and identification that are technically helped by mudras (i.e., ritual intertwining of fingers or gestures expressing the metaphysical aspect of the ceremonies or the transformation effected by the mantras) and muscular contractions-hatha-yoga consists of internal purifications (e.g., washing out stomach and bowels), shaking the abdomen, and some forms of self-torture. The whole process is intended to "control the 'gross body' in order to free the 'subtle body.'

Some Tantrists also employ laya yoga ("reintegration by mergence"), in which the female nature-energy (representing the shakti), which is said to remain dormant and coiled in the form of a serpent (kundalini) representing the uncreated, is awakened and made to rise through the six centres (chakras) of the body, which are located along the central artery of the subtle body, from the root centre to the lotus of a thousand petals at the top of the head, where it merges into the Purusa, the male Supreme Being. As soon as the union of shakti and Purusa has become permanent, according to this doctrine, wonderful visions and powers come to the adept, who then is emancipated. Some of the Tantric texts also pursue worldly objectives involving magic or medicine.

Tantric and Sakta views of nature, man, and the sacred. The Tantric movement is sometimes inextricably interwoven with Saktism. Saktism consists of doctrines and practices that assume the existence of one or more shaktis. These are "creative energies" that are inherent in and proceed from God and are also capable of being imagined as female deities. Shakti is the deciding factor in

Mudrae

vine should be faced calmly.

The Vedic goddess Vac (her name means "Word") was
then already the energetic and productive partner of Prajapati. As Ardhanársivara (the "Lord Who Is Half Female"). Siva presides over procreation. The Śaktas—often
markedly associated with Śaivism—drew the following
conclusions: creation is the result of the eternal lust of
the divine couple; the man who is blissfully embraced by
a belowed woman who is Pārvatī's counterpart assumes
Śiva's wonderful personality and, liberated, will continue

source, and that the frightening manifestations of the di-

the joy of amorous sport,

In all of his incarnations Vishnu is united with his consort, Laksmi. The sacred tales of his various relations with her manifestations led his worshipers to view human devotion as parallel to the divine love and hence as universal, eternal, and sanctified. In Vaishnava Tantrism, Laksmi plays an important part as God's shakti-that is. as a central metaphysical principle. In his supreme state, Vishnu and his shakti are indissolubly associated with one another so as to constitute the personal manifestation of the supreme brahman, also called Laksmi-Nārāvana. In mythical imagery, Laksmī never leaves Vishnu's bosom. In the first stage of creation, she awakens in her dual aspect of action-and-becoming, in which she is the instrumental and material cause of the universe; Vishnu himself is the efficient cause. In the second stage, her "becoming" aspect is manifested in the grosser forms of the souls and the power of maya, which is the immaterial source of the universe. In displaying her power she takes into consideration the accumulated karma of the beings, judging mundane existence as merit and demerit. Presented in myth as God's wife and the queen of the universe, she is always intent on liberating, by her favour and compassion, the incarnated souls of the devout; that is, she allows them to reenter into herself because they are really "parts," or rather "contractions," of her own essence. After entering her, the liberated soul takes part in the perfect embrace of the divine couple. Pañcaratra Vaishnavism emphasizes that Laksmi-who in the mythological sphere intercedes with her husband for the preservation of the world-spontaneously and by virtue of her own power differentiates herself from Vishnu because she has in view the liberation of the souls. This current of thought complicated its explanation of the relation between God and the universewhich was at the same time an attempt at assigning to God's manifestations a place in a harmonious theological and cosmological system-with an evolutionist theory of successive creations. God is assumed to manifest himself also in three other figures, mythologically his brothers, who, each with his own responsibility, have not only a creative but also an ethical function, by which they assist those who seek to attain to final emancipation.

Tantric ritual and magical practices. The ritual of the left-hand Tantrists consisted of a kind of black mass in which all of the taboos of conventional Hinduism were conscientiously violated. Thus, in place of the traditional five elements (*lattro*sy) of the Hindu cosmos, these

Tantrists used the five "m"s: māŋxsa (flesh, meat), matsya (fish), madə (fernented grapes, wine), mudrā (frunentum, eereal, parched grain, or gestures), and mainhuna (fornication). This latter element was made particularly antinomian through the involvement of forbidden women, such as one's sister, mother, the wile of another man, or a low-caste woman, who was identified with the Goddess. Menstrual blood, strictly taboo in conventional Hinduism, was also used at times. Such rituals, which are described in Tantric texts and in tracts against Tantrists, made the Tantrists notionus. It is likely, however, that the rituals were not regularly performed except by a relatively small group of highly trained adepts; the usual Tantric ceremony was purely symbolic and even more fastidious than the pujas in Hindu temples.

The cult of the Saktas is based on the principle of the ritual sublimation of natural impulses to maintain and reproduce life. Śākta adepts are trained to direct all their energies toward the conquest of the Eternal. The ritual satisfaction of lust and the consumption of consecrated meat or liquor are esoterically significant means of realizing the unity of flesh and spirit, of the human and the divine. They are not considered sinful acts but on the contrary, effective means of salvation. Ritual copulation-which may also be accomplished symbolically-is, for both partners, a form of sacralization, the act being a participation in cosmic and divine processes. The experience of transcending space and time, of surpassing the phenomenal duality of spirit and matter, of recovering the primeval unity, the realization of the identity of God and his Sakti, and of the manifested and unmanifested aspects of the All, constitute the very mystery of Saktism. The interpretation-metaphorical or literal-of the doctrines is, however, largely a matter of opinion and practice. Ritual practice is indeed as varied as the doctrines. Extreme Śākta communities perform the secret nocturnal rites of the śrīcakra ("wheel of radiance," described in the Kulārnava Tantra), in which they avail themselves of the natural and esoteric symbolic properties of colours, sounds, and perfumes to intensify their sexual experiences. Most Tantrists, however, eliminate all but the verbal ritual.

Individual and collective yoga and worship, conducted daily, fortnightly, and monthly "for the delectation of the deity," are of special importance. After elaborate purifications, the worshipers-who must be initiated, full of devotion toward the guru and God, have control over themselves, be well prepared and pure of heart, know the mysteries of the scriptures, and look forward to the adoration with eagerness-make the prescribed offerings, worship the mighty puissance of the Divine Mother, and recite the relevant mantras. Once they have become aware of their own state of divinity, they are qualified to unite sexually with the Goddess. If a woman is, in certain rituals, made the object of sexual worship, the Goddess is first invoked into her; the worshiper is not to cohabit with her until his mind is free from impurity and he has risen to divine status. Copulation with a low-caste woman helps to transcend all opposites; union with a woman who belongs to another man is often preferred because it is harder to obtain, nothing is certain in it, and the longing stemming from the separation of lover and beloved is more intenseit is pure preman (agape, or divine love); adoration of a girl of 16 aims at securing the completeness and perfection of which this number is said to be the expression. However, the texts reiterate how dangerous these rites are for those who are not initiated; those who perform such ritual acts without merging their minds in the Supreme are likely to go to one of the hells.

The esoteric Vaishnava-Sahajiyā cult, which arose in Bengal in the 16th century, was another emotional attempt at reconciling the spirit and the flesh. Displaying contempt for social opinion, its adherents, using the natural (sahajia) qualities of the senses and stressing the sexual symbolism of Bengal Vaishnavism, reinterpreted the Radhā-Krishna legend and sought for the perpetual experience of divine joy; because Krishna's nature is love and the giving of love and because man is identical with Krishna, the realization of love can, after an arduous training, be experienced in man's nature. Women, being a ritual necessity as well

Bengali Vaishnava-Sahajiyā cult

Vaishnava Šāktism as the embodiment of a theological principle, could even become spiritual guides, like Rādhā, conducting the worshiper in his search for realization. After reaching this state, he remains in eternal bliss, can dispense with guru and ritual, and be completely indifferent to the world,

'steadfast amidst the dance of maya,'

Tantric and Śākta ethical and social doctrines. These ethical and social principles, though fundamentally the same as those promulgated in the classical dharma works, breathe a spirit of liberality: much value is set upon family life and respect for women (the image of the Goddess); no ban is placed on traveling (conventionally regarded as bringing about ritual pollution) or on the remarriage of widows. Although Tantric and Sakta traditions did not oblige their followers to deviate in a socially visible way from the established order, they provided a ritual and a way of life for those who, because of sex or caste, could not participate satisfyingly in the conventional rites.

The ancient Tantric tradition, based on the esoteric tantra literature, has become, through time, so interwoven with more orthodox Hinduism that it is difficult to define precisely. Although it sees an identity between the soul and the cosmos, it speaks of the internalization of the cosmos rather than of the release of the soul to its natural state of unity. The body is the microcosm, and the ultimate state is not only omniscience but total realization of all universal and eternal forces. The body is real, not because it is the function or creation of a real deity but because it contains the deity, together with the rest of the universe. The individual soul does not unite with the One-it is the

One, and the body is its function.

The coiled

serpent

Tantrism, though not always in its full esoteric form, is a feature of much modern mystical thought. In Tantrism the consciousness is spoken of as moving-driven by repetition of the mantra and by other disciplines-from gross awareness of the material world to realization of the ultimate unity. The image is of a serpent, coiled and dormant, awakened and driven upward in the body through various stages of enlightenment until it reaches the brain. the highest awareness. The modern mystic Ramakrishna describes the process, which also describes the experience that all Hindu mystical processes seek:

When [the serpent] is awakened, it passes gradually through [various stages], and comes to rest in the heart. Then the mind moves away from [the gross physical senses]; there is perception, and a great brilliance is seen. The worshiper, when he sees this brilliance, is struck with wonder. The [serpent] moves thus through six stages, and coming to [the highest onel, is united with it. Then there is samādhi. When Ithe serpent] rises to the sixth stage, the form of God is seen. But a slight veil remains; it is as if one sees a light within a lantern, and thinks that the light itself can be touched, but the glass intervenes.... In samādhi, nothing external remains. One cannot even take care of his body any more; if milk is put into his mouth, he cannot swallow. If he remains for twenty-one days in this condition, he is dead. The ship puts out to sea, and returns no more. (Translation by Edward C. Dimock, Jr. Source is Śrīśrīrāmakrsna-kathāmrta; Calcutta: Ramakrsna Mission.)

VERNACULAR LITERATURES

Most of the texts cited in this survey are Sanskrit texts, which constitute the oldest layer of preserved Hindu literature. But the sacred literature of India is by no means as monolithic as these texts might suggest. Several other essential elements exist: independent sacred literatures in languages other than Sanskrit and material in other languages related to the Sanskrit texts either as sources of material now preserved only in Sanskrit or as new texts originating as translations of Sanskrit texts. Because Sanskrit has been in intimate contact with the "mother tongues" of India for such a long time, it is often impossible to determine in which of these categories a particular vernacular text belongs.

Indologists usually emphasize the influence of Sanskritic (often called "Aryan") culture on Dravidian culture, and indeed this influence was considerable. Sanskritic influence was already in evidence in the earliest Tamil (a principal Dravidian language) literature, perhaps dating from the 1st century AD. At this time in South India the orthodox

cults were aristocratic in character and were supported by kings and chiefs who gained in prestige by patronizing Brahmans and adopting Aryan ways. The Tamils were still primarily devoted to the old cults, some of which, however, were taking on an Aryan complexion. The pastoral god Murugan was identified with Skanda and his mother. the fierce war goddess Korravai, with Durga. Varunan, a sea god who had adopted the name of the old Vedic god but otherwise had few Aryan features, and Mayon, a black god who was a rural divinity with many of the characteristics of Krishna in his pastoral aspect, also are depicted in Tamil literature. The final Sanskritization of the Tamils was brought about through the patronage of the Pallava kings of Kanchipuram, who began to rule in the 4th century AD and who financed the making of many temples and fine religious sculptures. Similar processes were taking place in the Deccan, Bengal, and other regions.

Sanskritization is a term that refers to a style of text that imitates the customs and manners of the Brahmans, But, although most sacred texts in Sanskrit were composed by Brahmans, many were also composed by lower-class authors. Likewise, although some sacred texts in vernacular languages were written by authors of lower castes, many others were written by Brahmans. In addition, because Sanskrit ceased to be spoken as a primary language soon after the Vedas were composed, it is likely that most of the thoughts underlying all subsequent Sanskrit literature were first thought in some other language. Yet Indologists tend to be Sanskritists, and Sanskritists tend to assume that all texts originated in Sanskrit. Indeed, even the counterbalancing tendency to acknowledge the flow from non-Sanskrit to Sanskrit sources has often misfired; far too often it is merely asserted that anything that appears in post-Vedic Hinduism and is not attested in the Vedas is 'Dravidian," or, even worse, from the Indus civilization (about whose religion virtually nothing is known).

The issue is further clouded by the fact that, though Sanskrit texts tend to be written and vernacular traditions are primarily oral, there are important oral traditions in Sanskrit, too (including the traditions of the two great Sanskrit epics), and there are important manuscript traditions in some of the non-Sanskritic languages (such as Bengali and Tamil). Indeed, written and oral versions of the epics and Puranas have been, from the very start, in

constant symbiosis.

Little relevance, therefore, attaches to a distinction between "written" and "oral" traditions. A myth is essentially told or narrated, a process that is designated in Sanskrit by such words as purana (ancient story) and akhyana (illustrative narrative). In the oldest source, the Rigveda, myths are not so much told as alluded to: it is in the later Vedic literature of the Brahmanas that narratives are found, and these are often prejudiced by liturgical concerns of the authors.

The recitation of certain myths was prescribed for specific Oral and rituals. The epic Mahābhārata states that Vedic stories were narrated "in the pauses of the ritual," probably by Brahmans. The warrior class (Ksatrivas) had their own mythographers in their sūtas (charioteers and panegyrists), who celebrated the feats of great rulers. These sūtas, who became popular narrators of myth and legend, had their own bardic repertoire, which soon was extended to higher mythology. They-and other wanderers who found ready audiences at sacrifices or places of pilgrimage-disseminated the lore.

Such parrators still continue to repeat and embroider their ancient stories of gods, sages, and kings. At an early stage their narratives were dramatized and gave rise to the Sanskrit theatre, in which epic mythic themes preponderate, and to the closely related dance, which survives in the now largely South Indian schools of bharata natya (traditional dance) and the kathakali (narrative dance) of Kerala. Thus, even in Sanskrit literature, oral performance was an essential component, which further facilitated the assimilation of oral vernacular elements.

When the Indo-Europeans, who spoke Sanskrit, an Indo-European language, entered India in around 1500 BC, most of the people they encountered spoke languages that belonged to a major non-Indo-European linguistic group written Hindu

the Sanskrit tradition. Of the four primary Dravidian literatures-Tamil, Telugu, Kannada, and Malayalam-the oldest and bestknown is Tamil. The earliest preserved Tamil literature, the so-called Cankam or Sangam poetry anthologies, dates from the 1st century BC. These poems are classified by theme into akam ("interior," primarily love poetry) and puram ("exterior," primarily about war, the poverty of poets, and the deaths of kings). The bhakti movement has been traced to Tamil poetry, beginning with the poems of the devotees of Siva called Nayanars and the devotees of Vishnu called Alvars. The Nayanars, who date from about AD 800, composed intensely personal and devout hymns addressed to the local manifestations of Siva.

The most famous Nāyaṇār lyricists are Appar, Sambandar, and Cuntarar, whose hymns are collected in the Tevāram (c. 11th century). More or less contemporary were their Vaishnava counterparts, the Alvars Poykai, Pütan, Pēyār, and Tirumankaiyāl-vār, and in the 8th century the poetess Āṇḍal, Periyālvār, Kulacēkarar, Tirup-pānālvār, and notably Nammālvār, who is held to be the greatest. The devotion of which they sing exemplifies the new bhakti movement that seeks a more direct contact between man and God, carried by a passionate love for the deity, who reciprocates by extending his grace to man. These saints also became the inspiration of theistic systematic religion: the Saivas for the Saiva-siddhanta, the Vaishnavas for Viśistādvaita. In Kannada the same movement was exemplified by Basava, whose vācanams ("sayings" or "talks") achieved great popularity. His religion, that of Vīraśaivism, was perhaps the most "protestant" of

the bhakti religions.

Dravidian

traditions

New Dravidian genres continued to evolve into the 17th and 18th centuries, when the Tamil Cittars (from the Sanskrit siddhas, "perfected ones"), who were eclectic mystics, composed poems noted for the power of their naturalistic diction. The Tamil sense and style of these poems belied the Sanskrit-derived title of their authors, a phenomenon that could stand as a symbol of the complex relationship between Dravidian and Sanskrit religious texts.

The main languages derived from Sanskrit are Bengali, Hindi (with its many dialects, of which Maithili is the oldest and Urdu, heavily influenced by Persian and Arabic and written in a Perso-Arabic script, is the most important), Punjabi, Gujarati, Marāṭhi, Oriya, Kashmiri, Sindhi, Assamese, Nepali, Rajasthani, and Sinhalese. Most of these languages began to develop literary traditions around AD 1000. The earliest texts in Hindi are those attributed to the 13th-14th-century Muslim poet Amīr Khosrow.

Hindi literature produced its own great religious lyricists beginning with the disciples of Rāmānanda (c. 1450), who was a follower of the philosopher Rāmānuja. Among them the most famous is Kabīr, whose bhakti was nonsectarian. Tulsīdās, apart from his Rāmcaritmānas, composed Rāmaite lyrics. Sūrdās (1483-1563), a follower of the Vallabha school of Vedanta, is famous for his Sūrsāgar ("Ocean of the Poems of Sūr"), a collection of poems based on the childhood of Krishna, following the account of the Bhāgavata-Purāṇa. In the Marāthi tradition, Nāmdev (c. 1300) celebrated Vishnu, particularly in his manifestation as Vitthobā at the Pandharpur temple; and in the 17th century Tukārām, the greatest poet of this literature, sang of the god of love in numerous hymns.

A small sect, the Kabīrpanthīs, acknowledges Kabīr as its founder, but its importance is less than that of the vigorous new religion (Sikhism) founded by one of Kabīr's disciples, Nānak. In its final form, Sikhism contains elements taken from Islām (equality in the faith, opposition to iconolatry, extreme reverence for the sacred book) and probably also from Christianity (the Sikh baptism and communion meal), but its theology is still essentially Hindu.

Although the earliest Hindu text in Bengali is a mid-15th-century poem about Rādhā and Krishna, medieval texts in praise of gods and goddesses, known as mangalkāvvas, must have existed in oral versions long before that. In later Bengal Vaishnavism, the emphasis shifts from service and surrender to mutual attachment and attraction between God (i.e., Krishna) and humankind: God is said to yearn for the worshiper's identification with himself, which is his gift to the wholly purified devotee. The mystical and devotional possibilities of the Krishna legend are made subservient to religious practice: the divine sport and wonderful feats of this youthful hero are interpreted symbolically and allegorically. Thus, the highest fruition of bhakti is admission to the eternal sport of Krishna and his beloved Rādhā, whose sacred love story is explained as the mutual love between God and the human soul. Various gradations of bhakti are distinguished, such as awe, subservience, and parental affection. These are correlated with the persons of the Krishna legend; the highest and most intimate emotion is said to be the love of Rādhā and her girlfriends for Krishna.

A particularly rich tradition centred in Bengal concentrated on the love of Rādhā, who symbolizes the human soul, for Krishna, the supreme God. In this tradition are Candidas and the Maithili poet Vidvapati (c. 1400). The greatest single influence was Caitanya, who in the 16th century renewed Krishnaism. He left no writings but inspired many hagiographies, among the more important of which is the Caitanya-caritamrta ("Nectar of Caitanya's

Life") by Krishna Das (born 1517).

Caitanya had a profound and continuing effect on the religious sentiments of his Bengali countrymen and propagated the community celebration (samkīrtana) of Krishna as the most powerful means of bringing about the proper bhakti attitude. Caitanya also introduced the worship of God, the director of man's senses, through the very activity of man's senses, which must be free from all egoism and completely filled with the intense desire (preman) for the satisfaction of the beloved (i.e., Krishna).

The religious lyric continues in the so-called pādas (verses); one of the greatest poets in this bhakti genre in which divine love is symbolized by human love is Govinda Das (1537-1612). The songs of Ramprasad Sen (1718-75) similarly honour Sakti as mother of the universe and are still in wide devotional use. The most famous religious lyrics in Gujarati are the poems of the saint Mīrā Bāī (1503-73), who wrote passionate love poems to Krishna, whom she regarded as her husband and lover.

The complex interaction between Sanskrit and non-Sanskrit religious classics may be seen in the development of the epics. Parts of the two great Sanskrit epics, the Mahābhārata and the Rāmāyaṇa, and many Purāṇas (especially the Bhagayata-Purana) were translated into various vernaculars. Technically, these works were not literal translations, but free versions in which the authors placed their own emphases, different from the original and from one another. The oldest of the vernacular versions of the Rāmāyaṇa is the Tamil one of Kampan (c. 12th century), a work suffused with devotion (bhakti) and of high literary distinction. Another famous translation in Tamil, written by Villiputturar, exists from the 18th century. A Telugu rendering was made by Ranganatha about 1300. In Bengali several translations were made, with some interesting and probably authentic variations from the "official" Rāma story by Vālmīki, the best-known one by Kṛttibās Ojhā (1450). Equally, if not more, famous is the Hindi version by Tulsīdās (c. 1550), entitled Rāmcaritmānas ("Holy Lake of the Acts of Rama")

The Mahābhārata was translated into Bengali about 1600 and into Telugu by Nannaya and Tikkana in the 13th century. The Bhāgavata-Purāṇa, which was translated frequently (e.g., into Bengali by Maladhar Vasu, 1480), was popular both as a text and because it gave the canonical account of Krishna's life and especially his boyhood, which is the perennial inspiration of the bhakti poets.

In Marāthi the teacher Jñānadeva (also known as

The work of Caitanya

Regional language versions of the Rāmāvana and Mahāhhārata

Jāānésvara: c. 1275-96) composed a commentary on the Bhagawadgid that remains a classic in that literature. His work was continued by Eknath (c. 1600), who also composed bhakti poerty: In the 16th century the Kannada poet Gadugu produced his own highly individual version of the Mahabharata. In addition to the above literal or not-so-literal translations of the Sanskrit epics, the Tamilis composed their own epics, notably Ilañko Ajikaļ's Cilappatikāram ("The Lay of the Anklet") and its sequel, the Mapimekhalat ("Jeweled Girdle"). In Telugu there is the great Palhaḍu Epic; Rajasthani has an entire epic cycle about the hero Pabuji. The remaining vernaculars have produced many other works of the epic genre.

produced many other works of the epic genre.

Hindiu mythology in contemporary India. Much of the classical mythology persists today, and Hindus are exposed to it year-round. Meanwhile, the mass media have made their contributions: the type of motion picture called "mythological" is extremely popular, perpetuating the ancient stories to the village level, and so are "devotionals," in which an example of bhakti is illustrated. The radio regularly carries bhajams (devotional songs) and classical South Indian songs, the themes of which are often mythic. Every orthodox Hindu's home has at least one corner set aside as a domestic sanctuary where representations of a chosen deity are placed, and puja (worship) is done with prayers, hymns, flowers, and incress. Richer establishments set aside entire rooms as shrines. Mythic illustrations are favourites in Indian calendar art.

Mythology has adjusted itself effortlessly to modernity. The ashram of the 20th-century mystic and religious leader Śrī Aurobindo in Pondicherry, dedicated to the Mother Goddess (personified by this group as a single principle), is an extremely modern establishment complete with tennis courts. New temples are constructed with modern techniques; one temple in Vārānasi contains mirrors onto which are etched the entire Ramcaritmanas. This same poem is the basis of the annual celebration of Rām Līlā (the play of Rama) in northern India, in which the entire community participates. The Rama story was evoked by Mahatma Gandhi when he set the Ram Rai ("Kingdom of Rāma") as India's governmental ideal. On occasion, social protesters arm themselves with myth to make a point. For example, the personality of Karna, an antagonist in the Mahābhārata who is berated for his low birth, is extolled in intellectual circles as a truer champion than the aristocratic heroes. A Kannada-language play of the 1960s based on the life of King Yayati enjoyed great popular and critical success. Anti-northern groups in Tamil Nadu revised the story of Rāma, whose expedition against the demon Rāvana is believed by some to be the Aryan invasion of South India, by reversing it to abuse Rāma and to glorify Rāyana.

On a popular level, people at temples and fairs are continually reacquainted with their mythological heritage by paurāŋikas, tellers of the ancient stories, heirs of the sūtas of 3,000 years ago, and no festival ground is complete without tents where the religious are reminded of their myths by pious speakers, modestly compensated by fees but richly rewarded by the honour in which they are held.

FOLK HINDUISM

Myth and

modernity

Despite the impact of the West, the propaganda of modern reform movements, and the spread of education and secularist modernization, Hinduism has changed only slowly. For ordinary Hindus, religion primarily consists of the manual and verbal performance of rites to promote their private interests. The innumerable ceremonies, observances, fasts, feats, pilgrimages, and visits to nearby temples constitute the essence of religion.

General characteristics of folk traditions. For millions, the main motive of religious practices is still the fear of ambivalent powerful beings. Most Hindus prophitate the meat-eating, sometimes benevolent but largely malevolent delities concerned with man's daily events, their ancestors or the founder of their community, and those various spirits that have no permanent residence and cause evil and misfortune. Hindus strive to escape the powers of the evil eye; to manipulate those spirits dwelling in wells, trees, stones, water, and ground; to counteract curses, witchcraft,

plague, and cholera; and to worship village godlings who may give rain or a bountiful harvest. They make use of astrology, divination, and the reading of omens and auspicious moments. A large variety of purifications and ritual prohibitions, charms, and amulets to ward off any kind of misfortune (including bad luck in lawsuits and examinations) are, in the eyes of the majority, of greater importance than the atman-brahman doctrine. Even the hope of heaven or the fear of hell has little vogue in various regions, except among the higher castes.

It is difficult to draw a sharp line of distinction between popular Hinduism, the beliefs and practices of more or less Hinduized "external" groups, and Indian tribal religion. Many elements of tribal culture that in a particular region have not been adopted by those recognized as belonging to the Hindu fold are in fact similar to what has been adopted by Hindus in other areas. Tribal people and outcaste groups are, on the other hand, always willing to worship a few more gods or to imitate the rituals of lowercaste Hindus. Age-long processes of interpenetration and fusion have led to an adoption of many local and popular cults into general Hinduism-or, because it expressed itself mainly in Sanskrit, into the Great, or Sanskritic, tradition-and to the identification of regional gods with the great figures of the Hindu pantheon. Popular belief is integrated rather than discounted or discarded. This process is facilitated by a tendency toward the assimilation of local beliefs by pan-Indian Hinduism and by an unwillingness to deny gods and cults (the worship of a local river deity, for example, may be identified with that of the Ganges). The inheritors of the Little, or regional, traditions accepted, as a result of continual and complicated Hinduizing influences, vegetarianism, regular fasts, and food restrictions; they also began to object to the remarriage of widows, to observe Hindu festivals, to sing Hindu religious songs, to perform funeral and other ceremonious worship and, most importantly, to imbibe the ideas embodied in religious and mythological narratives. Thus, various tribal or outcaste groups have a religion with some affinities to a simple Saivism without sacred books or regular liturgy.

While many Hindus pursue their approach to the divine individually, corporate worship in families, villages, and sects is far more common in some castes. These groups exhibit the utmost variation in beliefs and practices. As a rule, each community practices only a small segment of the whole spectrum of religious behaviour as the expression of its own religious life. As to the relation between religion and social structure, there are in many communities differently structured systems, each with its own religious behaviour, in which their members may be involved. As members of a joint family, they take part in the domestic cult and ritually express family solidarity at such critical points as mourning or marriage; as members of a village community, they take part in its particular cult, which is a collective action of that community. Different castes, however, establish their own rituals in order to foster unity and to differentiate themselves from others. There is, on the other hand, ritual cooperation between different villages of the same region.

For many communities, spiritual reality is complex: while many women may address local spirits, family ancestors, and goddesses of disease, some of the men may embrace monotheistic ideas. The village's guardian spirit and the saint of a Muslim shrine may also be worshiped, Rāma's name is invoked in prayers, and the major deities are honoured chiefly during their periodic festivals. Marriage and other ceremonies combine ancient Sanskritic rites with popular and local features, and even members of the higher classes may accept the entire range of belief. In many regions, each caste has both general Hindu and "parochial" rituals and beliefs, but the proportions in which the two are found together vary from caste to caste and from locality to locality. The upper castes everywhere, however, have a certain amount of Sanskritic ritual in common; but even those who are more or less exclusively devoted to Siva, for example, do not necessarily constitute a Saiva community.

The bhakti movements have long influenced the religious feelings of their followers, and religious problems Relation of folk Hinduism to Indian tribal religions are discussed by people of all professions and intellectual levels. Divine assistance is implored on every imaginable occasion; ancient Vedic rites have even been used as a

defense against atomic danger. Regional varieties of folk religion. In the hilly and mountainous regions of North India, Saivism, aligned with Śāktism, is prevalent. The awe and mystery of the jungle and mountains are, there and elsewhere, personified as forest "Mothers" or mountain deities, represented by piles of stones or branches of trees to which every passerby contributes an offering. Mother Earth is a great goddess whose marriage (with the Earth god or the Sun) is festively celebrated and whose annual period of impurity is observed by a cessation of all agricultural activities. During the harvest season she is propitiated with wild orgies. In secluded parts of central India she is identified with Devi, a goddess mostly worshiped in North India. Very often, however, she shows herself in her malevolent form, as Mother Death (Mārī) or as Kālī. There are also many lower caste groups that have adopted a Vaishnava way of life either in order to raise their social status or to have a

Folk

goddesses

prospect of salvation. In the east and northeast, where, broadly speaking, Śāktism is dominant, though Vaishnavism is also common, popular belief has modified the transmigration doctrine by the assumption that the soul of the deceased reappears in a child born in the same family within a year after the person's death. Among the female deities, there are tutelary goddesses of young children and women in childbed: Sasthī, "the Sixth," is worshiped on the sixth day after birth and is represented by a compost pile of cow dung or earth that is placed in the birth room; and Candi, a form of the goddess Durga, lives in trees and is propitiated by lumps of earth. The snake goddess Manasa is personified in a plant of the same name or in a stone carved into the shape of a female seated on a snake; a day in the rainy season, when reptiles are most dangerous, is devoted to her priestless and unpretentious worship. In literary works she is eulogized as the Great Mother who is expected to give a prosperous journey through life and, to a certain extent, is also Sanskritized by being identified with epic snake demons. Another example of fusion of general and local Hindu institutions is the conviction that ghosts and demons are warded off by performing a ceremony in honour of the deceased at Gaya in modern Bihar state.

In many regions-especially in western India, where Vaishnavism is dominant-believers admit that virtue will improve their lot in a subsequent existence, but they do not seem to strive for final union with the Supreme. Here, and elsewhere, a workaday religion meant to meet the requirements of everyday life exists alongside a higher religion understood only by the Brahmans, who are called on to officiate on important occasions. In order to discover the divine will, exorcists and mediums, possessed by mother goddesses and submitting themselves to selftorture, are called upon to prophesy about future events. In these regions the worship of snakes is more prominent, and some temples are even dedicated to them. Practices based on the belief in scapegoats, ritual nudity, and black

magic are also widespread.

The whole of peninsular India is mainly devoted to Saivism, devotional forms of Vaishnavism, and the worship of the goddess in her many forms. A striking feature in the religion of South India is the propitiation of usually local female village deities of varied and ambivalent character, to whom in almost every settlement a simple shrine or other sacred place is dedicated. These deities are thought to be particularly competent for dealing with the facts of village life, such as diseases of the inhabitants and their cattle. Special cholera and smallpox goddesses are the subject of elaborate stories. In a few cases-e.g., that of Märiyammä, the smallpox goddess of South India-such a goddess is known to a large region. These mothers, from whom all good and bad luck emanate, are almost universally worshiped with animal sacrifices, and the priestly ministrants (pūjārī) officiating in their cult belong to the non-Brahman groups. The goddesses may be represented by various symbols (stone pillars, sticks, clay figures) that need not be permanent. Most of their shrines are simple, small brick buildings or rough stone platforms under a tree. Offerings of rice, fruit, and flowers may be made every day or on fixed days; although there often is a fixed annual festival, it is not uniformly celebrated and no calendar of festivals is established. An exception to this is the male deity Aiyanar, who in the countryside of Tamil Nādu state is worshiped as the watchman and patron of the villages but also is implored to grant children and other blessings. He is a vegetarian and therefore ranks as socially superior to the female village goddess with whom he has entered into a complementary relation. Aiyanar is worshiped either as a village deity or in a temple dedicated to Siva, where he is given the rank of a son of that god. In these Siva temples he is legitimated by higher Hinduism and fulfills the function of a double of Siva representing "All-India" or general Hinduism in the village, which does not regard him as an outsider. Siva himself is also worshiped and given a consort, who, though considered a manifestation of Durga, has various names according to the tradition of temple or village.

Sacred snakes, especially cobras, are also given offerings-partly to avert danger from these reptiles, partly to propitiate them with the aim of obtaining rain, fertility, or children; to that end women worship snake stones (nagalkals) or erect stone figures of cobras. Every joint family of the Coorgs in Karnātaka state and most other peoples have a snake deity of their own that is said to embody their welfare. Here and there, Brahmans officiate in this cult. which usually takes place in small sanctuaries in private gardens. Although also known in other parts of India, the methods of exorcising evil spirits known as devil-dancing are most fully developed in South India. The notorious hook-swinging festival, Cadak-pūjā, held for propitiatory purposes in cases of famine or other calamities-a man was suspended by hooks at the end of a long pole and swung around-though strictly prohibited, survived to the 20th century. Greater festivals are, generally speaking, either celebrated at the chief agricultural seasons or connected with the expulsion of malign powers.

Folk and tribal myths. There is a great diversity in folk mythology throughout the entire Indo-Pakistan subcontinent, but these myths have neither been fully collected nor systematically studied. Among locally important deities, Manasa, a snake goddess, worshiped in Assam and Bengal to ward off snakebites and secure prosperity, has an enormous mythology of her own. In South India one finds popular cobra cults with a variety of myths and lore. In Mahārāshtra, a form of Vishnu, known as Vitthal or

Vitthobā, has also spawned a rich mythology. The sources of folk and tribal mythology are vernacular literature, oral tradition, folklore, and folk and tribal arts. Folk mythology derives from the most ancient times and has influenced both Vedic and classical mythology. Classical mythology became what it is by continuously assimilating myths not previously known or accepted, so that the line between classical and folk (and tribal) mythology is apt to be arbitrary. The Great (Sanskrit) tradition of classical mythology (as contrasted with the local, or Little, traditions of folk mythology) may include within its scheme a god who continues to have an independent existence on a folk level. Sacred manifestations of purely local interest are associated with the higher mythology by becoming a Little manifestation of a Great god, such as the footstep of Rama and the bathing place of Sītā (Rāma's wife). Conversely, an incident of the Great tradition may be adopted and adapted on the folk level. For example, the local Mahārāshtrian god Vitthobā is identified with a manifestation of Vishnu and thus assured a place in the Great tradition; on the other hand, in North India, the widely celebrated festival of Navarātrī ("Nine Nights") is associated with the village goddess Naurtha.

Certain concepts that evolved in Puranic mythology have facilitated the absorption of folk elements; two of these should be singled out: avatar (avatāra, incarnation), and vāhana (vehicle).

The concept of avatar (literally "descent") issues from the belief that in times of trouble a god, notably Vishnu, incarnates himself as a man or hero to set matters right. Such a concept provides the opportunity for identifying a

concepts of avatar and vāhana

associated

with the

newborn

local deity (like Vitthoba, above) with an all-Indian god like Vishnu. The concept may also extend to the worship of very local hierophanies (manifestations of the sacred; e.g., South Indian Vaishnavism accepts "icon-incarnation" [arcāvatāra], in which Vishnu "descends" in a local icon).

According to the concept of a vāhana (literally "mount"), every god has an entourage of his own, which includes a favourite riding animal; this facilitates many folk associations. Vishnu's mount is the bird Garuda, an old solar symbol; Śiva's is the bull Nandi, whose worship may go back to the ancient Harappan civilization. There are other mythological patterns, such as adoption in a family: thus the folk god Ganesa, an elephant-headed god, is made the son of Siva, as is Kumāra Kārttikeya, the war god, who arose from the South Indian war god Murugan. Hanuman, the monkey god, becomes an all-Indian god as a helper of Rāma, who is an avatar of Vishnu.

Other spirits and godlings of folk provenance are not absorbed to the same degree and thus retain their folk character. Important are the snakes (nagas), to which great power is attributed; the yakshas, koboldlike keepers of wealth, whose king is Kubera; vetālas, ghoulish pranksters who haunt corpses; and spirits of the restless dead (bhuts, pretas), who must be warded off. Though the existence of these spirits is fully recognized in the classical mythology.

they operate primarily on the folk level.

It is therefore difficult to find folk myths and cults that are not in one form or another elevated into the Sanskrit tradition by a specific association with a major god. Only where there has been no appreciable cultural contact between Indian tribal people and Hindus (or "Hinduized" folk groups) can a significant distinction be drawn between classical Hindu mythology and "folk" mythology. The myths of the tribes of Chota Nagpur (Bihar state), the Santal (West Bengal and Bihar states), the Toda in the Nîlgiri Hills (Tamil Nădu state), and others are examples of such mythology. Much religious material lies hidden in folktales.

(J.A.B.v.B./E.C.D./A.L.B./W.Do./B.K.S./Ed.)

Rituals, social practices, and institutions

SACRIFICE AND WORSHIF

Although the Vedic fire rituals were largely replaced in Puranic and modern Hinduism by image worship and other forms of devotionalism, many Hindu rites can still be traced back to Vedism. Certain royal sacrifices-such as the rāiasūva, or consecration ritual, and the horse sacrifice (aśvamedha)-remained popular with Hindu kings until very recently. Other large-scale Vedic sacrifices (śrauta) have been regularly maintained from ancient times to the present by certain families and groups of Brahmans, By and large, however, the surviving rituals from the Vedic period tend to be most clearly observed at the level of the domestic (grhya) ritual.

Domestic rites. The Vedic householder was expected to maintain a domestic fire into which he made his offerings. Normally he did this himself, but in many cases he employed a Brahman officiant. In the course of time, the family priest was given a large part in these ceremonies. so that most Hindus have employed Brahmans for the administration of the "sacraments" (samskara). The samskaras include all important life-cycle events, from conception to cremation, and are the main constituents of the domestic ritual.

The sacraments are transitional rites intended to make a person fit for a certain purpose or for the next stage in life, by removing taints (sins) or by generating fresh qualities. If the blemishes incurred in this or a previous life are not removed, the person is impure and will acquire no reward for any ritual acts. The sacraments, while sanctifying critical moments, are therefore deemed necessary for unfolding a person's latent capacities for development. Sudras are allowed to perform some samskaras if they do not require the use of Vedic mantras.

Samskaras: rites of passage. In antiquity there was a great divergence of opinion about the number of rites of passage, but in later times 16 were regarded as the most important. The impregnation rite, consecrating the supposed time of conception, consists of a ritual meal of pounded rice (mixed "with various other things according to whether the married man desires a fair, brown, or dark son; a learned son; or a learned daughter"), an offering of rice boiled in milk, the sprinkling of the woman, and intercourse; all acts are also accompanied by mantras. In the third month of pregnancy the rite called pumsavana (begetting of a son) follows. The birth is itself the subject of elaborate ceremonies, the main features of which are an oblation of ghee (clarified butter) cast into the fire; the introduction of a pellet of honey and ghee into the newborn child's mouth, which according to many authorities is an act intended to produce mental and bodily strength; the murmuring of mantras for the sake of a long life; and rites to counteract inauspicious influences. There is much divergence of opinion as to the time of the name-giving ceremony; in addition to the personal name, there is often another one that should be kept secret for fear of sinister

designs against the child In modern times most samskaras (with the exceptions of impregnation, initiation, and marriage) have in many areas fallen into disuse or are performed in an abridged or simplified form without Vedic mantras or a priest. This tendency was encouraged by the accommodating spirit of the Brahmans, who allowed their clients easy atonements for the nonobservance of rites. The important upanayana initiation is held when a boy is between the ages of eight and 12 and marks his entry into the community of the three higher classes of society. In this rite he becomes a "twice-born one," or dvija. Traditionally, this was also the beginning of a long period of Veda study and education in the house under the guidance of a teacher (guru). In modern practice, the haircutting ceremony-formerly performed in a boy's third year-and the initiation are usually performed on the same day, the homecoming ceremony at the end of the period of study being little more than a formality.

Wedding ceremonies, the most important of all, have not Marriage only remained elaborate-and often very expensive-but have also incorporated various elements-among others, propitiations and expiations-that are not indicated in the oldest sources. Already in ancient times there existed great divergences in accordance with local customs or family or caste traditions. However, the following practices are usually considered essential. The date is fixed only after careful astrological calculation; the bridegroom is conducted to the home of his future parents-in-law, who receive him as an honoured guest; there are offerings of roasted grain into the fire; the bridegroom has to take hold of the bride's hand; he conducts her around the sacrificial fire; seven steps are taken by bride and bridegroom to solemnize the irrevocability of the unity; both are, in procession, con-

customs

A young boy performs his first puja after initiation into the community of the "twice-born."

Rites of passage

ducted to their new home, which the bride enters without touching the threshold.

Of eight forms of marriage recognized by the ancient authorities, two have remained in vogue: the simple gift of a girl and the legalization of the alliance by means of a marriage gift paid to the bride's family. In the Vedic period, girls do not seem to have married before they had reached maturity. Child marriage and the condemnation of the remarriage of widows, especially among the higher classes, became customary later and have gradually, since the mid-19th century, lost their stringency.

Death rites and customs

Gāyatrī

mantra

The traditional funeral method is cremation (a family affair), burial being reserved for those who have not been sufficiently purified by samskaras (i.e., children) and those who no longer need the ritual fire to be conveyed to the hereafter, such as ascetics who have renounced all earthly concerns. An important and meritorious complement of the funeral offices is the sraddha ceremony, in which food is offered to Brahmans for the benefit of the deceased. Many people are still solicitous to perform this rite at least once a year even when they no longer engage in any of the five obligatory daily offerings.

Daily offerings. There are five obligatory offerings: (1) offerings to the gods (food taken from the meal); (2) a cursory offering (bali) made to "all beings"; (3) a libation of water mixed with sesame offered to the spirits of the deceased; (4) hospitality; and (5) recitation of the Veda. Although some traditions prescribe a definite ritual in which these five "sacrifices" are performed, in most cases the five daily offerings are merely a way of speaking about

one's religious obligations in general.

Other private rites. The morning and evening adorations (sandhvā), being a very important duty of the traditional householder, are mainly Vedic in character, but they have, by the addition of Puranic and Tantric elements, become lengthy rituals. If not shortened, the morning ceremonies consist of self-purification, bathing, prayers, and recitation of mantras, especially the Gayatri mantra (Rigveda 3.62.10), a prayer for spiritual stimulation addressed to the Sun. The accompanying ritual includes (1) the application of marks on the forehead, characterizing the adherents of a particular religious community, (2) the presentation of offerings (water, flowers) to the Sun, and (3) meditative concentration. There are Saiva and Vaishnava variants. and some elements are optional. The observance of the daily obligations, including the care of bodily purity and professional duties, leads to mundane reward and helps to preserve the state of sanctity required to enter into contact with the divine

Temple worship. Image worship in sectarian Hinduism takes place both in small shrines in each house and in the temple. Many Hindu authorities claim that regular temple worship to one of the deities of the devotional cults procures the same results for the worshiper as did the performance of one of the great Vedic sacrifices, and one who provides the patronage for the construction of a

temple is called a "sacrificer" (yajamāna).

Temples. The erection of a temple, which belongs to whoever paid for it or to the community that occupies it, is a meritorious deed recommended to anyone desirous of heavenly reward. The choice of a site, which should be serene and lovely, is determined by astrology and divination as well as by its location with respect to human dwellings; for example, a sanctuary of a benevolent deity should face the village. The construction of a temple is, because of its symbolic value, described in great detail. There is much diversity in size and artistic value, ranging from small village shrines with simple statuettes to great temple-cities whose boundary walls, pierced by monumental gates (gopura), enclose various buildings, courtyards, pools for ceremonial bathing, and sometimes even schools. hospitals, and monasteries. From the point of view of construction there is no striking difference between Saiva and Vaishnava sanctuaries, which are easily recognizable by the image or symbols in the centre, the images on the walls, the symbol fixed on the finial (crowning ornament) of the top, and Siva's bull, Nandi, or Vishnu's bird, Garuda (the theriomorphic duplicate manifestations of each god's nature), in front of the entrance. Services, which may be held by any qualified member of the community, are neither collective nor carried out at fixed times. Those present experience, as spectators, the fortifying and beneficial influence radiating from the sacred acts. Sometimes worshipers assemble to meditate to take part in chanting, or to listen to an exposition of doctrine. The puia (worship) performed in public "for the well-being of the world" is, though sometimes more elaborate, largely identical with that executed for personal interest. There are, on the other hand, many regional differences, and even significant variations within the same community

Hindu worship (puja) consists essentially of an invocation, a reception, and the entertainment of God as a royal guest. It normally consists of 16 "attendances" (upacāra): invocation by which the omnipresent God is invited to direct his attention to the particular worship; the offering of a seat, water (for washing the feet, for washing the hands, and for rinsing the mouth), a bath, a garment, a sacred thread, perfumes, flowers, incense, a lamp, food, and homage; and a circumambulation of the image and

dismissal by God.

The Pañcaratra Vaishnavas in South India introduced the songs of the Dravidian poets into their temple cult and regard these poets and their great teachers as incarnations of God, even to the point of worshiping their images. The Saivas also have songs of their own but were. generally speaking, more open to Tantric elements and to the admission in their cult of dances executed by dancing girls. In both religious groups, some communities cling to the traditional Sanskrit mantras while others also use other languages.

The first phase of worship is the reverential opening of the temple door and the adoration of the powers presiding over it: according to the Vaikhānasa Vaishnavas, the symbolic opening of heaven; and to the Saivas, an act to secure the building's protection. The divine powers whose images are carved in the doorjambs promote the process of transmutation without which man cannot even enter into the presence of God, whose image is established in the cella (garbhagrha). This image is honoured with gifts, notably flowers, fruit, and perfumes. Small portions of the consecrated food (prasāda) are given to visiting worshipers. The offering into the fire (homa) of Vedic origin has been retained in nearly all extended puja ceremonies. The main purpose of the rites is the meditative identification of the worshiper with the divine Presence; the enactment, in a gradual process of development, of the realization of the union of the worshiper's soul and God. The Vaikhānasas distinguish between the transcen-

The significance of the temple

A temple puja to Krishna

dent and unanalyzable Brahman and its immanent and analyzable aspect and invoke God to descend out of compassion from the immovable image-the permanent "seat" of the former-into a movable cult image in which he converses with the world, represented by the worshiper. Those denominations (both Śrīvaiṣṇavas and Śaivas) that adopted Tantric practices believe that God comes, during these ceremonies, also out of the worshiper's heart or that the worshiper's soul leaves his body to reach God's feet in heaven, to descend from there in a new body that is meditatively created.

A remarkable rite of yogic-Tantric origin, also used in other ritual contexts, is the transmutation of water into the elixir of life and immortality (amrta), the essential element of which is drawn from the spot between the worshiper's eyebrows, regarded as the seat of Siva's highest aspect.

Saivas transform themselves into Siva by means of complicated preparatory rites, because, they say, "Siva alone can worship Siva." Some authorities also enjoin a mental worship and sacrifice, without which "exterior" rites are rendered senseless. The merit of the performances is often said to be entrusted to God's keeping for the sake of the worshiper. Many Vaishnavas emphasize that puja is meant

to propitiate God disinterestedly.

Saiva rites. Ascetic tendencies were much in evidence among the Pāśupatas, the oldest Śaiva tradition in North India, the last adherents of which now live in Nepal, Pasupatas often gave offense because of their customs and ritual practices. Their yoga, consisting of a constant meditative contact with God in solitude, required that they frequent burning places for cremated bodies. More extreme groups carried human skulls (hence the name Kāpālikas, from kapāla, "skull") which they used as bowls for liquor into which they projected and worshiped Siva as Kāpālika, "the Skull Bearer," or Bhairava, "the Frightful One," and then drank to become intoxicated. Their belief was that an ostentatious indifference to anything worldly was the best method of severing the ties of samsara.

The view and way of life peculiar to the Vīrašaivas, or Lingayats (lingam-bearers), in southwestern India is mainly characterized by a deviation from some common Hindu traditions and institutions such as sacrificial rites, temple worship, pilgrimages, child marriages, and inequality of the sexes. Initiation (dīksā) is, on the other hand, an obligation laid on every member of the community. The spiritual power of the guru is bestowed upon the newborn and converts, who receive the eightfold shield, which protects devotees from ignorance of the supremacy of God and guides them to final beatitude, and the lingam (phallic symbol). The miniature lingam, the centre and basis of all their religious practices and observances, which they always bear on their body, is God himself concretely represented. Worship is due it twice or three times a day. When a Lingāyat "is absorbed into the lingam" (i.e., dies), his body is not cremated, as is customary in Hinduism, but is interred, like ascetics of other groups. Those Lingayats who have reached a certain level of holiness are supposed to die in the state of emancipation.

Saivism, though inclined in doctrinal matters to adoptive inclusivism, inculcates some fundamental lines of conduct: one should worship one's spiritual preceptor (guru) as God himself, follow his path, consider him to be present in oneself, and dissociate oneself from all opinions and practices that are incompatible with the Saiva creed. Yet some of Siva's devotees also worship other gods, and the "Sivaization" of various ancient traditions is sometimes rather superficial. Like many other Indian religions, the Saiva-siddhanta has developed an elaborate system of ethical philosophy, primarily with a view to preparing the way for those who aspire to liberation. Because dharma leads to happiness, there is no distinction between sacred and secular duties. All deeds are performed as services to God and with the conviction that all life is sacred and God-centred. A devout way of living and a nonemotional mysticism are thus much recommended. Kashmir Śaivism developed the practice of a simple method of salvation: by the recognition (pratyabhijñā)-direct, spontaneous, technique-free, but full of bhakti-of one's identity with God.

Vaishnava rites. The day of the faithful Śrīvaiṣṇava

Śiva and his family at the burning ground. Pārvatī, Śiva's wife, holds Skanda while watching Ganeśa (left) and Siva string together the skulls of the dead. The bull, Nandi, rests behind the tree. Kangra painting, 18th century; in the Victoria and Albert Museum, London.

Brahman is usually devoted to five pursuits: purificatory rites, collecting the requisites for worship, acts of worship, study and contemplation of the meaning of the sacred books, and meditative concentration on the Lord's image. Lifelong obligations include the performance of sacrifices and other rites, restraint of the senses, fasting and soberness, worship, recitation of the scriptures, and visits to sacred places. In addition, to those who aspire to liberation, Rāmānuja recommends concentration on God, a virtuous way of living, and insensibility to luck and misfortune. According to Madhya (c. 1199-c. 1278), a faithful observance of all regulations of daily conduct-including bathing, breath control, etc .- will contribute to eventual success in the quest for liberation. Devout Vaishnavas are inclined to emphasize God's omnipotence and the far-reaching effects of his grace. They attach much value to the repeated murmuring of his name or sacred formulas (japa) and to the praise and commemoration of his deeds as a means of selfrealization and of unification with his essence. Special stress is laid on ahimsa as a virtue.

SACRED TIMES AND PLACES

Festivals. Hindu festivals are combinations of religious ceremonies, semi-ritual spectacles, worship, prayer, lustrations, processions (to set something sacred in motion and to extend its power throughout a certain region), music, dances (which by their rhythm have a compelling force), magical acts-participants throw fertilizing water or, during the Holī festival, coloured powder at each other-eating, drinking, licentiousness, feeding the poor, and other activities of a religious or traditional character. The original functions of these activities are clear from ancient literature and anthropological research: they are intended to purify, avert malicious influences, renew society, bridge over critical moments, and stimulate or resuscitate the vital powers of nature (hence the term utsava, meaning both the generation of power and a festival). Because such festivals relate to the cyclical life of nature, they are supposed to prevent it from stagnating. These cyclic festivals-which may last for many days-continue to be celebrated throughout India.

Vīrašaivas (Lingavats)

Varieties of Śaivism

Such festivals refresh the mood of the participants, further the consciousness of their own power, and help to compensate for their sensations of fear and inferiority concerning the unknown forces of nature. Such mixtures of worship and pleasure require the participation of the entire community and create harmony among its members, even if not all participants are now aware of the original character of the festival. There are also innumerable festivities in honour of specific gods, celebrated by individual temples, villages, and religious communities.

An important festival, formerly celebrating Kāma, the

god of sexual desire, survives in the Holi, a saturnalia connected with the spring equinox and in western India with the wheat harvest. The lower classes observe it in its hoisterous and licentious form. There are local variants: among the Marathas, heroes who died on the battlefield are "danced" by their descendants, sword in hand, until they believe themselves possessed by the spirits of the heroes. In Bengal, swings are made for Krishna; in other regions a bonfire is also essential. The mythical tradition that accounts for the festival describes how young Prahlāda, in spite of his demonic father's opposition, persisted in worshiping Vishnu and was carried into the fire by the female demon Holika, the embodiment of evil, who herself was believed to be immune to the ravages of fire. Through Vishnu's intervention, Prahlada emerged unharmed, while Holika was burned to ashes. The bonfires are intended to commemorate this event or rather to reiterate the triumph of virtue and religion over evil and sacrilege. This explains why objects representing the sickness and impurities of the past year-the new year begins immediately after Holi-are thrown into the bonfire, and it is considered inauspicious not to look at it. Moreover, people pay or forgive debts, reconcile quarrels, and try to rid themselves of the evils, conflicts, and impurities that have accumulated during the preceding months, translating the central conception of the festival into a justification for dealing anew with continuing situations in their lives. The New Year festival, according to another Indian calendar, Dīwālī, though celebrated by all classes of society, is traditionally believed to have been given by Vishnu to the Vaisyas (traders, etc.); it takes place in October, with worship and ceremonial lights in honour of Lakşmî, the goddess of wealth and good fortune; fireworks to chase away the spirits of the deceased; and gambling, an old ritual custom intended to secure luck for the coming year. The nine-day Durgā festival, or Navarātrī, is, especially in Bengal, splendid homage to Sakti, and in South India, a celebration of Rāma's victory over Rāvaņa.

Pilgrimages and fairs. Like processions, pilgrimages (tīrthavātrā) to holy rivers (tīrtha) and other places were already known in Vedic and epic times and are even now one of the most remarkable aspects of Indian religious life. Many sections of the Purāṇas eulogize temples and the sacredness of places situated in beautiful scenery or wild solitude (especially the Himalayas). The whole of India, and especially Kurukshetra (presumed to be the scene of the great war portrayed in the Mahābhārata) in the northwest, is considered holy ground that offers everyone the opportunity to reach emancipation. The number of places of pilgrimage of regional significance amounts to many hundreds, but some of them (Ayodhyā, Mathura, Hardwar, Varanasi [Benares], Kanchipuran, Ujjain, and Dwarka) have for many centuries possessed exceptional holiness. The reason for such sanctity derives from their location on the bank of a holy river, especially of the Ganges, from their connection with legendary figures of antiquity who are said to have lived there, or from the local legend of a manifestation of a god, Many places are sacred to a specific god; the district of Mathura, for example, encompasses many places of pilgrimage connected with the Krishna legends. Visits to holy places may bestow special benefits upon pilgrims; temples or ponds dedicated to Sürya (the Sun) are visited in order to recover from leprosy, other places to escape from astrological threats. Pilgrimages to Gayā (Bihār state)-where visitors are escorted around the sacred centres by Brahman temple priests who maintain certain ritual connections with their clients-are undertaken for the sake of the welfare of deceased ancestors. In most cases, however, the devotee hopes for worldly rewards (health, wealth, children) or for spiritual rewards such as deliverance from sin or pollution, preservation of religious merit, rebirth in a heaven, or even emancipation. The last prospect is held out to those who, when death is near, travel to Väränasi to die near the Gannes.

On special occasions, be they auspicious or, like a solar eclipse, inauspicious, the devout crowds increase enormously. Most important shrines also organize gatherings (melas), that are partly fairs, partly religious demonstrations. These journeys, which are undertaken by individuals or groups in order to discharge a vow or to please a god, confirm the devotees in their faith, provide them with an opportunity for spiritual retreat, or bring their inner life nearer to a state of perfection. They have contributed much to the spread of religious ideas and the cultural unification of India.

RITUAL AND SOCIAL STATUS

Some observers have claimed that Hinduism is as much a way of social life as it is a religion. The caste system, which has organized Indian society for many millennia. is thoroughly legitimated by and intertwined with Hindu religious doctrine and practice. Four social classes, or varnas-Brahmans, Ksatriyas, Vaisyas, and Sūdras-provide the simplified structure for the enormously complicated system of thousands of castes and subcastes within Indian society. Although it is not certain whether a society limited to four classes was ever more than a theoretical ideal, there is a sense in which they map out socioreligious reality. Such is evident from the Purusa hymn (Rigyeda 10.90), in which the statement that the Brahman was the Purusa's mouth, the nobleman (Ksatriya) his arms, the Vaisva his thighs, and the Sudra his feet, gives an idea of their functions and mutual relations.

The Brahmans, whatever their worldly avocations, claim to be by virtue of their birth a perpetual incarnation of the dharma, guardians and dispensers of divine power, entitled to teach the Veda, sacrificing for others and accepting gifts and subsistence; the term alms is misleading, and the daksinā offered at the end of a rite to a Brahman officiant is not a fee but an oblation through which the rite is made complete. Brahmans are held to be the highest of all human beings because of their preeminence, the superiority of their origin, their sanctification through the samskaras (rites of passage), and their observance of restrictive rules. The main duty of the nobility (the Ksatriyas) is to protect the people, that of the commoners (the Vaisvas) to tend cattle, to trade, and to cultivate land. Even if a king (theoretically of Kşatriya descent) was not of noble descent, such an upholder of dharma was clothed with divine

Pilgrims bathing in the Ganges River at Hardwar, India.

New Year festivals less demanding. While this tripartition seems, in the main, to have been inherited from Indo-European times, the fourth class (the Śūdras), whose sole duty it was "to serve meekly" (Mānava Dharmaśāstra 1.91) the other classes, are partly descended from the subjugated non-Aryans, a fact that accounts for their many disabilities and exclusion from religious status. According to Hindu tradition, the Veda should not be studied in their presence, but they may listen to the recitation of epics and Purāṇas. They are permitted to perform the five main acts of worship (without Vedic mantras) and undertake observances, but even today they maintain various ceremonies of their own, carried out without Brahmanic assistance. Yet a distinction is often made among Śūdras. Some are purer and have a more correct behaviour and way of living than others, the former tending to assimilate with higher castes, the latter to rank with the lowest in the social scale, who, often called candalas, were at an early date sweepers, bearers of corpses, or charged with other impure occupations. Ritual purity was indeed an important criterion; impure conduct and neglect of Veda study and the rules regarding forbidden food might suffice to stigmatize a "twice-born man" as a Sudra. On the other hand, in later times the trend of many communities has been toward integrating all Südras into the Brahmanic system. The Brahmans, who have far into modern times remained, on the whole, a respected, traditional, and sometimes intellectual upper class, were generally (until the 1930s) much in demand because of their knowledge of rites and traditions. Although Kşatriya rank is claimed by many whose title is one of function or creation rather than of inheritance, this class is now rare in many regions. Moreover, for a considerable time none of the four varnas represented anything other than a series of hierarchically arranged groups of castes.

Castes. The origin of the caste system is not known with certainty. Hindus account for the proliferation of the castes (jātis, literally "births") by the subdividing of the four classes, or varnas, due to intermarriage (which is prohibited in Hindu works on dharma). Modern theorists, however, tend to assume that castes arose from differences in family ritual practices, racial distinctions, and occupational differentiation and specialization. Many modern scholars also doubt whether the simple varna system was ever more than a theoretical socioreligious ideal and have emphasized that the highly complex division of Hindu society into nearly 3,000 castes and subcastes was probably in place even in ancient times.

In general, a caste is an endogamous hereditary group of families, bearing a common name; often claiming a common descent; as a rule professing to follow the same hereditary calling; clinging to the same customs, especially regarding purity, meals, and marriages; and often further divided into smaller endogamous circles. Moreover, tribes, guilds, or religious communities characterized by particular customs-for example, the Lingayats-could easily be regarded as castes. The status of castes varies in different localities. Although social mobility is possible, the mutual relationship of castes is hierarchically determined: local Brahman groups occupy the highest place, and differences in ritual purity are the main criteria of position in the hierarchy. Most impure are the untouchables, or, to use modern names, the exterior or scheduled castes, which, however, have among themselves numerous divisions, each of which regards itself as superior to others.

Traditional Hindus are inclined to emphasize that the ritual impurity and "untouchability" inherent in these groups does not essentially differ from that temporarily proper to mourners or menstruating women. This, and the fact that some exterior group or other might rise in estimation and become an interior one, or that individual outcastes might be well-to-do, does not alter the fact that the spirit of exclusiveness was in the course of time carried to extremes. The scheduled castes were subjected to various socioreligious disabilities before mitigating tendencies helped bring about reform; after independence, social discrimination was prohibited, and the practice of untouchability was made a punishable offense (it was not abolished, however). Scheduled castes were harred from the use of temples and other religious institutions and from public schools. These groups also had many disabilities in relations with private persons. From the traditional Hindu point of view, this social system is the necessary complement of the principles of dharma, karma, and samsara. Corresponding to hells and heavenly regions in the hereafter, the castes are the mundane, social frame within which karma is manifested. A low social status is the inevitable result of sins in a former life but can, by virtue and merit, be followed by a better position in the next existence.

Religious orders and holy men. Those members of the various denominations who abandon all worldly attachment enter an "inner circle" or "order" that, seeking a life of devotion, adopts or develops particular yows and observances, a common cult, and some form of initiation. Initiation. Generally speaking, Hindus are free to join an order or inner circle, and once they have joined it they must submit to its rites and way of living. The initiation (dīkṣā), a sort of purification or consecration involving a transformation of the aspirant's personality, is regarded as a complement to, or even a substitute for, the previous initiation ceremony (the upanayana that all twice-born Hindus undergo at adolescence), which it strikingly resembles. Such religious groups integrate ancient, widespread ideas and customs of initiation into the framework of either the Vaishnava or Saiva patterns of Hinduism. Vaishnavism emphasizes their character as an introduction to a life of devotion and as an entrance into closer contact with God, although happiness, knowledge, a long life, and a prospect of freedom from karma are also among the ideals to which they aspire. Saivas are convinced of the absolute necessity of initiation for anyone desiring final liberation and require an initiation in accordance with their rituals. All communities agree that the authority to initiate belongs only to a qualified spiritual guide (guru). usually a Brahman, who has previously received the special guru-dīkṣā (initiation as a teacher) and is often regarded as representing God himself. The postulant is sometimes committed to a probationary period, to training in yoga mysticism, or to instruction in the esoteric meaning of the scriptures. The initiate receives a devotional name and is given the distinctive mantras of the community, which, because they are sacred, must never be misused

There are many complicated forms of initiation: the Vaishnavas differentiate between the members of the four classes; the Saivas and Tantrists take into account the natural aptitude and competency of the recipients and distinguish between first-grade initiates, who obtain access to God, and higher-grade initiates, who remain in a state of holiness.

Yoga. The initiate guided by his guru may apply himself to yoga (a "methodic exertion" of body and mind) in order to attain, through mortification, concentration, and meditation, a higher state of consciousness in which he may find the supreme knowledge, achieve spiritual autonomy, and realize his oneness with the Highest (or however the ultimate goal is conceived). Yoga may be atheistic or combined with various philosophical or religious currents. Every denomination attempted to implement vogic practices on a theoretical basis derived from its own teachings. There are many different forms of yoga, and the practices vary according to the stage of advancement of the adepts. All serious yogis, however, agree in disapproving the use of yogic methods for worldly purposes.

Sectarian symbols. The typical Hindu ascetic (sadhu) usually wears a distinctive mark (pundra) on his forehead and often carries some symbol of his religion.

If he is a Vaishnava he might possess a discus (chakra) Symbols and a conch shell (sankha), replicas of Vishnu's flam- of Vishnu ing weapon and his instrument of beneficent power and and Siva

Mental and

external

fashioning of images

omnipresent protection, or a śālagrāma stone or a tulasi plant, which represent, respectively, Vishnu's essence and that of his spouse Laksmi. If he is a Saiva, he might impersonate Siva and carry a trident (triśūla), denoting empire and the irresistible force of transcendental reality; wear a small lingam; carry a human skull, showing that he is beyond the terror inspired by the transitoriness of the world; or smear his body with apotropaic (supposed to avert evil) and consecratory ashes. These emblems are sacred objects of worship because the divine presence, when invoked by mantras, is felt to be in them.

The attitude toward asceticism has always been ambivalent. On the one hand, there is a genuine regard for hermits and wandering ascetics and a desire to gain spiritual merit by feeding religious mendicants. On the other hand, the fact that fringe members of society may find a sort of respectable status among Saiva ascetics often led to a decline in the moral reputation of the latter. (B.K.S./Ed.)

Cultural expressions: visual arts, theatre, and dance

The structure of Indian temples, the outward form of images, and indeed the very character of Indian art are largely determined by religion and a traditional view of the world, which penetrated the other provinces of culture and welded them into a homogeneous whole.

Indian art is highly symbolic. The much-developed ritualreligious symbolism presupposes the existence of a spiritual reality that, being in constant touch with phenomenal reality, may make its presence and influence felt and can also be approached through the symbols that belong to both spheres.

The production of objects of symbolic value is therefore more than a technique. The artisan must model a cult image after the ideal prototype that appears in his mind (in certain canonical forms) only when he has brought himself to a state of supranormal consciousness. After undergoing a process of spiritual transformation himself, he also transforms the material of which the image is to be made into a receptacle of divine power. Like the artisan, the worshiper (sādhaka, "the one who wishes to attain the goal") must grasp the esoteric meaning of a statue, picture, or pot and identify his or her self with the power residing in it. The usual offering, a handful of flowers, is the ve-

hicle used to convey the worshiper's "life-breath" into the

external image, which has already been transformed into

an adequate internal vision of the same divine power.

TYPES OF SYMBOLS

If they know how to handle the symbols, the worshiperswho must achieve their object themselves and cannot come into contact with God unless they insistently invoke him-have at their disposition an instrument for utilizing the possibilities lying in the depths of their own subconscious as well as a key to the mysteries of the forces dominating the world.

Yantra and mandala. The general term for an "instrument [for controlling]" is yantra, which, while denoting in a wider sense cult images, pictures, and other such aids to worship, is often especially applied to ritual diagrams. Any yantra represents some aspect of the divine and enables devotees to worship it immediately within their hearts while identifying themselves with it. Except in its greater linear complication, a mandala does not differ from a yantra and both are drawn during a highly complex ritual in a purified and ritually consecrated place. The meaning and the use of both are similar, and they may be permanent or provisional. A mandala, delineating a consecrated place and protecting it against disintegrating forces represented in demoniac cycles, is the geometric projection of the universe, spatially and temporally reduced to its essential plan. It represents in a schematic form the whole drama of disintegration and reintegration, and the adept can use it to identify with the forces governing these. As in temple ritual, a vase is employed to receive the divine power so that it can be projected into the drawing and then into the person of the adept. Thus the mandala becomes a support for meditation, an instrument to provoke visions of the unseen. A good example of a mandala is Śrīcakra the śricakra, "the Wheel of Śri" (i.e., of God's shakti) composed of four isosceles triangles with the apices upward, symbolizing Siva, and five isosceles triangles with the apices downward, symbolizing Sakti; the nine triangles are of various sizes and intersect with one another. In the middle is the power point (bindu), visualizing the highest, the invisible, elusive centre from which the entire figure and the cosmos expand. The triangles are enclosed by two rows of (eight and 16) petals, representing the lotus of creation and reproductive vital force. The broken lines of the outer frame denote the figure to be a sanctuary with four openings to the regions of the universe. A "spiritual" foundation is provided by a vantra, called the mandala of the Purușa (spirit) of the site, that is also drawn on the site on which a temple is built. This rite is a reenactment of a variant of the myth of Purusa, an immortal primeval being who obstructed both worlds until he was subdued by the gods; the parts of his body became the spirits of the site.

Lingam and yoni. One of the most common objects of worship, whether in temples or in the household cult, is the lingam (phallus). Often much stylized and an austere rather than literally sexual symbol, erect and representing the cosmic pillar, it emanates its all-producing energy to the four quarters of the universe. As the symbol of male creative energy it is frequently combined with its female counterpart (voni), the latter forming the base from which the lingam rises. Although the lingam originally may have had no relation to Siva, it has from ancient times been regarded as symbolizing Siva's creative energy and is widely

worshiped as his fundamental form.

Visual theology in icons. The beauty of cult objects contributes to their force as sacred instruments: their ornamentation facilitates the process of inviting the divine power into them. Statues of gods are not intended to imitate ideal human forms but to express the supernatural. A divine figure is a "likeness" (pratimā), a temporary benevolent or terrifying expression of some aspect of a god's nature. Iconographic handbooks attach great importance to the ideology behind images and reveal, for example, that Vishnu's eight arms stand for the four cardinal and intermediate points of the compass and that his four faces, illustrating the concept of God's fourfoldness, typify his strength, knowledge, lordship, and potency. The emblems express the qualities of their bearers-e.g., a deadly weapon symbolizes destructive force, many-headedness omniscience. Much use is made of gestures (mudras), conventional devices for denoting activities that express an idea; thus, the raised right hand, in the "fear-not" gesture (abhaya-mudrā), bestows protection. Every iconographic detail has its own symbolic value, helping devotees to direct their energy to a deeper understanding of the various aspects of the divine and to proceed from external to internal worship. For many Indians, an installed and consecrated image becomes a container of concentrated divine energy; according to Hindu theists, it is an instrument for ennobling the worshiper who realizes God's presence in it.

Purposes of Hindu iconography

THE ARTS

Religious principles in sculpture and painting. The dance executed by Siva as king of dancers (Natarāja), the visible symbol of the rhythm of the universe, represents God's five activities: he unfolds the universe out of the drum held in one of his right hands; he preserves it by uplifting his other right hand in abhaya-mudra; he reabsorbs it with his upper left hand, which bears a tongue of flame; his transcendental essence is hidden behind the garb of apparitions, and grace is bestowed and release made visible by the foot that is held aloft and to which the hands are made to point; and the other foot, planted on the ground, gives an abode to the tired souls struggling in samsara. Another dance pose adopted by Siva is the doomsday tandava, executed in his destructive Bhairava manifestation, usually with 10 arms and accompanied by Devī and demons. The related myth is that Siva conquered a mighty elephant demon whom he forced to dance until he fell dead; then, wrapped in the blood-dripping skin of his victim, the god executed a horrendous dance of victory.

Images sustain the presence of the god: when Devi is

shown advancing against the buffalo demon, seated on her lion, she represents the affirmative forces of the universe and the triumph of divine power over wickedness. Male and female figures in uninterrupted embrace, as in Saiva iconography, signify the union of opposites and the eternal process of generation. Lovers sculpted on temples are auspicious symbols on a par with foliage, water jars, and other representatives of fertility.

Like literature and the performing arts, the visual arts also contributed to the perpetuation of myths. Hindu sculpture tends to be less narrative than Buddhist, which delights in scenes from the Buddha's lives. In Hindu sculpture the tendency is toward hieratic poses of a god in a particular conventional stance (mūrti), which, once fixed, perpetuates itself. An icon is a frozen incident of a myth. For example, one mūrti (image) of Šiva is the "destruction of the elephant," in which Siva appears dancing before and below a bloody elephant skin that he holds up before the image of his horrified consort; the stance is the summary of his triumph over the elephant demon. A god may also appear in a characteristic pose while holding in his multitudinous hands his various emblems, on each of which hangs a story. Carvings, such as those that appear on temple chariots, tend to be more narrative; even more so are the miniature paintings of the Middle Ages. A favourite theme in the latter is the myth of the cowherd god Krishna and his love of the cowherd wives (gopīs).

Religious organization of sacred architecture. Temples must be erected on a site that is subha (i.e., suitable, beautiful, auspicious, and near water) because the gods will not come to other places. However, temples are not necessarily designed to be congenial to their surroundings, because a manifestation of the sacred is an irruption, a break in phenomenal continuity. Temples are said to constitute an opening in the upward direction to ensure communication with the gods; they are visible representations of a cosmic pillar and their site is said to be a navel of the world. Their outward appearance must raise the expectation of meeting with God. Their erection is a reconstruction and reintegration of Purusa-Prajāpati, enabling him to continue his creative activity, and the finished monuments are symbols of the universe that is the unfolded One. The owner of the temple (i.e., the individual or community that paid for its construction)-also called the sacrificerparticipates in the process of reintegration and experiences his spiritual rebirth in the small cella, aptly called the "womb room" (garbhagrha), by means of meditative contact with God's presence, symbolized or actualized in his consecrated image. The cella is in the centre of the temple above the navel-i.e., the foundation stone; it may contain a jar filled with the creative power (shakti) that is identified with the goddess Earth (who bears and protects the monument), three lotus flowers, and three tortoises (of stone, silver, and gold) that represent Earth, atmosphere, and heaven. The tortoise is a manifestation of Vishnu bearing the cosmic pillar; the lotus is the symbol of the expansion of generative possibilities. The vertical axis or tube (coinciding with the cosmic pillar), which connects all parts of the building and is continued in the finial on the top, corresponds with the mystical vertical vein in the body of the worshiper through which his soul rises to unite itself with the Highest.

The designing of Hindu temples, like that of religious images, was codified in the Silpa-sastras (craft textbooks), and every aspect of the design was believed to be symbolic of some feature of the cosmos. The idea of microcosmic symbolism is strong in Hinduism and comes from Vedic times: the Brahmana texts are replete with similar cosmic interpretations of the many features of the sacrifice. This same Vedic idea of the correspondence (bandhu) between microcosm and macrocosm was applied to the medieval temple, which was laid out geometrically to mirror the structure of the universe, with its four geometric quarters and a celestial roof. The temple also represents the mountain at the navel of the world and often somewhat resembles a mountain. On the periphery were carved the most worldly and diverse scenes, including luxurious celebrations of human life: battle scenes, hunts, circuses, animals, birds, as well as images of the gods.

The erotic scenes carved at Khajuraho in Madhya Pradesh and Konārak in Orissa express a general exuberance that may be an offering of thanksgiving to the gods who created all. However, that same swarming luxuriance of life in all of its aspects may also reflect the concern that one must set aside worldly temptations upon the threshhold of the sacred space of the temple, for the carvings only decorate the outside of the temple; at the centre, the sanctum sanctorum, there is little if any ornamentation, except for a stark symbol of the god or goddess. Thus, these carvings simultaneously express a celebration of samsara and a movement toward moksha.

Theatre and dance. Theatrical performances are also events that can be used to secure blessings and happiness; the element of recreation is indissolubly blended with edification and spiritual elevation. The structure and character of the classical Indian drama reveal its origin and function: it developed from the last part of a magicoreligious ceremony, which survives as a ritual introduction, and begins and closes with benedictions. Drama is produced for festive occasions with a view to spiritual and religious success (siddhi), which must also be prompted by appropriate behaviour from the spectators; there must be a happy ending; the themes are borrowed from epic and legendary history; the development and unraveling of the plot are retarded; and the envy of malign influences is averted by the almost obligatory buffoon (vidūsaka, "the spoiler"). There are also, in addition to films, which often use the same religious and mythic themes, yātrās, a combination of stage play and various festivities that have contributed much to the spread of the Puranic view of life.

Yatras.

Krishna dancing with the gop's, painting from western Rājasthān, c. 1610. In the N.C. Mehta Collection of the Gujarāt Museum Society, Ahmadābād, India.

Dancing is not only an aesthetic pursuit but also a divine service. Hence there are halls for sacred dances annexed to some temples. The rhythmic movement has a compelling force, generating and concentrating power or releasing superfluous energy. It induces the experience of the divine and transforms the dancer into whatever he or she impersonates. Thus, many tribal dances consist of symbolic enactments of events (harvest, battles) in the hope that they will be accomplished successfully. Musicians and dancing girls accompany processions to expel the demons of cholera or cattle plague. Even today, religious themes and the various relations between humans and God are danced and made visual by the codified symbolic meanings of gestures and movements (see SOUTH ASIAN ARTS). (A.L.B./J.A.B.v.B./W.Do./Ed.)

The place of Hinduism in world religions

HINDUISM AND OTHER RELIGIONS OF INDIAN ORIGIN Hinduism, Buddhism, and Jainism originated out of the same milieu: the circles of world-renouncers of the 6th century BC. Although all share certain non-Vedic practices (such as renunciation itself and various yogic meditational techniques) and doctrines (such as the belief in rebirth and the goal of liberation from perpetual transmigration), they differ in the respect they accord to the Vedic tradition.

Requirements of temple architecture and planning

Temple design as cosmic symbolism

Vishnu with his 10 avatars (incarnations): Fish, Tortoise, Boar, Man-Lion, Dwarf, Râma-with-the-Ax, King Râma, Krishna, Buddha, and Kalkin. Painting from Jaipur, India, 19th century; in the Victoria and Albert Museum, London.

Virtually all Hindus affirm the sacredness and authority of the Veda; Buddhists and Jains do not and therefore are regarded as less than orthodox by Hindus.

Buddhism. Although Buddhism did not interfere with Hindu customs and usages, allowing its adherents to approach Hindu or local supernatural powers for immediate favours, Hindu criticism of Buddhism came mainly from Brahman philosophers who opposed its adherents because they rejected the authority of the Veda and the Brahmans and the doctrine of the atman (soul) and because they admitted persons of any age and caste to monastic life. The spread of Buddhism was often regarded as an indication of degeneration. In the course of time, the Buddha was recognized as an incarnation of Vishnu, but this was often qualified by the addition that Vishnu assumed this form to mislead and destroy the enemies of the Veda, and this avatar is rarely worshiped. Buddhist emblems also were often ascribed to Vishnu or Šiva. Some Buddhist shrines have remained partly under the supervision of Hindu ascetics and are visited by pilgrims notwithstanding their much neglected condition.

After the rise of Buddhological studies in the West and the archaeological discoveries and restorations beginning at the end of the 19th century had made Indians more aware of the Indian origin of Buddhism, the Republic of India adopted the Buddhist emperor Asoka's lion capital, marking the place of Buddha's first teaching, as its national emblem. The Buddha jublies in 1956 was an occasion for enthusiastic celebrations. The number of Indian Buddhists has again increased, due mainly to the conversion of persons of low social rank who hope for higher social status as Buddhists than they were afforded as Ifindus.

Jainism. With Jainism, which always remained an Indian religion, Hinduism has so much in common, especially in social institutions and ritual life, that nowadays Hindus tend to consider it a Hindu sect. Many Jains also are inclined to fraternization. The points of difference—e.g., a stricter ahimsa practice and the absence of sacrifices for the deceased in Jainism—do not give offense to orthodox Hindus (see BUDDHISM, THE BUDDHA AND; JANISM).

HINDUISM AND ISLĀM

Because Islām was so different from Hinduism in creed and institutions, it was neither absorbed nor powerful enough to make India a Muslim country. The religious situation created by the presence of its numerous adherents always had explosive potentialities: Muslims do not respect bovine life and regard Hindu cult practices as objectionable idolatry. Although Indian Muslims, with few exceptions, are of native descent, they are theoretically outcastes with whom dealings must remain restricted by formal rules; however, as with Christians, they are less polluting than the Hindu lower castes. The Islamic way of life meets with opposition, and orthodox Muslims and Hindus do not ordinarily intermarry or dine together. This situation has had acute and even devastating consequences, but it does vary somewhat from region to region, from village to village, and from class to class. Very often mutual differences are accepted. Although they repudiate caste. Muslims often observe it in practice, and some have even retained their original caste organization after their conversion to Islām.

Throughout centuries of close proximity and daily interaction, Hindus and Muslims have made efforts to accommodate the existence of the other religion within their own. One manifestation of such syncretism occurred among mystically inclined groups who believed that the one God, or "the universal principle," was the same regardless of whether it was called Allah or brahman. Various syntheses between the two religions, including Sikhism and other movements that emphasize nonsectarianism, have arisen in North India.

Those who, like Gandhi, could not understand the intolerance of orthodox Islam sympathized with the moderation and eclecticism of such groups. Most of the educated class, however, have always remained aware of the cleavage. To the Muslims-who, as part of an ecumenical community stretching over large parts of Asia and Africa, are concerned about the political and religious crisis of Islam since the late 19th century-the collapse of the Mughals after the Indian Mutiny (1857-58) was a severe blow that worsened relations with Hindus. This is particularly true because anti-Muslim tendencies had won ground since the renascent Hinduism of the Maratha movement and in later times in the Arya Samaj (see above), while Muslims became self-assertive and even more determined to maintain their distinctive position. After the partition of the subcontinent into India and Pakistan-partly based on religious differences-and independence (1947), the political controversies between India and Pakistan constituted a further complication for relations between the religions.

HINDUISM AND CHRISTIANITY

The relations between Hinduism and Christianity have been shaped by unequal balances of political power and cultural influence. Although small communities of Christians have lived in South India since the middle of the Ist millennium, Christianity was widely introduced into the Indic subcontinent only in modern times by missionaries working under the auspices of British colonialism and imperialism. Their denigration of Hindu beliefs and practices—such as image worship and widow burning—provoked a Hindu response. Beginning in the 19th century and continuing to the present, a movement that might be called neo-Vedanta has emphasized the monism of certain Upanishads, decried "popular" Hindu "degenerations" such as the worship of idols, and acted as an agent of social reform, modernization, and dialogue between other world religions.

The relations between Hindus and Christians, then, have been complicated. Many Hindus are ready to accept the ethical teachings of the Gospels, particularly the Sermon on the Mount (whose influence on Gandhi is well-known) but reject the theological superstructure. Many adherents of bhakti movements—the Christian influence on which has been grossly exaggerated—feel that the Christian conceptions, which are regarded as a kind of bhakti, do not realize in God the multiplicity of human relations of love and service. Educated Hindus, though assimilating some Christian ideas, often regard missionary propaganda as an attack on their national genius and time-honoured institutions and take offense at what they regard as the disrespectful utterances of Christian missionary literature.

Syncretism of Hindu and Islāmic religion The Arya Samai movement

They are averse to the organization, the reliance on authorities, and the exclusiveness of Islām and Christianity, considering these as obstacles to harmonious cooperation. They subscribe to Gandhi's opinion that missionaries should confine their activities to humanitarian service. Since independence, conversion has indeed been viewed with disfavour by many influential Indians, who often also find in Hinduism what might be attractive in Christianity. Movements that advocate a Hindu theism designed to rival Islām and Christianity, like the Arva Samaj, make serious efforts to reconvert Christians to the Hindu community. People tolerate the proximity of Christian converts, even if they transgress Hindu taboos, provided they form a more or less separate community. Thus Christians often form castes or endogamous bodies analogous to castes. They sometimes are even admitted to temples to which untouchable Hindus have no entrance. In Malabar, due to their high economic position, Christians came to be practically equal with Brahmans. Nationalism has challenged the more serious-minded Indian Christians to express the genius of their faith in Indian modes and patterns. This has led, since 1921, to the emergence of Christian ashrams in the south. The dialogue between Hinduism and Christianity is more or less institutionalized at Bangalore in Karnātaka state, where the Christian Institute for the Study of Religion and Society is located. Its bulletin offers an opportunity for discussion between, for example, Christians and supporters of the Ramakrishna Mission.

BIBLIOGRAPHY. Among the many overviews of Hinduism are THOMAS J. HOPKINS, The Hindu Religious Tradition (1971): DAVID R. KINSLEY, Hinduism: A Cultural Perspective (1982); R.C. ZAEHNER, Hinduism, (1962, reissued 1977); and LOUIS RENOU, Religions of Ancient India (1953, reissued 1972). An excellent survey of all aspects of pre-Muslim ancient India is A.L. BASHAM, The Wonder That Was India, 3rd rev. ed. (1967, reprinted 1985). More detailed and technical accounts may be found in JAN GONDA, Die Religionen Indiens, 2 vol. (1960-63); and in R.C. MAJUMDAR (ed.), The History and Culture of the Indian People, 11 vol. (1951-69). A basic resource for the study of Hinduism is the series "The History of Indian Literature, including the volumes by JAN GONDA, Vedic Literature (Samhitās and Brāhmaṇas) (1975), and Medieval Religious Literature in Sanskrit (1977); and by TEUN GOUDRIAAN and SANJUKTA GUPTA, Hindu Tantric and Śākta Literature (1981). A detailed outline is also provided by J.N. FARQUHAR, An Outline of the Religious Literature of India (1920, reprinted 1967). For historical overviews, consult VINCENT A. SMITH. The Oxford History of India, 4th ed. (1981); ROMILA THAPAR and PERCIVAL SPEAR A History of India, 2 vol. (1965-66); and D.D. KOSAMBI, The Culture and Civilisation of Ancient India in Historical Outline (1965, reissued 1970; U.S. title, Ancient India: A History of Its Culture and Civilization, 1966, reissued 1969).

For the original sources of the principal texts of Hinduism in English translation, convenient collections include AINSLIE T. EMBREE (ed.), The Hindu Tradition (1966, reissued 1972); WENDY DONIGER O'FLAHERTY (ed. and trans.), Textual Sources for the Study of Hinduism (1988); AINSLIE T. EMBREE and STEPHEN N. HAY (eds.), Sources of Indian Tradition, 2nd ed., 2 vol. (1988); and R.C. ZAEHNER (ed. and trans.), Hindu Scriptures (1966), Compendiums of Hindu mythology in translation include WENDY DONIGER O'FLAHERTY (ed. and trans), Hindu Myths: A Sourcebook (1975); and CORNELIA DIMMITT and J.A.B. VAN BUITENEN (eds. and trans.), Classical Hindu Mythology: A Reader in the Sanskrit Purāņas (1978).

Some of the individual textual classics of Hinduism have been translated and published in the series "Sacred Books of the East": F. MAX MULLER and HERMANN OLDENBERG (trans.), Vedic Hymns, 2 vol. (1891-97, reprinted 1979), selections from the Rigveda; MAURICE BLOOMFIELD (trans.), Hymns of the Atharva-Veda: Together with Extracts from the Ritual Books and the Commentaries (1897, reissued 1973); JULIUS EGGELING and the Commentaries (187), resisted 1973, follows edgeling (trans.), The Satapatha-Brāhmana, According to the Text of the Mādhyandina School, 5 vol. (1882–1900, reprinted 1978); G. BCHLER (trans.), The Laws of Manu (1886, reprinted 1971), with extracts from seven commentaries; JULIUS JOLLY (trans.), The Institutes of Vishnu (1880, reprinted 1965), and The Minor Law-Books (1889, reprinted 1965); GEORGE THIBAUT (trans.), The Vedanta-Sutras, with the Commentary by Ramanuia, 3 The Vedanta-Sutras, with the Commentary by Ramanuja, 3 vol. (1890–1904, reprinted 1977); and HERMANN OLDENBERG (trans.), The Grithya-Sutras: Rules of Vedic Domestic Ceremonies, 2 vol. (1886–92, reissued 1973). See also WENDY DONIGER O'FLAHERTY (ed. and trans.), The Rig Veda: An Anthology (1981), a collection of 108 hymns. ROBERT ERNEST HUME

(trans.), The Thirteen Principal Upanishads, 2nd ed. rev. (1931, reissued 1983), remains the best translation. R.C. ZAEHNER, The Bhagavad-Gita: With a Commentary Based on the Original Sources (1969, reprinted 1973), is one of the best translations of this text. Translations of the epics include PRATAP CHANDRA ROY (trans.), The Mahabharata of Krishna-Dwaipayana Vyasa, 12 vol. (1883-96, reprinted 1981-82); J.A.B. VAN BUITENEN 12 Vol. (1883-yo, reprinted 1903-96F, 163B, 1881 PERSADD, (ed. and trans.), The Mahabhārata (1973-); HARI PERSADD, SHASTRI (trans.), The Ramayana, 3rd ed., 3 vol. (1976); and ROBERT P. GOLDMAN (trans.), The Ramayana of Valintic An Epic of Ancient India (1984-), with 2 vol. published by 1988. Translations of several Purāṇas are available in J.L. SHASTRI, Ancient Indian Tradition & Mythology (1970-), with 35 vol. published by 1987; and in the Puranas, ed. by ANAND SWARUP GUPTA (1968-)

Although many of the vast sources for the vernacular literatures have not been translated, there are some, including: w. DOUGLAS P. HILL (trans.), The Holy Lake of the Acts of Rāma (1952), a translation of the Rāmcaritmanas of Tulasī Dās; CH. VAUDEVILLE (trans.), Kabir, vol. 1 (1974); LINDA HESS and SHUKDEV SINGH (trans.), The Bijak of Kabir (1983, reissued 1986); KENNETH E. BRYANT, Poems to the Child-God: Structures and Strategies in the Poetry of Surdas (1978); JOHN STRATTON HAWLEY, Sur Das: Poet, Singer, Saint (1984); A.K. RAMANUJAN (trans.), Speaking of Siva (1973), Hymns for the Drowning: Po-ems for Visnu (1981), and Poems of Love and War: From the Eight Anthologies and the Ten Long Poems of Classical Tamil (1985); and DAVID DEAN SHULMAN, Tamil Temple Myths: Sacrifice and Divine Marriage in the South Indian Saiva Tradition (1980), and The King and the Clown in South Indian Myth and Poetry (1985).

A good introduction to tribal and Hindu folklore is provided by VERRIER ELWIN (trans.), Tribal Myths of Orissa (1954, reprinted 1980), Myths of Middle India (1949, reprinted 1977), and Myths of the North-East Frontier of India (1958, reissued 1968). See also BRENDA E.F. BECK et al. (eds.), Folktales of India (1987); and STUART H. BLACKBURN and A.K. RAMANUJAN (eds.), Another Harmony: New Essays on the Folklore of India (1986), For the prehistoric period and the Indus Valley civilization, see WALTER A. FAIRSERVIS, JR., The Roots of Ancient India. 2nd ed. rev. (1975); STUART PIGGOTT, Prehistoric India to 1000 B.C. (1950, reissued 1962); MORTIMER WHEELER, The Indus Civilization, 3rd ed. (1968); and JOHN MARSHALL, Mohenio-Daro and the Indus Civilization, 3 vol. (1931, reprinted 1973). The best works on the Vedic religion include the essays found in J.C. HEESTERMAN, The Inner Conflict of Tradition: Essays in Indian Ritual (1985); see also FRITS STAAL, C.V. SOMAYAJIPAD, and M. ITTI RAVI NAMBUDIRI, Agni: The Vedic Ritual of the Fire Alta, 2 vols. (1983). The classic work on the Vedic sacrifice is SYL-VAIN LÉVI, La Doctrine du sacrifice dans les Brâhmanas (1898, reissued 1966). Still useful are ARTHUR BERRIEDALE KEITH. The Religion and Philosophy of the Veda and Upanishads, 2 vol. (1925, reprinted 1971); and LOUIS RENOU, Vedic India, trans. from French (1957, reissued 1971). Works on the relations between Vedic religion and later Hinduism are JAN GONDA, Change and Continuity in Indian Religion (1965); MADELEINE BIARDEAU and CHARLES MALAMOUD, Sacrifice dans l'Inde ancienne (1976); and BRIAN K. SMITH, Reflections on Resemblance, Ritual, and Religion (1989).

The literature and teachings on dharma are presented in PAN-DURANG VAMAN KANE, History of Dharmasāstra (Ancient and Mediaeval Religions and Civil Law in India), 2nd ed., 5 vol. in 8 (1968-77), an indispensible work. A summary of dharma is found in ROBERT LINGAT, The Classical Law of India (1973; originally published in French, 1967). The best study on yoga is MIRCEA ELIADE, Yoga: Immortality and Freedom, 2nd ed. (1969; originally published in French, 1954); also consult JEAN VARENNE, Yoga and the Hindu Tradition (1976; originally published in French, 1973). The doctrine of karma and rebirth as it is presented in the texts is examined in the essays collected in WENDY DONIGER O'FLAHERTY (ed.), Karma and Rebirth in Classical Indian Traditions (1980). CHARLES F. KEYES and E. VALENTINE DANIEL (eds.), Karma: An Anthropological Inquiry (1983), is also useful. Of the many works on the theoretical underpinnings of the caste system, the most influential of recent years has been the magnum opus by LOUIS DUMONT, Homo Hierarchicus: The Caste System and Its Implications, rev. ed. (1980; originally published in French, 1966). Also noteworthy is VEENA DAS, Structure and Cognition: Aspects of Hindu Caste and Ritual, 2nd ed. (1982).

For a convenient summary of the Hindu practice and ideology of image worship, consult DIANA L. ECK, Darsan: Seeing the Divine Image in India, 2nd rev. and enl. ed. (1985); and the essays in JOANNE PUNZO WAGHORNE, NORMAN CUTLER, and VASUDHA NARAYANAN (eds.), Gods of Flesh/Gods of Stone: The Embodiment of Divinity in India (1985). The best work on Hindu temples is STELLA KRAMRISCH, The Hindu Temple, 2 vol. (1946, reprinted 1976); see also GEORGE MICHELL, The Hindu Temple: An Introduction to Its Meaning and Forms (1977). The practice of pilgrimage in general, and specifically pilgrimage to the holy city of Varanasi, is treated in DIANA L.

ECK, Banaras: City of Light (1982).

For an overview of the sects worshiping Vishnu or one of his forms, see JAN GONDA, Aspects of Early Visnuism (1954, reissued 1969); SUVIRA JAISWAL, The Origin and Development of Vaisnavism; Vaisnavism from 200 B.C. to A.D. 500, 2nd rev. and enl. ed. (1981); and MILTON SINGER (ed.), Krishna: Myths, Rites, and Attitudes (1966, reprinted 1981). For an excellent study on Krishna, see ALF HILTEBEITEL, The Ritual of Battle: Krishna in the Mahābhārata (1976). Other important works include JOHN STRATTON HAWLEY, Krishna, the Butter Thief (1983); and DAVID R. KINSLEY, The Divine Player: A Study of Kṛṣṇa līlā (1979). SUSHIL KUMAR DE, Early History of the Vaisnava Faith and Movement in Bengal, from Sanskrit and Bengali Sources, 2nd ed. (1961), is a historical approach.

Bengali Sources, and ed. (1901), is a historical approach. For the history of Saivism, see c.v. Narayana Ayyar (Sadanahda), Origin and Early History of Saivism in South India (1936, reprinted 1974); and v.s. Pathak, History of Saivism Cults in Northern India, from Inscriptions 700 A.D. to 1200 A.D. (1960, reissued 1980). The mythology of Siva is discussed in WENDY DONIGER O'FLAHERTY, Asceticism and Eroticism in the Mythology of Siva (1973, reprinted as Siva, the Erotic Ascetic, 1981); and in STELLA KRAMRISCH, The Presence of Siva (1981).

The best overviews of Tantrism are AGEHANANDA BHARATI, The Tantric Tradition (1965, reprinted 1977); and EDWARD C. DIMOCK, JR., The Place of the Hidden Moon: Erotic Mysticism in the Vaisnavasahajiyā Cult of Bengal (1966). For the worship of the goddess in her many forms, consult the essays in JOHN STRATTON HAWLEY and DONNA MARIE WULFF (eds.), The Divine Consort: Rādhā and the Goddesses of India (1982, reprinted 1986). See also thomas B. Coburn, Devi Māhātmya: The Crystalization of the Goddess Tradition (1984); CHEEVER MACKENZIE BROWN, God as Mother: A Feminine Theology in India: An Historical and Theological Study of the Brahmavaivarta Purāna (1974); DAVID KINSLEY, Hindu Goddesses: Visions of the Divine Feminine in the Hindu Religious Tradition (1986); and WENDY DONIGER O'FLAHERTY, Women, Androgynes, and Other Mythical Reasts (1980, reprinted 1982). An interesting and accessible comparison of certain themes in the worship of Krishna and the goddess is DAVID KINSLEY, The Sword and the Flute: Kali and Kṛṣṇa, Dark Visions of the Terrible and the Sublime in Hindu Mythology (1975, reprinted 1977).

Emphasizing the anthropology of "popular" Hinduism are the works by Lawrence A. Babb, The Divine Hierarchy: Popular Hinduism in Central India (1975); MCKIM MARRIOTT (ed.), Village India: Studies in the Little Community (1955, reprinted 1986): MILTON SINGER (ed.), Traditional India: Structure and Change (1958, reissued 1976), and When a Great Tradition Modernizes: An Anthropological Approach to Indian Civilization (1972, reprinted 1980); and C.G. DIEHL, Instrument and Purpose (1956). A classic case history of the process known as Sanskritization is M.N. SRINIVAS, Religion and Society Among the Coores of South India (1952, reissued 1978). For a psychoanalytic approach to Hinduism, consult G. MORRIS CARSTAIRS. The Twice-Born: A Study of a Community of High-Caste Hindus (1957, reissued 1967); and SUDHIR KAKAR, The Inner World: A Psycho-Analytic Study of Childhood and Society in India. 2nd ed. rev. and enl. (1981, reprinted 1982), and Shamans, Mystics and Doctors: A Psychological Inquiry into India and Its Healing Traditions (1982, reissued 1984).

The standard work on the philosophical and theological aspects of various Hindu traditions is SURENDRANATH DASGUPTA, History of Indian Philosophy, 5 vol. (1922-55, reprinted 1975). A fine series of volumes on Indian philosophy is KARL H. POT-TER (comp.), Encyclopedia of Indian Philosophies (1977-), with 4 vol. published by 1987. For an analysis of one of these traditions, see JOHN BRAISTED CARMAN, The Theology of Ramānuja: An Essay in Interreligious Understanding (1974).

Developments in the Hindu tradition as it confronted Western religions and modernity are covered in D.S. SARMA, Studies in the Renaissance of Hinduism in the Nineteenth and Twentieth Centuries (1944). Of special interest are the texts collected and translated by RICHARD FOX YOUNG, Resistant Hinduism: Sanskrit Sources on Anti-Christian Apologetics in Early Nineteenth-Century India (1981).

(W.Do./B.K.S.)

The Study of History

odern historians aim to reconstruct a record of human activities and to achieve a more profound task is quite recent, dating from the development in the late 18th and early 19th centuries of scientific history, cultivated largely by professional historians. It springs from an outlook that is very new in human experience: the assumption that the study of history is a natural, inevitable

human activity. Before the late 18th century, historiography (the writing of history) did not stand at the centre of any civilization. History was almost never an important part of regular education, and it never claimed to provide an interpretation of human life as a whole. This was more appropriately the function of religion, of philosophy, even perhaps of poetry and other imaginative literature. The article is divided into the following sections:

History of historiography 559 Ancient historiography Greco-Roman era Early Christian era Early China Medieval historiography 562 Europe from the 5th to the 11th century Europe from the 12th to the 14th century Byzantine historiography 564 Muslim historiography 565 Historiography in the European Renaissance 566 Early modern historiography 567 Historiography in the age of the Enlightenment Historiography in the 19th and 20th centuries 572 Methodology of historiography 573 Source material 574 Using source material 574 Ancillary fields 574 Archaeology 574 History of archaeology Fieldwork Interpretation Bibliography 579 Descriptive bibliography Critical bibliography Chronology 582 Chinese Japanese Indian Egyptian Babylonian and Assyrian

History of historiography

ANCIENT HISTORIOGRAPHY

Greco-Roman era. The older, pre-18th-century outlook has been particularly well studied in the historiography of the ancient Greeks and Romans, But, although two of the most important ancient historians, Herodotus and Thueydides, wrote as early as the 5th century sec, when recorded Greek historiography was only just beginning, they had few successors of comparable quality. It is a symptom of the relative lack of importance attached in antiquity to this type of activity.

Ancient history was a branch of literature. The most appreciated historians were the writers who, like Thucydides, were able to touch on universal human problems or who, like the Roman author Tacitus (died c. AD 120), wrote in a dramatic way about important events or who, at least, attracted readers by their excellent style and skill in composition. Many of the works that lacked some of these literary qualities failed to survive.

About 1,000 ancient Greeks wrote in antiquity on historical subjects, but most of these writers are mere names. Many of the losses appear to have occurred in antiquity itself. Even historians of first rank have fared badly. Only in a few cases have complete texts of all their writings survived. Of the voluminous history of Polybius (covering originally the period 220-144 Bc) only about one-third survives. Nearly half of Livy's Roman history (originally covering the period 753-9 bc) is lost. The text that remains is reasonably good only through the efforts of a group of Roman aristocrats who, in about Ao 500, were trying to salvage the chief glories of Roman literature. A considerable part of Tacitus is missing, and the surviving portions of his Annals and Histories (originally AD 14-96) derive from two unique manuscripts.

Herodotus, whom the Roman statesman Cicero called "the father of history," came from the western coast of Asia Minor. The writers who preceded him were mainly lonians from the Greek settlements in the same area. The origin of Greek historiography lies in the lonian thought of the 6th century. The Ionian philosophers were doing something unprecedented: they were assuming that the universe is an intelligible whole and that through rational inquiries men might discover the general principles that govern it. Hecateus of Miletus, the most important Ionian predecessor of Herodotus, was applying the same critical spirit to the largely mythical Greek traditions when he wrote, early in the 5th century, "the stories of the Greeks are numerous and in my opinion ridiculous." Herodotus are numerous and in my opinion ridiculous." Herodotus was an "inquiry" (historia).

A glance at the older historiography of the Egyptians, the Babylonians, and the other peoples of the ancient Near East will heighten one's appreciation of the novelty of the task undertaken by Herodotus. The kings of Egypt, of Babylonia and Assyria, and of the Hittites and the Persians all sought to preserve their glorious deeds for posterity in monumental inscriptions. The more im-

Egyptian and Babylonian historiportant rulers also accumulated large archives, including both ordinary administrative documents and records specially commemorating their achievements. Some 20,000 clay tablets remain from the collections written for Ashurbanipal of Assyria (668-627 BC). Both in Egypt and in Babylonia lists of kings were kept in the temples, and these were sometimes supplemented by brief annals recording the principal events, though the hatred felt by certain rulers for their predecessors led to periodic destructions of older material. The exceptional meagreness of the narrative sources for Babylonian history before 747 BC seems due to the obliteration of the older annals by Nabonassar of Babylonia (ruled 747-734). Apart from changes in literary style, there was surprisingly little development over a period of more than 1,000 years in all these types of commemorative records. The inscriptions and temple records were normally intended to perpetuate the glory of the gods in whose service these rulers had accomplished great deeds. The names and dates of dynasties and of particular rulers can be reconstructed fairly adequately with the aid of these sources, but one cannot expect much accurate information about particular events. Nor, with rare exceptions, were those who had access to this material interested in using it to write continuous histories.

Herodotus and his immediate Ionian predecessors shared a very novel outlook. Its distinctive features were a lively curiosity and a capacity to treat sources in a critical spirit. Boundless curiosity about people and their diverse customs is one of the most endearing traits of Herodotus. Like other Greeks from western Asia Minor, he was particularly stimulated by contacts with the great Persian Empire, which offered opportunities for reasonably secure travel. The resultant immense widening of historical perspective is illustrated by a story told by Herodotus about Hecateus. When the latter assured the Egyptian priests at Thebes that he could trace his descent through 16 generations, the Egyptians showed him evidence of the descent of their high priests through 345 generations. Herodotus was the first to link his geographic inquiries with true history. His descriptions of the barbarian world that confronted the Greeks provided an introduction to the epic of the suc-

cessful Greek resistance to the Persians. The types of history written by the ancient Greeks and Romans influenced profoundly all subsequent historiography down to the 18th century. In order to interpret sympathetically this classical historiography, it is necessary to bear in mind the literary conventions that governed this branch of literature. The ancient Greeks distinguished between history and biography. The origin of both forms can be traced back to at least the 5th century BC, and the differences between them were observed throughout antiquity. The writer of history was supposed to aim at giving a true story, but the biographer was entitled to treat historical personages in a manner that resembled legend. There existed, of course, some exceptions. The lives of the early Roman emperors written by Suetonius in the 2nd century AD, while conforming to the traditional, topical arrangement of biographies, constitute an unusually valuable historical source, especially for Augustus, whose correspondence is repeatedly quoted. Yet another distinction was drawn between history and the study of "antiquities," to use a term employed by Varro (116-27 BC), perhaps the greatest of all the ancient Roman scholars. This distinction was already implicit in Aristotle's contemptuous dismissal of history (in his Poetics) as a branch of literature dealing with the particular rather than with things of general significance. The histories he condemned provided chronological narratives of wars and political events. Aristotle and his disciples were engaged in several enterprises that they regarded as something quite different from history. For example, they embarked on the study of the constitutions of all the Greek states. Such work was to be based on systematic inquiries. The student of the "antiquities" tried to use a wider range of evidence than the sources normally consulted by the ancient historians, and he arranged his results systematically by topics.

In antiquity a writer of history was usually preoccupied at least as much with style as with content. A generation before Aristotle, the rules of rhetoric, as they might be applied to history, were fully elaborated by Isocrates, a teacher of rhetoric at Athens. Cicero tried (especially in his De oratore, 55 BC) to familiarize the Romans with these Isocratean precepts. History was to be written in a clear but solemn style, akin to fine oratory. The historian was to introduce all manner of literary embellishments but was also to stress the moral lessons of his story. At its worst this type of historiography could lead to serious misrepresentations of the past. Among the Roman historians, Livy (died AD 17) was an important practitioner of this kind of writing, which was particularly well suited to the patriotic myths that he was trying to immortalize, of a Rome that owed its magnificent destiny to the unique virtues of its citizens and the perfection of its antique institutions. Some outstanding historians, such as Polybius (2nd century BC) and Caesar (died 44 BC), eschewed these rhetorical precepts, but in all the ancient writers an important element of literary artifice was always present. This is one of the reasons why they offend modern standards, which demand absolute accuracy in the presentation of evidence. One of the most striking contrasts is the reluctance of the ancient historians to quote documents. Tacitus might rely heavily on the archives of the Roman Senate, but he never mentions his documentary sources. An inscription discovered at Lyons, France, preserves a speech delivered by the emperor Claudius to the Senate in AD 48, and it is clear that Tacitus utilized another version of the same text. His skill in using it is matched by the freedom with which he adapts it to suit

The greatest and the most original achievement of the best Greek historians lay in their clear grasp of the need to distinguish truth from fiction and their conscious preoccupation with the methods of achieving this. This is admirably conveyed in a famous passage of Thucydides. And with reference to the narrative of events, far from permitting myself to derive it from the first source that came to hand, I did not even trust my own impressions, but it rests partly on what I saw myself, partly on what others saw for me, the accuracy of the report being always tried by the most severe and detailed tests possible. My conclusions have cost me some labour from the want of coincidence between accounts of the same occurrences by different eye-witnesses, arising sometimes from deficient memory, sometimes from deficient impartiality.

His practice did not fully live up to this ideal, however. The greatest of his Greek successors, Polybius, is reasonably impartial, except in his treatment of some of the events in Greece. Among the Romans, the writing of history was chiefly the preserve of members of the senatorial class. who almost invariably had some personal axes to grind. But the correctness of the rules formulated by Thucydides was accepted, in principle, by most ancient historians.

Thucydides had deliberately restricted himself to the history of his own time, and many of the subsequent ancient historians did likewise. They could depend on their own experience or could question well-informed contemporaries. The surviving fragments of Livy relating to his own lifetime (64/59 BC-AD 17) are much more vivid and convincing than the earlier books of his history (surviving today only down to 167 BC). The tendency to prefer contemporary history was strengthened by the practical bent of many of these writers. Several ancient historians were men of action familiar with warfare and politics. Interested in history as a source of instruction for statesmen, they could write with authority only about wars and political transactions of their own time. Polybius, the exiled Achaean general and a great traveller, derides unpractical, sedentary historians such as Timaeus, who had been writing about the peoples of the western Mediterranean without stirring for 50 years from Athens.

The historians of antiquity were much less skillful in dealing with noncontemporary history, for which they relied on older historians. Where none was to be found, they felt lost, as Livy complains in the early portions of his Roman history. The modern recourse to non-narrative sources was alien to the habits of most ancient historians. They were usually incapable of doing this successfully, just as they were ill equipped to discuss critically the sources used by the older writers.

Methods of Thucyd-

Ancient biography

Purpose

of Jewish

histories

Herodotus chose for his theme the successful resistance of the Greeks against the Persians at the beginning of the 5th century BC. Thucydides wrote about the Peloponnesian War, in which virtually all the Greek states became involved in the last decades of that century. These were limited subjects of obvious importance for which it was possible to find ample evidence. The strength of the ancient historians lay precisely in imposing an interesting pattern on the events of a selected period, usually contemporary or fairly recent, for which they had manageable sources. The best of them could thereby achieve a sense of dramatic unity and produce literary masterpieces. The speeches that Thucydides invented for some of the main protagonists in his story are artistically the most satisfying parts of his work, and at times they even seem to recapture the spirit of what might have been said on these occasions. In a superb writer like Tacitus, whose political career had included long periods of frustration and insecurity, one does not look for impartiality or for scrupulous truthfulness but, rather, for fascinating insights into what the development of Roman imperial power from Augustus to Domitian (the period AD 14-96) meant to the proud, sophisticated Roman aristocracy for whom he was writing,

The study of "antiquities," as opposed to parrative history, did not normally produce works of literary merit, and this is probably the main reason why most of them disappeared. One important group of such writings originated with Aristotle and his collaborators, writing in the third quarter of the 4th century BC. They were interested in both literary "antiquities" and in the systematic study of the constitutions of Greek states. They had described 158 different constitutions, though only their account of Athens now survives. A comparison of its two main parts illustrates the contrast between the deficiencies of ancient historiography and the impressive achievements of the antiquarian researchers. In the introductory, historical section, Aristotle was baffled by the problem of dealing with the fairly remote past. For each particular period he tried to follow some contemporary sources. The resultant juxtaposition of several writers differing widely in their political outlook produced an account full of contradictions. The second part, however, containing a systematic description of the Athenian constitution, is a masterpiece of shrewd analysis, as are the empirical portions of Aristotle's Politics (Books IV-VI), which are based on a wealth of concrete examples derived from the different Greek states.

Aristotle inspired in the 3rd and 2nd centuries BC a great mass of philological and antiquarian research. The most important scholars were to be found in the new Hellenistic states, especially at Alexandria in Egypt and at Pergamum in Asia Minor. Among the surviving Hellenistic fragments, there are commentaries on Herodotus and Thucydides. The Hellenistic scholars were interested in many subjects connected with history and did pioneering work in chronology, geography, and topography. They were accustomed to using every kind of source and to quoting documents extensively. Their greatest Roman disciple was Varro, who tried to recover all the vestiges of the old Roman society and to make a systematic survey of Roman life based on the evidence provided by language, literature, religion, and ancient customs. Most of his writings have been lost, but he supplied the conjectural (though incorrect) date of 753 BC for the foundation of Rome and knowledge of the probable boundaries between some of the groups whose union produced the city of Rome. Unfortunately, antiquarian researches of such penetrating nature were almost never applied in antiquity to the writing of narrative histories.

Early Christian era. The triumph of Christianity in the Roman Empire during the 4th century assured the predominance of a type of historiography radically different from the works of the pagan Greek and Roman historians. Its origins were Jewish. The Jews were the only people of antiquity who had the supreme religious duty of remembering the past because their traditional histories commemorated the working out of God's plan for his chosen people. By contrast, no Greek ever heard his gods ordering him to remember. It was the duty of every Jew to be familiar with the Jewish sacred writings, which were

ultimately gathered into what became the Old Testament. The writers of these biblical books only gave an authoritative version of what everybody was supposed to know, and they were only concerned with the selection of such facts as seemed relevant in interpreting God's purpose. In addition, the Jews also cherished unwritten traditions. To quote Josephus, a Jewish historian of the 1st century AD, "what had not been written down, was yet entrusted to the collective memory of the people of Israel and especially of its priests."

The Christians took over the Old Testament and added to it an additional body of sacred history. The writers of the four Gospels included in the New Testament were bearing witness to assured truths that the faithful qualit to know, and no convincing reconstruction of historical facts is possible from these books of the New Testament. The only avowedly historical book in it is the Acts of the Apostles. The New Testament as a whole represents merely a selection from the early Christian writings. It includes only what conformed to the doctrine of the church when, later on, that doctrine became fixed in one form. Between the Acts of the Apostles, dating probably from the late 1st century, and the writings of Eusebius of Caesarea (died c. 340) and his contemporaries in the first quarter of the 4th century, there is an almost complete gap in Christian historiography.

For the Christian writers the story of Jesus, as recorded in the Gospels, represented the fulfillment of the prophecies that could be found in various parts of the Old Testament. The Jewish part of the Bible also assured for Christianity the authority of a long antiquity. The history contained in the two parts of the Bible, now indissolubly linked together, became the only authentic record of God's revelation for mankind, dwarfing into insignificance all the records of other peoples and religious groups. The concept of a universal history had not been wholly unknown to the pagan world, but the Christians were the first to apply it effectively. Christian history had to be a universal history, though of a very peculiar sort, where only one sequence of privileged events. Jewish and Christian, deserved detailed record. The Christian claims must have seemed more extravagant to the pagans than even the Jewish ones. Thus Eusebius stated that the Christians were, in fact, born with the world, anticipating St. Augustine's vision of the city of God existing since the beginning of time.

In defending their religion against hostile critics, the early Christians were forced to fit some pagan history into their universal scheme. This was achieved by means of universal chronologies from the creation of the world to each writer's own time. The events of Jewish and Christian history were thus synchronized with the main dates of the pagan myth and history. Sextus Julius Africanus, who wrote in the early 3rd century, is the first Christian writer known to have attempted this feat. He allotted 6,000 years to the whole span of human history and placed the birth of Christ in the year 5500 from the creation of the world. This work provided the model for the more elaborate Chronographia (Chronicle) of Eusebius. It became the foundation for a long succession of Greek chronographies produced by Byzantine writers. A Latin adaptation by St. Jerome (died 419/420) was immensely influential in western Europe for more than 1,000 years. A modern scholar is filled with mingled admiration and despair at the ingenuity of Eusebius and of his more eminent successors and at the absurdity of many of their conclusions. But they did originate and impose on the world a unified scheme of universal chronology. The dating from the birth of Christ was introduced by Dionysius Exiguus, who wrote at Rome in the early 6th century, and it was successfully popularized in the 8th century by the English historian Bede.

The writing of history of their own time was not an essential task for the Christians of the 4th and 5th centuries. When they did so, they wrote primarily in defense of their religion against the pagan world or against irval Christian groups branded as heretical. All these histories belong to religious apologetics. They suffer from inevitable distortions in the choice of what should be mentioned and what must be suppressed, and they are often excessively unfair to outsiders and opponents. These faults were not uncom-

Universal chronolomon among the classical historians, though the Christians were somewhat unusual in their extreme conviction that they alone must be right. A comparison between the Christian historians and an outstanding pagan writer, such as Ammianus Marcellinus (second half of the 4th century), who was very ready to admire those Christians who merited it, brings out the intolerance and narrowness of outlook of his Christian contemporaries.

Eusebius was the earliest and the most important of the Christian historians of the 4th century. He is quite frank about the practical and apologetic aims of his Historia ecclesiastica (written 312-324; Ecclesiastical History) designed to show how, through a long series of acts of Divine Providence, a Christian empire was finally brought into existence by Constantine. He admits that "we shall introduce into this history in general only those events which may be useful first to ourselves and afterward, to posterity." This work, like his other historical writings, is a mixture of devout fiction and invaluable detail. But there is plenty of the latter in Ecclesiastical History. Contrary to the usual practice of the ancient historians, Eusebius tries to specify his sources, and he quotes from them extensively in order to document as fully as possible the developments that resulted in the triumph of Christianity. He provided in this respect a valuable model for his medieval successors. The most astonishing thing about Eusebius was his capacity to handle his sources critically, in matters where it seemed permissible to do so. In one passage of his Chronicle he sets aside the authority of St. Paul in favour of a piece of evidence contained in the Book of Judges. In later patristic literature nothing similar is found.

Biography, as it was habitually written in antiquity, could be readily adapted to Christian purposes. St. Jerome modelled himself on Suetonius in compiling the lives of 135 Christian writers (written in 392) as a way of demonstrating the high level of culture attained by his coreligionists. The ancient biographers had freely mingled fact with fiction for the edification of their readers and could be readily imitated by the writers of the lives of Christian saints. The life of St. Anthony of Egypt by St. Athanasius (mid-4th century) set the pattern for this most popular type of

medieval literature. St. Augustine, the greatest of the Latin Church Fathers of the 4th and 5th centuries, was certainly not concerned with writing of history in any ordinary sense of the term. In his De civitate Dei (City of God) he might invoke historical evidence to demonstrate the utter degradation of all the non-Christian societies, and he encouraged his pupil Orosius to develop this theme more fully in the latter's Historiarum libri VII adversus paganos (Seven Books of History Against the Pagans, to 417). Nearly 200 manuscripts of Orosius have survived, testifying to the immense popularity of his work in the Middle Ages. Augustine's greatest influence on historiography lay in his main message. His vision of the divine and the earthly cities confronting each other dominated the outlook of all the medieval Christian thinkers and profoundly affected their treatment of history. Within that divine plan for the world, purely secular history seemed an insignificant thing. Early China. The preservation of some records of his-

torical events can be traced in China to at least the early part of the 1st millennium BC. Confucius (551-479 BC) was credited, rightly or wrongly, in the later Chinese tradition with editing the annals of his native state of Lu. But the appearance of the first works fully deserving the name of histories resulted from the unification of China under a single ruler in 221 BC. The first such work to survive, the Shih chi ("Historical Records"), dates from c. 85 BC. Its author, Ssu-ma Ch'ien, is quite justifiably called the father of Chinese historiography. His history exhibits many of the main features of the later Chinese official histories as they continued to be written down to the deposition of the last Chinese imperial dynasty in 1911. Within this fairly unified tradition, China produced a mass of historical writings unequalled by any other country before modern times. Until the late 19th century, Japanese historiography formed an offshoot of this tradition.

Chinese scholars showed an interest in the history of China from the earliest times. According to the Chinese conception, history makes sense only if it can furnish practical directives for action or supply correct information upon which action can wisely be based. All the schools of Chinese thought quoted the lessons of history. Confucius, with his stress on the moral content of these lessons, formed part of this universal belief in the value of history. One of the duties inculcated by him was the scrupulous transmission of authentic records. When, some centuries after his death, the unified Imperial state began to recruit its bureaucracy among the Confucian scholars. the recording of all the necessary information and the careful preservation of records became one of the main functions of the Chinese government, both centrally and locally. A long series of official histories and of records connected with them has survived from the time of the T'ang dynasty (618-907) onward. From then on, the great bulk of Chinese history was written by bureaucrats for bureaucrats. From a practical point of view this immense body of historical writings fulfilled a very useful purpose. Such histories were bound to be highly stereotyped and restricted in content to what interested the higher officialdom. It is easy to condemn it by modern Western standards for its excessive preoccupation with concrete details and inability to produce works of wider synthesis. But this Chinese tradition did gradually evolve in the direction of greater rationality and subtlety. Its scope widened as the sphere of government expanded. Furthermore, within this tradition there appeared from time to time writers of genius, men of bold critical spirit, genuine historical insight, and overriding integrity. One of the greatest was Liu Chih-chi (661-721), the writer of the Shih t'ung, the first thorough treatise in Chinese, or any other language, on historical method, which also constituted in effect a history of Chinese historiography. He had a successor in Ssu-ma Kuang (1019-86), the author of the first fairly comprehensive general history of China (covering the years 403 BC-AD 959). In the 17th century a remarkable group of historical scholars virtually founded a school of critical Chinese philology. None of these writers succeeded in radically transforming Chinese historiography, but they created an increasingly sophisticated and critical tradition. Their successors in the 20th century assimilated some valuable features of modern Western historiography.

MEDIEVAL HISTORIOGRAPHY

Europe from the 5th to the 11th century. The period stretching from the 5th to the 11th century was a time of very profound cultural decline in regions that had once constituted the western half of the Roman Empire. Almost all the inhabitants of these provinces again became illiterate. There are long periods for which there are virtually no narrative sources, and the bulk of surviving historical writings consists merely of meagre factual annals. Virtually all the writers were ecclesiastics, in marked contrast to the Byzantine lands, where a strong tradition of lay historiography persisted throughout the Middle Ages. The annalists and chroniclers of the West were predominantly monks, and their lack of experience of the secular world outside their cloisters made them into blinkered and unpractical historians. This was true even of Bede, an Anglo-Saxon monk, who was by far the greatest historian of the early Middle Ages.

All the historians of this period were seriously affected by the cultural decline around them. They were having to write in part for a more uncultured audience. Sulpicius Severus, probably the best Western historian of the early 5th century, still intended his Chronica (to 403) for educated Roman Christians, but his life of St. Martin of Tours is a piece of medieval hagiography. This model could inspire lives full of folklore and miracle, from which the real human personalities of the saints were almost wholly absent. The same duality of purpose is a notable feature of Bede's voluminous writings. He explicitly recognized that he must adapt himself to his audience when he explained that he was writing in a simple Latin style so that he might be more easily understood by his Anglo-Saxon readers. There is a marked contrast of tone between his theological and his historical writings. As a theologian, Bede follows Eusebius and the earlier Church Fathers in not exaggerat-

The "Historical Records' of ancient China

Augustine

ing the frequency of miracles and in believing that they were most common in the earliest days of Christianity. But Bede's lives of the English saints and his Historia ecclesiastica gentis Anglorum (Ecclesiastical History of the English People), covering chiefly the years 597-731, are full of miracles and visions. There is one or other on almost every page. It is possible that some of these incidents were included by Bede because he thought that his readers expected mentions of these familiar, traditional stories.

In preparing his historical works, Bede not only took great care to assemble the widest possible collection of sources but also tells the reader what he is using. In dedicating his Ecclesiastical History to King Ceolwulf of

Northumbria, he requests that

in order to remove all occasions of doubt about those things I have written, either in your mind or in the minds of any others who listen to or read this history, I will make it my business to state briefly from what sources I have gained my

An impressive list follows, including mentions of documents copied for him by friends at Rome, Canterbury, and other places. Like Eusebius, on whom Bede modelled himself, he quotes some of the documents integrally Bede's methods of securing and recording information are so similar to the practices of modern historians and the judicious tone of his writing is so impressive that the reader is almost taken in into treating him as if he were a modern scholar. But Bede's Ecclesiastical History was written as a work of edification in order to strengthen the faith of his readers in Divine Providence, through which, as he saw it, his Anglo-Saxon countrymen had been converted to Christianity. All matters not connected with his main theme are ignored. Bede's handling of evidence on subjects that he regarded as embarrassing inspires mistrust. But these are small matters in comparison with the enormous mass of information that he alone has preserved and the encouragement that Bede continued to give for many centuries to the writing of history.

The influence of Bede and other Anglo-Saxon scholars was greatly felt during the later 8th and the 9th centuries in the Frankish kingdom, where under Charlemagne and his successor, Louis the Pious, there was a modest revival of historical writing. Besides the annals kept at various monasteries, which tended to convey information in a manner that suited the Frankish rulers, there were a few more ambitious ventures. The important Historia Langobardorum (History of the Lombards), written c. 774-785 by Paulus Diaconus, or Paul the Deacon, was the work of one of the best educated men of the time. Nithard, a grandson of Charlemagne, left an invaluable narrative of the disintegration of the Carolingian state during his lifetime. The work that exerted the greatest influence on the medieval writers of biographies was Einhard's Vita Karoli Magni (written c. 830-833; Life of Charlemagne). The author was a leading official and a close companion of Charles, and his work was naturally intended as a eulogy of the great king. Einhard says that Charlemagne retreated safely from Spain, returning with his army safe and sound, except that on a ridge of the Pyrenees, on the way home, he happened to experience some small effects of Gascon perfidy. Nobody would gather from this that the Franks had narrowly escaped a major disaster. Einhard was merely echoing the story told in the semiofficial contemporary annals. Another source of distortion was Einhard's use of a classical model, the Lives of the Caesars by Suetonius. The subject headings under which he described Charles and even the very words used were partly borrowed from the lives of Roman emperors, but his Charlemagne is probably in essentials an authentic and credible portrait.

If bulk alone is to be taken as a criterion, annals were the main product of medieval historiography. The annalist merely sets down the most important events of the current year. In the case of the earliest medieval annals, the events were often noted down in Easter tables, in the blank spaces between the dates calculated for the forthcoming Easters. Such paschal annals would be extremely brief. When, as often happened, annals came to be written down in separate manuscripts, distinct from the Easter tables, there was room for the expansion of individual entries. In either case, the resultant annals cannot be regarded as history since the events are necessarily recorded in isolation. But they preserve in a right order the essential facts, which could be rearranged into a continuous narrative. Such a narrative, if it still followed the chronological arrangement of its various annalistic sources, should properly be termed a chronicle

Medieval historians show little awareness of the process of historical change. They were unable to imagine that any earlier age was substantially different from their own, The unawareness of the meaning of anachronism helps to explain the strange wanderings of medieval annals and chronicles. If a religious community wanted to acquire a historical narrative, it copied some work that happened to be most readily accessible. A continuation might then be added at the manuscript's new abode, and, later on, this composite version might be copied and further altered by a succession of other writers. Hence there are at least six main versions of the annals known as the Anglo-Saxon Chronicle. They all derive from the annals kept down to 892 at Winchester, the West Saxon capital. Thereafter, copies were acquired by religious centres in the most diverse parts of England, and one manuscript was being kept up to date at the abbey of Peterborough as late as 1154. An extreme case of wanderings is represented by the annals of the cathedral church of Cracow, the medieval Polish capital. The first section is based on Orosius, the next comprises annals beginning with the death of Bede and containing notices of Frankish and German events, while the Polish section starts with the conversion of Poland to Christianity (965-966) and ends in the 13th century

The Anglo-Chronicle

Europe from the 12th to the 14th century. Historians are accustomed to regarding the late 11th and 12th centuries as an age of intensified progress in culture and learning; this development, however, did not greatly affect historiography. There was a modest revival of interest in some of the ancient Latin writers, but would-be historians were unsure which ancient models they ought to imitate. A whole series of attempts was made to apply to other races the theme in Virgil's Aeneid of a noble group of people guided by the gods toward a splendid destiny. The first essential step was to establish the descent of one's nation from the ancient Trojans and then to trace subsequent history through a series of heroic conquests. The most ambitious of these writings was the Historia regum Britanniae (History of the Kings of Britain), by Geoffrey of Monmouth (died 1155), which attempted to establish for the Celts a historical destiny greater than any other. Although some, even contemporary, readers were not de-ceived by the work, and William of Newburgh, one of the best English historians of the 12th century, denounced it as a tissue of absurdities, many seriously accepted it as history.

With a few exceptions, the ablest minds of the 12th century were attracted into enterprises that ignored history; they were more concerned with systematization of thought and with philosophical speculations. One of the exceptions was Otto, bishop of Freising, in Bavaria. He was a grandson of the Holy Roman emperor Henry IV. He received the best education that his age could give, but he was also briefly a Cistercian monk during the most austere period of that order's history. Otto was torn between conflicting impulses to seek the city of God as the only reality and yet to hope for the progress of the German empire. Out of this conflict came his first work, Chronica (The Two Cities), a chronicle of world history to 1146, perhaps the most profound medieval attempt at a Christian philosophy of history. As Otto himself confessed, it was composed "in bitterness of spirit . . . in the manner of The election in 1152 of his nephew and friend Frederick Barbarossa, as emperor, filled Otto with a new elation. The excellence of his second work, Gesta Friderici I imperatoris (The Deeds of Frederick Barbarossa), derives in a considerable measure from a quality rare in medieval historians, a sense of optimistic belief in the value of writing history because it might become a record of human progress. The Deeds of Frederick Barbarossa contains a penetrating analysis of the problems encountered by the

The works of Otto of

German rulers in trying to rule the precociously urbanized

As in antiquity, the best medieval works were accounts of contemporary history by men who had participated in the events that they were describing. It is, however, very significant that some of the writers that are prized most highly today survive in only very few manuscripts and were presumably not appreciated by most of their contemporaries. One such work was the Historia pontificalis ("Pontifical History") covering the period 1148-52, of John of Salisbury, one of the most accomplished scholars of his age, who was writing about the period when he was in the papal service. Another instance of undeserved neglect is furnished by the Liber de regno Siciliae ("Book of the Kingdom of Sicily") covering the period 1154-69, written by an anonymous member of the Sicilian court.

Unlike the ancient historians, the medieval writers of contemporary history had no inhibitions about extensively quoting official documents. In England, a succession of writers preserved a large quantity of such texts. Roger of Hoveden was, in the last quarter of the 12th century, treated by the English kings as a kind of court historian. He preserved valuable legal and administrative records with which he was familiar through his activities as a royal official and justice. Matthew Paris, the most important English monastic historian of the 13th century, was highly regarded by King Henry III and had excellent sources of information. He left behind a collection of transcripts of royal and ecclesiastical documents that today fills a large printed volume. Some writers made their chronicles into an anthology of official records, thinly connected by the author's brief comments. Such is the chronicle of Robert of Avesbury, consisting mainly of the military dispatches of King Edward III and other interesting documents to 1356. Another variant of the same method was for a wholly mediocre chronicle to incorporate exciting pieces of evewitness narratives by other writers. A dull English monastic product of the late 14th century, the Anonimalle Chronicle, includes a narrative of the Peasants' Revolt of 1381, which is one of the most dramatic and interesting eyewitness accounts to be found in medieval

The most popular histories of the 13th and 14th centuries were encyclopaedic compilations giving all the important facts neatly arranged under the dates of popes, emperors, and other rulers. There were even more ambitious ventures aiming at summarizing all the important facts from all the different branches of human activity. The Dominican Order, created at the beginning of the 13th century, was especially concerned with producing such aids for the dissemination of useful knowledge. The best known of these Dominican works is the immense Speculum historiale ("Mirror of History"), by Vincent of Beauvais, written under the patronage of King Louis IX of France. It is a compilation made up of excerpts from many authors.

The 13th and 14th centuries were not a period of any fundamental innovations in the techniques and nature of historiography, but there was a growing diversity of types of historical writing. Very detailed, chatty narratives multiplied, often badly organized and inaccurate, but conveying the authentic atmosphere of the times and vividly portraying leading personalities. Such were the St. Albans chronicles of Matthew Paris (to 1259), the reminiscences of Joinville about St. Louis during the Seventh Crusade (1248-54), the Lombard chronicle of Fra Salimbene (to 1287), or the vast history of the first part of the Hundred Years' War written in the second half of the 14th century by Froissart. Memoirs and histories written in vernacular languages, such as those of Joinville and Froissart, came to be quite common. Laymen began to write histories. Some were great men, like Geoffroi de Villehardouin, one of the leaders of the Fourth Crusade (which captured Constantinople 1202-04), of which he wrote an account. Important urban chronicles began to appear, such as the Florentine chronicle of Giovanni Villani, with its invaluable statistics of Florentine population and activities around 1338. The extraordinary personality of St. Francis. who died in 1226, inspired lives of him more convincingly human than any previous medieval biographies of saints. The Humanist historians of the 15th century tried to make a deliberate break with the tradition of medieval historiography. By their insistence on a more coherent arrangement of subject matter, by their superior critical outlook, and, above all, by their much more accurate awareness of the process of historical change, they had introduced innovations of fundamental importance. In part they owed their grasp of these new possibilities to the influence of Byzantine scholars. In historiography, as in other matters, the new humanistic scholarship was a joint

BYZANTINE HISTORIOGRAPHY

product of Western and Byzantine traditions.

During the millennium that elapsed between the collapse of the Roman Empire in the West in the 5th century AD and the Italian Renaissance of the 15th century, in no part of Europe did the writers of history consistently maintain as high a standard of achievement as in the Byzantine Empire. Parts of the 7th and the 8th centuries form lengthy gaps in the record of Byzantine historiography, but this seems mainly to be the result of subsequent losses of manuscripts. When, in the middle of the 9th century, Photius, future patriarch of Constantinople, compiled a record of some 280 books that he had read, he mentioned works of 33 Greek historians, dating mostly from the late Roman Empire and the Byzantine period, 20 of which are now lost. But, among the Byzantines of the 7th and 8th centuries, there was certainly no parallel to the Dark Ages in western Europe.

The Byzantine historians were heirs to the combined traditions of classical Greek writing, of the subsequent Hellenistic historiography, and of the Christian historical writing of the 4th century. Few ancient Latin historians were ever translated into Greek, and their influence on the Byzantines was, therefore, very slight. The older classical Greek historians provided the Byzantines with their cherished models of language and style. Like all educated Byzantines, the historians continued for a millennium to write in a literary language that soon became unintelligible to the vast majority of their compatriots. Hence, from the 6th century onward, there appeared, side by side with the learned historiography, a succession of popular chronicles written in the ordinary language. Most of these popular writings form-in their prejudice, ignorance, and crudity-a startling contrast to the works of the more eminent classicizing historians, but they do provide valuable glimpses of the sort of hagiographical history, more religious myth than sober fact, that ordinary Byzantines

apparently wanted to read. Herodotus and Thucydides were frequently invoked by Byzantine historians as models of fine prose. The influence of these two writers on the substance of what was written usually remained slight and superficial, however. The only Byzantine writers who seriously modelled themselves on these two oldest Greek historians wrote during the 15th century. The earlier Byzantine historians owed most to Polybius and to the Greek biographer Plutarch (died c. AD 119), the two Hellenistic writers who had the greatest influence on Byzantine notions of how history and historical biography should be written.

Like Polybius, the majority of Byzantine historians, including most of the best ones, perferred to write about their own times; and within these limits they produced some real masterpieces. Unlike the majority of the ancient historians, Polybius had included much autobiographical detail, and his influence reinforced the readiness of the Byzantine historians to talk about themselves, thus providing abundant information about several of these authors. Their histories are likely to be one-sided and full of details about what interested them, while remaining silent about a great mass of other contemporary happenings. They are frequently gossipy and patently prejudiced, inspiring much less confidence than the austere, impartial writings of authors such as Thucydides. This is one of the main reasons why the Byzantine historians have often been excessively underestimated by modern readers. The bulk of the Byzantine contemporary histories were written by statesmen, high officials, and prelates-men with access

Sources of Byzantine historiography

Vernacular histories to important information. They have to be used critically and cautiously but can be immensely valuable.

Priscus of Panium (c. 450), a member of a Byzantine embassy to Attila's camp, is the best source of information about that terrible king of the Huns and his followers. A century later, the reconquest of Vandal Africa and of Ostrogothic Italy by the emperor Justinian was the main theme of the History of the Wars of Procopius, a leading civilian adviser of Belisarius, the Byzantine commander. Subsequently, Procopius also wrote a Historia arcana (Secret History), containing a horrible indictment of the activities of Justinian and Belisarius. Many of his details about the corruption at court and the oppressive nature of the government may be substantially correct. In the 11th century Michael Psellus, who wrote a history of his own times, was a leading Byzantine scholar and official. for a time even the chief adviser of emperors. His Chronographia is concerned almost entirely with the hannenings at the Byzantine court and is one of the most gossipy and amusing narratives ever written on such a subject. His psychological insight and his lively and subtle style delighted the educated Byzantines, Anna Compena, the daughter and biographer of the emperor Alexius I, greatly admired Psellus. Her own Alexiad is a much less fascinating work. but the recovery of the Byzantine power under her father

Procopius'

histories

provided her with an important theme. The last, increasingly disastrous, centuries of Byzantine history are recorded by a series of scholarly and interesting historians. Nicetas Choniates, a high imperial official, provides a surprisingly balanced eyewitness account of the siege and capture of Constantinople by the forces of the Fourth Crusade (1202-04). George Acropolites, a leading adviser of the Greek emperors of Nicaea, carries the story from 1203 to the recapture of Constantinople by the Byzantines in 1261. The later 13th and 14th centuries are covered by a succession of writers deeply immersed in contemporary theological disputations. Perhaps the most readable of all Byzantine histories is the largely autobiographical work of the leading politician and emperor John VI (reigned 1347 to 1354), written after his deposition during his years of enforced retirement in a monastery. George Sphrantzes, a close friend of the last emperor, Constantine XI, included in his history an eyewitness account of the siege and capture of Constantinople by Mehmed II in 1453. Two of Sphrantzes' contemporaries chose to write primarily about the Turks. Their methods place them among Renaissance historians. Laonicos Chalcocondyles wrote (in about 1464) an account of the rise of the Turkish state. He did so in the manner of Herodotus, with long digressions on various neighbouring nations. A little later, Critobulos of Imbros, in his account of the Turkish conquest of Constantinople, made Mehmed II his chief hero and modelled his history on Thucydides.

The study of what might be called "historical antiquities" was not much cultivated by Byzantine scholars. The most notable exception was the emperor Constantine VII, but only some fragments of his voluminous collections have survived (dating from about 940 to 959). They include a very interesting account of the various peoples with whom the Byzantines had to deal. Such ancient Greek literature as still survives, including that of all the historians, was preserved by the Byzantine scholars. When, around the year 1400, the teaching of Greek was introduced into Italian universities by Byzantine scholars, they brought also their superior techniques of literary scholarship, transforming thereby the study of Latin authors as well as introducing into western Europe the treasures of Greek literature. One result was the emergence of the new Rénaissance historiography.

MUSUM HISTORIOGRAPHY

Muslim historiography appears to have originally developed independently of European influences. Until the 19th century Muslim writers only very seldom consulted Christian sources and almost never noted events in Christian countries. Fortunately, they displayed at times more curiosity about the non-Muslim peoples of Asia. The first and best history of the Mongol conquests in the first half of the 13th century was the work of a Persian, Joveyni. On a visit to Mongolia in 1252-53, he was able to consult the recently compiled, earliest Mongol narrative (Secret History of the Mongols).

The origins of Arabic historiography still remain obscure because of the gap between the legendary traditions of pre-Islamic Arabia before the start of the Muslim era (AD 622) and the sophisticated and fairly exact chronicles that began to appear in the later 8th and 9th centuries. But while the detailed stages of this development still await reconstruction, the main influences shaping the early Muslim historiography are clear enough. As in the case of the ancient Jews, it was created and perpetuated by religion. Muhammad (died 632) regarded himself as a successor to a long series of Jewish and Christian prophets, and he made Islām a religion with a strong sense of history. The Our'an, Islam's holy book, is full of warnings derived

from the lessons of history. Teachings of Muhammad not included in the Qur'an came to be regarded after his death as authoritative tradition left behind by him. All his sayings and actions were therefore carefully treasured and ultimately came to form. in combination with the Our'an, the foundation for the body of Muslim law (Sharifah), common to all Islamic communities. These traditions (Hadith) were transmitted orally for several generations, until they were written down in the 8th and 9th centuries. The resultant collections were only partly historical, as myths and inventions crept into them. The scholars who were engaged in preserving and verifying these traditions were chiefly preoccupied with organizing them into legal and theological systems, and they were frequently hostile to the historians. The earliest authoritative life of Muhammad, written by Ibn Ishaq (died 768), was attacked by a leading exponent of the legal "traditionist" learning. This confirms the independence of the historical scholars from the theological and legal interests. But both groups shared some common materials. and the strict rules evolved by the legal "traditionists" for recording their sources and tracing a continuous chain of authoritative transmitters of the traditions encouraged similar exact habits in the Muslim historians. The resultant histories were often pedantic, full of unrelated facts. and deficient in reflective comment, though there are some astonishing exceptions, such as the writings of Ibn Khaldun (1332-1406). But the better Muslim historians scrupulously quoted their authorities and tried to be truthful. This was particularly true of the "classical" school of historians, who were writing at the centre of the 'Abbasid caliphate in Iraq in the 9th and 10th centuries. At-Tabari (died 923), the most authoritative of them all, wrote his "History of Prophets and Kings" as a supplement to his earlier commentary on the Qur'an, and subsequent Muslim historians were content to follow his reconstruction of the early Islāmic history. The Syrian and Iraqi historiography of the 12th and early 13th centuries is at least as valuable as the Western historical writing of this period, and sometimes it is clearly better.

To orthodox Muslims, the development of the Islāmic community represented a continuous manifestation of God's purpose. Consequently, the recording of the religious progress of the Islâmic society continued to be sacred duty. One of the original features of Muslim historiography is the large amount of attention devoted to the lives of devout men and of scholars. To many Muslim historians, these spiritual and intellectual activities were of much greater importance than the doings of princes and warriors. One of the peculiarities of Muslim historiography was the liking for encyclopaedic dictionaries of famous men. The earliest of these were devoted to the Companions of Muhammad and to the early transmitters of the Muslim traditions. For a thousand years extremely diverse types of biographical collections have continued to appear in the Muslim world. Those devoted to religious scholars attained a particularly wide diffusion. Saladin (Salāh ad-Dīn), who took Jerusalem from the crusaders in 1187 and later opposed the Third Crusade, offered to the Muslim writers the particularly congenial subject of a ruler dominated by a sense of religious duty. A particularly fine example of medieval Muslim historiography is the biography of Saladin by Bahā' ad-Dīn (died 1234), which gives

Origins of Arabic historiogan exceptional insight into Saladin's motives for many of his critical decisions.

The works of Ibn Khaldūn

But the greatest Arab historian and one of the most penetrating thinkers about historiography in any time or place was undoubtedly Ibn Khaldun. The introduction (al-Muqaddimah) to his Kitāb al-'ibar, a universal history (begun in 1375), is, in A.J. Toynbee's judgment (1934), "the greatest work of its kind that has ever yet been created by any mind." Ibn Khaldun had absorbed all the learning accessible to a Muslim of his time. He was a master of religious learning, an outstanding judge, a writer on logic. He turned a subtle and most disciplined mind to historiography in order to explain his personal tragedy. He had served a succession of rulers in Islamic Spain and the Maghrib (Northwest Africa) as a general, a politician, and even once as a chief minister, and his activities had always ended in disaster. In order to explain what had gone wrong, he sought to achieve a correct understanding of the forces that governed the societies known to him. He concluded that political stability had become impossible in his native Maghrib, because over centuries economic prosperity had declined excessively and the forces of lawlessness had become too strong.

As a detailed chronicler of events Ibn Khaldun is not always exact, but, like contemporary historians, he knew how to reconstruct correctly the main trends over several centuries. His ability to formulate general laws that govern the fate of societies and to establish rules for the criticism of sources provided him with an intelligent framework for

the correct reconstruction of past history.

Ibn Khaldin's Mugaddimah has survived in at least a score of manuscripts, but he has had no effective influence on Muslim historiography until recently; after his time, as before, the writing of history continued to be a normal feature of Muslim civilization in the more advanced Islāmic societies. In several countries, notably in parts of India, the first works that deserve the name of history appeared only after the Muslim conquest or the conversion to Islām. After the 12th century Arabic ceased to be the main language of Muslim historiography. Distinguished histories were written in Persian in the 13th century, and subsequently Turkish and other vernaculars came to be used by historians in different parts of the Islamic world. But, in its isolation from non-Muslim influences and its traditional interests, Islāmic historiography underwent no intrinsic change until the 19th century, when it began to be affected by the impact of modern Western civilization.

HISTORIOGRAPHY IN THE EUROPEAN RENAISSANCE

If there is one thing that united the men of the Renaissance, it was the notion of belonging to a new time. Lorenzo Valla, one of the ablest of the early Humanists, in a preliminary draft of his history of King Ferdinand I of Aragon (written in 1445-46), proudly enumerates the modern technical inventions made in recent centuries, and especially near his own day. The sense of the novelty and excellence of their achievements was particularly felt by the men of the Renaissance in connection with their attempts to imitate the works of the ancient Greek and Roman writers and artists. They were not yet claiming that an era of unlimited progress was dawning for mankindsuch concepts belong to the 18th century-but the belief in the progressiveness of their own age soon spurred the best Renaissance scholars and artists into achievements that, in some important respects, surpassed their ancient models. This happened in historiography, and especially in the sciences connected with it. The pace of change must not be exaggerated, however. Despite promising beginnings, historiography as a systematic discipline did not emerge during the Renaissance and, in fact, this development did not occur until the 19th century. The reasons for this delay form one of the main problems in any study of historiography between the years 1400 and 1800

In the early Renaissance one by-product of the newly won sense of modernity was the tendency to regard the millennium between the collapse of the Roman Empire in the West and the 15th century as an era of prolonged decline. The concept of the Middle Ages was thus introduced for this intervening period. Two very important histories written in the first half of the 15th century deliberately concentrate on the medieval centuries. Their authors were leading Italian Humanists. The first to appear was the Historiae Florentini populi ("History of Florence") of Leonardo Bruni, the city's chancellor from 1427 to 1444. The second, the Historiarum ab inclinatione Romanorum imperii decades ("Decades"; mainly devoted to Italy), was written by Flavio Biondo, an important papal official. It covered the period from the sack of Rome by Alaric in AD 410 to the writer's own time. The "invention" of the Middle Ages as a separate historical period remains one of the most enduring legacies of Renaissance historiography. Unlike the medieval historians, the Renaissance Humanists became much more acutely aware of the process of historical change. This was a gradual development. They were trying to understand the ancient writers, whom they were seeking to emulate, and they became increasingly aware of the need to replace these writers in their correct historical setting. When Petrarch (1304-74), the pioneer Italian Humanist, unearthed in 1345 a collection of Cicero's letters, he was shocked to discover that Cicero was not a cloistered scholar of the medieval tradition but a busy politician who wrote his dialogues in moments of banishment from active life. In 1361, in a letter to the Holy Roman emperor Charles IV, Petrarch was able to use his increased familiarity with classical documents to expose a medieval forgery of the Austrian archduke masquerading as a charter of Julius Caesar.

Between about 1440 and his death in 1457. Valla was one of the most influential Humanists, His Elegantiae linguae latinge (1444; "Elegancies of the Latin Language") was a treasury of information about correct Latin usages. For Valla the meaning of words was not natural but conventional and historical, because it was derived from changing custom. Thus a sense of ceaseless historical evolution was planted at the very centre of Humanist preoccupations

with the recovery, the correction, and the interpretation

of ancient texts. In 1440 Valla's patron, King Alfonso of Naples, at war with the papacy, asked Valla to write a treatise against Pope Eugenius IV. Valla obliged by decisively disproving, on both linguistic and historical grounds, the genuineness of the "Donation of Constantine." From the middle of the 8th century, when this document was probably concocted, it had been used by the popes as one of the weightiest justifications for their claims to secular authority in Italy. Its authenticity had been sometimes questioned in the past by some of the acutest minds, such as Bishop Otto of Freising in the 12th century and Marsilius of Padua in the first half of the 14th century, but it required Valla's expert techniques to dispose of the "Donation" forever. The validity of Valla's methods of historical criticism was at once recognized by at least one other leading Humanist, Biondo wrote the relevant portions of his "Decades" of papal and Italian history between 1440 and 1443, while remaining in the service of the very same Eugenius IV who had been the chief object of Valla's attack, Yet Biondo tacitly accepted Valla's conclusions, and he never mentions the "Donation of Constantine," Biondo's critical outlook found still another expression in his summary dismissal of the fabulous history of Geoffrey of Monmouth. In his copy of Geoffrey he entered only a single note: "I have never come across anything so stuffed with lies and frivolities."

Valla's work on the texts of the New Testament proved in the long run to be one of the most influential applications of the new science of historical philology. His aim was to recover, so far as possible, the original Greek version through the use of the oldest extant manuscripts. He defended these researches by pointing out that he was not correcting the Holy Scriptures but merely the Latin Vulgate translation of St. Jerome that had been adopted by the Catholic Church. The revolutionary nature of Valla's historical approach comes out most strikingly in his comment that "none of the words of Christ have come to us, for Christ spoke in Hebrew and never wrote down anything." The corrections assembled by Valla became generally known when, in 1505, Erasmus published them as Annotationes on the New Testament. They provided a model for Erasmus' edition of a Greek New Testament in

Historical philology

Denigration of the Middle Ages

1516, from which stem all the new Protestant versions of the 16th century.

The new historical philology was also soon applied to the study of philosophical and legal texts. In this, the most striking progress was made in the second half of the 15th century by Politian, who lectured at Florence, and by his friend Ermolao Barbaro, who taught at Padua. They were inaugurating the history of ideas and of intellectual movements. In his studies of Aristotelian texts, Barbaro insisted on using only the commentators of antiquity. In his lectures and writings (1489-94). Politian tried to reestablish from internal evidence the correct sequence of Aristotelian treatises, and he traced the gradual liberation of Aristotle's thought from the influence of Plato. The meaning of the terms used by Aristotle was rigorously investigated in the light of the linguistic usage of his Greek contemporaries Politian's ventures into the field of legal texts proved particularly influential. He had at his disposal a very good 6th-century version of the Digest-that is, the section of Justinian's Corpus Juris Civilis (Body of Civil Law) based on the rulings of the Roman jurists. Politian's collation of it with the first printed edition of the Digest (in 1490) formed part of an inquiry into the transmission of the texts of the Roman law during the Middle Ages. Politian's researches stimulated a remarkable school of Humanist jurists, mostly Frenchmen, headed by Guillaume Budé, who published the first historical commentary on the Digest in 1508. In the course of the 16th century, these scholars laid the foundations of a new branch of scholarship, the history of laws and institutions.

The methods of textual criticism used by Politian and his friends were designed to produce definitive editions of classical texts. Politian was aware of the need to establish the correct descent of manuscripts and to disentangle the best textual tradition. In all this he was far ahead of almost all his contemporaries, and he was anticipating the procedures that were systematically adopted for the first time by Karl Lachmann and other German scholars in the 19th century. The historical philology of Politian was a program for the future rather than a dawn of a new era in the editing of classical texts. In contrast to his methods, most of the other Humanist editions of the Latin and Greek classics are very unsatisfactory. This is particularly true of the editions produced between about 1400 and 1550. The reckless emendations of Humanist editors, coupled with the subsequent disappearance of some of the manuscripts used by them, created grave problems for later scholars. Ever since the 17th century the task of the more modern editors has consisted largely in reconstructing, so far as possible, the manuscript versions available before 1400.

Modern historiography was created in the 19th century through a successful combination of the use of narrative sources with every other type of evidence. Some 15thcentury Italian Humanists were already aware of these possibilities. The idea of recovering an entire civilization through a systematic collection of all the relics of the past was not alien to them. Biondo used mainly conventional narrative sources for his "Decades" of Italian history, but his description of the city of Rome in antiquity (Roma instaurata, 1444-46) was based on a novel combination of the narratives of other historians with a wide range of miscellaneous sources. These included topographical guides, public and private documents, studies of surviving buildings, inscriptions, and coins, But in practice most histories and biographies continued to be written in a conventional way, while the revived study of "antiquities" was cultivated in separation from narrative historiography.

Biondo's

description

of ancient Rome

> Imitation of ancient models is the feature most often stressed in the modern descriptions of Humanist histories. This meant that style mattered at least as much as content and that historical truth might be obscured by literary conventions. On the more positive side, there was the renewed insistence on the choice of definite, clearly delimited subjects and on a more coherent arrangement of material. The abler Humanist historians, however, were also making innovations that bring their practice a little nearer to present notions of writing history.

> Several Humanist historians were particularly attracted to the study of the origins of the states about which they

were writing. In the 15th century Bruni did this for Florence, and Biondo and Bernardo Giustiniani for Venice, to mention some notable examples. In the 16th and early 17th centuries, French and English scholars inaugurated a critical study of the origins of their national institutions. Humanist historians prided themselves on their critical ability to overthrow the legends in which various countries had concealed their ignorance of their own origins. The incentives to revise the earliest history were often political Bruni deemed it essential to prove that Florence had not been founded under the tyranny of the Roman emperors but in the time of the free republic. He happened to be right. The Humanist historians were more confident than their ancient predecessors that they could write competent histories of a remote past. In practice they were much less successful in this than they imagined. In dealing with periods before their own time, they usually followed only a restricted number of earlier narratives, though the best of them, such as Bruni and Biondo, displayed in their histories of medieval Italy a novel ingenuity in combining well-chosen sources. Biondo, for example, made effective use of Dante's correspondence.

There was also some modest progress through the better use of documentary sources. This is often far from obvious, because Humanist historians, like their ancient predecessors, do not usually refer to their sources, even when they quote texts verbatim. Hence came Leopold von Ranke's utter misjudgment of the historical value of the Storia d'Italia ("History of Italy") of Francesco Guicciardini, Before Ranke's time it was universally accepted as the most authoritative contemporary history of Italy in the years 1494 to 1534. Ranke, who became one of the pioneers of "scientific" history in Germany, first established his reputation in 1824 by his attack on the reliability of Guicciardini. Ranke argued that the statements of that great Florentine statesman were contradicted by documentary evidence and that his history must have been based on unreliable secondary authorities. The discovery in the 20th century of Guicciardini's private archive proved that his history was scrupulously based on original documents of the highest value.

Guicciardini, in a work that forms the nearest Renaissance parallel to the history of Thucydides, tries to comprehend the succession of tragedies that befell Italy from the start of the French invasions in 1494. This desire to recapture the rational causes of events is one of the most mature features of the best Renaissance historiography.

EARLY MODERN HISTORIOGRAPHY Italian Humanist historians provided models that could be imitated easily in other countries. Almost everywhere in western and central Europe, local writers were encouraged to produce descriptions and histories of their own lands, intent with patriotic pride. In such countries as Spain and Poland, which had only recently achieved their unity, this was a way of commemorating their newly won cohesion. In the 15th century it was the object of a pioneer work on the earliest antiquities of Spain, the Paralipomena Hispaniae, by the Catalan Humanist bishop Joan Margarit i Pau, and of the invaluable Annales seu cronicae incliti regni Poloniae ("History of Poland"), by Jan Długosz, which included an exceptionally precise geographic description of his country. In Germany a sense of national identity could be vindicated by Humanist historians striving to minimize the importance of the continued political division of their land. The Germania of Tacitus was printed in Germany as early as 1473 and started the fashion of using this collective name for that country. Tacitus called the Germans "the indigenous inhabitants. This was used by a leading patriotic Humanist, Conradus Celtis, as a proof that Germany should be free from all foreign domination. Celtis and his other Humanist contemporaries deliberately hunted for manuscripts of medieval German writers to prove that their country, despite its disunity, could have a national history. Some important masterpieces were recovered, including the histories of Otto of Freising. Celtis' pet project of a description of Germany modelled on Biondo's Italia illustrata was carried out in 1530 by Sebastian Münster, and Münster's

Guicciardini's history of Italy

fuller Cosmographia (1544; "Cosmography"), though purporting to describe the known world, devoted one-half of its 818 pages to "the German nation." There was also a spate of histories of Germany, mostly very laborious and unreflective but incorporating the newly rediscovered medieval narratives and even some documentary sources. Greater originality came only in the wake of the Reformation. The same thing happened in France and in England. In both countries patriotic preoccupations were a leading feature of works written by Humanist historians, and the appearance of Protestantism reinforced in a peculiar way the existing nationalist tendencies.

The influence of the Reformation on historiography must first be discussed at a more universal level. As the philosopher Francis Bacon shrewdly observed, Martin Luther had been obliged "to awake all antiquity and to call former times to his succours . . . so that the ancient authors . . . which had a long time slept in libraries, began generally to be read." This was not because Luther would have regarded himself as a historian. But as early as 1519, in his disputation with Johann Eck, he encountered the assertion that the primacy of the pope was of divine origin. In order to disprove this and to demonstrate that they alone represented the true church, the Protestants had to retell in a new way the entire history of Christianity. In a preface to the Vitae Romanorum pontificum ("Lives of the Pontiffs"), published by Robert Barnes in 1535, Luther himself confessed that, although he himself had not originally attacked the papacy with historical arguments,

now it is a wonderful delight to me to find that others are doing the same thing ... from history-and it gives me the greatest joy ... to see ... that history and Scripture entirely coincide in this respect.

The starting point for the Protestant rewriting of Christian history could best be found in St. Augustine's teachings. The true church, the city of God, had always existed, even though at times it seemed to be overshadowed by the enemies of the divine order. Those enemies were not only the pagans and the heretics, as St. Augustine had believed. In more recent times they had included also the upholders of the papal authority and the persecutors of such medieval true Christians as John Wycliffe (died 1384) and John Hus (died 1415). The writings of Eusebius provided the model for chronicling the sufferings of the faithful until the dawn of freedom for the true church in the 16th century. These views about the correct history of Christianity were presented with exceptional cogency in John Calvin's Christianiae religionis institutio (fullest edition 1559; Institutes of the Christian Religion) and were shared by most Protestant scholars. The only obvious disagreements arose when Protestants tried to pinpoint the moment at which the church took the fatal turn away from God's true purpose. While the radical sectarians considered that the papacy had always been corrupt, less extremist Protestants were prepared to accept the earlier popes and to argue that the rot set in at some date between the time of Eusebius (died c. 340) and the 7th century. The choice of precise date might depend on the national traditions of each country. Thus, Bishop Richard Davies, in his preface to the New Testament in Welsh (1567), treats Pope Gregory the Great (died 604) as a special enemy because Gregory's effort to convert the Anglo-Saxons led ultimately to the subjugation of the autonomous British church.

Historians writing in this spirit were incapable of impartiality. But the historical controversies between the Catholics and the Protestants produced from both sides huge compilations. Their authors were determined to prove their respective cases by a stupendous marshalling of authorities and documentary sources. The habit of giving copious references and long, exact quotations, missing from the Humanist historiography, was reintroduced by the religious controversialists. On the Protestant side, the largest work is the Ecclesiastica historia, or the socalled Centuriae Magdeburgenses (13 volumes, 1559-74; "Magdeburg Centuries"), retelling the history of the church down to 1200. The Catholic reply, equally huge and graceless, was produced in 12 volumes by Cardinal Baronius. The chief Protestant critic of this work, the great Greek scholar Isaac Casaubon, was astonished by the Cardinal's ignorance of Greek and Hebrew, his gross mistakes, and his boundless credulity.

The narratives of contemporary events written in the 16th and early 17th centuries by the participants in the religious struggles, though equally partisan, include some works of great historical value and high literary merit. The earliest and best German Protestant narrative, that by Johannes Sleidanus, received a grudging tribute from his great opponent, the Holy Roman emperor Charles V, who remarked that "the rogue has certainly known much . . . ; he has either been in our privy council or our Councilors have been traitors," John Foxe's Book of Martyrs (1563) contains a great mass of exact information about the persecution of reformed religion in England and Wales during the reign of Mary Tudor, and it has influenced many generations of British Protestants. The achievements of Queen Elizabeth I and the Anglican Church's settlement of her reign found an outstanding defender in William Camden, who was encouraged to write by Elizabeth's leading ministers. In his Annales Rerum Anglicarum, et Hibernicarum Regnante Elizabetha ("Annals of Elizabeth's Reign") Camden made excellent use of a mass of official records at his disposal, though his treatment of confidential matters had to be discreet.

Out of a conflict between Venice and the papacy in the first years of the 17th century was born the Istoria del concilio tridentino (1619; History of the Council of Trent. 1676) of Fra Paolo Sarpi. A Catholic friar, but a passionate defender of Venetian autonomy, Sarpi drew a dark picture of worldly papal policies and the unscrupulous machinations of the Jesuits. It is a bitter, prejudiced, but splendidly written and well-informed work, which profoundly influenced the anticlerical historians of the 18th century. All these contemporary narratives, however, have one serious limitation. They deal almost exclusively with political events and with changes in ecclesiastical organization. The Protestant schism is treated as merely a revolt against the abuses of the old church, and the deeper reasons for the alienation of the Protestants from the Catholic faith are never explained. Furthermore, these historians. by attributing the origins of the schism almost exclusively to Luther's sudden conflict with the papacy, obscured the existence in the early 16th century of numerous Catholic reformers, whose sole aim was to transform the Catholic Church from within. This one-sided approach to the history of the Reformation was destined to persist for a long time. Two influential histories published in the years 1683-88, one by a great Catholic prelate, Bishop Jacques-Bénigne Bossuet, and the other by Pierre Jurieu, a leading Protestant, still agreed on the same superficial account of the causes of the Reformation.

The rewriting by the Protestants of universal church history naturally involved a drastic revision of the history of the national churches. In Germany, particularly, the history of the church had become inextricably intermixed with the destinies of the German empire. Their hatred of the papacy made the Lutherans visualize the course of German history with unusual clarity. Nobody before them had attempted to impose on that history a single intelligible pattern of any sort. Theirs was bound to be a prejudiced pattern, a story of gradual national disintegration as the result of the successive defeats of the German emperors by the papacy. Johannes Stumpf's tragic chronicle of the Holy Roman emperor Henry IV (published in 1556) treated his struggles with Pope Gregory VII as the beginning of the empire's tribulations. The whole course of German history was retraced in this fashion under the influence of Luther's chief Humanist collaborator, Philipp Melanchthon, in the so-called Chronicle of Carion, written in its final versions (1572-73) by Melanchthon's son-inlaw, Caspar Peucer.

One of the most novel features of the English Protestant historiography was the reawakening of scholarly interest in the period before the Norman Conquest of England in the 11th century. Matthew Parker, Queen Elizabeth's first archbishop of Canterbury, thought he could discern in the pre-Conquest church elements of true Christianity that were destroyed thereafter and had only been reintroduced by the Protestants. The Anglican Church could be repre-

Foxe's Book of Marturs

Protestant history

Legal

histories

sented as a return to the traditional practices and beliefs of the early English Christians. Thus the replacement of Latin by English in the Protestant church services could be justified by citing the presence in Anglo-Saxon England of Bibles, liturgies, and devotional literature in the Old English language. Parker and his friend Lord Burghley, Elizabeth's most trusted minister, gathered around them a circle of enthusiastic scholars, whose work preserved most of the important Anglo-Saxon texts as well as of some leading post-Conquest chronicles. Parker's own method of editing texts horrifies modern scholars, but some of the antiquarian works published by members of this group were of high quality. Camden's Britannia (first edition 1586, later much enlarged) was a pioneer work on the topography of Roman and early medieval Britain. The edition by Sir Henry Spelman of the records of the pre-Conquest church councils was the first serious attempt to apply to an important type of early sources the best methods of continental scholarship.

The growth of a historical outlook can be traced in the 16th century in many diverse fields of learning. For the first time men were realizing that there was a historical side to every branch of knowledge concerned with human affairs. "I have become aware that law books are the products of history," wrote the French legal historian François Baudouin in 1561. In each branch of study there developed a special historical technique particularly appropriate to it. The most sophisticated scholarship was to be found in the field of classical studies. A group of scholars active in the second half of the 16th century were achieving results much superior to the work of the earlier Renaissance classicists. They combined philological expertise with a determination to reach a really adequate understanding of the ancient Greek and Roman civilizations. A few were Italians, such as Carlo Sigonio, but most of the important works were written in France and in the Protestant centres of Switzerland and Holland. As textual critics these scholars were reacting sharply to the earlier, more haphazard, methods of emending and editing classical authors. They were trying to bring the text of one writer after another to a state of near perfection. Some leading ancient historians, such as Tacitus, benefitted greatly from this treatment (edition of Lipsius in 1575). Though their methods do not quite reach the standards of modern scholarship, they anticipate intelligently many of the procedures more systematically adopted in the 19th century. Isaac Casaubon was the first to point out in his edition of Suetonius (1595) that Einhard's 9th-century life of Charlemagne was modelled on the work of that Roman historian. Casaubon's friend Joseph Scaliger renewed the science of classical chronology (1583) and was the first to reconstruct the original Greek Chronicle of Eusebius lying behind St. Jerome's Latin translation. Sigonio's pioneer work on the rights and duties of Roman citizens (1560) was later much used by Theodor Mommsen, one of the founders in the 19th century of the modern study of Ro-

In the course of the 16th century, non-narrative historical work of the highest originality and complexity was being carried on in the legal faculties of French universities. One important stimulus was provided by the existence in France of different legal systems-the uncodified provincial customs in the north and the written law in the south. The latter ultimately derived from the Roman law, and, in the southern French universities, there arose an eager demand for the introduction of the new Italian methods of interpreting the Roman legal texts. Andrea Alciato, a pioneer in the historical treatment of the Roman law, taught at Bourges from 1529 to 1533, and his pupils founded the

"Romanist" school of French legal historians. Important advances were made in the study both of the Roman law and of the origins of the French legal customs, laying virtually the foundations of a new branch of scholarship, the history of law and institutions. François Baudouin published in 1545 the first historical survey of the development of the Roman legal science. The treatise on the custom of Paris by Charles Dumoulin (published 1539-58) resulted from his advocacy of the codification of the northern French legal customs. It was the first scholarly exposition of a body of customary French law derived from feudal practices, and it amounted to a first comprehensive history of European feudalism. It prompted a series of controversial works by a succession of scholars. The Roman, the Germanic, and the Celtic roots of feudalism all found advocates, and the respective claims of Lombard and Frankish texts to provide the best clues were vigorously canvassed. The complexity of the problems presented by the unravelling of the origins of feudalism dawned on scholars for the first time. The most valuable of these attempts to rediscover the "ancient French constitution" were the researches on "the antiquities of France" of Étienne Pasquier (published 1560-1607), which form a basis for all later study of medieval French institutions

One of the novel features of European civilization in the later 16th and 17th centuries was a secularization of mental interests. Secular learning could now produce ideas more fascinating to intelligent men than theology. History was one of the most popular types of literature sought by a growing reading public. Several treatises on the proper way of writing history appeared in the third quarter of the 16th century. An anthology consisting of 12 such works, including the famous Methodus of the French political philosopher Jean Bodin, was published at Basel in 1576, Nearly 100 years later a "Catalogue of the Most Vendible Books in England" (1657) showed that history books constituted a large proportion of the total works published. It has been estimated that between 1460 and 1700 at least 2,500,000 copies of 17 leading ancient

historians were published in Europe.

The late 16th century and the 17th witnessed the publication of several great collections of historical materials. The men who undertook these gigantic tasks often were antiquarians accumulating miscellaneous records rather than historians, but they were supplying materials for generations of future historians. Some of the most important publications of sources appeared in France and the Netherlands. Pierre Pithou was a pioneer in editing materials for the history of the Frankish period. The collections of André Duchesne are a vast storehouse of chronicles and other sources for the study of medieval French history. Le Nain de Tillemont edited 20 volumes of records devoted to Roman and church history during the first six centuries of the Christian Era, which a century later furnished one of the principal sources for Edward Gibbon's work The History of the Decline and Fall of the Roman Empire. In 1629 a Belgian Jesuit, Jean Bolland, embarked systematically on the editing of records connected with all the saints whose feasts had at any time been celebrated by the church, and this series of publications has been continued to the present day. In the second half of the 17th century, the French Benedictine congregation of Saint-Maur started an immense series of publications commemorating the history of the Benedictines and of other monastic orders. The greatest Maurist scholar, Jean Mabillon, was accepted throughout Europe as the most erudite historian of his time

In spite of its popularity among an expanding reading public and of the large number of learned editions of materials that it inspired, history was not, for most of the 17th century, one of the sciences that made men proud of living in a modern age. Immense progress was taking place in mathematics, astronomy, and physics. History not only did not seem capable of much further development. but scientifically minded men were beginning to dismiss it as a branch of knowledge that would never be worthy of serious respect. Mabillon's De Re Diplomatica (1681) helped to challenge this pessimistic view, but a further century elapsed before history began to be accepted as an

authoritative discipline. One major obstacle to the progress of historiography was the hostility of rulers to publications that did not favour their governments. The growth of an influential reading public made rulers increasingly suspicious of historical writings; for example, the censorship exercised by Cosimo I de' Medici, ruler of Florence from 1537 to 1574, precipitated the decline of Florentine historiography. Comparisons with the past also could be invidious. In 1599 Elizabeth I of England censured an author for describing

Hostility of rulers toward historiography

the deposition of one of her predecessors, Richard II, 200 years earlier. Fear of possible trouble made highly intelligent scholars into one-sided historians. The great jurist Hugo Grotius avoided in his history of the wars of the Dutch against Spain discussions of the religious aspects. Samuel Pufendorf, the historian of the Swedish conquests, carefully left out the internal developments in

17th-century Sweden. The scholars who in that century were responsible for the great advances in the mathematical sciences were convinced that their achievements would ultimately give mankind a novel mastery over its natural environment. This is particularly true of Francis Bacon and of René Descartes. Their optimism was laying the foundations for a belief in a possibility of continuous progress without which the purposeful and assured historiography of the 19th century would be inconceivable. But the attitude toward history of most of the leading thinkers and scientists of the 17th century was not helpful to its immediate development. Bacon, who wrote a readable and rationally argued biography of King Henry VII of England, attached no importance to accuracy; for example, he antedated Henry's death by a whole year and could not be bothered to undertake any detailed research. Gottfried Wilhelm Leibniz was a great mathematician, but his attempts to apply science to historiography led to mechanistic constructions from which real human beings were largely missing. Numerous influential thinkers were decidedly hostile to history. Descartes, the most eminent of the anti-historical scientists, was not simply disgusted by the unsystematic and imprecise methods of the historians of his time but also doubted whether, strictly speaking, history could be regarded as a branch of knowledge at all. But it is important to remember that much of the 17th-century criticism of history was an attitude of men who simply had other priorities and were concerned to attack doctrines that, for one reason or another, historians seemed to support. In the late 17th century the most successful defenders of history were the members of certain particularly scholarly Catholic orders. Catholicism rested its authority on tradition to a much greater extent than did its Protestant opponents. For Catholic scholars such as Mabillon, the defense of history became really a defense of their religion. They were trying to show that historians were capable of discovering scientifically demonstrable truths. The decisive publication was Mabillon's De Re Diplomatica of 1681. A member of a rival order, the Jesuit Daniel van Panebroch. had challenged (in 1675) the authenticity of the oldest charters of two French Benedictine monasteries, Saint-Denis and Corbie. Mabillon applied his powerful critical intelligence not only to vindicating these documents but also to formulating the general rules that must be used to prove the authenticity of medieval records. He illustrated his rules by admirable examples and stated his conclusions with a candor and a common sense that convinced most readers. Mabillon's survey of the tests that must be applied by scholars covered the writing materials, the scripts (thus founding the science of medieval Latin paleography), the seals and other devices of authentication, the official formulas, and the vocabulary used at different periods. Above all, he stressed that the authenticity of a document usually rested not just on isolated details but on consistent correctness of all its features.

Mabillon was not just a "historical scientist." He had a passionate interest in the past and a vivid historical imagination. He displayed these qualities abundantly in his last and most important work, the Annales Ordinis s. Benedicti ("Annals of the Benedictine Order," to 1066). In the Traité des études monastiques, (1691; "Manual of Monastic Studies"), he defended the importance of scholarly work as the principal activity of an elite of Benedictine monks. But it would be an anachronism to regard Mabillon and his chief associates as fully comparable to modern historians. They were constrained by the limitations of their time and of their special position as monks. For example, Bernard de Montfaucon, Mabillon's most important successor, is the creator of the science of medieval Greek paleography. But he shares with most of his contemporaries a complete inability to treat the Old Testament as a historical source.

Historical and antiquarian studies developed in 17thcentury England in several very distinctive ways. The political struggles and religious controversies of that period made some issues of older English history into matters of immediate practical importance. The other distinctive feature was the delay in the absorption of European continental learning, so that the great progress made in the study of feudal origins in the 16th century began to affect the thinking of English scholars only by about 1625. But there persisted also elements of continuity growing out of earlier Tudor scholarship. The interest in the Anglo-Saxon church and civilization continued to stimulate important editions of records throughout the 17th and early 18th centuries, including, especially, Sir Henry Spelman's edition of the records of church councils and Sir William Dugdale's Monasticon Anglicanum (1655-73), which is still valuable today. Another element of continuity with the Tudor period was the perennial interest of the English notables in heraldry, genealogy, and the antiquities of their native regions. Dugdale's Antiquities of Warwickshire (1656) set a pattern and a standard for county histories.

Students of English law and institutions, lacking the stimulus that was provided for French lawyers by the diversity of legal systems and by the notable progress in the study of Roman law in that country, continued to ascribe immemorial origins to the common law of England and to approach the development of English institutions in a completely unhistorical spirit. Among the parliamentary opposition to the Stuarts, these attitudes were part of a belief in the "ancient constitution," which these sovereigns were supposed to be defying. Spelman, who was a devout Anglican and a royalist, though a moderate one. was perhaps the first major scholar to break away from this myth. Under the influence of continental publications and correspondents, he accepted that feudal tenure had been introduced into England after the Norman Conquest and that all the English institutions after 1066 must be redefined in feudal terms. But his discoveries were hidden in a dictionary of antiquarian words (Archaeologus, vol. 1, 1626; 2 vol. 1664) and made very little impact until some 50 years had elapsed. Spelman had an acute sense of historical development, and he sadly castigated his countrymen for their lack of it in their attitude to parliamentary origins:

when States are departed from their original Constitution and that original by tract of time worn out of memory; the succeeding Ages viewing what is past by the present, conceive the former to have been like to that they live in. (Of Parliaments, written in about 1640, published 1698.)

His greatest contribution to English history was to grasp that parliaments had developed out of feudal assemblies convoked by the Norman kings and that the Commons were introduced into parliaments subsequently, as a result of the growing prosperity of the lesser landholders. These views first became generally accessible in the 1664 edition of Spelman's dictionary. They were adopted by Robert Brady (in 1681) and by other partisans of the Stuarts and expanded into a Royalist statement of the English past. Violently polemical though this view was, it did at least lay to rest the myth of the immemorial "ancient constitution. The Whig triumph at the Glorious Revolution of 1688, which established a doctrine that the king ruled by parliamentary consent, led to the neglect of these discoveries for much of the 18th century. This was the common fate of much of the research of 17th-century antiquarians, who were very much ahead of their time and were writing for a limited audience. John Aubrey's pioneer description in the 1670s of the prehistoric sites of Avebury and Stonehenge had to wait two centuries for full publication. Even the best of these antiquarians, such as Spelman and Dugdale, were less critical in their handling of the original sources than Mabillon was. Higher standards were reached by a few of their successors in the early 18th century, especially by Thomas Madox, whose Formulare Anglicanum (1702) imitated Mabillon by attempting a systematic introduction to English medieval documents. But this did not save Madox from prolonged oblivion. After about 1730 this English tradition of antiquarian scholarship largely ended and remained unfashionable for most of the 18th century. Achievement of Sir Henry Spelman

The rules of diplomatics

The impulse given to historiography by the Italian Humanists and the religious controversialists had largely spent itself by about 1715. Men knew again how to write rationally satisfying contemporary histories, though often it needed courage to do so. Much less progress had been achieved in reconstructing the more distant past Impressive collections of historical materials were being accumulated, but most scholars still lacked the capacity to rethink the thoughts of past generations and thus really to understand them. Mabillon could write with insight about early Benedictine history, as he possessed both sympathy with the subject and adequate technical expertise, but he was exceptional. Spelman had grasped that a particular society would be molded in a peculiar way by its institutions. He could not reconstruct and explain the gradual changes from one set of institutions to a later one, but he was aware of the problem.

Judged by the quality of its historical output, the 18th century was not, on the whole, an age of successful historians, but some of the defects of earlier historiography were beginning to be overcome. There were also losses, however, for some of the achievements of the preceding period were in danger of being forgotten. In the leading countries of western Europe, religious controversies were becoming less important, and a massive secularization of interests took place, which affected even ecclesiastical scholars. The French Maurists continued until 1790 to publish imposing historical collections, but their choice of subjects was determined much less than in the time of Mabillon by religious priorities. The greatest Italian ecclesiastical disciple of Mabillon was Ludovico Antonio Muratori, a social reformer. In a divided country like Italy, the best way of expressing his patriotism lay in reminding Italians of the former greatness of their country. Muratori spent much of his long life on his editions of Italian medieval sources.

The nationalist motivation shown by Muratori was peculiar to Italy and also to parts of Germany, another divided country. Elsewhere in Europe there was a danger that, as men lost interest in constitutional or religious disputes that might be settled by appeals to the past, they might turn away altogether from history or at least neglect long stretches of it. This did happen to some extent in the 18th century. Some of the radical French reformers, such as Jean Le Rond d'Alembert, one of the main inspirers in the 1750s of the French Encyclopédie, wanted to jettison completely much of the past. The Marquis de Condorcet, an early prophet of the doctrine of endless progress of mankind and a pioneer historian of European civilization, was a prominent member of a French parliamentary commission that in 1792-93 deliberately destroyed some of the royal records as comprising relics of past servitude.

During much of the 18th century it was safer and easier to publish controversial works of history than it had been in the past. The point is important, as without this greater freedom, the peculiarly radical "philosophical" historiography, so typical of that century, would have been inconceivable. In Italy such writing was still dangerous. Pietro Giannone, the author of an anticlerical history of Naples (1723), was tracked down by the Inquisition and spent 12 years in prison, where he died in 1748. Even the great Muratori, who tried to help Giannone, came into danger of having some of his works banned and had to be rescued by the personal intervention of Pope Benedict XIV. In France, Louis XIV in 1714 imprisoned Nicolas Fréret in the Bastille for alleging (correctly) that the Franks were originally a confederacy of German tribes and not descendants of more illustrious ancestors. Under the successors of Louis, nothing quite so absurd happened again, but critics of the government or the church were often in trouble. Great Britain, Holland, Switzerland, and parts of Germany, on the other hand, provided safe oases where most things could be published. It was no accident that the most independent and historically minded group of German professors should have congregated at the University of Göttingen, founded in 1734, in the Hanoverian territory of the kings of Great Britain.

raphy

sophical"

historiog-

A real renewal of historiography in the 18th century could only come if fresh reasons were discovered for making it again worthwhile. Nationalism could supply one such motive; but this only became decisively influential in the 19th century. An alternative was a historiography inspired by the progress in the natural sciences and based on formulating the general rules governing the development of human societies. The chief features of this 'new' historiography were a sense of the unity of all human history, including an interest in the continents outside Europe; a capacity for bold generalizations about the salient features of particular periods or societies; and a preference for topies connected with the progress of human civilization. Condorcet's historical sketch of the progress of the human mind, written in 1794, subdivided all known history into nine periods, each starting with some great invention or with geographical discoveries.

The shortcomings of this "rationalistic" historiography have been rehearsed often enough. For many of its writers it was primarily a weapon of propaganda against their enemies in church and state. Their redeeming virtue was the fearlessly critical attitude to all existing authorities, however august or sacred. The vast scale of their generalizations often precluded any detailed research. This was particularly true of the attempts to write histories of civilization, as the existing collections of printed materials did not cater for such interests, while systematic research in archives was seldom possible in the 18th century. In preparing his pioneer essay on the history of civilization. covering the millennium from the Carolingians to Louis XIV (Essai sur les moeurs et l'esprit des nations, 1745-53), the French author Voltaire had to collect bits and pieces from most diverse sources.

One of the most valuable achievements of the thinkers of the 18th century was their capacity to study particular societies as coherent units and to formulate the theory that the various aspects of each society's life were closely interrelated. This was not an entirely novel idea, but it first became commonly accepted during this period. Nor were all its adherents anticlericals. Giambattista Vico, a Neapolitan Catholic, was ahead of his contemporaries in his particularly subtle sense of the complex influences by which one phase of society gives place to another. In his reconstruction of these transitions during the early stages of Roman history, he makes no clear lines between periods. His countryman Giannone explains in his autobiography that he had studied Roman law not for its own sake but in order to understand the changes in the society of the Roman Empire. The French philosopher Montesquieu, who owed much to Giannone, was not really a historian. but he displays an acute sense of historical realities. His De l'esprit des lois (1748: The Spirit of Laws), more than any other book, accustomed his contemporaries to ponder the complex factors that shaped each society. It inspired Gibbon's definition of the kind of history he wanted to write. It was to be a "history related to and explained by the social institutions in which it is contained.'

This ideal was realized in Gibbon's History of the Decline and Fall of the Roman Empire (1776-88), one of the masterpieces of "philosophical" historiography. Gibbon was preoccupied above all with the problem of human progress. The belief that continuous progress was possible for mankind had been publicly formulated in the mid-18th century by Anne-Robert-Jacques Turgot in France and by Adam Smith in Scotland, independently, it seems, of each other. Gibbon had read works and known scholars influenced by both these thinkers. A belief in continuous progress would confer a new purposefulness on the study of the entire course of human history and could justify a lengthy account of what otherwise might have seemed very obscure stretches of the past. Such a justification was to inspire most of the historiography of the 19th century. But the problem of progress had a special urgency for Gibbon's generation, which worried at the thought that their own enlightened civilization might also subsequently collapse. By unravelling the causes of the decline of the Roman Empire, Gibbon was determined to show that the Europe of his own day had attained a much superior degree of development and was immune from the fate of the ancient world.

In the 18th century, historiography was still only very

Gibbon's Decline and Fall rarely connected with the universities; and thus, except in such isolated places as Göttingen in Germany, no continuous schools of history could develop. Some of the most important achievements of the 18th-century historians meant much less to their contemporaries than to their successors in the 19th century. Gibbon was a pioneer in utilizing in a "rationalist" history the vast materials accumulated by generations of erudite antiquarians, but he had no immediate followers. The German archaeologist Johann Joachim Winckelmann tried to revive the true understanding of Greek sculpture and to make the history of art into something more than just the biographies of artists, but his work bore little fruit until the next century. The saddest fate was that of Vico's work. He was hardly ever read before the 19th century, when he at last influenced Barthold Georg Niebuhr and the rest of the German historical school, while Jules Michelet's rediscovery of Vico in 1824 started a new era in French writing on the Middle Ages.

HISTORIOGRAPHY IN THE 19TH AND 20TH CENTURIES

From the early 19th century, historiography began to develop in a radically different way. The decisive changes occurred among the German historians, largely through a reaction to the French Revolution and to a temporary subjugation of their country by Napoleon. Organized teaching of history in schools and universities became a matter of national importance, first in Prussia and then in other parts of Germany. As universal education spread to most European countries in the course of the 19th century, history was accepted everywhere as a necessary subject in schools. For the first time the bulk of historical writing came to be done by professional historians, for whom it became a condition of securing academic appointments or of consolidating their standings as university teachers. Historiography eventually became a continuously cooperative venture, where the achievements of past historians could be used systematically by their successors. But the growth of specialization and the bewildering number of types of works that came to be published constituted a new danger. In the past, important discoveries were frequently lost through lack of interest. But, by the second half of the 20th century, discoveries were in danger of being simply overlooked amid the flood of publications.

Another great change lay in the growth of intellectual freedom. Free expression of independent or unorthodox ideas had become dangerous during the French Revolution and under Napoleon, both in the territories controlled by the French and, by way of frightened reaction, in the lands of their unconquered opponents. After 1815 conditions for freer historiography improved gradually in much of Europe. Charles Darwin's Origin of Species (1859), which put forth a theory of evolution at first unacceptable to church authorities, probably could not have been published with the same impunity any earlier,

One feature of the growing tolerance of governments toward historiography was the gradual creation of public archives, such as the British Public Record Office in London, created in 1838, and the freer opening of the collections already in existence. Even the papacy accepted these changes, and Pope Leo XIII opened up the papal archive in 1883 as part of a deliberate new policy of encouraging historical study of Catholicism. For the first time historiography came to be based largely on unpublished records, and scholars were tempted into excessive reliance on original documents while unduly neglecting the older types of narrative sources.

In the 20th century some grievous threats to the persistence of free scholarship recurred, and historiography suffered with other branches of humane studies. The establishment of a Communist regime in Russia led, at first, to the rejection of most pre-1917 history as a fit subject for schools and universities. This decision was reversed in the 1930s, and from 1945 Communist countries were encouraging a form of historiography especially concerned with economic history and the class struggles of the past. There was also an enthusiastic interest in the material remains of past ages, leading to an impressive development of archaeology, particularly in Poland. The rise of dictatorships in Italy and Germany had disastrous effects on historiography in those countries, and recovery after World War II was only gradual.

Judged merely by the number of "practicing" historians and of their publications, historiography seemed in a very flourishing state in the 1970s. Its European traditions had spread to all the other continents and were largely accepted in all non-Communist countries.

The Introduction aux études historiques (Introduction to the Study of History) of Charles V. Langlois and Charles Seignobos (1898), supplemented by critical comments of another outstanding French historian, Ferdinand Lot (in Le Moyen Age, 1898), provides an excellent starting point for the discussion of modern historical methods. History is an autonomous branch of learning, and some of its methods may be unique. Historians should not try to formulate general laws; their branch of learning merely "aims at explaining reality." Langlois and Seignobos particularly stress that history is not a science of observation but a science of reasoning how to extract from imperfect documentary or narrative records some glimpses of what actually happened.

A historian has to subject his sources to a whole series of preliminary investigations. First comes "external criticism," aimed at determining whether the sources are appropriate and adequate for the particular task in hand. The provenance, date, and authenticity of each source must be established by using the techniques of diplomatic, the detailed study and assessment of documents, and of paleography, the study of ancient handwriting, and of other auxiliary sciences that were elaborated after the 17th century. In France a special institution for teaching some of these techniques, the École des Chartes, was created in 1821. The first specialized seminar for instruction in these subjects was established in 1854 at Vienna by Theodor von Sickel, one of the greatest medievalists of the 19th century, and it was gradually imitated by leading German universities. One of the most important critical refinements introduced in the course of the 19th century was the improved handling of narrative sources brought about by seeking to discover the literary sources that lay behind them. Leopold von Ranke, one of the foremost German historians, who began his career as a teacher of classics, was gradually attracted to history through a desire to understand better the sources of the Greek and Latin authors whom he was expounding. In the later decades of the 19th century, such a quest became a normal feature of historical scholarship.

Once a historian has decided, through the application of "external criticism," on the sources that are relevant to his purpose, he must next, by "internal criticism," make sure that he fully understands what he has selected. German classical philologists were the first to bring these latter investigations to a high degree of perfection. Karl Lachmann, an editor of the Latin poets, is justly regarded as the creator of modern textual criticism in its most rigorous forms, and historians gradually adopted similar methods. The language of the sources must be understood, corruptions in the text must be eliminated, and the historian must, as accurately as possible, penetrate the minds of the authors with whom he is dealing.

All these critical operations on the sources are merely preliminaries, and the work of the historian proper only starts when he attempts a synthesis of his materials. F. Lot stresses that in this qualities other than the erudite skills come into play. There must be sympathy with the subjects under study, for without it there can be no imaginative insight into the past. Ideally, a historian must display capacities akin to those of a poet or an artist.

Such a quality was, by and large, lacking in the work of the historians of the Enlightenment, who had been unable to achieve imaginative insight into civilizations very different from their own. The greatest shortcoming of Gibbon was his temperamental inability to appreciate religion. The new historiography of the 19th century was created chiefly by Germans, who, through a reaction to the ungodly and cosmopolitan Enlightenment, were endowed to excess with a passion for extolling the unique nature of their fatherland and for tracing the roots of this The historian's task

Growth of specializa-

of Henry

Baxter

uniqueness through the whole course of German history. These developments in German historiography can be traced back to some strands of German thought in the 18th century, especially to some features of the writings of Johann Gottfried von Herder. He denied that the purpose of history was to provide a bird's-eye view of the progress of the human mind. It was, rather, to reconstruct history as it had been, which means that all countries and periods are equally deserving of study. This view anticipated Ranke's oft-quoted aim to describe what has actually happened and his conviction that the description of all human history displays the workings of God's providence. The disasters inflicted upon Germany by Napoleon brought forth a patriotic school of historians whose urgent task it became to propagate these views as a means of restoring German independence. The centre of this movement was in Prussia, at the newly founded University of Berlin (1809). Wilhelm von Humboldt, its effective founder, believed that the task of the historian lay in discovering the ideas behind the facts. The concepts that had special validity for him were ideas of religion and of a national state. The German historical school prided itself on the scientific precision of its methods, on its determination to get all the details right, and on the scrupulous quotation of sources. This display of exact scholarship represented a great gain for historical sciences, but its chief purpose was to convince the reader. Yet these German historians were fundamentally inspired by a prejudiced, arbitrary set of assumptions. It is particularly difficult to detect Ranke's hidden bias, as he made a parade of refusing to pass judgments on the past. His preference for the study of foreign relations between states and his treatment of states as natural entities with a right to fulfill their individual destinies justified the successes of Prussia. The defeat in 1848 of the German aspirations to national unity inspired his pupil Wilhelm von Giesebrecht to write the history of the medieval German empire to remind his countrymen of their past glories. When German unification was achieved in 1871. Giesebrecht doubted whether there was any need to bring out any further volumes of his great work. But many German historians, having contributed mightily to the unification of Germany, continued to describe complacently the triumphs of the Bismarckian state. This was one of the purposes of the school of historical economists led by Gustav von Schmoller. There were some dissenting voices. Theodor Mommsen, the greatest historian of antiquity produced by the 19th century, deplored the tendency of his countrymen to worship state power. Friedrich Meinecke, a leading German historian of political ideas, who until 1914 accepted the ordinary nationalistic assumptions of his countrymen, gradually entirely changed his views and, after the defeat of Germany in two world wars, pleaded in his Deutsche Katastrophe (1946; The German Catastrophe) for a historiography concerned with the higher values of general civilization. Among the German historians, particularly striking progress was achieved in medieval studies. Meanwhile, attempts at imaginative reconstructions of the past were being made in other countries of western Europe. Jules Michelet wrote in 1833-43 the first history of medieval France based on the French national archives, of which he was at that time keeper. Macaulay's History of England (1848-61), covering chiefly the years 1685-1702, represented again a remarkable though prejudiced attempt to relive the past.

to relive the past. German scholarly techniques and the methods of German historical teaching spread to other countries in the course of the later 19th centure, though it is important to note that until 1914 a significant proportion of leading historians from states outside Germany spent some time in that country. This is particularly true of some of the greatest Russian scholars, such as M.I. Rostovizeff, one of the most important modern historians of antiquity. In England, William Stubbs, though self-taught, applied the results of German scholarship to the reconstruction of English medieval history. Gabriel Monod, who had studied in Germany, was prominent in introducing more scientific techniques into medieval Firstor, historiography, and he founded in 1876 the Revue Historique as the main organ of French historical scholarship. A succession of

American students went to Germany, and some, on their return home, reorganized historical studies. Measured by the sheer bulk of publications, the amount of American history written since the 18th century is probably greater than that of any other modern nation. But apart from editions of sources, very few works on American history published before about 1900 are of much practical use today. The most influential pioneer in organizing scientific historiography was Herbert Baxter Adams, who between 1876 and his death in 1901 made the Johns Hopkins University at Baltimore into the foremost American centre of historical studies. He was also one of the founders of the American Historical Association in 1884 and played a large part in successfully launching the American Historical Review in 1895 as the main organ of historical scholarship Some of Adams' pupils became great scholars in various fields of general history. Charles Homer Haskins' works on Norman institutions and on science and culture in the 12th and 13th centuries made him one of the foremost medievalists of the 20th century. But a movement for creating a purely American history was launched in 1893 by another of Adams' pupils, Frederick Jackson Turner, who inaugurated a "progressive" school of historians through his conviction that the fundamental fact of American history down to 1890 was the settlement of a continent. In Turner's eyes the main theme of American history in the 19th century was the conflict between the patrician and capitalist groups of the Eastern Seaboard and the needs of the new settlers in the Middle West. Charles A. Beard inaugurated by his Economic Interpretation of the American Constitution (1913) an attempt to rewrite the entire history of the U.S. in terms of conflicts between different groups of economic interests. The weakness of this type of historiography was that it encouraged an excessive parochialism. After 1945 the "progressive" historians came under fire both from more conservative scholars who preferred to stress elements of common tradition and purpose in American development and from the historians of the "new left." In the 1960s and 1970s the close connection between writings on American history and the active political life was infusing great variety and vitality into its historiography, though making it perhaps too susceptible to rapidly changing external pressures.

(E.B.Fr./Ed.)

Methodology of historiography

The methodology of history does not differ in broadest outline from that of other disciplines in its regard for existing knowledge, its search for new and relevant data, and its creation of hypotheses. It is the same for all historical writing, success depending on skill and experience; and division of the past on temporal or topical lines merely reflects the human limitations of historians. Although historical methodology has four facets, the more skilled the historian the less he gives them conscious consideration; and any historian is likely to be concerned with two or more concurrently. The four facets are heuristic, knowledge of current interpretation, research, and writing.

The first two may be briefly considered. Heuristic has been adopted as a convenient term for the technique of investigation that can be acquired solely by practice and experience. In the case of the historian it embraces such things as knowledge of manuscript collections, methods of card indexing and classifying material, and knowledge of bibliography. It underlies other aspects of methodology as in knowledge of the capabilities of historians working in the same and similar fields or in the power of dealing expeditiously with documentary material. The necessity for knowledge of current interpretation is based on the working principle that inquiry proceeds from the known to the unknown; and the historian has to be well acquainted with existing work in his own field, in contiguous historical fields and in allied disciplines. The work in each case consists of both "fact" and interpretation, and the amount the historian accepts will vary. In his own field he will normally not accept facts, and certainly not current interpretation, on trust; in contiguous historical fields he will accept facts and current interpretation by experts in those

fields, but qualified by heuristic and his general historical knowledge; in allied disciplines, such as anthropology, economics, geography, natural science, philology, psychology, sociology, he must unless there is strong evidence to the contrary presume the technical skill and intellectual honesty of scholars in those fields. There is, of course, no reason why a historian cannot be reasonably versed in one or more of these and other disciplines, and should the nature of his enquiry demand it he must be.

Historical research is the term applied to the work necessary for the establishing of occurrences, happenings, or events in the field with which the historian is concerned. Knowledge of these is entirely dependent on the transmission of information from those living at the time, and this information forms what is known as the source material for the particular period or topic. The occurrences themselves can never be experienced by the historian, and what he has at his disposal are either accounts of occurrences as seen by contemporaries or something, be it verbal, written, or material, that is the end product of an occurrence. These accounts or end products have been variously termed relics, tracks, or traces of the occurrences that gave rise to them; and from them the historian can, with varying degrees of certainty, deduce the occurrences. The traces are thus the "facts" of history, the actual occurrences deductions from the facts; and historical research is concerned with the discovery of relevant traces and with deduction from those traces insofar as this will aid the search for further relevant traces.

SOURCE MATERIAL

Source material falls into three groups which can be differentiated as written, material, and traditional. Written source material has two subdivisions, literary, sometimes called subjective, and official. The first consists of events as seen through the eyes of an individual and therefore as interpreted by him, normally entailing selection of occurrences or attribution of motive. The second subdivision, the official, consists of records produced in transacting business at any level from individual to international. The information given is basically in statement form, impersonal, and containing only the most superficial suggestions of causation and motivation. In practice the boundary between literary and official sources is blurred and a document may contain elements of both. The second main division, material source material, consists of objects that have resulted from activities of human beings in the past. The third group, traditional source material, covers what is handed on verbally or as practices, although later generations may commit such things to writing. Obvious examples are archaic forms, traditional practices, nursery rhymes, folklore, and place names. Comparison with parallel source material and knowledge of current interpretation will normally show the historian whether his particular source can be presumed true, partially true, or faked. If true or partially true allowance has to be made for the subjective element in literary and some traditional sources and for the difficulty of reconstructing the events themselves from the traces surviving in official, material, or other traditional sources.

The classification of source material is essentially pragmatic, based on the differing techniques required in handling sources of the different groups: an inscribed tombstone, for example, can be either a written or a material source depending on whether the historian's concern is with the content of the inscription or with the stone. Specialized training in what are sometimes known as ancillary disciplines may, depending on the nature of his investigation, be necessary for the historian. The most important of these are archaeology, bibliography, chronology, diplomatics, epigraphy, genealogy, paleography, sigillography, and textual criticism. It need hardly be said that the historian must have competence in the languages used in his source material. Many historians give part of their time to the editing of source material. This is not historical writing but is of use to other historians in the same field. The collection of facts as an end in itself is, however, antiquarianism not history, and the essential end product of historical investigation is the historian's own writing.

USING SOURCE MATERIAL

The question of what history is belongs to the philosophy rather than the methodology of history. The word history itself is used ambiguously to describe both the past and what is written about the past; but it is this second meaning that is relevant to the working definition that history is the past experience of society. For what reasons society may wish to utilize its past experience is not the concern of the historian, whose task is to make available to society that past experience and to record it for future reference. An individual utilizing his own past experience has to recall the significant elements of that experience with accuracy and establish their causal and chronological relationships. The historian behaves similarly concerning the past experiences of society; but the reconstruction of events from traces, the selection of those relevant to his task, and the establishing of relationships allow a varying freedom of choice by the historian, which thus introduces the subjective element of the historian's personality. This cannot be eliminated from historical writing, and the historian's aim is to make the margin of intellectual error as small as possible. The handling of source material demands only care and technical competence, and it is mainly in the construction of hypotheses and in the establishing of relationships that this intellectual error can enter. A check is provided by the opinions of other historians working in the same field. His work will, if accepted, become part of current interpretation, sometimes described as accepted history but, as with all current interpretation, subject to revision by himself or others.

Historical methodology became more clearly formulated during the 19th and 20th centuries, but there have been historians at times long past whose work can be judged by present-day standards. There are, however, certain important differences between present methodology and the general run of past methodology. Much medieval writing, for example, bows to precedent in literary sources and in current interpretation, and uncritical acceptance of an earlier writer's work can occur century after century. The comparative neglect of official sources by the majority of European historians before the 19th century gave no corrective to literary sources. The greatest impediment to the development of modern methodology lay, however, in the varying concepts of history, some of which survive today. The concept of history as a form of literature made it a type of imaginative art on which judgment was passed on grounds of elegance rather than accuracy. Closely allied with this is the "ethical" concept of history whereby historical writing became a series of value judgments on individuals and actions. The converse of this was the impossible "objective" or "scientific" history of the later 19th century, though it did popularize the concept of research and developed the ancillary disciplines. The use of history for propaganda purposes is in its crudest form virtually a branch of fiction and thus independent of research; in its more subtle forms it can encourage accuracy in research, but it will encourage also the suppression of inconvenient traces and intellectual dishonesty in the elucidation of relationships. In this it indicates one of the main impediments to methodological and historical development: the holding by the historian of a priori theories or laws to which all events and relationships must conform, whether it be the theory of divine intervention in human affairs favoured in medieval times or the Marxist theory current over much of the modern world.

ARCHAEOLOGY

The word archaeology comes from the Greek archaia ("ancient things"), and logos ("theory" or "science"). It has been used in varying ways, but from the late 18th century onward has come to mean that branch of learning that studies the material remains of man's past. This includes man's artifacts, from the very earliest stone tools, of perhaps 2,000,000 years ago, to the man-made objects that are buried or thrown away at the present day: everything made by human beings-from simple tools to complex

machines, from the earliest houses and temples and tombs to palaces, cathedrals, and pyramids.

The archaeologist is first a descriptive worker: he has to describe, classify, and analyze the artifacts he studies. An adequate and objective taxonomy is the basis of all archaeology, and many good archaeologists spend their lives in this activity of description and classification. But the main aim of the archaeologist is to place the material remains in historical contexts, to supplement what may be known from written sources, and, thus, to increase understanding of the past. Ultimately, then, the archaeologist is a historian: his aim is the interpretive description of the past of man.

Increasingly, many scientific techniques are used by the archaeologist, and he uses the scientific expertise of many persons who are not archaeologists in his work. The artifacts he studies must often be studied in their environmental contexts; and botanists, zoologists, soil scientists, and geologists may be brought in to identify and describe plants, animals, soils, and rocks. Radioactive carbon dating, which has revolutionized much of archaeological chronology, is a by-product of research in atomic physics. But although archaeology uses extensively the methods techniques, and results of the physical and biological sciences, it is not a natural science; some consider it a discipline that is half science and half humanity. Perhaps it is more accurate to say that the archaeologist is first a craftsman, practicing many specialized crafts (of which excavation is the most familiar to the general public), and then a historian.

The nature

of archae-

ological

work

The justification for this work is the justification of all historical scholarship: to enrich the present by knowledge of the experiences and achievements of our predecessors. Because it concerns things people have made, the most direct findings of archaeology bear on the history of art and technology; but by inference it also yields information about the society, religion, and economy of the people who created the artifacts. Also, it may bring to light and interpret previously unknown written documents, providing even more certain evidence about the past.

But no one archaeologist can cover the whole range of man's history, and there are many branches of archaeology divided by geographical areas (such as classical archaeology, the archaeology of ancient Greece and Rome, or Egyptology, the archaeology of ancient Egypt) or by periods (such as medieval archaeology and industrial archaeology). Writing began 5,000 years ago in Mesopotamia and Egypt; its beginnings were somewhat later in India and China, and later still in Europe. The aspect of archaeology that deals with the past of man before he learned to write has, since the middle of the 19th century, been referred to as prehistoric archaeology, or prehistory. In prehistory the archaeologist is paramount, for here the only sources are material and environmental.

The scope of this article is to describe briefly how archaeology came into existence as a learned discipline; how the archaeologist works in the field, museum, laboratory, and study; and how he assesses and interprets his evidence and transmutes it into history.

History of archaeology. No doubt there have always been people who were interested in the material remains of the past, but archaeology as a discipline has its earliest origins in 15th- and 16th-century Europe, when the Renaissance Humanists looked back upon the glories of Greece and Rome. Popes, cardinals, and noblemen in Italy in the 16th century began to collect antiquities and to sponsor excavations to find more works of ancient art. These collectors were imitated by others in northern Europe who were similarly interested in antique culture. All this activity, however, was still not archaeology in the strict sense. It was more like what would be called art collecting today.

The Mediterranean and the Middle East Archaeology proper began with an interest in the Greeks and Romans and first developed in 18th-century Italy with the excavations of the Roman cities of Pompeii and Herculaneum. Classical archaeology was established on a more scientific basis by the work of Heinrich Schliemann, who investigated the origins of Greek civilization at Troy and

Mycenae in the 1870s; of M.A. Biliotti at Rhodes in this same period; of the German Archaeological Institute under Ernst Curtius at Olympia from 1875 to 1881; and of Alexander Conze at Samothrace in 1873 and 1875. Conze was the first person to include photographs in the publication of his report. Schliemann had intended to dig in Crete but did not do so, and it was left to Arthur Evans to begin work at Knossos in 1900 and to discover the Minoan civilization, ancestor of classical Greece.

Egyptian archaeology began with Napoleon's invasion of Egypt in 1798. He brought with him scholars who set to work recording the archaeological remains of the country. The results of their work were published in the Description de l'Égypte (1808-25). As a result of discoveries made by this expedition, Jean-François Champollion was able to decipher ancient Egyptian writing for the first time in 1822. This decipherment, which enabled scholars to read the numerous writings left by the Egyptians, was the first great step forward in Egyptian archaeology. The demand for Egyptian antiquities led to organized tomb robbing by men such as Giovanni Battista Belzoni. A new era in systematic and controlled archaeological research began with the Frenchman Auguste Mariette, who also founded the Egyptian Museum at Cairo. The British archaeologist Flinders Petrie, who began work in Egypt in 1880, made great discoveries there and in Palestine during his long lifetime. Petrie developed a systematic method of excavation, the principles of which he summarized in Methods and Aims in Archaeology (1904). It was left to Howard Carter and Lord Carnarvon to make the most spectacular discovery in Egyptian archaeology, that of the tomb of

Tutankhamen in 1922 Mesopotamian archaeology also began with hectic digging into mounds in the hopes of finding treasure and works of art, but gradually these gave way in the 1840s to planned digs such as those of the Frenchman Paul-Émile Botta at Nineveh and Khorsabad, and the Englishman Austen Henry Layard at Nimrud, Kuyunjik, Nabi Yūnus, and other sites. Layard's popular account of his excavations, Nineveh and Its Remains (1849), became the earliest and one of the most successful archaeological best-sellers. In 1846 Henry Creswicke Rawlinson became the first man to decipher the Mesopotamian cuneiform writing. Toward the end of the 19th century, systematic excavation revealed a previously unknown people, the Sumerians, who had lived in Mesopotamia before the Babylonians and Assyrians. The most impressive Sumerian excavation was that of the Royal Tombs at Ur by Leonard Woolley in 1926. First steps to archaeology. The development of scientific archaeology in 19th-century Europe from the antiquarianism and treasure collecting of the previous three centuries was due to three things; a geological revolution, an antiquarian revolution, and the propagation of the doctrine of evolution. Geology was revolutionized in the early 19th century with the discovery and demonstration of the principles of uniformitarian stratigraphy (which determines the age of fossil remains by the stratum they occupy below the earth) by men like William Smith, Georges Cuvier, and Charles Lyell, Lyell, in his Principles of Geology (1830-33), popularized this new system and paved the way for the acceptance of the great antiquity of man. Charles Darwin regarded Lyell's Principles as one of the two germinal works in the formation of his own ideas on evolution. Early stone tools had been identified in Europe since mid-16th century. That they were, however, older than 4004 BC, the date of man's origin according to biblical chronology, was not recognized until late in the 18th century, when John Frere suggested a great age for artifacts found in Suffolk, England, based on their location in certain strata. The discoveries of Jacques Boucher de Perthes in the Somme Valley in France, and of William Pengelly in the caves of South Devon in England, were used to demonstrate the antiquity of man in 1859, the same year that saw the publication of Darwin's revolutionary Origin of Species. Approximate dates for the Paleolithic Period (Old Stone Age) of the prehistoric past were thus established, although the expression "Palaeolithic" was not used until John Lubbock coined it in his book

Pre-historic Times (1865).

The development of Egyptology

Studies

of the

Stone Age

Darwin's Origin of Species implied a long past for man, and the acceptance of the idea of human evolution in the last four decades of the 19th century created a climate of thought in which archaeology flourished and that led to great advances in the unfolding of the full story of man's

development.

In his Pre-historic Times, Lubbock expanded the threeage system of Thomsen and Worsaae to a four-age system, dividing the Stone Age into Old and New periods (Paleolithic and Neolithic). In the last quarter of the 19th century remarkable Paleolithic discoveries were made in France and Spain; these included the discovery and authentication of actual works of sculpture and cave paintings from the Upper (later) Paleolithic Period (c. 30,000-c. 10,000 BC). When Marcellino de Sautuola discovered the cave paintings at Altamira, Spain (1875-80), most experts refused to believe they were Paleolithic; but after similar discoveries at Les Eyzies in France around 1900, they were accepted as such and were recognized as one of the most surprising and exciting archaeological discoveries. A succession of similar finds has continued in the 20th century. The most famous of these was at Lascaux, France, in 1940.

During the last quarter of the 19th century, Gen. A.H. Pitt-Rivers' excavations of prehistoric and Roman sites at Cranborne Chase, Dorset, laid the foundations of modern scientific archaeological field technique, which was later developed and improved in England and Wales by men such as Sir Mortimer Wheeler and Sir Cyril Fox.

20th-century developments. The 20th century has seen the extension of archaeology outside the areas of the Near East, the Mediterranean, and Europe, to other parts of the world. In the early '20s, excavations at Mohenjo-Daro and Harappa, in present Pakistan, revealed the existence of the prehistoric Indus civilization. In the late '20s, excavations at An-yang in eastern China established the existence of a prehistoric Chinese culture that could be identified with

the Shang dynasty of early Chinese records.

The Stone Age has been described and studied throughout the world; among the most sensational discoveries are those of L.S.B. Leakey, who found stone tools and skeletal remains of early man dating back 2,000,000 years in the Olduvai Gorge in Tanzania. Intensive work of great importance has brought to light early Neolithic sites at Jericho in Palestine; Hassuna, Iraq; Çatalhüyük, Turkey; and elsewhere in the Near East, establishing the origins of agriculture in that region.

Serious archaeological work began later in America than Europe, but as early as 1784 Thomas Jefferson had excavated mounds in Virginia and made careful stratigraphical observations. The 20th century has seen a great increase in archaeological knowledge about prehistoric America: two startling advances were the discovery of the origin of domesticated crops (including maize) in Central America and of the Olmec civilization of Mexico (1000-300 BC)the oldest of the New World civilizations and probably

the parent of all the others.

The enormous growth of archaeological work has meant the establishment of archaeology as an academic discipline; few important universities anywhere in the world are now without professors and departments of archaeology. There are now a very large number of scholarly journals in the field, as well as a considerable body of popularized books and journals that attempt to bridge the gap between professional and layman.

Fieldwork. Preliminary work. Some archaeologists call everything they do out-of-doors fieldwork, but others distinguish between fieldwork, in a narrower sense, and excavation. Fieldwork, in the narrow sense, consists of the discovery and recording of archaeological sites and their examination by methods other than the use of the spade and the trowel. Sites hitherto unknown are discovered by walking or motoring over the countryside: deliberate reconnaissance is an essential part of archaeological fieldwork.

In Europe, a study of old records and place-names may lead to the discovery of long-forgotten sites. The mapping of new and old sites is an essential part of archaeological survey. This process has been brought to a very high standard of perfection, both in the marking of archaeological sites on ordinary topographical maps and in the production of special period maps. The distribution map of artifacts, especially when studied against the background of the natural environment, is a key method of archaeo-

logical study

The formerly earthbound archaeologist has been greatly helped by the development of aerial photography. The application of aerial photography to archaeological investigation began in a small way during World War I, as a side effect of military reconnaissance, and was given further impetus by World War II; the photographic intelligence departments of all the combatant nations were extensively staffed by archaeologists, who then carried their expertise and enthusiasm into the postwar years. The University of Cambridge now has its own department of air photography under J.K.S. St Joseph: using its own pilot and aircraft, it flies photographic missions over Ireland, Great Britain, Denmark, and The Netherlands. The number of new sites discovered each year by aerial photography is very large. Some of these are surface sites, especially partly destroyed sites that show up well in special conditions of light, as in early morning or late evening. But many are sites that could not be found on the ground and that show up in aerial photographs as variations in soil colour or in the density of crop.

Archaeological reconnaissance may be advanced from ordinary surface or aerial methods in a wide variety of ways. A very simple method is tapping the ground to sound for substructures and inequalities in the subsoil. Deep probes have made it possible to trace walls and ditches. The Lerici Foundation of Milan and Rome has had great success with this method since its development of the Nistri periscope, first used in 1957 in an Etruscan tomb in the cemetery of Monte Abbatone. The periscope is inserted into the burial chamber and can photograph the walls and contents of the whole tomb.

Other modern techniques that have been applied to archaeological prospecting employ electricity and magnetic fields (geophysical prospecting). A method of electrical prospecting had been developed in large-scale oil prospecting: this technique, based on the degree of electrical conductivity present in the soil, began to be used by archaeologists in the late 1940s and has since proved very useful. Magnetic methods of prospecting detect buried features by locating the magnetic disturbances they cause: these were introduced in 1957-58 and use such machines as the proton magnetometer, the proton gradiometer, and the fluxgate gradiometer. An American expedition discovered the site of Sybaris in Sicily by magnetic prospecting. Electromagnetic methods have been in use only since 1962; they employ developments of the concepts used in mine detectors. Instruments such as the pulsed-induction meter and the soil-conductivity meter detect magnetic soil anomalies, but only if the features are fairly shallow

Excavation. Excavation is the surgical aspect of archaeology: it is surgery of the buried landscape and is carried out with all the skilled craftsmanship that has been built up in the last hundred years since Schliemann and Flinders Petrie. Excavations can be classified, from the point of view of their purpose, as planned, rescue, or accidental. Most important excavations are the result of a prepared plan-that is to say, their purpose is to locate buried evidence about an archaeological site. Many are project oriented: as, for example, when a scholar studying the life of the pre-Roman, Celtic-speaking Gauls of France may deliberately select a group of hill forts and excavate them,

Aerial photography in archaeology

Archaeology in urban areas

Excavation

method

as Sir Mortimer Wheeler did in northwestern France in the years before the outbreak of World War II. But many excavations, particularly in the heavily populated areas of central and northern Europe, are done not from choice but from necessity. Gravel digging, clearing the ground for airports, quarrying, road widening and building, the construction of houses, factories, and public buildings frequently threaten the destruction of sites known to contain archaeological remains. Emergency excavations then have to be mounted to rescue whatever knowledge of the past can be obtained before these remains are obliterated forever. Partial destruction of cities in western Europe by bombing during World War II allowed rescue excavations to take place before rebuilding. A temple of Mithras in the City of London, Viking settlements in Dublin and at Arhus, Denmark, and the original 6th-century-BC Greek settlement of Massalia (Marseille) were discovered in this way. An extension of the runways at London Airport led to the discovery of a pre-Roman Celtic temple there

The role of chance in the discovery of archaeological sites and portable finds is considerable. Farmers have often unearthed archaeological finds while plowing their fields. The famous painted and engraved Upper Paleolithic cave of Lascaux in southern France was discovered by chance in 1940 when four French schoolboys decided to investigate a hole left by an uprooted tree. They widened a smaller shaft at the base of the hole and jumped through to find themselves in the middle of this remarkable pagan sanctuary. Similarly, the first cache of the Dead Sea Scrolls was discovered in 1947 by a Bedouin looking for a stray animal. These accidental finds often lead to important excavations. At Barnénès, in north Brittany, a contractor building a road got his stone from a neighbouring prehistoric cairn (burial mound) and, in so doing, discovered and partially destroyed a number of prehistoric burial chambers. The French archaeologist P.-R. Giot was able to halt these depredations and carry out scientific excavations that revealed Barnénès to be one of the most remarkable and interesting prehistoric burial mounds in western Europe.

All forms of archaeological excavation require great skill and careful preparation. Years of training in the field, first as an ordinary digger, then as a site supervisor, with spells of work as recorder, surveyor, and photographer, are required before anyone can organize and direct an excavation himself. Most museums, universities, and government archaeological departments organize training excavations. The very words dig and digging may give the impression to many that excavation is merely a matter of shifting away the soil and subsoil with a spade or shovel: the titles of such admirable and widely read books as Leonard Woolley's Spadework (1953) and Digging Up the Past (1930) and Geoffrey Bibby's Testimony of the Spade (1956) might appear to give credence to that view. Actually, much of the work of excavation is careful work with trowel, penknife, and brush. It is often the recovery of features that are almost indistinguishable from nonarchaeological aspects of the buried landscape: one example of this is the recovery of mud-brick walls in Mesopotamia; another is the tracing of collapsed walls of dry stone slabs in a cairn in stony country in the southwest Midlands of England. Sometimes it is the recovery of features of which only ghost traces remain, like the burnt-out bodies from the buried city of Pompeii, or the strings of a harp that were found among the furnishings of Mesopotamian tombs at Ur.

Because of the damage he may cause by inexperience and haste, the untrained amateur archaeologist often hinders the work of the professional. Amateur archaeology is forbidden in many countries by stringent antiquity laws. At the same time, it is certainly true that nonprofessionals have made important contributions in many areas of archaeology. Occasionally, an amateur does make an important discovery the further excavation of which can then be taken over by trained professionals. Such was the case at Sutton Hoo in Suffolk in 1939, when work begun by a competent amateur was taken over by a team of experts who were able to uncover a great Anglo-Saxon burial boat and its treasure, without doubt the most remarkable archaeological find ever made in Britain.

There are, of course, many different types of archaeological sites, and there is no one set of precepts and rules that will apply to excavation as a whole. Some sites, such as temples, forts, roads, villages, ancient cities, palaces, and industrial remains, are easily visible on the surface of the ground. Among the most obvious archaeological sites that have yielded spectacular results by excavation are the huge man-made mounds (tells) in the Near East, called in Arabic tilāl, and in Turkish tepes or hūyūks. They result from the accumulation of remains caused by centuries of human habitation on one spot. The sites of the ancient cities of Troy and Ur are examples. Another type consists of closed sites such as pyramids, chambered tombs, barrows (burial mounds), sealed caves, and rock shelters. In other cases there are no surface traces, and the outline of suspected structures is revealed only by aerial or geophysical reconnaissance as described above. Finally, there are sites in cliffs and gravel beds, where many Paleolithic finds have been made.

The wide range of techniques employed by the archaeologist vary in their application to different kinds of sites. The opening of the tomb chamber in an Egyptian pyramid is, for example, a very different operation from the excavation of a tell in Mesopotamia or a barrow grave in western Europe. Some sites are explored provisionally by sampling cuts known as sondages. Large sites are not usually dug out entirely, although a moderate-sized round barrow may be completely moved by excavation. Whatever the site and the extent of the excavation, one element of the technique is common to all digs, namely, the use of the greatest care in the actual surgery and in the recording of what is found by word, diagram, survey, and photography. To a certain extent all excavation is destruction, and the total excavation of a site subsequently engulfed by a housing estate or gravel digging is total destruction. This is why the archaeologist's field notes and his published report become primary archaeological documents. They are not themselves, strictly speaking, archaeological facts: they are the excavator's interpretation of what he saw, or thought he saw, but this is the nearest the discipline can ever get to archaeological facts as established by excavation. The really great excavators leave such a fine record of their digs that subsequent archaeologists can re-create and reinterpret what they saw and found. To delay publishing the results of an excavation within a reasonable time is a serious fault from the point of view of archaeological method. An excavation is not complete until the printed report is available to the world. Often the publication of the report takes as long as, or much longer than, the actual

When a site like the Palace of Minos at Knossos or the city of Harappä in Pakistan has been excavated, and the excavations are over, the excavator and the antiquities service of the country concerned have to face the problem of what to do with the excavated structures. Should they be covered in again, or should they be preserved for posterity, and if preserved, what degree of conservation and restoration is permissible? This is the same kind of problem that arises in connection with the removal of antiquities from their homeland to foreign museums, and there is no generally accepted answer to it. These problems remain to beset archaeology: should Sir Arthur Evans have reconstructed the Palace of Minos at Knossos? Should the art treasures of ancient Greece and Egypt, now in west-ern European museums, be returned? There is no simple, straightforward, overall answer to these difficult questions.

work in the field.

Underwater archaeology. Underwater archaeology is a branch of reconnaissance and excavation that has been developed only during the 20th century. It involves the same techniques of observation, discovery, and recording that are the basis of archaeology on land, but adapted to the special conditions of working underwater. It is obvious that no archaeologist working on submarine sites can get far unless he is trained as a diver. Helmeted sponge divers have made most of the important archaeological discoveries in the Mediterranean. The French scientist Jacques-Yves Cousteau developed the self-contained breathing apPublication of results

Petrologi-

paratus known as the scuba, of which the most commonly used type is the aqualung. Cousteau's work at Le Grand Congloué near Marseille was a pioneer underwater excavation, as was the work of the Americans Peter Throckmorton and George Bass off the coast of southern Turkey. In 1958 Throckmorton found a graveyard of ancient ships at Yassı Ada and then discovered the oldest shipwreck ever recorded, at Cape Gelidonya-a Bronze Age shipwreck of the 14th century BC. George Bass of the University of Pennsylvania worked on a Byzantine wreck at Yassı Ada from 1961 onward, developing the mapping of wrecks photogrammetrically with stereophotographs and using a two-man submarine, the "Asherah," launched in 1964. The "Asherah" was the first submarine ever built for archaeological investigation.

Interpretation. Excavation often seems to the general public the main and certainly the most glamorous aspect of archaeology; but fieldwork and excavation represent only a part of the archaeologist's work. The other part is the interpretation in cultural and historical contexts of the facts established-by chance, by fieldwork, and by digging-about the material remains of man's past. This

task of interpretation has five main aspects.

Classification and analysis. The first concern is the accurate and exact description of all the artifacts concerned. Classification and description are essential to all archaeological work, and, as in botany and zoology, the first requirement is a good and objective taxonomy. Second, there is a need for interpretive analysis of the material from which artifacts were made. This is something that the archaeologist himself is rarely equipped to do; he has to rely on colleagues specializing in geology, petrology cal analysis (analysis of rocks), and metallurgy. In the early 1920s, H.H. Thomas of the Geological Survey of Great Britain was able to show that stones used in the construction of Stonehenge (a prehistoric construction on Salisbury Plain in southern England) had come from the Prescelly Mountains of north Pembrokeshire; and he established as a fact of prehistory that over 4,000 years ago these large stones had been transported 200 miles from west Wales to Salisbury Plain. Detailed petrological analysis of the material of Neolithic polished stone axes have enabled archaeologists to establish the location of prehistoric ax factories and trade routes. It is also now possible, entirely on a petrological basis, to study the prehistoric distribution of obsidian (a volcanic glass used to make primitive tools).

In the third place, the archaeologist, having dealt with the material of his artifacts by classification and taxonomy, and with its physical nature by petrology and metallurgy. turns to the remaining information he can get from his colleagues in the natural sciences. These tell him the environmental conditions in which the people he is studying lived; he now sees his material remains not as isolated artifacts but in the context of their original environments.

Dating. Having analyzed his discoveries according to their form, material, and biological association, the archaeologist then comes to the all-important problem of dating. Many material remains of man's past have no dating problem: they may be, like coins, or most coins, self-dating, or they may be dated by man-made dates in written records. But the great and difficult part of the archaeologist's work is dating material remains that are not themselves dated. This can be done in one of three ways. Sometimes an object from another culture, the date of which is known (e.g., in the case of pottery, by its style), is found at a previously undated site. Then, using the relative dating principle (see below) the archaeologist reasons that the material found with the imported object is contemporary with it. Conversely, an object from an undated culture may be found at a site whose date is known. Thus nonliterate communities can be dated by their contact with literate ones. This technique is known as cross dating; it was first developed by Sir Flinders Petrie when he dated Palestinian and early Greek (Aegean) sites by reference to Egyptian ones. Much of the prehistoric chronology of Europe in the Neolithic, Bronze, and Early Iron ages is based on cross dating with the ancient Near East.

Aside from cross dating, the archaeologist faced with material in a site having no literate chronological evidence

of its own has two other ways of dating his material. The first is relative, the second absolute. Relative dating merely means the relation of the date of anything found to the date of other things found in its immediate neighbourhood. As has already been described, this method also plays a part in cross dating. Stratigraphy is the essence of relative dating. The archaeologist observes the accumulation of deposits in a gravel pit, a peat bog, in the construction of a barrow, or in accumulated settlements in a tell, and, like the geologists who introduced the principles of stratigraphy in the late 18th and early 19th centuries. he can see the succession of layers in the site and can then establish the chronology of different levels of lavers relative to each other. In the excavation of a great tell like Ur or Troy the relative chronology of the various levels of occupation is the first thing to be established. Some archaeologists, even until quite recent times, have mistakenly supposed that depth below ground level is itself an indication of antiquity.

But even in properly observed and recorded stratigraphic levels there is often doubt, and the question arises; are all the artifacts and human remains found in the same level contemporary? Is it possible that there could have been later intrusions that have been difficult to distinguish in the field? The analysis of the fluorine content of bones has been very helpful here. Recognized as a valuable technique by French scientists in the 19th century, it was developed in England by K.P. Oakley in the 1950s. If bones in apparently the same geological or archaeological level have markedly different fluorine content, then it is clear that there must be interference-for example, by a later burial or by deliberate planting of faked remains, as happened in the case of the Piltdown "Man" hoax in England

Absolute man-made chronology based on king lists and records in Egypt and Mesopotamia goes back only 5,000 years. For a long time archaeologists searched for an absolute chronology that went beyond this and could turn their relative chronologies into absolute dates. Clay-varve counting seemed to provide the first answer to this need for a nonhuman absolute chronology. Called geochronology by Baron Gerard De Geer, its Swedish inventor, this method was based on counting the thin layers of clay left behind by the melting glaciers when the European Ice Age came to an end. This gave a chronology of about 18,000 years-three times as long as the man-made chronology based on Egyptian and Mesopotamian king lists. Thus, absolute dates could be established for artifacts from the Late Paleolithic Period, the whole of the Mesolithic Period, or Middle Stone Age, and much of the Early Neolithic Period.

Dendrochronology, the dating of trees by counting their growth rings, was first developed for archaeological purposes by A.E. Douglass in the United States. The application of this method to archaeology depends, obviously, on the use in antiquity of old datable trees in the construction of houses and buildings. It has been possible by dendrochronology to date prehistoric American sites as far back as the 3rd and 4th centuries BC.

The greatest revolution in prehistoric archaeology occurred in 1948, when Willard F. Libby, at the University of Chicago, developed the process of radioactive carbon dating. In this method, the activity of radioactive carbon (carbon-14) present in bones, wood, or ash found in archaeological sites is measured. Because the rate at which this activity decreases in time is known, the approximate age of the material can be determined by comparing it to carbon-14 activity in presently living organic matter. There have been problems and uncertainties about the application of the radioactive carbon method, but, although it is less than perfect, it has given archaeology a new and absolute chronology that goes back 40,000 years.

Following the revolutionary discovery of radioactive carbon dating, other physical techniques of absolute dating were developed, among them potassium-argon dating and dating by thermoluminescence. Potassium-argon dating has made it possible to establish that the earliest remains of man and his artifacts in East Africa go back at least 2,000,000 years, and probably further.

Historical judgments. The last and most important task

Radioactive carbon dating

of the archaeologist is to transmute his interpretation of the material remains he studies into historical judgments. When he is dealing with medieval and modern history he is often doing no more than adding to knowledge already available from documentary sources: but even so his contribution is often of great importance; for example, in relation to the growth and development of towns and the study of deserted medieval villages. When he is dealing with ancient history and prehistory, he is making a contribution of the greatest importance and often one that is more important than that of purely literary and epigraphical sources. For the prehistoric period, which now appears to stretch from 2,000,000 years ago to about 3000 BC, archaeological evidence is the only source of knowledge about human activities. But prehistoric remains have always been the most difficult to interpret, precisely because there are no written records to aid in the task. Now, with exact dating techniques at his disposal, the prehistorian is becoming more like the historical archaeologist and is concerned with the periodization and the historical contexts of his finds. (G.E.D.)

BIBLIOGRAPHY

Kinds

of bibli-

ographies

Bibliography, the art or science of the description of books. has acquired special importance in the 20th century because of the need for effective organization of the records of human communication in the face of the enormous growth of publishing activity and the need, especially in undeveloped countries, for informed access to the world's scientific and technical information. It has been said that without bibliography, the records of civilization would be an uncharted chaos of miscellaneous contributions to knowledge, unorganized and inapplicable to human needs.

The word bibliography, in its literal sense, derived from the Greek bibliographia (2nd century AD), means the writing of books, and it was so defined in the 17th century; since the 18th century, it has been used to denote the systematic description and history of books. It is now commonly used in two widely divergent, though basically connected senses: (1) the listing of books, arranged according to some system (in this sense it is called enumerative. systematic, or descriptive bibliography); and (2) the study of books as material objects; i.e., the study of the material of which books are made and the manner in which they are put together (in this sense commonly called critical bibliography). It is the function of bibliography to provide useful information for the student, in the one case supplying him with information about material for study, in the other helping him to establish the place of a book (or a piece of writing) in an author's production and its quality and authenticity as a text for study.

Descriptive bibliography. The tasks of the compiler of a bibliography are (1) to find out what books on a particular subject exist; (2) to describe them item by item; and (3) to assemble the resulting entries into useful arrangements for reference and study. The need for lists of this kind arises as soon as the number of books in any subject is too great to be easily remembered. Among the earliest lists of books are those compiled by certain writers as guides to their own books-e.g., the celebrated physician Galen compiled, in the 2nd century AD, a description in subject order of his own writings (De propriis libris liber, "A Book About My Own Books"); the Venerable Bede attached at the end of his Ecclesiastical History of the English People, in 731, an autobiographical note with a list of his writings: Erasmus also published a catalog of his own writings in narrative form in 1523. Early bibliographies, however, were not confined to such autobibliographies; as early as the last decade of the 4th century AD, the idea of attaching lists of works to lives of ecclesiastical writers was adopted by St. Jerome in his De viris illustribus ("Concerning Famous Men").

The invention of printing in the 1440s made possible the rapid multiplication of books, thereby increasing the need for guides to the resultant literature and also bringing about changes in the manner of compilation. The earliest substantial bibliography after the invention of printing was that of Johannes Tritheim, abbot of Sponheim in the diocese of Mainz, who in Liber de scriptoribus ecclesias-

ticis ("Book About Ecclesiastical Writers," 1494) included in chronological order, with an alphabetical index, about 1.000 ecclesiastical writers and their books. In 1545 a German-Swiss writer and naturalist, Conrad Gesner, who has been known as the father of bibliography, published his Bibliotheca Universalis (Universal Bibliography) of all Latin, Greek, and Hebrew writers, living and dead; this was followed three years later by a second volume, Pandectarum sive Partitionum universalium libri XXI ("Twentyone Books of Encyclopedias or Universal Divisions [of Knowledge]"), in which the entries, arranged alphabetically in the earlier volume, are rearranged under 21 subject headings. Although Gesner was not the earliest descriptive bibliographer, his attempts at universality and classification earn him his fame. Gesner's idea of universality remained an ideal until recent times; in the face of the formidable problems of size, cost, and complexity, however, it has receded into the background of human aspirations. The Institut International de Bibliographie, founded in 1895 in Brussels by Henry Lafontaine and Paul Otlet with the object of creating a universal bibliography of books and articles in periodicals, arranged according to a specially designed system of classification, the Universal Decimal Classification (UDC), has assembled a card catalog of many millions of entries; but because of the immense bulk of the material and the growing cost of compilation, it is unlikely that it will ever reach the goal set by its founders. The hopes for universal bibliographies have been largely replaced by the published catalogs of such great comprehensive libraries as the British Museum (1961-67), the Bibliothèque Nationale (beginning in 1897), the Library of Congress, and, most promising of all, the United States National Union Catalogue, maintained in the Library of Congress and, in the early 1970's, in the course of being printed in an estimated 625 volumes. Investigations were (early 1970's) being made into the problems involved in programming and computerizing such catalogs, and if the complexities of programming multilanguage material can be solved, if the necessary financing can be found, and if world cooperation in the production and standardization of catalog entries can be assured, it seems possible that the ideals of the Brussels Institute may yet to some extent be realized.

Gesner's achievement was remarkable; besides writing many other books, including a number of bibliographical works, his universal bibliography with its appendix (1555) describes and classifies some 15,000 works by about 3,000 writers and provides alphabetical and subject indexes. His contemporaries turned their attention to detailed bibliographies of writings on particular subjects or in particular languages or relating to particular countries or places. Thus, John Bale, bishop of Ossory, published the earliest national bibliography, Illustrium maioris Britanniae scriptorum...summarium ("Summary of the Writings of the Most Eminent Britons," 1548), which lists British writers chronologically and sets out their writings in detail. The vastly improved extended second edition of this work, Scriptorum illustrium maioris Brytanniae . . . catalogus (1557), acknowledges Bale's indebtedness to John Leland, Henry VIII's library keeper and antiquary, who had made an antiquarian tour through England in 1534-42 and had made a survey of the writings of British authors. Other national bibliographies followed, such as those of the Italian Antonio Francesco Doni, La Libraria del Doni Fiorentino Nella quale sono scritti tutti gl'autori vulgari ("Library of . . . All Secular Authors," 1550; 2nd ed. also 1550); La seconda del Doni (1551); the Dutch theologian Cornelius Loos, Illustrium Germaniae scriptorum catalogus (1582); the French bibliographer François Grudé de la Croix du Maine, Premier Volume de la bibliothèque du Sieur de la Croix du Maine ("The First Volume of the Library of . . . ," 1584). The catalogs of the German book fairs held in Frankfurt and Leipzig each spring and autumn, beginning in 1564 and continuing until 1749, while not bibliographies in the strict sense, were book fairs nevertheless widely used as foundation material by early German bibliographers.

Types of descriptive bibliographies. Most countries now have national bibliographies, in a majority of cases pubHopes for a universal bibliography

of the German

lished officially by the national library and based on copies of national publications deposited in accordance with provisions of copyright acts. Some notable exceptions are the United States and The Netherlands, whose national bibliographies are published commercially, and the United Kingdom, whose British National Bibliography is published by a council representing libraries, publishers, and booksellers. These national bibliographies aim at, and attain, a high degree of completeness and promptitude. The British National Bibliography (beginning in 1950), for example, is published weekly and cumulated quarterly and annually; it is arranged in a classified order according to the decimal classification of the American librarian Melvil Dewey, with an alphabetical index of authors, titles, and subjects. The Bibliographie de la France (beginning in 1811), published weekly, is arranged in a classified order with an annual index of authors, titles, and subjects. The German Deutsche Bibliographie (beginning in 1947) is published weekly and provides both an author and catchword index. The Deutsche Bibliographie has been published by computer since the beginning of 1968-the first such work to be so produced.

Bibliographies of books published in particular countries are of great value to students. Outstanding examples of such bibliographies are Charles Evans, American Bibliography (1903-34), covering the period 1639-1799; A Short-Title Catalogue of Books Printed in England, Scotland and Ireland, and of English Books Printed Abroad, 1475-1640, compiled by A.W. Pollard and G.R. Redgrave (1926; revised and enlarged 2nd ed., 1976), and its continuation by D.G. Wing, Short-Title Catalogue ... 1641-1700 (1945-51; revised 2nd ed., 2 vol., 1972-82). While not strictly bibliographies, the British Museum catalogs of its holdings of pre-1600 books from several European countries are similarly valuable because of the richness of the muse-

um's collections.

Personal bibliographies may consist of no more than a simple list of an author's works, as, for example, those attached to articles in the Dictionary of National Biography. However, they may be more elaborate; take, for instance, F.W. Ebisch and L.L. Schücking, A Shakespeare Bibliography (1931; supplement 1937); Michael Sadleir, Trollope: A Bibliography (1928); Bertha Coolidge Slade, Maria Edgeworth (1937). Personal bibliographies are sometimes based on private collections, as exemplified by A Stevenson Library (1951-64), based on the collection of Edwin J. Beinecke; T.J. Wise's bibliographies, based on his own collections, of Tennyson, Swinburne, and others. A variant of personal bibliography consists of a narrative setting out an author's works with a comprehensive account of the circumstances surrounding the composition and publication of each work. An example of such a bibliography is J.E. Norton, A Bibliography of the Works of Edward Gibbon (1940).

Subject bibliographies vary in size, scope, and method, according to the purpose they are designed to serve. The following are examples of bibliographies that aim at offering comprehensive guidance: A. and A. de Backer and A. Carayon, Bibliothèque de la Compagnie de Jésus, ("Library of the Society of Jesus," 9 vol.; new ed. 1890-1909); F.W. Bateson, The Cambridge Bibliography of English Literature (4 vol., 1940; new ed. 1970 ff.); Bibliography of British History: C. Read, Tudor Period, 1485-1603 (1933), G. Davies, Stuart Period, 1603-1714 (1928), S. Pargellis and D.J. Medley, The Eighteenth Century, 1714-1789 (1951); P. Caron, Manuel pratique pour l'étude de la Révolution française ("Practical Manual for the Study of the French Revolution"; latest ed. 1947); F.C. Dahlmann and G. Waitz, Quellenkunde der deutschen Geschichte, ("Published Sources of German History"; 9th ed. 1931-32); W.W. Greg, A Bibliography of the English Printed Drama to the Restoration (4 vol., 1939-59); G. Lanson, Manuel bibliographique de la littérature française moderne ("Bibliographic Manual of Modern French Literature"; latest ed. 1947); F. Madan, The Early Oxford Press (3 vol., 1895-1931); L.-N. Malclès, Les Sources du travail bibliographique ("Sources of Bibliographic Work," 3 vol., 1950-52). Bibliographies of publications on particular subjects, frequently including articles on periodicals, are numerous and cover many branches of human knowledge and interests

The proliferation of bibliographies has led to the publication of bibliographical guides-bibliographies of bibliographies. Among these should be mentioned Bibliotheca Bibliographica (1866), compiled by Julius Petzholdt, librarian of the Royal Library at Dresden, Germany, and World Bibliography of Bibliographies (5 vol.; 1965-66) by Theodore Besterman, Guides to current publications in a number of subject fields are published annually sometimes in narrative form-e.g., The Year's Work in English-Studies (1921 ff.) and The Year's Work in Librarianship (1929 ff.; later title Five Years' Work in Librarianship. 1958 ff.)-and sometimes in list form-e.g., Internationale Bibliographie des Buch- und Bibliothekswesens ("International Bibliography of Book and Library Systems," 1926-41).

Methods of compilation. The method of compiling a bibliography and the amount of detail included vary according to the author's purpose, his view of the importance of the subject, and his knowledge of it. The task of compiling a bibliography of any subject is a matter for a specialist in that subject. After an author has determined his specific objective and what material exists, he must proceed to describe and arrange it as usefully for his purpose as he can. In order to ensure that the descriptions are accurate and consistent, they should be made from the works themselves. If, for any reason, this proves impossible, the source of the information given should

always be stated.

For most bibliographies it is usually necessary to give only the author, short title, place of imprint, and date; however, this information should be transcribed accurately from the book or article. Notes may be added on the scope and quality of the text and the location of a copy. In an author bibliography a chronological arrangement is frequently adopted, enabling the user to follow the development of the author's work. In such cases, later editions are listed with the earliest edition but additional mention is made at the appropriate chronological point. Subject bibliographies may be arranged in a systematic order to bring out the features important for the author's purpose, or a recognized classification system, such as the Dewey Decimal Classification or Universal Decimal Classification, may be employed.

Full descriptions are often given for early or rare books and for detailed author bibliographies. Elaborate rules have been evolved for compiling such descriptions, which make it possible for a skilled bibliographer to reconstruct from the text before him the makeup and appearance of a book. Such descriptions include information about the details of publication, number of copies printed, price, and binding. Semi-facsimile transcriptions are sometimes given, illustrating the various types of font used and the spacing of the title page. Modern methods of reproduction, however, make it possible to reproduce title pages photographically and thus obviate the use of such expedients, which in any case are not entirely satisfactory. The use of reproductions, however, has certain disadvantages, such as high cost and difficulty of layout, and, more important, reproductions themselves may be misleading, especially when the quality of the printing and paper of the original are poor. In 17th-century printing, for example, it is sometimes difficult to distinguish a mark of punctuation from a flaw in the paper, and a reproduction may give a wrong impression. If facsimiles are used, they should be as carefully edited as the text and the source of the reproduction should be stated.

The advent of computers and the application of dataprocessing techniques to library procedures such as cataloging have great potential value in bibliography. If a catalog is maintained in machine-readable form, it can be printed out in a number of different arrangements, or a variety of sublistings can be produced, with a relatively small increase in costs over the cost of printing the original arrangement. This method depends on the planning of requirements in advance and on the work of the programmer. It is thus possible for specialized lists, taken from the contents of a particular library, to be made available to a wide range of users. The best known and most highly

Bibliographies of hibliographies

reproduc-

sophisticated retrieval project of this kind is the Medlars project (Medical Literature Analysis and Retrieval System), which has as its main objective the publication of the Index Medicus (a monthly listing of current articles from about 2,300 biomedical journals throughout the world) but which also supplies printed listings on particular subiects in the field of medicine.

The full benefit of these methods will accrue when it is economically and administratively possible to contemplate the storage of the enormous amounts of information

available in the large comprehensive libraries In 1968 the Library of Congress began the production and distribution of cataloging data in machine-readable form. The scope of this enterprise was limited initially to monographic works in the English language, but with the intention of expanding the coverage to include other languages. The creation of the machine record of material already in the library before 1969, which is necessary if a full system of machine-readable records is to be created, was being investigated both in the Library of Congress and elsewhere in other large comprehensive libraries. The problems likely to cause most difficulty are the labour involved, the great cost of the operation, and the magnitude of the data storage. Clearly such costly and complex operations have to be related to a realistic assessment of the benefits to be derived therefrom. Such assessments are in keeping with an interest, current in the early 1970s. in research library management. The rapid rise in library costs has emphasized the need for libraries, particularly large research libraries, to study whether and how they can apply accepted management techniques to the fuller exploitation of the bibliographical riches of their own

approach

literature

to English

institutions Critical bibliography. A valuable approach to the study of English literature, particularly, though not exclusively, of the 17th and 18th centuries, was developed about the turn of the 20th century out of a concern with Shakespearean texts in general and in particular with the nature and authority of the so-called quarto texts and their relation to the text printed in the First Folio. Editors had previously tended to assume that all the early texts of Shakespeare had equal authority and that it was perfectly proper to select readings which, in their view, improved the text of the author. The earlier editors were handicapped, in addition, by their ignorance of printing and book production in Shakespeare's time and by a lack of understanding of the nature of the texts they were dealing with. The change that took place stemmed from a variety of causes, of which the most important were probably two: (1) the close association in studies of English literature, especially drama, of three eminent scholars, A.W. Pollard, R.B. McKerrow, and W.W. Greg, all of them interested in bibliography; and (2) the remarkable progress made by Robert Proctor, a colleague of Pollard's in the British Museum, in the study of incunabula, the name given to books printed in the first 50 years after the invention of printing (i.e., before 1501). The earliest printed books display the very individual characteristics of their printers in the type used, the typesetting, and the layout of the page, and it was found that, by studying these characteristics, useful deductions could be made about the place of individual books in a printer's total production and hence their approximate dates; in cases in which books contained no indication of the printer, it was often possible, using the same means, to assign a book to a particular printer. Important stages in the study of these earliest printed books, which had always been prized for their early date, their great aesthetic quality, and their rarity, were marked by a study of William Caxton, England's earliest printer, by William Blades, The Life and Typography of William Caxton (1861-63), in which typographical details were used to arrange Caxton's publications in chronological order; and by the work of a great antiquarian scholar and librarian, Henry Bradshaw, who made a special study of 15th-century books printed in the Netherlands. Bradshaw laid down an important principle: let the book speak for

This new method was still more widely applied by Robert Proctor, who succeeded in allotting the large collections of incunabula in the British Museum and the Bodleian Library at Oxford to places of origin, by countries and towns, and to printers. Proctor's work firmly established this method of study, and the definitive catalog of the incunabula in the British Museum, which he began demonstrated the valuable results that can be obtained by the meticulous examination of all the features of a bookpaper, type, makeup, ornamentation, sewing, binding, manuscript notes, and marks of ownership

It was against this background and, applying these methods to the literary and dramatic work of English authors of the 16th and 17th centuries, that Greg, McKerrow, and Pollard developed what has since come to be called critical, or analytical, bibliography, a method of bibliography that has been succinctly described as the study of books as tangible objects. By using the evidence of the physical features of books, it was often found possible to arrive at conclusions about the place of a book in an author's production that are beyond the scope of literary judgment.

One of the earliest and most illuminating examples of the application of this method concerns the question of the priority between the two issues of Shakespeare's play Troilus and Cressida that both bear a date of 1609. These differ in the preliminary matter: the title of one describes the play as having been acted at the Globe Theatre; in the other, the title page makes no mention of a production of the play, and an epistle to the reader stresses this fact by stating that the piece had never been "clapper-clawed with the palmes of the vulger." Literary considerations would suggest that the latter issue was the earlier. An examination of the books themselves, however, shows that the title page of the former is in its original state, while the latter's original title page had been cut away and two leaves substituted, containing the new title page and the address to the reader, thus demonstrating, without question, the order of the two.

In his edition of Beaumont and Fletcher's Elder Brother (1905), Greg similarly provided an irrefutable demonstration of the correct chronological order of the two quarto editions of 1637. In Q1 an improperly adjusted quad or space lead had produced a mark above the line before the word "young" in Act I, scene 2, line 72, which was mistaken by the compositor printing O2 for an apostrophe and printed as such. As a consequence, Q2 was shown to have been printed from Q1 and not from the author's manuscript.

The success of such demonstrations led to a much more detailed study of the physical features of books and the bibliographical deductions that can be made from them. The methods of critical bibliography have been substantially developed and have been widely applied to books of later periods, and it has been shown that, even in the sophisticated machine age, careful bibliographical examination has a significant role to play in determining the reliability of an author's text and the place of a book in an author's production.

The method was spectacularly displayed in the exposure of a number of alleged first editions of poems, essays, and other minor productions of well-known 19th-century authors, such as the "Reading" sonnets of Elizabeth Barrett Browning-i.e., an edition of these sonnets, dated 1847, with Reading as the place of imprint. These books, more than 50 in number, were shown, in An Enquiry into the Nature of Certain Nineteenth Century Pamphlets (1934), by John Carter and Graham Pollard, to have been printed on kinds of paper, made from esparto grass or wood pulp, known not to have been in use at the dates shown on the title pages, and using printing types that were first

cut much later. It has been clearly demonstrated that machine-printed books of the 19th and 20th centuries produce textual problems rivalling those found in hand-printed books. While editorial procedures and the principles governing the interpretation of bibliographical evidence remain the same, new printing methods force bibliographers to devise new procedures to deal with the new problems presented to them

Exposure of false editions

English books up to the end of the 17th century is provided by R.B. McKerrow's Introduction to Bibliography for Literary Students (1927). The publications of the Bibliographical Society of London, especially its journal, The Library (1889 ff.), contain valuable information about bibliographical methods and their application. A useful account of the work of the society and a study by F.P. Wilson of the application of bibliographical techniques to the works of William Shakespeare, "Shakespeare and the New Bibliography," is contained in The Bibliographical Society, 1892-1942: Studies in Retrospect, (1945). Other bibliographical journals that may be usefully consulted are: The Papers of the Bibliographical Society of America (1904 ff.), the Publications of the Oxford Bibliographical Society (1922 ff.), and the Transactions of the Cambridge Bibliographical Society (1949 ff.). Studies in Bibliography (1948 ff.), published by the Bibliographical Society of the University of Virginia, is especially valuable. (F.C.F.)

CHRONOLOGY

Chronology, in the broadest sense, is a time scale, a method of ordering time. This article, however, deals mainly with systems of chronology used by different peoples in recording their history.

Scientific chronology, which seeks to place all happenings in the order in which they occurred and at correctly proportioned intervals on a fixed scale, is used in many disciplines and can be utilized to cover vast epochs. Astronomy, for example, measures the sequence of cosmic phenomena in thousands of millions of years; geology and paleontology, when tracing the evolution of the Earth and of life, use similar epochs of hundreds or thousands of millions of years. Geochronology reckons the more distant periods with which it deals on a similar scale; but it descends as far as human prehistoric and even historic times, and its shorter subdivisions consist only of thousands of years. Shortest of all are the chronological scales used in the recording of human events in a more or less systematic and permanent manner. These vary in scope, accuracy, and method according to the purpose, degree of sophistication, and skill of the peoples using them, as do the calendrical systems with which they are inextricably bound up. For further details see the article CALENDAR.

It is difficult to fix ancient historical chronologies in relation to scientific chronology. The terms of reference of ancient peoples were vague and inconsistent when judged by modern standards, and many of their inscriptions and writings have inevitably disappeared. The gaps in their records are increasingly filled in and their inconsistencies removed by the results of archaeological excavation. Guided by these findings, scholars can confirm, refute, or amend chronological reconstructions already tentatively made. Astronomical calculation and dating by radioactivecarbon content are also helpful in the work of fixing ancient chronologies.

Chinese. Chinese legendary history can be traced back to 2697 BC, the first year of Huang Ti (Chinese: Yellow Emperor), who was followed by many successors and by the three dynasties, the Hsia, the Shang, and the Chou. Recent archaeological findings, however, have established an authentic chronology beginning with the Shang dynasty, though the exact date of its end remains a controversial topic among experts. The so-called oracle-bone inscriptions of the last nine Shang kings (1324-1122 BC) record the number of months up to the 12th, with periodical additions of a 13th month, and regular religious services on the summer and winter solstice days, all of which indicates the adjustment of the length of the lunar year by means of calculations based on the solar year. Individual days in the inscriptions are named according to the designations in the sexagenary cycle formed by the combination of the 10 celestial stems and 12 terrestrial branches. Every set of 60 days is divided into six 10-day "weeks." Also recorded are numerous eclipses that can be used to verify the accuracy of the Shang chronology. In the oracular sentences of the last Shang king, Chou Hsin, the year of his reign is referred to as "the King's nth annual sacrifice."

From the beginning of the following (Chou) dynasty, the word year was etymologically identical with "harvest,"

Thus, "King X's nth harvest" meant the nth year of his reign. The lunar month was then divided into four quarters-Ch'u-chi, Tsai-sheng pa, Chi-sheng pa and Chi-szu pa-and the practice of using the 60 cyclical names for the days was continued. Thus, in the inscription on a Chou bronze vessel, a typical date would read: "In the King's nth harvest, in the nth quarter of the nth month, on the day X-y, etc."

The tradition of recording events by referring to the king's regnal year continued until 163 BC, when a new system, nien-hao ("reign-period title"), was introduced by Emperor Han Wen Ti of the Former Han dynasty (206 BC-AD 8). Thereafter, every emperor proclaimed a new nien-hao for his reign at the beginning of the year following his accession (sometimes an emperor redesignated his nien-hao on special occasions during his reign). A typical date in the nien-hao system might read, "the third year of the Wan-li reign period" (Wan-li san nien). In order to date any event in Chinese history, it is necessary to convert the year in the period of the designated nien-hao into the Western calendar.

During the Chou dynasty the civil year began with the new moon, which occurred before or on the day of the winter solstice. This "first month" of the Chou year (Chou cheng) was equivalent to the 11th month of the Hsia year (Hsia cheng) or to the 12th month of the Shang year. The first emperor, Shih Huang-ti, of the short-lived Ch'in dynasty (221-206 BC) made the year begin one month earlier-i.e., with the lunation (the period of time between one new moon and the next) before the one in which the winter solstice occurred. The Ch'in year was continuously used until 104 BC, when Emperor Han Wu Ti promulgated the T'ai-ch'u calendar by reverting to the Hsia chengi.e., by taking the third month of the Chou year, or the second lunation after the winter solstice, as the first month of the civil year. This lunar year (or Hsia cheng) was used till the last day of the Ch'ing, or Manchu, dynasty (1644-1911/12). When in 1911 the first republic was founded, the solar year was officially adopted, but successive governments kept the nien-hao tradition by referring any date to the number of years since the establishment of the republic—e.g., 1948 was chronicled "the 37th year of the republic." In 1949, when the People's Republic of China was proclaimed, the old system was replaced by the Gregorian calendar.

Japanese. The principal chronicles describing the origins of Japanese history are the Nihon shoki ("Chronicle of Japan") and the Koji-ki ("Record of Ancient Matters"). The Nihon shoki (compiled in AD 720) assembled information in a chronological order of days, months, and years starting several years before 660 BC, which was the year of the enthronement of the first Japanese emperor, who was posthumously named Jimmu. The Koji-ki (compiled in AD 712) related events under the reign of each emperor without a strict chronological order. Sometimes the Kojiki gave the years of emperors' deaths and their ages at death. This information is different from that recorded in the Nihon shoki.

Native Japanese scholars since Fujiwara Teikan in the 18th century have realized that the Nihon shoki was historically inadequate and different from the Koji-ki, at least insofar as the chronological information is concerned. They have suggested that the foundation year of Japan was 600 years later than stated in the Nihon shoki. Naka Michiyo (late 19th century) argued with minute detail about the question of Japanese chronology. His ideas were supplemented by those of other Japanese scholars, who pointed out that: (1) the reigns of the earlier Japanese emperors as stated in the Nihon shoki are unnaturally long; (2) the date of the enthronement of the emperor Jimmu should be reconsidered; (3) a chronological gap exists between the Nihon shoki and contemporary Chinese and Korean chronicles. In comparison with Korean chronicles, they argued, the Nihon shoki has created an intentional expansion of chronology-i.e., the entries about the empress Jingo and the emperor Ojin can be identified with historical facts relating to the Korea of the 4th and 5th centuries and therefore must be placed 120 years later

Reforms of Naka Michiyo

nien-hao

system

583

than mentioned in the Nihon shoki. When comparing the Nihon shoki with Chinese chronicles, one finds the chronological gap somewhat reduced. The Chinese chronicles provide information about the tributes sent individually by five Japanese "kings" to Liu-Sung and Southern Ch'i during the 5th century. There are still questions about the identification of these kings, but it is generally accepted that the "king" written in Chinese character as Wu must be the Japanese emperor Yüryaku. By the late 5th century the gap between Japanese and Korean records, on the one hand, and Japanese and Chinese, on the other hand, disappears.

The intentional expansion of the chronology of the Nihon shoki was adopted by its compilers, who identified Queen Himiko (Pimihu) of Yamatai of the chronicle of Wei China with the Empress Jingo of Japanese legend.

The method of designating a year by the kan-shi (sexagenary cycle) appears to have begun about the reign of Emperor Yūryaku, when, as mentioned above, the gap between the continental and Japanese chronologies was bridged. The inscription on remarkable copper images of Buddha cast just after the period of Prince Shotoku's regency (AD 593-621) bears a nengō (nien-hao, or reignyear title), although not a strictly authorized one. It was at this time that the Chinese luni-solar calendar system was adopted. The first official nengō was Taika, which was adopted by the imperial court in 645. Since 701, when the second title, Taihō, was adopted, the reign-year system has been continuously used in relation to the emperors' reigns up to the present day. In medieval times Japanese chronology underwent a remarkable evolution: (1) when the Imperial dynasty split into two courts (1336-92), two series of nengô began to be used; (2) during the Ashikaga period some private nengō again appeared; (3) some dates of the authorized "central" calendars did not correspond with those of locally compiled calendars. Moreover, military leaders would not accept some of the new nengō. Minamoto Yoritomo, for example, did not use the nengo that was adopted by the emperor Antoku and the Taira regime, and Ashikaga Mochiuji and Ashikaga Shigeuji did not use the official, respectively Eikyo and Köshö, nengö.

In the Tokugawa period (1603-1867), gaps between central and provincial calendars disappeared, especially after the establishment of the Jokyo calendar, the first native calendar compiled in Japan, instead of the Chinese-based one that was in use until this period. On January 1, 1873, Emperor Meiji adopted the Gregorian calendar in use in the West and at the same time adopted the "Japanese Era," with Emperor Jimmu as its founder, in addition to the nengô system. (Hi.Mo.)

Indian. Two kinds of chronological systems have been used in India by the Hindus from antiquity. The first requires the years to be reckoned from some historical event. The second starts the reckoning from the position of some heavenly body. The historical system, the more common in modern times, exists side-by-side with Muslim and international systems successively introduced.

Reckonings dated from a historical event. The inscriptions of the Buddhist king Asoka (c. 265-238 BC) give the first epigraphical evidence of the mode of reckoning from a king's consecration (abhiseka). In these inscriptions (Middle Indian language in India or Greek and Aramaean in what is now Qandahar, Afghanistan) the dates are indicated by the number of complete years elapsed since the king's consecration. But the earlier existence of a reckoning of duration of reigns and dynasties is evidenced by the testimony of the Greek historian Megasthenes, who in 302 BC-was the ambassador of Seleucus I Nicator, founder of the Seleucid Empire, to the court of Candragupta Maurya, Aśoka's grandfather. According to Megasthenes, the people of the Magadha kingdom, with its capital Pațaliputra (Patna), kept very long dynastic lists, preserved in the later Sanskrit Puranas (legends of the gods and heroes) and later Buddhist and Jain chronicles. They generally indicate, in years or parts of years, the duration of each reign.

Similar records of other periods and regions exist, and a relative chronology may be established. Unfortunately, it is not always possible to connect them with any absolute chronology, the precise dates of the reigns given being still unsettled. For example, in the Scythian period of the history of northern India, several inscriptions are dated from the beginning of the reign of Kaniska, the greatest king of the Asian (Kushān) invaders, but his dates are still uncertain (AD 78, 128-129, 144, etc., have been suggested for the beginning of a Kaniska era).

Other records give regnal years that can be linked with absolute chronology through other data-e.g., those of

several rulers of the Rastrakuta of the Deccan. The dynastic eras, founded by several rulers and kept up or adopted by others, are also numerous. The most important were the Licchavi era (AD 110), used in ancient Nepal; the Kalacuri era (AD 248), founded by the Abhūri king Isvarasena and first used in Gujarat and Maharashtra and later (until the 13th century) in Madhya Pradesh and as far north as Uttar Pradesh; the Valabhi era (AD 318, employed in Saurastra) and the Gupta era (AD 320), used throughout the Gupta Empire and preserved in Nepal until the 13th century. Later came the era of the Thakuri dynasty of Nepal (AD 395), founded by Amsuverman; the Harsa era (AD 606), founded by Harsa (Harsayardhana) long preserved also in Nepal; the western Calukya era (AD 1075), founded by Vikramāditya VI and fallen into disuse after 1162; the Laksmana era (AD 1119), wrongly said to have been founded by the king Laksmanasena of Bengal and still used throughout Bengal in the 16th century and preserved until modern times in Mithilä; the Rajyabhīsekasaka or Marāthā era (1674), founded by Śivăjī but ephemeral.

Later, instead of the beginning of a reign or of a dynasty. the death of a religious founder was adopted as the starting point of an era. Among Buddhists the death of the Buddha and among the Jains the death of the Jina were taken as the beginning of eras. The Jain era (vīrasamvat) began in 528 BC. Several Buddhist sects (no longer existing in India) adopted different dates for the death (Nirvāna) of the Buddha. The Buddhist era prevailing in Ceylon and Buddhist Southeast Asia begins in 544 BC.

Historical events, now obscure, were the basis of the two most popular Indian eras: the Vikrama and the Saka.

The Vikrama era (58 BC) is said in the Jain book Kālakācāryakathā to have been founded after a victory of King Vikramāditya over the Śaka. But some scholars credit the Scytho-Parthian ruler Azes with the foundation of this era. It is sometimes called the Mālava era because Vikramāditya ruled over the Mālava country, but it was not confined to this region, being widespread throughout India. The years reckoned in this era are generally indicated with the word vikramasamvat, or simply samvat. They are elapsed years. In the north the custom is to begin each year with Caitra (March-April) and each month with the full moon. But in the south and in Gujarāt the years begin with Kārttika (October-November) and the months with the new moon; in part of Gujarāt, the new moon of Āṣāḍha (June-July) is taken as the beginning of the year. To reduce Vikrama dates to dates AD, 57 must be subtracted from the former for dates before January 1 and 56 for dates after.

The Saka, or Salivahana, era (AD 78), now used throughout India, is the most important of all. It has been used not only in many Indian inscriptions but also in ancient Sanskrit inscriptions in Indochina and Indonesia. The reformed calendar promulgated by the Indian government from 1957 is reckoned by this era. It is variously alleged to have been founded by King Kaniska or by the Hindu king Salivāhana or by the satrap Nahapāna. According to different practices, the reckoning used to refer to elapsed years in the north or current years in the south and was either solar or luni-solar. The luni-solar months begin with full moon in the north and with new moon in the south. To reduce Saka dates (elapsed years) to dates AD, 78 must be added for a date within the period ending with the day equivalent to December 31 and 79 for a later date. For Saka current years the numbers to be added are 77 and 78. The official Saka year is the elapsed year, starting from the day following that of the vernal equinox. A normal year consists of 365 days, while the leap year has 366. The first month is Chaitra, with 30 days in a normal year and

Hindu dynastic

Śaka era

Cosmic

cycles

31 in a leap year; the five following months have 31 days, the others 30.

A Nepalese era (AD 878) of obscure origin was commonly used in Nepal until modern times. The years were elapsed, starting from Kärttika, with months beginning at new moon. Another era, the use of which is limited to the Malabār Coast (Malayalam-speaking area) and to the Tirunelveli district of the Tamil-speaking area, is connected with the legend of the hero Parasivama, an avatar (incarnation) of the god Vishnu. It is called the Kollam era (AD 825). Its years are current and solar, they start when the Sun enters into the zodiacal sign of Virgo in north Malabār and when it enters into Leo in south Malabār. It is sometimes divided into cycles of 1,000 years reckoned from 1176 BC. Thus, AD 825 would have been the first year of the era's third millennium.

Eras based on astronomical speculation. During the period of elaboration of the classical Hindu astronomy, which was definitively expounded in the treatises called siddhāntas and by authors such as Āryabhaṭa I (born AD 476), Varähamihira, Brahmagupta (7th century AD), etc., the ancient Vedic notions on the cycle of years, embracing round numbers of solar and lunar years together, were developed. On the one hand, greater cycles were calculated in order to include the revolutions of planets, and the theory was elaborated of a general conjunction of heavenly bodies at 0° longitude after the completion of each cycle. On the other hand, cosmologists speculated as to the existence of several successive cycles constituting successive periods of evolution and involution of the universe. The period calculated as the basis of the chronology of the universe was the mahāvuga, consisting of 4,320,000 sidereal years. It was divided into four yugas, or stages, on the hypothesis of an original "order" (dharma) established in the first stage, the Kṛta Yuga, gradually decaying in the three others, the Treta, Dvapara, and Kali yugas. The respective durations of these four yugas were 1,728,000, 1,296,000, 864,000, and 432,000 years. According to the astronomer Aryabhata, however, the duration of each of the four yugas was the same-i.e., 1,080,000 years. The basic figures in these calculations were derived from the Brahmanical reckoning of a year of 10,800 muhūrta (see CALENDAR: The Hindu calendar), together with combinations of other basic numbers, such as four phases, 27 nakşatras, etc. The movement of the equinoxes was at the same time interpreted not as a circular precession but as a libration (periodic oscillation) at the rate of 54 seconds of arc per year. It is in accordance with these principles that the calculation of the beginning of the Kali Yuga was done in order to fix for this chronology a point starting at the beginning of the agreed world cycle. Such a beginning could not be observed, since it was purely theoretical, consisting of a general conjunction of planets at longitude 0°, the last point of the nakşatra Revati (Pisces). It has been calculated as corresponding to February 18, 3102 BC (old style), 0 hour, and taken as the beginning of the Kali era. In this era, the years are mostly reckoned as elapsed and solar or luni-solar.

In Hindu tradition the beginning of the Kali era was connected with (1) events of the Mahābhārata war; (2) King Yudhiṣhira's accession to the throne; (3) 36 years later, King Parikṣit's consecration; and (4) the death of Lord Krishna. Years of the era are still regularly given in Hindu almanacs.

An era resting upon a fictitious assumption of a complete 100-year revolution of the Ursa Major, the Great Bear (saptarsj), around the northern pole was the Saptarsj, or Laukika, era (3076 вс), formerly used in Kashmir and the Punjab. The alleged movement of this constellation has been used in Purāpa compilations and even by astronomers for indicating the centuries.

Two chronological cycles were worked out on a basis of the planet Jupiter's revolutions, one corresponding to a single year of Jupiter consisting of 12 solar years and the other to five of Jupiter Syears. The second, the brhaspaticakra, stars, according to different traditions, from Ad 427 or from 3116 sc. Before AD 907 one year was periodically omitted in order to keep the cycle in concordance with the solar years. Since 907 the special names by which

every year of the cycle is designated are simply given to present years of the almanac.

Side-by-side with Hindu and foreign eras adopted in India, several eras were created in the country under foreign influence, chiefly of the Mughal emperor Akbar: Bengall San (AD 593), Amli of Orissa and Vilayati (AD 592), Fasli (AD 590, 592, or 593 according to the district), and Sursan of Mahārāshtra (599).

Egyptian. At the end of the 4th millennium BC, when King Menes, the first king of a united Egypt, started his reign, the ancient Egyptians began to name each year by its main events, presumably to facilitate the dating of documents. These names were entered into an official register together with the height of the Nile during its annual inundation. Short notes at first, the year names developed into lengthy records of historical and religious events, especially of royal grants to the gods. These lists grew into annals, which were kept during the entire history of Egypt so that later kings could, after important events, consult the annals and ascertain whether a comparable occurrence had happened before. Unfortunately, these annals are lost. Only fragments from the 1st to the 5th dynasty (c. 3100-c. 2345 BC) are preserved, copied on stone. These fragments, however, are in such poor condition that they raise more chronological problems than they solve.

The Egyptian priests of the Ramesside period (c. 1300 ac) copied the names and reigns of the kings from Menes down to their time from the annals, omitting all references to events. Even this king list would have given a safe foundation of an Egyptian chronology, but the only extant copy, on a papyrus now kept at the Museo Egizio in Turin, has survived only in shreds, entire sections having been lost. Extracts from this king list, which name only the more important kings, are preserved in the temples of the kings Seti I and Ramses II at Abydos and on the wall of a private tomb at Saquárań (now in the Egyptian Museum).

seum), but they give little help in chronological matters. When the Greeks began to rule Egypt after the conquest of Alexander the Great, King Ptolemy II Philadelphus, hoping to acquaint the new ruling class with the history of the conquered country, commissioned Manetho, an Egyptian priest from Sebennytus, to write a history of Egypt in the Greek language. As Manetho had access to the ancient annals, he added some of their entries to his list of kings and reigns, especially during the first dynasties. The more he progressed in time, the more he added semihistorical traditions and stories as they were composed by the Egyptian priests to discuss moral problems in the disguise of a historical "novel." There had been, undoubtedly, fewer historical facts in Manetho's history than one might expect. But Manetho's work, too, is lost except for some excerpts used by Sextus Julius Africanus and Eusebius in writing their chronicles. These, in turn, represented the material used in part by George Syncellus in the 8th century AD. During copying and recopying, Manetho's text clearly suffered many changes, unintentionally or on purpose. The figures of the reigns, especially of the older dynasties, for instance, were enlarged when some of the early Christian historians tried to equate King Menes with Adam. In addition, the excerpts were done carelessly, Therefore, Manetho's work, as handed down to us, is short of useless. Nevertheless, together with the fragments of the annals and of the king list of Turin, they create a framework of Egyptian chronology; so the division into dynasties was taken over from Manetho. But to achieve a continuous history of Egypt and to bridge the gaps left by the fragmentary state of the extant chronological material, scholars must turn to other means, particularly astronomical references found in dated texts. These are related principally to the rising of Sothis and to the new moon.

Theoretically, the Egyptian civil year began when the Dog Star, Sirius (Egyptian Sothis), could first be seen on the eastern horizon just before the rising of the Sun (i.e., 19/2 20 of July). As the civil calendar of the ancient Egyptians consisted of 12 months (each of 30 days) and five odd days (called epagomenal days), the civil year was a quarter of a day too short in relation to the rising of Sothis, so that the new year advanced by one day every four years. New Year's Day and the rising of Sothis cionicided again

The Turin Papyrus

The Sothic

only after approximately 1,460 years, the so-called Sothic cycle. Dated documents mentioning the rising of Sothis can be translated into the present calendar by multiplying the number of days elapsed since the first day of the year by four and subtracting this sum from the date of the beginning of the particular Sothic cycle. The dates for the start of each Sothic cycle are fortunately known because the Roman historian Censorinus fixed the coincidence of New Year's Day and heliacal rising of Sothis in AD 139. Taking into account a slight difference between a Sothic year and a year of the fixed stars, the years 1322, 2782, and 4242 BC are taken as starting points of a Sothic cycle.

There are six ancient Egyptian documents extant giving Sothis dates, but only three of these are of value. The oldest is a letter from the town of Kahun warning a priest that the heliacal rising of Sothis will take place on the 16th day of the 8th month of year 7 of a king who, according to internal evidence, is Sesostris III of the 12th dynasty. This date corresponds to 1866 BC, according to the corrected Sothic cycle. The next date is given by a medical papyrus written at the beginning of the 18th dynasty, to which a calendar is added, possibly to ensure a correct conversion of dates used in the receipts to the actual timetable. Here it is said that the 9th day of the 11th month of year 9 of King Amenhotep I was the day of the heliacal rising of Sothis-i.e., 1538 BC. This date, however, is only accurate provided that the astronomical observations were taken at the old residence of Memphis: if observed at Thebes in Upper Egypt, the residence of the 18th dynasty, the date must be lowered by 20 years-i.e., 1518 BC. The third Sothis date shows that Sirius rose heliacally sometime during the reign of Thutmose III, which lasted for 54 years, on the 28th day of the 11th month; so year 1458 BC (point of observation at Memphis) or 1438 BC (point of observation at Thebes) must have belonged to the reign of this king. From these dates it is possible to calculate the absolute dates for the reigns of the 12th dynasty, as the durations of most of the reigns of the kings belonging to this dynasty are preserved on the king list of the Turin Papyrus. On the other hand, chronologists are able to compute the reigns of the kings of the 18th dynasty by utilizing the highest dates of their documents and the figures preserved by Manetho. Historians are also helped by the fact that the Egyptians sometimes identified a certain day as "exactly new moon"; they reckoned new moon from the morning after the last crescent of the waning moon had become invisible in the east just before sunrise. As there is a 25-year lunar cycle, such ancient Egyptian moon dates could be calculated with a fair amount of certainty but of course only if the ancient Egyptians themselves observed this celestial phenomenon accurately. There is some doubt, however, as it is shown by the attempts of very competent scholars to convert these moon dates. Sometimes even moon dates given by the same papyrus contradict themselves; in another case, the date given by a document had to be amended to achieve a reasonable result. These and other examples show that ancient Egyptian statements on celestial phenomena, especially on new moons, tend to be inaccurate because of faulty or inexact observations. Therefore, every date given for a fixed reign should be used with caution as the astronomical observation on which it is based may be inexact. Sometimes they are controlled by synchronism with Babylonian, Assyrian, or Hittite king lists or, later on, by the close interconnections between Greek and Egyptian history. Sometimes even biographical data are helpful. The statements found on small stelae inside the burial ground of the holy bulls of Memphis (Apis) register the dates of birth, enthronement, and death of these animals accurately. But the more time recedes, the more the chronology of the Egyptian history becomes uncertain, even when astronomical data are available. Up till now even carbon-14 data are of no great help, as uncertainties are mostly not greater than the standard deviations to be expected in a carbon-14 calculation.

Nevertheless, Egyptologists believe themselves to be on fairly firm ground when dating the beginning of the Ancient Kingdom (1st and 2nd dynasty) about 3090 BC, the beginning of the 11th dynasty at 2133 BC, and of the

Middle Kingdom (12th dynasty) at 1991 BC. The New Kingdom started at 1567 or 1552 BC, depending on a choice for the first year of Ramses II of either 1290 BC or 1304 BC-one lunar cycle earlier. The following centuries still pose many chronological questions down to 664 BC, when Greek historiography took over.

Babylonian and Assyrian. Mesopotamian chronology. 747 to 539 BC. The source from which the exploration of Mesopotamian chronology started is a text called Ptolemy's Canon. This king list covers a period of about 1,000 years, beginning with the kings of Babylon after the accession of Nabonassar in 747 BC. The text itself belongs to the period of the Roman Empire and was written by a Greek astronomer resident in Egypt. Proof of the fundamental correctness of Ptolemy's Canon has come from the ancient cuneiform tablets excavated in Mesopotamia. including some that refer to astronomical events, chiefly eclipses of the Moon. Thus, by the time excavations began, a fairly detailed picture of Babylonian chronology was already available for the period after 747 BC. Ptolemy's Canon covers the Persian and Seleucid periods of Mesopotamian history, but this section will deal only with the period up to the Persian conquest (539 BC).

The chief problem in the early years of Assyriology was to reconstruct a sequence for Assyria for the period after 747 BC. This was done chiefly by means of limmu, or eponym, lists, several of which were found by early excavators. These texts are lists of officials who held the office of limmu for one year only and whom historians also call by the Greek name of eponym. Annals of the Assyrian kings were being found at the same time as eponym lists. and a number of these annals, or the campaigns mentioned in them, were dated by eponyms who figured in the eponym lists. Moreover, some of the Assyrian kings in the annals were also kings of Babylonia and as such were

included in Ptolemy's Canon.

Good progress was therefore being made when, soon after 1880, two chronological texts of outstanding importance were discovered. One of these, now known as King List A, is damaged in parts, but the end of it, which is well preserved, coincides with the first part of Ptolemy's Canon down to 626 BC. The other text, The Babylonian Chronicle, also coincides with the beginning of the canon, though it breaks off earlier than King List A. With the publication of these texts, the first phase in the reconstruction of Mesopotamian chronology was over. For the period after 747 BC, there remained only one serious lacuna-i.e., the lack of the eponym sequence for the last 40 years or so of Assyrian history. This had not been established by the early 1970s.

Assyrian chronology before 747 BC. German excavations at Ashur, ancient capital of Assyria, yielded further eponym lists. By World War I the full sequence of eponyms was known from about 900 to 650 BC. A further fragmentary list carried the record back to about 1100 BC, and on this basis Assyrian chronology was reconstructed, with little error, back to the first full regnal year of Tiglathpileser I in 1115 BC. Without another eponym list, a king list was needed for substantial further progress. King lists found at Ashur proved disappointing. Those fairly well preserved did not include figures for the reigns, and those with figures were very badly damaged.

In 1933, however, an expedition from the University of Chicago discovered at Khorsabad, site of ancient Dur Sharrukin, an Assyrian king list going back to about 1700 BC. But for the period before 1700 BC the list is damaged and otherwise deficient, and Assyrian chronology prior to this date is still far from clear.

Before 747 BC it was the custom of the Assyrian kings to hold eponym office in their first or second regnal year. Thus, in an eponym list, the number of names between the names of two successive kings usually equals the number of years in the reign of the first of the two kings. It would have been easy to compile a king list from an eponym list, and there is evidence that this Assyrian king list was compiled from an eponym list probably in the middle of the 11th century BC. As an eponym list is a reliable chronological source, since omission of a name entails an error of only one year, the king list, if based The limmu

Babylonian chronology before 747 BC. In the long interval between the fall of the last Sumerian dynasty c. 2000 sc and 747 nc. there are two substantial gaps in chronology, each about two centuries long. The earlier gap is in the 2nd millennium, from approximately [600–1400 nc, the later gap in the 1st millennium, from c. 943–747 nc. During these gaps the names of most of the kings are known, as well as the order, but usually not the length of

their reigns. A means of checking the reliability of the Babylonian king list is provided by the chronicles, annals, and other historical texts that show that a given Assyrian king was contemporaneous with a given Babylonian king. There are no fewer than 15 such synchronisms between 1350 and 1050 BC, and, when the Babylonian and Assyrian king lists are compared, they all fit in easily. Only one of them, however, provides a close approximate date in Babylonian chronology. This synchronism shows that the two-year reign of the Assyrian king Ashared-apil-Ekur (c. 1076-c. 1075 BC) is entirely comprised within the 13-year reign of the Babylonian king Marduk-shapik-zeri. The Assyrian's dates are probably correct to within one year. Thus, if Marduk-shapik-zeri is dated so that equal proportions of his reign fall before and after that of Ashared-apil-Ekur, a date is obtained for the former that should not be in error more than six years. This synchronism constitutes a key to the structure of Babylonian chronology by providing the base date for all the reigns in the interval c. 1400-943 BC for which the Babylonian king list gives figures. All the dates thus obtained are subject to the six-year margin of error.

These synchronisms between Assyrian and Babylonian kings continue throughout the period that corresponds to the second gap in the Babylonian king list—from c: 943–747 ac. Since the Assyrian chronology in that period is firmly established, these synchronisms provide a useful framework for the structure of Babylonian chronology in that period.

The gap in the 2nd millennium acc, however, is not as easy to fill. The fact that the magnitude of the gap is uncertain constitutes the main problem in the chronology of the 2nd millennium e and also affects the chronology of the preceding Sumerian period. The problem is not yet solved. Observations of the planet Venus made during the regin of King Ammissaduqa, less than 50 years before the end of the 1st dynasty of Babylon, permit only certain possible dates for his reign. Translated into dates for the end of the dynasty, the three most likely possibilities are 1651, 1595, and 1587 ac. The evidence is not yet conclusive and leaves uncertain what choice should be made among the three. The chronology adopted here is based on the second of these dates for the end of the 1st Babylonian dynasty—Le, 1595 ac.

Prior to this gap in the 2nd millennium BC, there is a period of five centuries with a well-established chronological structure. All the kings in the major city-states are known, as well as their sequence and the length of their reigns, Which sets of dates should be assigned to these reigns, however, depends on the date adopted for the 1st dynasty of Babylon. This period of five centuries extends from the beginning of the 3rd dynasty of Ur to the end of the 1st dynasty of Babylon-i.e., on the chronology adopted here, 2113-1595 BC. During this period the Babylonians dated their history not by regnal years but by the names of the years. Each year had an individual name, usually from an important event that had taken place in the preceding year. The lists of these names, called year lists or date lists, constitute as reliable a source in Babylonian chronology as the eponym lists do in Assyrian chronology. One of the events which almost invariably gave a name to the following year was the accession of a new king. Hence, the first full regnal year of a king was called "the year (after) NN became king." In Assyria the number of personal names in an eponym list between the names of two successive kings normally equalled the number of years in the reign of the first king, and, similarly, in Babylonia the number of year names between two year names of the above kind nearly always equalled the number of years in the reign of the first king. Just as in Assyria, the eponym lists are almost certainly the source of the king lists, so in Babylonia the king lists are based on the year lists. Several of these king lists, compiled at a time when the year lists were still in use, survive. One gives the 3rd dynasty of Ur and the dynasty of Isin; another gives the dynasty of Larsa. Both may be school texts.

in the School text.

The 3rd dynasty of Ur and the dynasty of Isin also figure in the Sumerian king list, which reaches far back into the Sumerian period. The original version probably ended before the 3rd dynasty of Ur, but later scribes brought it up to date by adding that dynasty as well as the dynasty of Isin.

(M.B.R.

Jewish. The era at present in vogue among the Jews, counted from the creation of the world (anno mundi: abbreviated to AM), came into popular use about the 9th century AD. Traceable in dates recorded much earlier, this era has five styles conventionally indicated by Hebrew letters used as numerals and combined into mnemonics, which state the times of occurrence of the epochal mean conjunctions of moladim (see CALENDAR: Middle Eastern calendar systems: The Jewish calendar) or the orders of interealation in the 19-year cycle or both. The respective epochs of these styles fall in the years 3762–3758 ec, inclusive. By about the 12th century AD the second of the mentioned styles, that which is in use at present, superseded the other styles of the era anno mundi.

The styles of this era arise from variations in the conventional rabbinical computation of the era of the creation. This computation, like hundreds of other calculations even more variable and no less arbitrary, is founded on synchronisms of chronological elements expressed in the terms of biblical and early ostibiblical Jewish eras.

terms of noticed area anno mundi underlies the dating of events (mainly in the book of Genesis) prior to the Exodus from Egypt. This period of biblical chronology abounds in intractable problems caused by discrepancies between the lewish and Samaritan Hebrew texts and the Greek version known as the Septuagint, by apparent inconsistencies in some of the synchronisms, and by uncertainties about the method of reckoning.

Discrepancies in biblical

During the period from the Exodus to the founding of Solomon's Temple, the only continuous biblical era (chiefly in the remaining books of the Pentateuch) is the era of the Exodus. With regard to a crucial date expressed in this era—"in the four hundred and eightieth year after the people of Israel came out of the land of Egypt, in the fourth year of Solomon's reign over Israel, in the month of Ziv, which is the second month, he began to build the house of the Lord" (I Kings 6:1)—there is again a discrepancy between the Hebrew text and the Septuagint. Other problems to be met with during this period are due to the obscurity of chronological data in the book of Judges and in I and II Samuel.

During the following period, the Bible uses the eras of the regnal years of monarchs (the kings of Judah, Israel, and Babylon) and of the Babylonian Exile. This period of biblical chronology likewise poses numerous problems, also the result of apparent inconsistencies of the synchronisms—e.g., in the period from the accession of Rehoboam of Judah and of Jeroboam of Jarael to the fall of Samaria "in the sixth year of Hezekiah [of Judah], which was the ninth year of Hosbea king of Israel" (Il Kings 18:10) the reigns of the southern kingdom exceed those of

the northern kingdom by 25 years. The biblical data might be easier to harmonize if the occurrence of coregencies were assumed. Yet, as an every-ariable factor, these evidently would not lead to the determination of the true chronology of this period. Scholars therefore seek additional information from sources outside the Bible—e.g., inscriptions on Assyrian monuments, which are dated by the so-called eponym lists. Substantial use also has been made of the data in the king list known as Ptolemy's Canon (compiled in the 2nd Christian century) commencing in 747 Be with the reigns of the Babylonium of

chronol-

kings (see above Babylonian and Assyrian). Scholars differ widely, however, in their interpretation of details, and numerous chronological problems remain unsolved. Only a few dates in this period can be fixed with any degree of confidence

After the Babylonian Exile, as evidenced by the data in the Bible and the Aswan papyri, the Jews reckoned by the years of the Persian kings. The chronological problems of this period are caused by the apparent disorder in the sequence of events related in the biblical books of Ezra and Nehemiah and by the difficulty of identifying some of the Persian kings in question. For example, the King Artaxerxes of these books may stand for Artaxerxes I Longimanus (465-425 BC), for Artaxerxes II Mnemon (404-359/358 BC), or in the case of Ezra at any rate, for Artaxerxes III Ochus (359/358-338/337 BC)

From the Grecian period onward, Jews used the Seleucid era (especially in dating deeds; hence its name Minyan Shetarot, or "Era of Contracts"). In vogue in the East until the 16th century, this was the only popular Jewish era of antiquity to survive. The others soon became extinct. These included, among others, national eras dating (1) from the accession of the Hasmonean princes (e.g., Simon the Hasmonean in 143/142 BC) and (2) from the anti-Roman risings ("era of the Redemption of Zion") in the years 66 and 131 of the Common (Christian) Era. Dates have also been reckoned from the destruction of the Second Temple (le-hurban ha-Bayit). The various styles of the latter, as also of the Seleucid era and of the era anno mundi, have often led to erroneous conversions of dates. The respective general styles of these eras correlate as follows: 3830 AM = year 381 of the Seleucid era = year 1 of the Era of the Destruction = year 69/70 of the Common (Christian) Era.

The earliest Jewish chronologies have not survived. Of the work of the Alexandrian Jew Demetrius (3rd century BC), which deduced Jewish historical dates from the Scriptures, only a few fragments are extant. In the Book of Jubilees, events from the creation to the Exodus are dated in jubilee and sabbatical cycles of 49 and 7 years, respectively. Scholars differ as to the date and origin of this book. The era of the creation therein is unlikely to

have been other than hypothetical.

The earliest and most important of all Jewish chronologies extant is the Seder 'olam rabba' ("Order of the World"), transmitted, according to Talmudic tradition, by Rabbi Yosi ben Halafta in the 2nd century AD. The author was possibly the first to use the rabbinic Era of the Creation. His chronology extends from the creation to Bar Kokhba in the days of the Roman emperor Hadrian (2nd century AD); but the period from Nehemiah to Bar Kokhba (i.e., from Artaxerxes I or II to Hadrian) is compressed into one single chapter. The Persian phase shrinks to a mere 54 years. The smaller work Seder 'Olam zuta' completes the Rabba'. It aims to show the Babylonian exilarchs as lineal descendants of David.

Megillat ta'anit ("Scroll of Fasting"), although recording only the days and months of the year without the dates of the years, is nevertheless an important source for Jewish chronology. It lists events on 35 days of the year that have been identified with events in five chronological periods; (1) pre-Hasmonean, (2) Hasmonean, (3) Roman (up to AD 65), (4) the war against Rome (65-66), and (5) miscellaneous. The authors, or rather the last revisers, are identified with Zealots guided by Hananiah ben Hezekiah ben Gurion and his son Eliezer.

Greek. As the cities of ancient Greece progressed to their classical maturity, the need arose among them for a chronological system on a universally understood basis. In the archaic period, genealogies of local monarchs or aristocrats sufficed for the historical tradition of a given area, and events were associated with the lifetimes of wellknown ancestors or "heroes." The synoikismos (founding of the united city) of Athens took place "in the time of Theseus"; the Spartan ephorate (chief magistracy) was established "in the reign of King Theopompus." When the city-states adopted annual magistracies, the years were designated by the eponymous officials-"in the archonship of Glaucippus" or "when Pleistolas was ephor." This was the local usage throughout classical and Hellenistic Greece. the title of the magistrate varying in different cities. Sometimes tenure of a priesthood provided the chronological basis, as at Argos, where years were dated as the nth of the (named) priestess of Hera. The correctness of the series was a matter first of memory and later of careful record. The list of annual archons at Athens was known back to 683 BC (in modern terms). Lists of dynasties also amounted to recorded folk memory, and in all genealogical reckoning there is a point, for modern critics, at which acceptable tradition shades into myth. Corruption of the records was introduced through error or political design. and traditions often conflicted.

Chronology became subject to systematization when cities felt a national need for accurate clarification of their past. In literature the growth of historiography initiated a search for a method of dating that could be universally applied and acknowledged. In the 5th and 4th centuries, local historians used local magistracies as their framework; research was devoted to rationalization of conflicting traditions and production of definitive lists. Charon of Lampsacus, perhaps in the early 5th century, compiled a record of Spartan magistrates; Hellanicus of Lesbos, author of the earliest history of Athens, wrote on the priestesses of Argos. Lists of victors in the great Olympic games were valid for all Greece, pointing the way to the widely accepted reckoning by Olympiads (see below). The Athenian Philochorus was the latest (early 3rd century BC) of compilers of Olympionikai.

The 5th-century historian Herodotus relied for his chronology principally upon the reckoning by generations used by his informants, conventionally accepted as showing three generations to a century. In some cases a 40-year, or other, reckoning was used, and varying traditions sometimes produced difficulty of synchronism. Thucydides, writing "contemporary" history, recognized the chronological problems involved. He dated the beginning of the Peloponnesian War by the Athenian, Spartan, and Argive systems and thenceforward marked the passage of time by seasonal indications. Synchronization was not helped by the fact that the official year began at different times in different cities. In later historical writing the impossibility of accurately coordinating the Athenian and Roman years

resulted in serious chronological difficulties.

The system of dating by Athenian archons came to be recognized outside Attica as of wider value, but, in the Hellenistic period, Alexandrian scholarship, represented especially by Eratosthenes of Cyrene, the "father of chronology," was instrumental in promoting the use of the Dating Olympiads as an acceptable system, reckoning a fouryear period from each celebration of the Olympic Games. Timaeus of Tauromenium (c. 356-260 BC) was the first historian to employ it, but it was little used outside historical writing. Aristotle had been concerned to identify the generation of the first Olympiad, accepted as 776 BC on modern reckoning. For convenience, the beginning of the Olympic year was equated with the summer solstice, when the Athenian year also began. This makes it generally necessary for a Greek year to receive a double date in modern terms (e.g., the death of the philosopher Epicurus in 271/270 BC). Eratosthenes' system produced tables of dates, from which, for example, the fall of Troy could be dated to 1184/83 BC. The "Parian Marble" of 264/ 263 BC is an inscribed record of events from the time of Cecrops, first king of Athens, reckoning years between the date of the inscription, fixed by the Athenian archon, and each event concerned. Some cities inscribed lists of their eponymous magistrates; the Athenians were the first to do so c. 425 BC. A list from Sicilian Tauromenium originally spanned some 300 years. The regnal years of the Hellenistic monarchs or the count from a fixed event (a city foundation or refoundation) also provided acceptable chronological reckoning often useful for more than contemporary or local purposes.

The use of these chronological possibilities is best seen in historians using the annalistic method, of whom Diodorus Siculus is most notable. In the Christian period, Eusebius, followed by St. Jerome, began the work of reconciling all these indications to the Judaic tradition and produced

by the Olympiads

Dating by local records

the foundation of chronology in terms of the Julian calendar upon which modern historians have constructed their framework.

For modern scholarship the problem, in E.J. Bickerman's words, is "how we know Caesar was assassinated on March 15, 44 BC." Before 480 BC, no date can be precise in terms of the Julian calendar unless confirmed by astronomical phenomena. Archaic chronology relies upon the typology of Corinthian pottery in relation to the foundation dates for Greek colonies in Sicily implicit in Thucydides, book vi. Julian dates given for this period (e.g., for the tyranny of Peisistratus in Athens) stem from a complex combination of ancient chronographic tradition with modern archaeology, acceptable only with appropriate reserve. Literary tradition gives the succession of Athenian archons from 480 to 294 BC. The regnal, era, and Olympiad years also provide dates within a 12-month period. Closer dating is seldom possible unless the sources give precise information in calendric terms, as occasionally in literature and regularly in Athenian and Egyptian public documents. Even these are not translatable into Julian months and days unless coordinated with knowledge of contemporary solar or lunar phenomena and of possible official interference with the calendar.

(AGW)

Roman. The establishment of a sound chronology for Roman history, as for Greek, depends on the assessment of the evidence available, which falls into two categoriesliterary and archaeological.

Literary evidence. Although by the late 3rd century BC the Greek mathematician Eratosthenes was working on the systematization of chronography and a series of learned historians had used the documentary method-e.g., for Roman history, Timaeus of Tauromenium, to whom are probably due many of the synchronizations of Roman history with the Greek Olympiads-unfortunately this tradition of documentation and concern for chronology did not immediately pass over into Roman historiography. According to Cicero in De oratore, the earliest Roman historians did no more than "compile yearbooks"-for example, Fabius Pictor in the late 3rd century BC, Lucius Calpurnius Piso in the 2nd, and the so-called Sullan annalists in the 1st. Of these authors it is possible to judge only at second hand, and only those of the 1st century were much used directly by the historians whose work survives in any quantity, notably Livy, Dionysius of Halicarnassus, and Diodorus Siculus. In these authors, as in other 1st-century historians such as Sallust, there is little concept of documentation or research other than comparison of literary sources; for none was chronology a direct concern, and in many cases dramatic effectiveness took priority over fidelity to truth. Apart from the Greek Polybius, who treated the rise of Roman power in the Mediterranean from 264 to 146 BC, it was not until Cicero's time that the conception of historical scholarship developed in Rome, Cicero's friend Atticus not only was concerned to draw up a chronological table in his Liber annalis but had undertaken research to that end, and the great scholar Marcus Terentius Varro and a little later the learned Marcus Verrius Flaccus produced a vast body of erudite work, nearly all lost. To this source must probably be ascribed the Fasti Capitolini, a list of magistrates from the earliest republic to the contemporary period, set up near the regia (the office and archive of the pontifices, or high priests), perhaps on the adjacent Arch of Augustus, at the end of the 1st century BC. This work, since it is based on inscriptions, is sometimes given precedence over literary evidence, but, since it is a compilation, it is still subject to serious error.

Sources used by Roman historians. The traditionally early extant bodies of law, such as the Twelve Tables from the early republic, were of little chronological value. and juristic commentarii were liable to mislead through their zeal for precedent, while Cicero, in spite of Polybius' claim to have inspected early treaties preserved in the Capitol definitely states that there were no public records of early laws. A source frequently referred to is the Annales maximi, a collection made about 130 BC of the annual notices displayed on a white board by the pontifices and

containing notes of food prices, eclipses, etc. Dionysius of Halicarnassus implied that they gave a date for the foundation of the city but was reluctant to accept their authority; and one of the eclipses is referred to by Cicero as being mentioned also by Ennius, but unfortunately the number of the year "from the foundation of the city" is corrupt in the text. Although it is possible to calculate the dates of eclipses astronomically in terms of the modern era, it is difficult to link these to Roman chronology because of the uncertainty of the figures and because of the confused state of the Roman calendar before the Julian reform (see CALENDAR; Early calendar systems: The early Roman calendar). Another difficulty is that the early records may have been burned in 390 BC when Celtic tribes sacked the city; also they would probably have been largely unintelligible if authentic.

Livy quoted the 1st-century annalist Gaius Licinius Macer as having found in the temple of Juno Moneta "linen rolls" giving lists of magistrates; but he also said that Macer and Ouintus Aelius Tubero both cited the rolls for the consuls of 434 but gave different names. In any case, it is unlikely that the list could have been older than the temple, which dates from 344 BC. It is clear that the chief sources for the lists were the pedigrees of prominent Roman families, such as the Claudii Marcelli, Fabii, and Aemilii, drawn up by Atticus; but Cicero and Livy agree that tendentious falsifications had in many cases corrupted the records, and other suspicious facts are the appearance of obviously later or invented cognomina, or third names, and of plebeian gentile names for the earliest period, when only patricians bore them. Many scholars, however, accept the general authenticity of the lists-one reason being the appearance in them of extinct patrician families-but prefer Livy's version to that of the Capitoline lists, which show signs of late revision, often give names in incorrect order, and contain other anomalies.

The question, therefore, remains whether Roman chronography was dependent on the lists of magistrates or whether these were adapted to fit other known datings. The apparent advantages of the existence of a terminal date, the "foundation of the city," is illusory for Roman chronology, since it depended on back reckoning and was not agreed even in antiquity. Various ancient scholars each assumed a different date. Each computed his date by adding a different number of years of kingly rule from the foundation of the city to his estimate of the date of the foundation of the republic. This, in turn, was presumably computed by counting back over the yearly lists of magistrates. There may have been traditions about the intervals between certain events in early Roman history, but the frequently accepted reckoning of 244 years of kingly rule seems to be a calculation based only on the conventional 35-year generation for the rule of the seven legendary kings. Polybius claimed that the dating of the first republican consulship to 508/507 BC could be substantiated by an extant copy of a contemporary treaty. Combined with the traditional kingly period, this would give a foundation date of 751-750, reckoned inclusively, and 752-751, exclusively (Cato's date). The chronological scheme worked out by Varro added two years of nonconsular rule, thus the foundation of Rome was put in 754/753 and the beginning of the republic in 510/509. Varro's dates became standard for later Romans and are sometimes also used by modern scholars in a purely conventional sense. But it remains uncertain whether the dating depended on the magistrate lists or whether these were "doctored" to synchronize with given dates or intervals, whether these were traditional or calculated in some other way. Anomalies such as Livy's five-year anarchy 15 years after the Gallic invasion, Diodorus' repetition of magistrates' names, and the "dictator years" in the lists are perhaps attempts to synchronize the various pedigrees.

Contribution of archaeology. Archaeology can provide many dates useful to the detailed study of Roman history, especially from coins and inscriptions, but, for the general scheme of early chronology, its value is largely negative. It shows, for example, that Rome evolved over a lengthy period and was not really "founded," though a "foundation" date might perhaps refer to the first common celebration

Fixing the terminal

Magistrate

of the Septimontium, or festival of the seven hills; again, if that dating is dependent on the seven kings, archaeology shows that the tradition about them, though it may preserve genuine names and events, is largely legendary.

Datings after the 1st century BC. In this better documented period, datings to consul years, or later to the years of tribunician power of the emperors, are normally intelligible, despite a few notorious cruxes, although up to the Julian reform the state of the calendar has always to be taken into account. In parts of the empire, however, different eras were used-e.g., that of the Seleucids-and from the 4th century AD dates were often calculated in terms of the years of the indiction, a 15-year cycle connected with the levying of taxes, a method that continued in use for many centuries in spite of difficulties, such as lack of synchronization among the various provinces.

The Christian Era

Christian. The Christian Era is the era now in general use throughout the world. Its epoch, or commencement, is January 1, 754 AUC (ab urbe condita-"from the foundation of the city [of Rome]"-or anno urbis conditae-"in the year of the foundation of the city"). Christ's birth was at first believed to have occurred on the December 25 immediately preceding. Years are reckoned as before or after the Nativity, those before being denoted BC (before Christ) and those after by AD (anno Domini, "in the year of the Lord"). Chronologers admit no year zero between 1 BC and AD 1. The precise date of commencing the annual cycle was widely disputed almost until modern times, December 25, January 1, March 25, and Easter day each being favoured in different parts of Europe at different periods.

The Christian Era was invented by Dionysius Exiguus (c. AD 500-after 525), a monk of Scythian birth resident in Italy; it was a by-product of the dispute that had long vexed the churches as to the correct method of calculating Easter. Many churches, including those in close contact with Rome, followed 95-year tables evolved by Theophilus, bishop of Alexandria, and by his successor, St. Cyril; but some Western churches followed other systems, notably a 532-year cycle prepared for Pope Hilarius (461-468) by Victorius of Aquitaine. In 525, at the request of Pope St. John I, Dionysius Exiguus prepared a modified Alexandrian computation based on Victorius' cycle. He discarded the Alexandrian era of Diocletian, reckoned from AD 284. on the ground that he "did not wish to perpetuate the name of the Great Persecutor, but rather to number the years from the Incarnation of Our Lord Jesus Christ.'

Somehow Dionysius reckoned the birth of Christ to have occurred in 753 AUC; but the Gospels state that Christ was born under Herod the Great-i.e., at the latest in 750 AUC, Dionysius' dating was questioned by the English saint Bede in the 8th century and rejected outright by the German monk Regino of Prüm at the end of the 9th. Nevertheless, it has continued in use to the present day, and, as a result, the Nativity is reckoned to have taken place before the start of the Christian Era.

The new chronology was not regarded as a major discovery by its author; Dionysius' own letters are all dated by the indiction (see below). The use of the Christian Era spread through the employment of his new Easter tables. In England the Christian Era was adopted with the tables at the Synod of Whitby in 664. But it was the use, above all by Bede, of the margins of the tables for preserving annalistic notices and the consequent juxtaposition of historical writing with calendrical computations that popularized the new era. Outside Italy it is first found in England (in a charter of 676) and shortly afterward in Spain and Gaul. It was not quickly adopted in royal diplomas and other solemn documents, however, and in the papal chancery it did not replace the indiction until the time of John XIII (965-972). The Christian Era did not become general in Europe until the 11th century; in most of Spain it was not adopted until the 14th and in the Greek world not until the 15th.

Of the alternative chronologies used by Christians, the most important were: (1) the indiction, (2) the Era of Spain, and (3) the Era of the Passion. The indiction was a cycle of 15 years originally based on the interval between imperial tax assessments but during the Middle Ages always reckoned from the accession of Constantine, in 312. Years were given according to their place in the cycle of 15, the number of the indiction itself being ignored. This chronology was the most widespread in the early Middle Ages, but its use diminished rapidly in the 13th century, although public notaries continued to use it until the 16th, The Era of Spain was based on an Easter cycle that began on January 1, 716 AUC (38 BC), marking the completion of the Roman conquest of Spain. First recorded in the 5th century, it was in general use in Visigothic Spain of the 6th and 7th centuries and, after the Arab invasions, in the unconquered Christian kingdoms in the north of the Iberian Peninsula. It was abolished, in favour of the Era of the Incarnation, in Catalonia in 1180, in Aragon in 1350, in Castile in 1383, and in Portugal in 1422. The Era of the Passion, commencing 33 years after that of the Incarnation, enjoyed a short vogue, mainly in 11thcentury France.

Muslim. Unlike earlier chronological systems in use before Islām, Islāmic chronology was instituted so soon after the event that was to be the beginning of the Muslim era that no serious problems were encountered in its application. According to the most reliable authorities, it was 'Umar I, the second caliph (reigned 634-644), who introduced the era used by the Muslim world. When his attention was drawn by Abū Mūsā al-Ash'arī to the fact that his letters were not dated, 'Umar consulted with men at Medina and then ordered that the year of the hijrah (hegira), the Prophet's flight from Mecca to Medina, be taken as the beginning of an era for the Muslim state and community. According to the Muslim calendar, the hijrah took place on 8 Rabi' I, which corresponds to September 20, 622 (AD), in the Julian calendar. But, as Muharram had been already accepted as the first month of the lunar year, 'Umar ordered that (Friday) 1 Muharram (July 16. 622) be the beginning of the reckoning. It is generally accepted that this was done in AH 17 (anno Hegirae, "in the year of the Hegira").

There are a few points in connection with this that deserve mention: first, there is no real agreement on the exact date of the hijrah-other dates given include 2 and 12 Rabi' I; second, the year in which 'Umar issued the order is a point of contention-the years 16 and 17 are sometimes given; third, some people have ascribed the use of the chronology to the Prophet himself. According to some sources, the hijrah date was first used by Ya'lā ibn Umayyah, Abū Bakr's governor in Yemen. This sounds somewhat plausible because Yemenis were probably used to affixing dates to their documents. There is, however, a consensus among workers in the field that 8 Rabi' I was the day of the hirah, that 'Umar instituted the use of the date for the new era, and that this was done in AH 17. The choice of the hijrah as the beginning of the epoch has two reasons. On the one hand, its date had been fixed; on the other, 'Umar and his advisers must have recognized the importance of the migration-Islam had become, as a result, a religion and a state.

Before the introduction of the new epoch, the Arabs had been acquainted with chronologies used by their neighbours, the Seleucids and the Persians. In Yemen the practice of dating had been perfected to the extent that inscriptions show the day, the month, and the year. In Mecca the "year of the Elephant," supposedly coinciding with the birth of the Prophet, had been in use. For the period between the migration and the institution of the new epoch, the Muslims of Medina resorted to naming the year after local events-"the year of the order of fighting" and "the year of the earthquake," etc.

The lunar year was adopted by the Muslims for the new chronology. In this there was hardly any innovation insofar as Arabia was concerned.

The chronology introduced by 'Umar was adopted throughout the Muslim world, although earlier epochs continued in use in outlying provinces. Muslim historians, annalists, and chroniclers met with difficulties when writing their books on pre-Islamic history. No practice had as yet developed for pre-hijrah dating; therefore, when writing about the history of various lands in pre-Islamic times,

The era of the hijrah

authors resorted to the use of chronologies previously in existence there (e.g., Persian, Indian, Seleucid, Alexandrian). For the histories of the area under Islam, writers used only Muslim chronology, while non-Muslim authors (e.g., Bar Hebraeus) used the Seleucid and the hijrah dates when discussing events pertaining to provinces that had been Byzantine and therefore still had fairly large groups

The era of the hijrah is in official use in Saudi Arabia, the two Yemens, and in the Persian Gulf area. Egypt, Syria, Jordan, Morocco, Algeria, Libya, and Tunisia use both the Muslim and the Christian eras. Many Muslim countries, such as Turkey, Nigeria, and Pakistan, use the

Christian Era.

Variants of the hijrah era

Within the general uniformity of applying the hijrah era proper, there existed differences, some of which were the result of earlier pre-Islāmic practices; others were the result of continuous contacts of Muslim countries with their European neighbours, with whom they had economic as well as political relations. An example of the former was the work of the 'Abbasid caliph al-Mu'tadid, who brought the Nowrûz (Persian New Year's Day) back to date in keeping with the agricultural activities of the community. Maḥmūd Ghāzān introduced the Khānian era in Persia in AH 701, which was a reversion to the regnal chronologies of antiquity. It continued in use for some generations, then the ordinary hijrah era was reintroduced. A similar step was taken by Akbar when he established the Ilāhī era, which began on Rabi' II 963 (February 13, 1556), the date of his accession; the years were solar.

Two Muslim countries. Turkey and Iran, introduced more drastic changes into their chronology because of Eu-

ropean influences.

In Turkey the Julian calendar was adopted in AH 1088 (AD 1676-77) and used solar months with hijrah dating. The year was officially called the Ottoman fiscal year but was popularly known as the marti year, after mart (Turkish for March), which was the beginning of the year. Under Mustafa Kemal Atatürk, the Gregorian calendar and the Christian Era were officially adopted in Turkey (1929). Iran also adopted a solar year; the names of the months in its calendar are Persian, and the era is still that of the hiirah (NAZ)

Pre-Columbian American. Maya and Mexican. The lowland Maya had a 365-day year formed of 18 "months," Each month consisted of 20 days, plus five "nameless" days, which the Maya considered an extremely dangerous and unlucky period and during which activities were kept to a minimum. Leap days were not intercalated.

Reckoning was not by those years but by tuns (360 days) and their multiples of 20: katuns (20 tuns), baktuns (400 tuns), pictuns (8,000 tuns), calabtuns (160,000 tuns), and kinchiltuns (3,200,000). In practice, the last three were seldom used. The tun comprised 18 uinals, each of 20 kins (days), but these did not coincide with the equivalent divisions of the 365-day year. The Maya normally carved or wrote these in descending order; students transcribe them in Arabic numerals-e.g., 9.10.6.5.9 represents nine baktuns, ten katuns, six tuns, five uinals, nine kins.

With this system, current dates were related to the start of the Maya era, which, because of the Maya system of reentering cycles, marked both the end of 13 baktuns (written 13.0.0.0.0) and the start of another cycle of baktuns and perhaps commemorated a re-creation of the world. the baktun about to enter being numbered 1, not 14. Because of the construction of the calendar, this start of the era happened to be day 4 Ahau falling on the eighth day of the month Cumku,

Such reckonings are called Initial Series, or Long Counts, the former because they usually stand at the start of an inscription (see CALENDAR). For example, the combination day 8 Muluc, falling on second of Zip (third month), recurs every 52 years, but the Initial Series (here 9.10.6.5.9 8 Muluc 2 Zip) pinpoints its position. The next occurrence, 52 years later, would be 9.12.19.0.9 8 Muluc 2 Zip. Each unit had its own glyph (or symbolic character), with appropriate number (normally a dot for 1 and bar for 5) attached

A shorter dating system was by "Period Endings"-that

is, by recording the ending of the current baktun, katun. or tun. Thus, day 13 Ahau and month position 13 Muan with 13 tuns added is an abbreviation of 9.17,13.0.0 13 Ahau 13 Muan, a combination that will not repeat for over 900 years (949 tuns). A still shorter but less precise method was to give the day and its number ending the current katun.

Several Maya dates were commonly linked to Initial Series or Period Endings by series of additions or subtractions-a glyph signifying count indicated forward or

backward by secondary attachments.

Dates were normally reckoned from the 4 Ahau 8 Cumku base, nearly 4,000 years before most inscriptions, but some calculations ranged far into the past and a few into the distant future. One reaches backward nearly 1,250,000 years, but the deepest probings of eternity are embodied in texts that seemingly record positions respectively 90,000,000 and 400,000,000 years ago. Although the interpretation of these last computations is disputable, the Maya certainly thought in millions of years a millennium before Europe discarded the view that the world was only some 6,000 years old.

The Maya conceived of time as a journey through eternity in which each deified number-all time periods and their numbers were gods-carried his period on his back supported by a tump line. Each evening the procession rested. Next morning, carriers whose period was completed were replaced. For instance, if the uinal and kin numbers were 15 and 19 respectively, the new carriers would be the deified 16 and 0 (the latter because kin numbers go no higher than 19). Other period numbers would journey on until it came time to change the tun carrier. Much ritual and imagery grew out of this concept of the march of time; sculpture illustrates bearers lowering their burdens

at journey's end.

Correlation of the Maya calendar with ours depends on several factors. First, the 260-day almanac still functions in some Maya villages in the Guatemalan highlands. As there is excellent evidence it has neither gained nor lost a day since the Spanish conquest, despite strong Spanish efforts to suppress it, one may reasonably assume no break under the more favourable pre-Columbian conditions. Lunar and other data support such a view, Second, month positions in Yucatán and southern Petén at the Spanish conquest also are reliably correlated to the day with the present Western calendar. Third, the combined day and month parts of the Maya calendar are in day-forday agreement with the present Western calendar within a 52-year span (after that given day and month positions repeat). The katun (specifically, 13 Ahau) current at the Spanish conquest is, however, known, thereby fixing any day and month position in a longer range of 260 years because a named katun repeats only after 260 tuns. Those conditions produce a correlation of the two calendars that is either correct to the day or is 260 or even 520 years wrong, since historical evidence does not specify which particular katun 13 Ahau coincided with the Spaniards' arrival. Fourth, such factors as astronomy (Maya records of heliacal risings of Venus and of many dates with moon age stated), pottery sequences, architectural changes (less reliable), and data from neighbouring areas govern choice of the applicable katun 13 Ahau. Weight of evidence led to wide acceptance of the Goodman-Martinez-Thompson correlation that equates 13.0.0.0.0 4 Ahau 8 Cumku, start of the Maya era, with August 10, 3114 BC, and the Classic period with AD 300 to 900. Fifth, when the carbon-14 dating technique was first applied to the problem, various difficulties attendant on the use of new techniques and failure to take into account that a tree dies year by year from its centre outward (so that a sample from the core might give a date well over a century before felling) distorted readings, producing results favourable to the correlation making Maya dates 260 years earlier. Now, with better technique and averaging of many "runs" of samples of latest growth from beams at Tikal with secure Maya dates, carbon-14 readings overwhelmingly support the Goodman-Martinez-Thompson correlation.

The only other Middle American calendar with a known era is that of the Cakchiquel of highland Guatemala.

conception of time

The system was vigesimal: kih, day; uinak, 20 days; a, 400 days; and may, 8,000 days. The 400-day "year" ran concurrently with the 260-day almanac, which, in turn, synchronized with all other Maya almanacs. Like the 360day tun of the lowlands, the 400-day a was the counting unit, for reckoning was always in multiples of the a, never by days, as in our Julian calendar. May signifies twenty. and is so named because it comprised 20a. At the arrival of the Spaniards, reckoning was from a revolt in AD 1493. Earlier eras may be postulated, but inscribed calendrical texts are lacking in Cakchiquel territory.

Aztec. The Aztec and related peoples of central Mexico employed the cycle of 52 years, constructed, like its Maya equivalent, of concurrent 365-day years and 260day cycles, any position of the former coinciding with a given position of the latter only at 52-year intervals. Again leap days were not used. At completion of the 52 years, known as "binding of the years," elaborate ceremonies were held to avert destruction of the world expected on that occasion. The last occurrence before the Spanish conquest was in AD 1507. Although the last creation of the world was designated by a day name, neither that nor any other was in general use in central Mexico as the start of an era. Aztec reckoning is normally from their arrival in the Valley of Mexico, supposedly the year 1 Flint (AD 1168).

There is much confusion in placing events in Mexican history because no system of distinguishing one 52-year cycle from another was employed except by writing every year glyph throughout the period covered, a clumsy arrangement. Each year was named for either its last day (omitting the five-day unlucky period) or for the last day of the fifth month (both choices have distinguished supporters). In either case, only four day names (House, Rabbit, Cane, and Flint), each with its accompanying numeral, could designate a year. The Spanish conqueror Hernán Cortés seized the Aztec capital in 1521, year 3 House, but some past event, also assigned to a year 3 House but unlocated in a full sequence of years, might refer to AD 1261, 1313, or 1365, etc. Month positions were rarely given in chronological statements.

Peoples of Oaxaca and the Isthmus of Tehuantepec. Pictorial books of the Mixtec of Oaxaca record events in the lives of ruling families covering seven centuries, but, again, happenings are fixed only by the day on which each occurred and the year in which the day fell. Sequence is usually clear, but at times there is doubt as to which 52-year period is meant when parenthetical material, such as life histories of secondary characters, is

No era is recognizable. A clouded entry concerning the descent to Earth of the Sun and Venus, perhaps assignable to AD 794, is a logical starting point, but other entries are earlier.

Little is known of the calendar of the Zapotec, neighbours of the Mixtec. Years began on a different set of days, and glyphs differ from those of Mixtec and Aztec. Months are not recorded on monuments, which are numerous, and no chronological system has survived. Most Zapotec texts are early.

Rare inscriptions in western Chiapas, southern Veracruz, and the Guatemalan Pacific coast resemble the abbreviated lowland Maya Initial Series used in script and on a single sculpture in that numerical bars and dots are in a vertical column with period glyphs and month signs suppressed, clearly place numeration, that is, the value of each unit was shown by its position in the column. The linguistic affiliation of their sculptors is unknown.

All texts are either fragmentary or damaged; the two complete ones, unlike Maya Initial Series, open with days signs (and different ones at that). If, as one may reasonably assume, the series of bars and dots departed from those day signs, a fixed era is questionable. Nevertheless, some scholars postulate use of the Maya era (13.0.0.0.0 4 Ahau 8 Cumku). This little understood system may have been ancestral to the Maya Initial Series, the Maya perhaps developing a fixed era, for they alone seem to have been interested in an exact chronological system.

DIPLOMATICS

Diplomatics, broadly speaking, is the study of documents. The term is derived from the Greek word diploma, meaning "doubled" or "folded." Besides the documents of legal and administrative import with which it is properly concerned, diplomatics also includes the study of other records such as bills, reports, cartularies, registers, and rolls. Diplomatics is therefore a basic and not simply an auxiliary historical science. This article deals with its development and practice in the Roman Empire and in Europe. During Roman antiquity certain documents containing different sorts of authorizations were engraved on a bronze diptych and then folded and sealed, in order to keep the contents secret-hence the term diploma. Rarely found during the Middle Ages, the word was used by the Renaissance Humanists to denote formal documents of ancient rulers. The interest in and description of such documents came to be called res diplomatica after the famous 17th-century work De Re Diplomatica Libri VI, by Jean Mabillon, a member of the scholarly Benedictine congregation of Saint-Maur. Mabillon's work first made the study of old documents a reputable science. The major task of diplomatics is to distinguish between genuine and false documents, and this involves detailed examination of their external and internal features. Diplomatic studies have been applied mainly to Western documents, usually medieval ones, because it requires less specialist training to analyze more recent documents.

History of the study of documents. Medieval and Renaissance work. The forging of documents took place on a vast scale during the earlier Middle Ages, partly because wars and disturbances so frequently upset possession and also because the increasing use of written records made it necessary for those whose title was, in fact, perfectly good in old unwritten "customary" law to give it written substantiation. Thus forgeries, partly intentionally honest. partly dishonest, occurred frequently, despite the fact that the Germanic tribes that settled in western Europe inherited, with other aspects of Roman law, the concept of forgery as a felony, which was soon also reinforced by the church's canon law. This legal concept of forgery was, however, mainly applied to cases concerning property or inheritance; and literary forgeries, such as the famous Donation of Constantine, which purported to be the gift by the Roman emperor Constantine I the Great (died 337) to Pope Sylvester I of spiritual primacy throughout the church and of temporal power in Italy, were not concerned. Serious critical efforts to detect forgery did not begin in the Middle Ages, although obvious forgeries might be challenged in the course of a dispute. As early as the 6th century, the Merovingian king Childebert II declared a charter recording the gift of land from himself to the Bishop of Reims a forgery on the simple ground that the royal official denied the signature on it to be his. Pone Innocent III (1198-1216) tried to establish infallible criteria for the detection of fraudulent papal documents. but knowledge of earlier documentary forms was totally inadequate. In the Renaissance the Humanists began to use philological and technical criteria; on these grounds Lorenzo Valla authoritatively pronounced the Donation of Constantine to be a forgery, though authenticity had already been questioned.

Post-Renaissance scholarship. Three events in the 17th century forced the development of more sophisticated standards of evaluation. The Thirty Years' War in Germany led to endless legal conflicts, and in France the nobility engaged in a concerted action known as the bella diplomatica ("diplomatic wars") to assert their ancient privileges against royal absolutism. The decisive impetus, however, came from a much more particularist dispute. Daniel van Papenbroeck, a member of the Jesuit commission known as the Bollandists (from another member, Jean Bolland), which was charged with the publication of the Acta Sanctorum ("Acts of the Saints,"), finding that some monastic documents he inspected were forgeries, assumed (1675) that this was true of almost all earlymedieval documents. Since most of the monasteries with which the documents had been concerned were of the Benedictine Order, the Benedictines resented the sugges-

The forging of documents Lack of

study in

England

tion, and Mabillon undertook to refute it. In his De Re Diplomatica (1681), Mabillon set out the fundamental principles of the science of verifying documents; Papenbroeck soon afterward acknowledged the correctness of his tenets. Nearly a century later, René-Prosper Tassin and Charles-François Toustain published their six-volume Nouveau traité de diplomatique (1750-65; "New Treatise on Diplomatic"), a work that surpassed Mabillon's only in its greater wealth of material. Another important event in the history of the science of diplomatics was the founding of the École des Chartes (an institute for the training of French archivists) in Paris in 1821. During the next decades important collections of earlymedieval French documents were printed in the Recueil des actes by a variety of eminent editors. But the greatest advances were made by German and Austrian scholars, among whom Julius von Ficker investigated the differentiation between actum and datum (that is, between verbal legal procedure and its formal documentation), and Theodor von Sickel defined a basic technique of studying and comparing the script of charters and thus of identifying the individual notaries or scribes. The diplomas of the Carolingian and the German kings and emperors were edited in the series of the Monumenta Germaniae Historica, by members of the Institut für österreichische Geschichtsforschung (Institute of Austrian History Research), established by Sickel in 1854. Meanwhile, the Regesta, comprising short, synoptical condensations of the contents of papal documents down to 1198, published by Philipp Jaffe in 1851, gave a decisive momentum to the study of the papal chancery, while August Potthast covered the period from 1198 to 1304. Prominent scholars in the research of papal records in Germany at the beginning of the 20th century were Michael Tangl, Rudolf von Heckel, and, particularly, Paul Fridolin Kehr. In comparison with the amount of work done in France and Germany, historical scholarship in England long paid relatively little attention to legal, as opposed to literary, records. Although John Mitchell Kemble published his collection of Anglo-Saxon documents, the Codex Diplomaticus Aevi Saxonici (1839-48), an extensive study of Anglo-Saxon and Norman legal and administrative documents was delayed until the 20th century. Since then notable contributions have been made by scholars such as Helen Cam, H.W.C. Davis, Vivian Hunter Galbraith, Frank M. Stenton, Dorothy Whitelock, David Charles Douglas, and many others. Christopher Robert Cheney has made important contributions to the research of papal documents. In Italy Luigi Schiaparelli made vital contributions to the study of Lombard documents. From the 19th century, some study of documents has formed part of the medieval-history curriculum in

Diplomatic method. Types of documents. Documents that have been preserved are either originals, drafts, or copies. Originals, of which many survive, are formal documents drawn up on the order of the sender or donor, and they were designated to serve the recipient or beneficiary as evidence of the transaction recorded. Handwritten copies of documents, made either before or after the deed was actually executed (sealed), are not classified as originals. If made before an "original," they were in fact rough drafts of it; if made afterward, they were copies. The particularly Anglo-Saxon method of chirography, however, gave the possibility of producing several "originals." By this process two or more specimens of a document were written on the same page of the vellum sheet, and the free space between the texts was filled in with the word chyrographum ("handwriting") or other words and symbols. Then the sheet was cut irregularly right through these words or symbols; the originals thus separated could later be reassembled, an exact fit being complete proof of authenticity. But to provide documents having the force of "originals," copies of the original were usually made and formally certified as such, by public notaries, or by high ecclesiastical or secular dignitaries. Copies certified in this way were accorded the same legal value as the originals. In practice, lack of critical judgment on the part of the certifiers often led to the certification of forged records. In documents known as transumpts, which recited earlier documents

most European universities.

or charters as part of their text, it often happened that the earlier document was forged, but, being included in the new, it received validation. The original documents and copies considered above were issued at the request of the recipient or beneficiary or of his legal heir. It also happened quite often that the sender or donor wished for various reasons to retain a record of the documents issued by him. The chanceries (record offices) of secular rulers or great ecclesiastics therefore kept copies of outgoing documents in registers, and often of incoming documents, too. The popes were among the first to adopt the old Roman practice of keeping registers; although nearly all the earlier ones have been lost, an almost uninterrupted series of papal registers is extant from the pontificate of Innocent III onward. An important group of registers are the rolls kept by the medieval kings of England; the earliest extant rolls date from the 12th century. The keeping of registers in the chanceries of the French kings began about the year 1200, in Aragon about 1215, in Sicily under the Hohenstaufen emperor Frederick II (died 1250), and in the German imperial chancery from the early 14th century. Another manner of studying documents is in the formula books of the various chanceries. Notaries drawing up the various forms of medieval documents did not usually compose each new text afresh but, rather, copied from books in which such text formulas had been collected, a practice that can be traced back to Roman procedure. These model texts frequently contained only the legally relevant passages, while the individually applicable parts, such as names, figures, and dates, were either abridged or totally omitted. During the time of the Frankish kings, important collections were made, such as the Formulae Marculfi (early 8th century) and the Formulae imperiales (828-832). Significant collections of formulas serving as models for papal documents have been preserved from the 13th century.

Classification of documents. The documents of the Middle Ages are usually classified under two groups: public documents, which are those of emperors, kings, and popes, and private documents, which comprise all others. Another way of classifying documents is according to whether they are evidentiary or dispositive. The former merely record a valid legal act already executed orally, while the actual issuing of the latter forms in itself the legal act. This distinction, found among Roman documents from the 3rd century AD onward, gradually ceased to exist after the early Middle Ages. After the collapse of the Carolingian empire in the 9th century, private documents lost much of their function and were replaced by simple memorandums about legal acts and the witnesses to them. It was not until the late 11th and early 12th centuries that sealed charters of high secular or ecclesiastical dignitaries were again gradually considered as dispositive. Papal documents can be classified mainly as either letters or privileges, and royal documents can be classified as diplomas or mandates. Privileges and diplomas give evidence of legal transactions designed to be of long duration or even of permanent effect, while mandates and many

papal letters contain commands. Physical appearance of documents. Documents were written on a variety of material. In antiquity there were documents of stone, metal, wax, papyrus, and, occasionally, of parchment, but only papyrus and parchment (and, very occasionally, wax) were used during the Middle Ages. From the 12th to the 13th centuries, paper also was sometimes available. Papyrus, made from the stem of the papyrus plant, was produced mainly in Egypt; after the Arab conquest of Egypt in the 7th century, the import of papyrus to Europe became difficult. The Merovingian kings wrote their documents on papyrus until the second half of the 7th century, and the popes did so until far into the 11th century. North of the Alps papyrus had finally disappeared by the 8th century, when it was replaced by parchment. Parchment was made from animal hides and was thus easier to obtain. In southern Europe it was made mainly from sheep and goat hides; the insides of the skin were thoroughly smoothed and calcined, while the hairy sides were left rougher. In central and northern Europe, parchment was usually made from calves' skins,

Use of formulas

Introduction of parchment

and both sides of the hides were thoroughly smoothed and calcined. Paper came originally from China, During the 8th century AD, it spread to the Arab world and from thence to Byzantium, where it was manufactured from linen and was used from the 11th to the 13th centuries for imperial documents. After that time ordinary paper was used in the Byzantine Empire. In the West the use of paper, most common at first in southern Italy and Spain, had begun to spread by the beginning of the 12th century. Germany and southern France began to import paper from Spain and Italy in the 13th century, and soon afterward it had reached England by way of Bordeaux. But paper did not altogether replace parchment, which long remained in use, especially for solemn documents. The medium for writing was ink, generally a mixture of oak gall and copper vitriol. Originally black, ink made north of the Alps sometimes shows a reddish-brown hue, while that made in Italy may contain tinges of brown and yellow, Over the centuries most of these colours have lightened as a result of atmospheric conditions. The Byzantine emperors used purple ink for their signatures. This custom was occasionally taken over by the Lombard rulers of Italy and, later, by the Norman kings of Sicily. Another custom of Byzantine origin is the use of gold lettering.

Throughout the entire Roman Empire, the language used in documents was primarily Latin. Greek was also used, and, during the latter part of the 6th century AD, it slowly superseded Latin in the East. From then onward, Greek was the language of Byzantine documents until the end of the Byzantine Empire (1453). In the West, the collapse of the empire and the establishment of barbarian kingdoms led to a vulgarization of Latin, written as well as spoken.

Latin has always been used for papal documents and for most public and private charters, and it was used for international documents well into post-Renaissance times, until it was superseded by French as the language of diplomacy. In public and private documents, use of the vernacular alongside Latin gradually developed. Apart from its early and unique appearance in the documents of the Anglo-Saxons in England, no vernacular was used in charters before the 12th century. At the Norman Conquest (1066), use of Anglo-Saxon in English documents soon stopped, and no more vernacular was used there until some Norman French was introduced in the 13th century. and Middle English in the 15th century. There was an increasing use of the vernacular in Italian and French documents from the 12th century and in Germany from the 13th; but in medieval times Latin was never outstripped by the vernacular.

A correct assessment of the hand in which it was written is vital to ascertaining the provenance and authenticity of a document. Thus, the knowledge of paleography, different styles of ancient writing, is a skill essential to diplomatics. The broad basis of such knowledge begins with acquaintance with the general styles of writing current at particular times and places. This varied with the way the pen was held; whether the writing was cursive or had the letters formed separately; whether it was majuscule, all the letters being contained between a single pair of horizontal lines, or minuscule, with parts of the letters extending above and below the lines. There is a further distinction between what is called book hand and the business, or court, hand at one time used for documents.

In Europe the Roman capital letters, distinguished as rustic or square, uncial, and Roman majuscule and minuscule cursive, influenced all subsequent writing in the West. The Roman curial style (from the Curia, or papal court), used in the papal chancery until the 12th century, was a derivation of late Roman minuscule cursive. After the disintegration of the Western Empire, the Merovingian Franks used a Roman provincial script for their documents. Distinctive forms developed elsewhere, in Visigothic Spain and in Ireland. The Irish script, a half uncial (uncials are rounded letters) and a minuscule script, spread to Anglo-Saxon England and thence to the European continent. Under the Carolingian rulers, a particularly clear and attractive minuscule book hand (Caroline minuscule) was developed; modifications of this gradually became used in documents and eventually spread also to Italy, England,

and Spain. A "Gothic," more pointed form of script developed since the 11th century in northern France and soon spread all over Europe, so that writing became more spidery in appearance. In the early years of the Renaissance, Italian scholars such as Poggio (Poggio Bracciolini) and Niccolò Niccoli developed a minuscule based on the Carolingian, and variants of this style were used by the Venetian Aldus Manutius and other pioneers of printing.

Abbreviations were used in both documents and books Again, their particular characteristics would contribute to a correct assessment of the probable date and provenance of a document. Roughly two types were used: the suspension, involving the writing of only the first letter or syllable of a word; and the contraction, used first for Hebrew and Christian sacred names, the writing of only the first and last letter or letters of a word or syllable. The Carolingians sometimes used Tironian notes, a form of shorthand devised by Tiro, a freedman of the Roman orator Cicero.

From Roman times the two most important methods of validating documents were by appending the signature or the seal of the sender or promulgator. The practice of using seals for this purpose (and not merely to close a document) was carried over from imperial usage and, by the 8th century, was current among the Lombards and other Germanic tribes in western Europe. Until about the 8th century, the signature of the Merovingian ruler or his delegate was also required for the validation of public documents, but thereafter the seal alone, together with the recognition by a high chancery official, was held sufficient, the king's signature dwindling into a monogram or mere stroke (the "stroke of execution"). This change was probably accelerated because many medieval kings could not write. Thus, in England, King John sealed, and did not sign, the Magna Carta.

Seals were made of wax or of metal; if the latter, they were called bulls (hence, the use of this term for a certain group of papal documents). The Byzantine emperors used gold seals for their documents: Byzantine officials and ecclesiastics used lead and silver for their bulls. Papal seals were of lead or gold. Wax seals were increasingly used from about the 11th and 12th centuries, and wax was also used for the impression when, later, less formal documents were validated by use of the signet or privy seal. Seals could be two-sided, suspended from the document, or impressed upon it.

Form and content of documents. Normally, each document was divided into three distinct parts; the introduction (protocol), the main text (context), and the concluding formulas or final protocol. There were various subdivisions, and not all the parts here mentioned are necessarily found in every document. The introduction comprises, first, the invocation (invocatio) of God, either by name or through a symbol such as the cross; second, the superscription (intitulatio), giving the name and title of the sender; and third, the address (inscriptio), naming those to whom the document is directed, usually followed by a formula of greeting (salutatio). The actual text of the document can be divided into a number of parts. The first, known as the arenga, expresses in general terms the motive for the issue of the document. The notification (promulgatio), briefly explaining the legal purpose of the document, is followed by the narratio, or exposition of the particular circumstances involved. In the dispositio the donor or promulgator firmly declares his purpose ("I hereby decree" or "I hereby give"); this clause is the vital core of the document, its legal decree of enactment. There usually followed the sanctio, a threat of punishment should the enactment be violated. The main text concluded with the corroboratio, a statement of the means to be used for validation of the document. The final protocol consisted of subscriptions or lists of names of all those, such as the scribe, who took part in the issue of the document and of witnesses to the enactment. The date and place of issue are given, and the final sentence, the apprecatio, is a short prayer for the realization of the contents of the charter. At the bottom of the document, the signs of validation (the recognition, monogram, seal) were then added.

The date given on a document might be either that of legal enactment (actum) or that of the issue of the doc-

Use of vernacular Problems of chronology ument recording the (already performed) legal enactment (datum). The form in which dates are given in a document is of particular import in determining its provenance and authenticity. A wide variety of practices were followed at different places and times. For instance, days of the month could be given according to the old Roman system of calends, ides, and nones; by continuous counting throughout the month; or by reference to a saint's day. Years might be computed from the presumed time of the creation of the world; by the Roman indiction, a 15-year cycle; by the names of officiating Roman consults by regnal years of emperor, king, or pope; or from the birth of Christ. Moreover, there were also a variety of ways to determine when the year began.

Development and characteristics of chanceries. The Roman and Byzantine empire. Rulers, all of whom needed to issue directives and edicts, developed writing offices, or chanceries, in which formal documents were drawn up. The Roman imperial chancery, called the Office of Letters (ab epistulis), was subdivided into a Greek and a Latin department. In the 5th century four letter offices existed, all under the ultimate control of the magister officiorum ("master of offices"): the scrinium epistolarum ("letter office") handled mainly foreign, legal, and administrative affairs; the scrinium libellorum ("petitions office") handled petitions and investigations; the scrinium memoriae ("memorandum office") composed shorter imperial decrees; and the scrinium dispositionum dealt with administration. From the 4th century, a group (schola) of notaries had come into being, some of whom served the emperor as personal secretaries. Two centuries later a special confidential (a secretis) secretary existed. In the Byzantine Empire in the 8th to 9th centuries, the scrinium epistolarum and the scrinium libellorum merged to form a new department under the koiaistor (a high palace official), while the secretaries had all come under the office of the protoasekretis (head of the secretaries). An official called the mystikos handled the emperor's secret correspondence. In preparing edicts or other laws, the koiaistor, after consulting the emperor, made a first draft of the bill, had the official copy drawn up by notaries, and then verified its accuracy before it was validated. From the 9th century onward other high court officials participated in the validation of Byzantine charters.

The important governmental documents of the late Roman and early Byzantine empires include laws, edicts, decrees (imperial decisions concerning civil and penal law), and rescripts (the emperor's replies to inquiries from corporate and administrative bodies or private persons). In the Byzantine era documents concerning more day-to-day affairs can be grouped under the headings of foreign letters, privileges, and administration. Foreign letters include correspondence with other rulers, treaties (regarded not as an agreement between equals but as an act of grace or privilege granted by the emperor, and made out as such), and letters accrediting imperial ambassadors. The most solemn and splendid form of privilege was the chrysobullos logos, so named because the word logos, meaning the emperor's solemn word, appeared in it three times, picked out in red ink. Written in the carefully embellished chancery script reserved for the emperor's personal documents, the text consists of the usual parts-that is, the invocatio, intitulatio, inscriptio, arenga, narratio, dispositio, sanctio, date. and the subscriptio. It was sealed with the golden bull.

From about the 12th to the mid-14th century, a simplified form, the chrysolulou situllion, was used for privileges of lesser importance. It was not signed by the emperor himself but was held to be validated by the insertion, by the emperor, in red ink of the memologema, a statement of month and indiction. It, too, was sealed with a golden bull. The administrative documents of the Byzatinie imperial chancery include the prostagma, or horismos, a plain and short document known since the beginning of the 13th century. If directed to a single person, the document starts out with a short address, but, in all other cases, it begins immediately with the narratio, followed by the dispositio. The emperor replaced his signature with the memologema. Unlike the privileges, this document was not rolled up but, instead, was folded, and then closed by means of a wax

seal stamped with the imprint of the imperial signet ring. In addition to those emanating from the imperial offices, there were other types of documents issued in the Byzantine Empire. These include those issued by despots and imperial officials and, in the ecclesiastical sphere, by patriarchs and bishops. There were also private documents. The documents issued by the despots carried a silver seal, showing their intermediate status between that of imperial documents sealed with the gold seal and that of documents drawn up by imperial officials and sealed with lead bulls. Documents issued by imperial officials were simpler. They lacked the protocol, and the personal signature of the issuing official was written in black ink. The detailed date comprises the menologema. The documents of the Byzantine patriarchs are in many respects analogous to the imperial documents and symbolize the high status of the patriarch of Constantinople. They were, however, sealed with lead bulls. Byzantine private documents are almost exclusively notarial instruments. They are immediately recognizable by the crosses marked at the top of the documents. Used in lieu of the signature, the cross was the mark of the sender and contained his name and official function in one of its angles. The document was either signed by witnesses, or at least the cross preceding their names is autograph. Following that is the signature

of the notary. These documents were not usually sealed.

The papal chancery. Knowledge about early papal documents is scant because no originals survive from before the 9th century, and extant copies of earlier documents are often much abridged. But it is clear that the popes at first imitated the form of the letters of the Roman emperors. The papal protocol consisted only of the superscription and address and the final protocol of the pope's personal "signature"-not a mention of his name but merely a blessing. Toward the end of the 8th century, it became customary in certain documents to mention in the final clauses the name of the scribe responsible for the drawing up of the document; this was given with the date of issue, indicated by month and indiction, immediately following the subject matter of the document. There followed another clause, the great dating formula, datum per manus ("given by the hand of . . ."), naming a high chancery official and giving the date by reference to the regnal years of both emperor and pope. Both were used in documents containing decrees of permanent legal force, which came to be called privileges. Under Pope Leo IX (1049-54), the benediction written by the pope was changed into a monogram not written by him, but his signature was now introduced, placed in a round symbol, the rota. By the early 13th century, papal documents had evolved into two distinctive groups: solemn privileges and letters. Solemn privileges can be distinguished by their enlarged letters (elongata) of the first line, by the phrase in perpetuum ("in perpetuity") at the end of the address, by a threefold amen at the end of the text, by use of the rota, the pope's signature, the monogram, signatures of the cardinals, and by the datum per manus. Among letters, those whose bull was fastened on silken cords (litterae cum serico) brought some benefit to the recipient, while those with bulls fastened on a hempen cord (litterae cum filo canapis) contained either orders or the papal delegation in a dispute.

The number of solemn privileges began to decline from the mid-13th century, and eventually they were completely discontinued, their function being partly taken over by the litterae cun serico, which became increasingly elaborate in form. A new type of document also developed, the papal bull, distinguishable primarily by its use of formulas such as ad perpetually known") in the superscription. Yet another new papal document appeared at the end of the 14th century, the brief (breve), used for the popes' private or even secret correspondence. Written not in the chancery but, instead, by papal secretaries (an office dating from about 1338), the briefs were sealed on wax with the imprint of the papal signet ring.

The papal chancery of the 4th to the 8th centuries was similar to the late-Roman imperial chancery. Its notaries (notarii, scriniarii), organized in a guild (schola), were headed by the primicerius notariorum and the se-

Great dating formula

Imperial

privileges

cundicerius notariorum (first and second of notaries) and included the especially important notaries of Rome's seven ecclesiastical regions. But, during the 9th century, the bibliothecarius, the papal librarian, became the most important chancery official; a little later, various important bishops and dignitaries seem to have acted occasionally as datarius (the official named in the datum per manus formula). During the mid-11th century, a phase of German influence led to the temporary employment of notaries from the court of the emperor Henry III, who drew up papal privileges according to imperial formulas. A more important and permanent outcome of German influence was the gradual replacement of the bibliothecarius by a chancellor as the highest chancery official. The chancellor was invariably a cardinal, and in his absence another cardinal acted in his place as vice chancellor. Lesser chancery personnel still included the seven regional notaries; increasing business involved the use of lesser paid scribes in addition to the established notaries. From the late 11th century, a papal chapel, modelled on those of contemporary emperors and kings, developed, and its staff was often employed in chancery tasks.

From the early 13th century, the vice chancellor became the permanent head of the chancery, the office of chancellor remaining vacant. During that century the vice chancellors were ordinary clerics, who renounced the office if elevated to the cardinalate; thus, the chancery became directly subordinate to the pope himself. Both the numbers and the official standing of the notaries in the chancery, which then functioned entirely separately from the chapel, gradually increased. Higher chancery officials were often distinguished canonists (legal experts), such as Sinibaldo Fieschi (later Pope Innocent IV), Godfrey of Trani, and Richard of Siena. From the beginning of the 14th century, bishops or cardinals filled the office of vice chancellor. During the Great Schism (1378-1417) there were two papal chanceries and two vice chancellors, one

in Rome and one in Avignon.

Under Innocent III the procedure of the papal chancery had changed. Letters concerning matters of import to the papal Curia (de Curia) were drafted by the pope himself or else by a cardinal, the vice chancellor, or a notary. But the majority of the papal documents were elicited by their recipients, who had first to present to a notary the substance of their petition in a form the text of which largely anticipated the wording of the desired document. Professional proctors attached to the Curia assisted in the drafting and were also responsible for the documents during later stages of the procedure. Once a petition was approved, the notaries or the abbreviatores drafted a suitable document. drawing on a selection of formula books. After a final copy (engrossment) had been made and checked, it was read, if necessary, to the pope or in a special department of the chancery, the Audientia litterarum contradictarum. It was then passed to the Cistercian lay brothers who had charge of the papal bull, sealed, and given to the petitioner, who had had to pay a fee at almost every stage of the proceedings.

Insufficient research has so far been done on the papal chancery during the 14th and 15th centuries. Whereas formerly, when the vice chancellor was absent, one of the notaries had deputized for him, a new official, the regens cancellariam, was now created to fulfill this function. The number of notaries increased steadily, and, from the 13th century onward, an increasing number of public notaries worked in the papal administration. In order to distinguish between them and the papal notaries proper, the latter became unofficially known as protonotaries. The notaries were now in charge of the letters of justice, while the letters of grace were handled by the abbreviatores. The scribes remained in charge of the engrossments. A computator, aided by several assistants, was responsible for collecting fees.

The royal chanceries of medieval western Europe. Of the nations that held power in western Europe after the collapse of the Roman Empire there, the Ostrogoths, who occupied Italy from the late 5th to the mid-6th century, took over the ancient Roman imperial-chancery system in its entirety. Very little is known about the royal documents of the Lombards, their successors in Northern Italy, since not one of them has been preserved in its original form. But Lombard officials in charge of drawing up the documents were still trained in the Roman tradition. As well as referendarii, there were notaries who also acted as scribes. It is very likely that all of them were laymen.

Until the 12th century two main types of documents, diplomas and mandates, were produced north of the Alps, in the Merovingian, Carolingian, German, and French royal chanceries. Very little is known about the Merovingian royal chancery and its organization. The names of the scribes are never mentioned in the documents, but they were signed by high chancery officials, the referendarii.

When the Merovingian dynasty was supplanted by the Carolingians, chancery procedure changed drastically. In contrast to the Merovingian kings, the first Carolingian king, Pepin the Short, was unable either to read or write. He therefore entrusted the responsibility for the correctness of the royal documents to an official of the court. At about the same time, the task of drawing up documents was taken over by those clerics whose original duty had been to look after the most important relic of the royal court, the coat (cappa) of St. Martin of Tours. Collectively named the capella (chapel), these clerks were individually called capellani, chaplains. This close connection between the court chapel and the chancery existed under the later Carolingians and at the German and French and other royal courts, including that of England. Until well into the 12th century, European chanceries were not bureaucratic offices in the modern sense but, rather, in most cases an assemblage of chaplains suited for the task of issuing documents and usually working under a cleric who was not the head of the chapel. Not all chaplains wrote documents, however, and the chapel and chancery thus remained separate institutions. From the reign of the emperor Louis I the Pious (814-840), the heads of the chancery were not personally involved in writing the documents, a task performed by unnamed and unknown scribes. At first the scribes were indiscriminately designated as either notarii or cancellarii (higher, Roman provincial officials of the 5th and 6th centuries, who stood at the barriers, cancelli, of the council rooms), but, by the 9th century, the title of cancellarius was gaining ground and was increasingly applied to the head of the chancery. The 9th century was a period of transition, during which, for a while, the archchaplain, the head of the chapel, became also the head of the clerks who wrote the charters.

Under the Ottonian dynasty, which came to power in the eastern division of the original Carolingian empire early in the 10th century, the German royal chancery developed the organization that was to characterize it throughout the remainder of the Middle Ages. The heads of the chancery were the archchancellors, but the office was entirely honorary and soon came to be automatically held, as far as Germany was concerned, by whoever was archbishop of Mainz. When the German kings or emperors established administrations in Italy, Italian bishops were at first made archchancellors for Italy, but in 1031 the office was attached to the archbishopric of Cologne. From the 11th century, Burgundian bishops were archchancellors for Burgundy, but, in the second half of the 13th century, the archbishop of Trier took over the office.

The actual heads of the chancery were the chancellors. Imperial At first there was a chancellor, as well as an archchancel- chancellors lor, for each separate part of the empire-Germany, Italy, and Burgundy-but from 1118 there was only one chancellor for all three kingdoms. But even the chancellors, all of whom were clerics, were rarely involved in the actual composition and engrossing of documents, being usually engaged, as important advisers to the king or emperor, in much weightier matters. They do seem to have been especially concerned, however, with decisions about the granting of charters, and they supervised the work of the scribes or notaries. From among the ranks of these notaries, a group of protonotaries gradually developed after the mid-12th century, as a result of influence from the chancery of the Norman rulers of Sicily. Often called upon to deputize for the chancellor, the protonotaries, from the

The capella Martin

late 13th century onward, frequently titled themselves vice

From the 12th century onward, the documents issued by the German royal chancery were divided into various classifications. The diploma, by then usually called a privilege, existed in two categories, the solemn and the simple privilege. A solemn privilege included the invocatio, the signum and recognition line, and a detailed dating or at least one of these three elements, which were entirely lacking in simple privileges. Gradually, simple privileges merged into documents called mandates; it is not always easy to distinguish between them, but, in general, privileges were concerned with rights in perpetuity, while the mandates dealt mainly with matters of only temporary importance. From the early 14th century, mandates were superseded by the use of letters patent and letters close (open or closed letters). Privileges continued to be sealed with a hanging seal; the seal on letters patent was impressed on the document and was used to seal up letters close.

As the power of the German kings declined during the later Middle Ages, so that of the archchancellors increased, and in the 14th century they attempted to win control of the chancery. But, despite fluctuations in the power struggle, the king retained control of the chancellor, who, by the end of the 15th century, held the title of imperial vice chancellor.

Under the Carolingians and the first Capetians in France, various bishops and archbishops, especially the archbishops of Reims, held the office of royal chancellor. But at that time the office was merely titular, and, by the end of the 11th century, it disappeared entirely. From the 12th century onward, the title of chancellor became reserved to the head of the chancery. These new chancellors became so powerful that in 1185 King Philip II Augustus left the office vacant, and, during almost the whole of the 13th century, the chancery was administered by subordinate officials. Chancellors, often laymen, were appointed again in the 14th century, however, and the office remained important until 1789. As in other parts of Europe, the French chancellor merely directed the work of the notaries, and it was they who were responsible for drawing up the documents. From 1350 onward, the notaries were called secretaries, and both their numbers and their importance steadily increased. From the 15th century, the tremendous expansion of business occupying the Grande Chancellerie led to the establishment of several subsidiary petites chancelleries, all issuing royal documents sealed with the king's signet. Until the reign of Henry I (1031-60), the old Frankish type of diploma was issued almost exclusively. Then, gradually, charters in the simpler form of letters began to replace the diplomas, and, during the 13th century, the lettres patentes became the common type of document. These lacked the invocatio, the monogram, and the signature of the high dignitaries, and they gave the simple form of dating. From the 14th century, two forms of lettres patentes existed: the charte, which was sealed with a green wax seal hanging on red and green silk cords; and the lettre patente, used mainly for administrative mandates, which was sealed with a yellow wax seal on double and single cord. Besides, lettres closes were used from the 13th century onward.

The English royal documents of the Anglo-Saxon period (before 1066) can be divided into two large groups: the charters, mostly written in Latin; and the writs, written in Old English. The charters, for the most part concerning grants of land, began with either a verbal or a symbolic invocatio (a cross or the monogram XP for Christ). There was an arenga but no intitulatio. Charters were not sealed, the validation comprising the nonautographed signatures of the king and of ecclesiastic and secular dignitaries. Many of the extant charters of this era are forged or interpolated; the series of those apparently genuine starts shortly after the arrival in Canterbury (669) of the archbishop Theodore, and these show similarities with late-Roman private documents. It therefore seems probable that the Anglo-Saxon charters derive from Italian models brought to England by the Roman missionaries. Most of the charters were apparently written by the recipients. From the 11th century, the charters were gradually superseded by sealed writs, which became the most important type of document in medieval England. At first written in Anglo-Saxon, they were produced in Latin soon after the Norman Conquest. No continental document was anything like them. Written on a narrow strip of parchment, their entire text occupied only a few lines. A symbolic invocatio in the form of a cross was followed by the king's name and the address, which contained a salutation clause. There was no arenga, and the address was followed by a short description of the bequest, if the writ concerned a grant, or a directive, if the writ was a mandate. The Anglo-Saxon writs had no signatures of witnesses and no date, but after 1066 these elements were added. The dating consisted at first only of a mention of the place of issue, days and month being usually given only toward the end of the 12th century. From the very beginning the writs were supplied with a pendant seal as a means of validation. From the reign of Henry II (1154-89), it is possible to distinguish mandate-like writs of the old type and charter writs, which mainly concerned questions of feudal enfeoffments and confirmations of privileges and were usually more carefully executed than the mandate writs. By the early 13th century, the charter writs had developed into a new form of charter. It contained the intitulatio, including all the titles of the king; the general address; the dispositive text, which in most instances was introduced with the expression sciatis ("know that"); and the final clauses, consisting of the names of several witnesses and of the datum per manus clause mentioning the chancellor and giving the date and place of issue. During the final stage of its development, the great seal of green wax, pendant on silk cords, served as the means of validation. The ordinary writs further evolved into the common-law writs (containing orders to persons mentioned by name), the writs of summons, and, particularly, the letters patent (the latter eventually assuming the function of the charter writs, which disappeared at the end of the 13th century) and the letters close. The letters patent were furnished with a general address. Often introduced with the sciatis, the text concerns either limited grants or commissions to royal officials, introduced by the word precipio ("I order") or a similar expression.

The dating begins with a series of witnesses and contains the place of issue, day, month, and year of the king's reign. Occasionally the dating is followed by the words "per N.," which are assumed to designate the household official transmitting to the scribe the royal order to issue the writ. The means of validation was the great seal in white wax, pendant on a single strip of parchment (simplequeue) or on a double strip of parchment or silk (doublequeue). The letters close obtained their name from the fact that they were closed by means of the great seal. They contained either commands or information directed to a single individual or to several persons. Characteristic of these letters are the words teste me ipso ("witnessed myself") introducing the regular dating clause. These types of royal documents remained essentially unchanged throughout the Middle Ages and were imitated by both secular and ecclesiastic English magnates and dignitaries.

The English royal chancery grew out of the royal household. As on the Continent, it was at first merely a group of royal chaplains, and, until the Norman Conquest, there was no chancellor at their head. The chancellor was the keeper of the seal but usually took no part in the issuing of documents. During the 12th century the number of scribes was still low, between two and eight. At first this "chancery" travelled about with the king, only in the course of the 13th century establishing a permanent location at Westminster. At first English royal documents were not dispositive but merely evidentiary, confirming a previously arranged, orally discharged legal act, and the king's order for issuing the document was given orally. But, from the late 13th century, a royal secretariat came into existence, which was in charge of relaying to the chancellor, by warrant sealed with the privy seal, the royal order for issuing a writ under the great seal. In many ways the secretariat thus became a competitor of the chancery. In addition, during the first half of the 14th century, the Signet Office was established, so called after the small seal (signet). The king's secretary was also the head of this office. All these

shifts made the issuing of royal documents increasingly complicated. From the end of the 14th century, the common procedure involved, first, the petitioner submitting a petition to the king. If the king approved of it, his secretary forwarded a warrant carrying the signet to the keeper of the privy seal with the request to send, in his turn, a warrant carrying the privy seal to the chancellor. The chancellor then ordered the issue of the document, which would bear the great seal. So far as the issuing of royal documents is concerned, the fact that the secretariat developed into the secretariat of state is of great significance. The king's secretary (later on, there were two of them) became the centre of the royal administration. It was in his office that the state papers originated, which already under Henry VIII (died 1547) far surpassed in importance the old chancery records. Among the state papers there are in-letters, out-letters, drafts, reports, and schedules. The decline of the rolls (document registers) during the 16th century gave rise to yet another new office, the State Paper Office, headed since 1578 by the clerk of the papers. The second holder of this office, Sir Thomas Wilson, established the division of the state papers into foreign and domestic. As departments of state proliferated during the 18th and 19th centuries, they developed their own archives. In 1838 all the public archives became subject to an official called the master of the rolls.

Smaller European nations usually modelled their documents on those of the papacy, the empire, France, or England. The influence of papal letters and privileges can be observed particularly in Aragon, Castile, and Portugal, while German royal diplomas served as models in Bohemia (which was part of the empire), Hungary, and Poland. Because of the close political ties between the two kingdoms, Anglo-Saxon influence can be traced in the seal of the royal Danish documents during the 11th century, but, in the course of the 12th century, royal and princely German documents became the models for Danish as well as Swedish royal documents. Norwegian royal documents were modelled on Anglo-Saxon writs, probably as a result of the influence of English missionaries working in Norway from the early 11th century. The Norwegian writs were drawn up in the vernacular. The chancery of the Norman rulers of southern Italy and Sicily was highly developed. Influenced by the form of papal documents, the Norman documents comprise mainly privileges, either formal (with rota, witnesses, and gold bull) or simple (with rota, leaden bull, or wax seal), and mandates. They all have a detailed dateline that includes the name of the chancellor or other high court officials, the number of years since the birth of Christ, the regnal year of the king, and the apprecatio. The mandates are more simply executed. They lack the invocatio and start out with a simple intitulatio and inscriptio that ends with a salutation clause. There is neither arenga nor corroboratio, but there is a command clause in the text. The dating consists only of the place of issue, the day of the month, and the indictio. There is no rota or signature. The seal is of red wax. The head of the royal chancery of the Norman kingdom of Sicily was the chancellor, a layman who was an influential court official. The notaries who drafted and wrote the documents were also laymen. Because the German Hohenstaufen emperors also ruled in Sicily from 1194 to 1250, Norman chancery practice influenced subsequent German documents. (Pe.He.)

EPIGRAPHY

Epigraphy (from the classical Greek epigraphein, "to write upon, incise," and epigraphē, "inscription") denotes a branch of scholarship devoted to the study of written matter recorded on hard or durable material. Because such media were exclusive or predominant in many of mankind's earliest civilizations, epigraphy is a prime tool in recovering much of the firsthand record of antiquity. It is thus an essential adjunct of the study of ancient man; it secures and delivers the primary data on which historical and philological disciplines alike depend for their understanding of the recorded past. In a narrower sense, epigraphy is the study of such documents as remains of the written self-expression of early cultures and as communication media in their own right, attesting to the

development of visible sign systems and the art of writing as such. Finally, in later periods including our own, where perishable writing media predominate, epigraphy affords insights into the styles and purposes of monumental or otherwise exceptional techniques of written recording.

Materials and techniques. The delimitation of epigraphy vis-à-vis contiguous and related areas of antiquarian scholarship meets with some ambiguity. In a wide sense, epigraphy concerns itself with the total firsthand transmission of the written remains of ancient civilizations (as opposed to post-factum copying) and the nature of the material (e.g., stone, marble, metal, clay, terra-cotta, pottery, wood, wax tablets, papyrus, parchment) and the technique of recording (cutting, carving, engraving, casting, embossing, scratching, painting, drawing, etc.) have mere secondary relevance. Under this maximum definition certain subdisciplines may be included under the overall canopy of epigraphy: notably numismatics, which concerns itself with legends on coins and medals, and papyrology, the study of a special type of perishable record that is normally preserved only in the dry climate of Egypt and in adjacent desert regions. In the case of Egypt, papyrology tends to impinge upon wood and clay media as well, thus leaving mainly stone and metal objects as the concern of epigraphy proper.

In general, however, unless so subdivided, epigraphy encompasses inscriptions at large, be they on primary writing surfaces or on such assorted objects as vases, potsherds, gems, seals, stamps, weights, rings, lamps, and mirrors. A further related discipline is paleography, which concerns itself with the study of scribal hands and styles of writing and has significance for the dating of epigraphic as well as

other written documents. The nature of the materials and techniques used for inscriptions is closely tied to the external purpose of the record itself. Thus, inscriptions may be divided into monumental, archival, and incidental. Monumental inscriptions were intended for enduring display and were therefore, as a rule, executed in lasting material, such as stone or metal. Maximal exposure to mortal eyes need not have been the prime purpose of their originators-e.g., the tomb chambers of Egyptian pharaohs, intended to be sealed forever, had their inner surfaces covered with monumental hieroglyphs; the great Bisitun inscription of King Darius I of Persia is on a high rock surface and legible only after precarious rock-climbing or from airborne convevances. Under this classification may be included also Archival inscriptions were essentially a feature of those

micromonumental inscriptions found on such objects as coins, seals, and rings, meant to endure in their own right. early societies that kept records and that used such materials as have been preserved thanks to their intrinsic. accidental, or incidental durability. Many ancient Near Eastern cultures employed clay tablets for writing, which they fired to insure their soundness. Minoan and Mycenaean archivists in ancient Crete and Greece used perishable temporary clay records that were preserved by unintentional baking in the conflagrations that destroyed their storerooms. Papyrus records from Egypt have survived as a result of climatological chance-mainly low humidity. The official purposes of public display and of archival preservation were sometimes complementary, and therefore coincidental or overlapping matter has been preserved. In some cultures the techniques employed in monumental and archival writing tended to differ (notably in Egypt, where increasingly cursive hieratic or demotic script contrasted sharply with monumental hieroglyphic), and occasionally the language itself would be different (for example, in the Hittite Empire, where the clay tablets in cuneiform employed mainly straight Hittite or Akkadian, whereas the monumental "hieroglyphic" rock inscriptions and seals used a distinct language)

Incidental inscriptions may be defined as those not seriously meant for preservation. They include, for example, wall scrawlings of the graffiti type and casual records that were kept on cheap writing matter such as potsherds (ostraca) and scraps of papyrus. Many a city dump of ancient Egypt has yielded a rich harvest for the study of daily life. Inscriptions as historical source material. In studyMonumental archival incidental inscriptions

Evidence of extinct civilizations

ing the political, administrative, legislative, and dynastic records of extinct civilizations, the modern historian must bring to bear all the evidence at his disposal; and such evidence may vary sharply from one locality and period to another. Historiography in the modern sense-the analytical ordering and interpretation of past institutions and events-is an invention of ancient Greece, and even there it only gradually eschewed the fabulous. In many early societies (e.g., Mesopotamia, Egypt), chronographic records were either annalistic or legendary in kind and sometimes apologistic or propagandistic in purport; and in others (e.g., India) a cyclical world view prevailed, and a lack of feeling for linear time depth precluded an ordered appreciation of the past, leaving only legendry-in such cases only synchronisms with time-anchored events elsewhere allow a precise dating.

Thus, the amount of predigested ancient information bearing on antecedent events may vary from sophisticated literary to scrupulous epigraphic or may be wholly lacking or largely valueless. In the latter instances the historian is almost exclusively dependent for native information on primary documents, and such documents are in most

cases inscriptional.

Ancient Mesopotamia. Surviving epigraphic matter from the 3rd and early 2nd millennia BC includes both historical and quasi-historical material. The Sumerian king list is a compilation of names, places, and wholly fabulous dates and exploits, apparently edited to show and promote time-hallowed oneness of kingship in the face of the splintered city-states of the period. The Sargon Chronicle is a piece of literary legendry concentrating on spectacular figures and feats of the past, whereas contemporary royal inscriptions, notably by Sargon I of Akkad and Gudea of Lagash, are historical documents in the proper sense.

Both kinds of texts are preserved also from the Babylonian and Assyrian periods, from the reign of Hammurabi (1792-1750 BC) to the 6th century BC. There are lists of date formulas and year names from Hammurabi's reign and from that of his son Samsuiluna: lists of Assyrian eponymous year names, based on those of dignitaries; the Babylonian king lists, running from Hammurabi through the Kassite era and the Assyrian domination of Babylon to the last flicker of Babylonian self-assertion in the early 6th century BC; the Assyrian king list from Khorsabad, which made good use of earlier compilations; and notably the so-called Synchronistic Chronicle, which juxtaposed the kings of Assyria and Babylonia in the same millennial sequence. Historical documents comprise, above all, the stately sequence of annals by the kings of Assyria, recorded on stone slabs, stelae, foundation markers of buildings, bronze gates, statues, and obelisks and in clay archives (prisms, cylinders, tablets). Starting in the Old Assyrian period, they were especially extensive in the reigns of Tiglath-pileser I (1115-1077 BC), Ashurnasirpal II (883-859 BC), Shalmaneser III (858-824 BC), Adadnirari III (810-783 BC), Tiglath-pileser III (744-727 BC), Shalmaneser V (726-722 BC), Sargon II (721-705 BC), Sennacherib (704-681 BC), Esarhaddon (c. 680-669 BC), and Ashurbanipal (668-627 BC).

For all their swaggering bombast and flaunting of deliberate cruelty, the annals provide prime historical source material. The detail of the Assyrian conquest of Syria, Palestine, parts of Asia Minor, Cyprus, Arabia, and Egypt would be spotty indeed without recourse to these annals. for they show the centre of political power, unlike such provincial records as those from contemporary Egypt or the Old Testament.

Legal com-

Legal compilations and law codes also have pride of place in the epigraphic record of ancient Mesopotamia. These form a unique succession, starting in the 3rd millennium BC with that of King Ur-Nammu of the Sumerian 3rd dynasty of Ur (c. 2100 BC), continuing with those of the Sumero-Akkadian king Lipit-Ishtar (in Sumerian) and King Bilalama of Eshnunna (in Akkadian) during the interval of the 3rd dynasty of Ur, and the rise of the Amorite dynasty of Hammurabi (c. 2000 BC), culminating in the great diorite stela of Hammurabi (c. 1750 BC), showing retardation and recrudescence in the Middle Assyrian laws that are found on clay tablets at Ashur (at the time of Tiglath-pileser I), and petering out in the fragmentary Neo-Babylonian laws dating from the 7th century BC.

The stela of Hammurabi must have been originally set up in some Babylonian population centre for the literate to read and know their rights. Some Elamite invader must have carried it off to Susa (perhaps c. 1200 BC), where it was found in 1901 and removed to the Louvre in Paris. The bulk of the stela contains the text of the code, partly erased on the obverse but restorable in some measure from clay-tablet versions of the same laws. The top depicts the king in a worshipful pose, receiving the laws from the sun god, Shamash. In reality Hammurabi-the sixth of 11 kings of the Old Babylonian or Amorite dynasty-was a practical codifier rather than a revelatory mediator of law. His code was an effort to fuse into a workable whole the ancient inheritance of Sumerian-based jurisprudence and the Semitic talion law (punishment according to the "evefor-an-eye and tooth-for-a-tooth" principle) of the Akkadian superstratum. The result is not a model of economy or arrangement or logical organization, but the code of Hammurabi constitutes nevertheless the first great legal monument in the history of mankind. The later Assyrian laws show traces of further removal from the cradle of Sumerian civilization since they are both harsher and noticeably more primitive.

Ancient Egypt. Egypt attracted the special curiosity of the Greeks, and Herodotus (5th century BC) devoted an entire book to on-the-spot observations and fanciful tales about the land of the Nile. The lost Aigyptiaka (or Aegyptiaca) of Manetho (3rd century BC) contained the roster of 30 dynasties, which still underlies the chronology of ancient Egypt. Such classical writers as Strabo, Plutarch, and Pliny the Elder all dealt with various aspects of Egyp-

Yet the fund of knowledge would be woefully skeletal and inaccurate without the explicit testimony of contemporary records from Egypt itself. The decipherment of the Egyptian writings gave the impetus to Egyptian epigraphy. The progress of excavations multiplied the corpora of texts, especially adding the papyrological dimension. In addition, cuneiform Akkadian on clay tablets was the international diplomatic medium of writing during the most brilliant phases of Egyptian history and is hence an integral part of the Egyptian epigraphic record.

Decipherment of Egyptian writings

The historically significant Egyptian epigraphic texts, apart from their external peculiarities, have likewise special traits relating to genres. There is little attempt at historiography and great fluctuation in bulk in the course of dynastic vicissitudes. They are mainly annalistic and thus firsthand accounts of pharaonic or other high-level deeds; but the peculiar features of stylization, stereotyping, and usurpation must frequently give the careful historian pause and sometimes debase the face value of the record. Written monuments became somewhat numerous during the 4th dynasty (c. 2575-c. 2465 BC), that of the pyramid builders Khufu, Khafre, and Menkaure. Notable are the fragmentary annals of Snefru, which already alluded to dealings with Asia, the chronic goal of Egyptian territorial ambitions. Historic records persisted under the following two dynasties, with particular articulateness in the reign of Pepi I, third king of the 6th dynasty (c. 2325-c. 2150 BC), then subsided until a modest reemergence in the (Theban) Middle Kingdom of the 12th dynasty (1938-c. 1756 BC). Another silence shrouded the period of the Hyksos kings (c. 1630-c. 1523 BC), broken only subsequently by such retrospective revulsion at the memory of barbarian domination as that in Queen Hatshepsut's (1479-58 BC) temple inscription at Istabl Antar in Middle Egypt. The golden age of historical recording began in the 15th century BC with the central rulers of the 18th dynasty, notably Thutmose III and Amenhotep II and III. Thutmose's annals on the walls of the temple of Karnak describe 20 years of ceaseless military activity in Asia, some 16 campaigns in all, and are supplemented by stelae from Armant in Upper Egypt and Gebel Barkal near the Fourth Cataract, as well as by lists of conquered lands at Karnak. Similar material continued in the reigns of Amenhotep II and III, in the latter's case importantly supplemented by the cuneiform correspondence with foreign powers (Mitanni, Arzawa,

Golden age of Egyptian historical recording

pilations and law codes

etc.), which was subsequently stockpiled and archived by Ikhnaton in his transitory new capital, where it lay buried to await the modern excavators of Tell el-Amarna. Ikhnaton's religious preoccupations (he changed the official religion to the worship of the sun good Aton), and political apathy led to the loss of many of Egypt's Asian possessions. Records of Ikhnaton's short-lived son-in-law, Tutankhamen, at Thebes (1332–23 Bc), make recantation and restoration for the heresy. Tutankhamen's successor, the warlord-pharaoh Horemheb, left boastful accounts of foreign conquest that sound suspiciously grandiose in reliation to plausible reality.

In the 19th dynasty (1292-1190 BC) Seti I went to war against the Syrians, Hittites, and Libyans, letting the world know about it on the walls of Karnak. But in this respect he was no match for his long-lived son, Ramses II. who usurped the monuments of others and covered unprecedented amounts of wall space with his own real or inflated exploits. (The Battle of Kadesh against the Hittites in 1299 BC, which ended in a stalemate, was given lavish coverage as a triumph on temple walls at Karnak, Abydos, and Abu Simbel.) In the 20th dynasty (1190-1075 BC) occurred incursions of the "sea peoples," and the records of Ramses III detailed both the crisis and the increasing accumulation of wealth and power in the religious establishment. Subsequently, Egyptian history receded from the world scene, with "Libyan" and "Ethiopic" dynasties and a brief Saite renaissance of the 26th dynasty (664-525 BC), already under the Assyrian and Babylonian shadow, soon to be replaced by the Persian. The firsthand political records declined accordingly, although they remain of significance for local history down to the Ptolemaic era, a dynasty that ruled Egypt beginning in 304 BC, founded by Ptolemy I Soter, a general under Alexander the Great.

No law codes have been found in Egypt, presumably because codification was not practiced. There are, however, royal administrative and legal decrees granting privileges and immunities and also records of legal proceedings, especially of the Theban tomb-robbery trials during the

20th dynasty.

Other ancient Middle Eastern regions. Regions adjacent to the power centres of Mesopotamia, Egypt, and Iran were frequently mere political and administrative adjuncts, often obscure vassaldoms or adversaries without notable or attested written traditions. The Mitanni kingdom in northern Mesopotamia had some ephemeral big-power dealings with Egypt in the days of Amenhotep III, but its capital city is still lost in the sands, and thus its presently known epigraphic tradition is merely part of the correspondence in the Tell el-Amarna archives. The records of the Elamite kingdom with its capital at Susa were mostly ancillary to Mesopotamia in the 2nd millennium BC and to Iran later on. The region of Syria and what later came to be called Palestine was in the 2nd millennium the object of an extended tug-of-war between Egypt and the Hittite kingdom.

The Hittites were, in fact, the third great international power in the Near East during part of the 2nd millennium BC, and the epigraphic yield of their royal archives at Boğazköy in central Asia Minor matches or even surpasses in richness that of Mesopotamia and Egypt for the few centuries in question. The cuneiform records of the Hittites contain a tradition of unique royal political selfexpression. These documents begin with the oldest known Hittite text, the inscription of the early ruler Anittas, detailing dynastic struggles of an obscure and possibly apocryphal past. From the founder of the Old Kingdom, the firmly historical Hattusilis I (Labarnas II), came an annalistic autobiography (excavated in 1957) and a "farewell address," or political testament, in Hittite as well as Akkadian versions. Subsequent events, including the capture of Babylon by Hattusilis' son, Mursilis I (c. 1590 BC), and the succeeding era of regicidal upheavals, are known from an edict of King Telipinus, who detailed them as he set about regulating the rights of royal succession. The subsequent founder of the Hittite Empire, Suppiluliumas I (c. 1350 BC), and his son Mursilis II left annals detailing their military and political deeds. Mursilis was a particularly prolific annalist and edited his father's annals as well.

The great encounter with Ramses II at Kadesh in 1299 Bec occurred in the reign of Mursilis'son, Muwaallis, and left an echo in the autobiography of his brother and successor, Hattuslis III. Hattuslis' autobiography is a tract of self-justification for a breach of the edic of Telipinus in deposing his nephew and predecessor Urhi-Teshub (Mursilis III).

Other Hittite documents inveigh against treasonable behaviour ("Indictment of Madduwattas") or contain detailed instructions for military, civil, and court officialdom. Hittite queens had prerogatives of independent high-level initiative, and examples of their correspondence with foreign potentates supplement the archives of their husbands. The most remarkable external political documents are numerous state treaties, sometimes between equals but more often covenants specifying protectorate or vassaldom status for subordinate states on the fringes of the kingdom. Equally notable is the Hittite Law Code, relatively enlightened and mild in the face of its contemporary counterparts in Mesopotamia. Altogether, the inscriptional documents are practically the exclusive source material for knowledge of the Hittites; not even the existence or location of their empire was surmised prior to the discovery of their archives.

After the collapse of the Hittite Empire (c. 1190 BC), significant records from Asia Minor ceased for many centuries, whereas local history in the Syro-Palestinian carea was recorded in the inscriptions of petty dynasts increasingly under the shadow of Assyrian domination. The break with the past is evident in the writing systems (Hittite Hieroplyhs or West Semitic alphabet rather than cuneiform) and in the languages (Indo-European Anatolian, Cananian, Laraniai). Into this category fall the stela of King Mesha of Moab (c. 830 Bc) now in the Louvre, the Phoenician-Hieroglyphic Luvian bilingual inscription of Azitawadda of Adana (late 8th century Bc), and those of the kings of Ya'diya-Sam'al. Contemporary cuneiform documents from the Urartu kingdom around Lake Van in eastern Anatolia are historically and culturally an offshoot

of the history of 8th-century Assyria.

Ancient Iran. Epigraphically recorded history in ancient Persia began dramatically with the rise of the Achaemenid dynasty in the 6th century BC. Cyrus II the Great's conquest of Media, Lydia, and Babylonia, Cambyses' occupation of Egypt, and the incursions into Greece of the succeeding side branch of the family, beginning with Darius I, created in short order a world power destined for centre stage on the international scene for the following two centuries. The international character of the empire is reflected in the frequently trilingual royal inscriptionswith Akkadian and Elamite versions in traditional syllabic cuneiform, and the Old Persian text in its own simplified quasi-alphabetic system of wedge-shaped writing. The Achaemenids' time span ranges from Darius' greatgrandfather, Ariaramnes, to their less glorious progeny, who were ultimately extinguished by Alexander the Great, The empire was centred in Persia; but a granite stela of Darius, found near the Suez Canal, recorded in Old Persian, Elamite, Akkadian, and hieroglyphic Egyptian the opening of a canal from the Red Sea to the Nile. The epigraphic material included rock surfaces, building walls, columns, doorways, cornices, statues, and doorknobs; bricks, plaques, plates, and tablets of clay, stone, gold, and silver; vases; weights; and seals. Almost all the longer texts were by Darius and Xerxes I; an important one of Xerxes was found on a stone tablet at Persepolis in 1967. The great Bīsitūn rock inscription of Darius runs to several hundred long lines in Old Persian alone, besides the Elamite and Akkadian versions. It is accompanied by 11 minor inscriptions, serving as keys to the sculpted scene of the panel, which shows Darius triumphant over the usurping impostor Gaumata and nine other rebels. The text is a selfstatement of how Darius gained and consolidated his rule. It apparently had currency in the realm, apart from being tucked away on a sheer cliff wall, for a partial duplicate of the Akkadian version has been found on a dolerite (basalt) block from Babylon, and papyrus fragments from Elephantine have yielded scraps of an Aramaic edition. One peculiar documentary value of the text is that the

Rise of the Achaemenid dynasty

key to

Indian

same period in Persian history is extensively covered in the Greek literary tradition by Herodotus, Ctesias, and others, and scholars can thus juxtapose Darius' own accounts with those of almost contemporary foreign historians. As an example, Darius stressed his role as saviour of the fatherland from the clutches of an upstart who pretended to be Smerdis, the brother of Darius' predecessor Cambyses. The latter had murdered Smerdis and was carrying on various outrages in Egypt when word came of the impostor's takeover back home. Darius stated that thereupon Cambyses "died his own death," meaning that it was a fatal matter without human interference, and that thus Darius' hands were clean in taking action against the impostor. According to Herodotus, Cambyses' legendary death involved a freak occurrence as he prepared to leave for home-an accidentally self-inflicted wound leading to gangrene. Both the meaning and intent of Darius' description are thus confirmed.

From later Arsacid (Parthian) and Sāsānid periods of Iranian history, there are likewise royal inscriptions that shed light on their respective eras down to the Islāmic conquest in the 8th century AD, and new specimens are

still being discovered.

Ancient India. India's past became anchored in historical time and separable from legend only with the establishment of firm synchronisms with outside data. One such link is the Seleucid embassy of Megasthenes to the Maurya king Candragupta (Greek Sandrokottos) at Pāṭaliputra (Greek Palimbothra) in Magadha (modern day Bihar). The Maurya dynasty was continued in the early 3rd century BC by Candragunta's son Bindusara (Amitrochates in the Greek sources) and had extended its power over much of the subcontinent. But then the Greek sources fall silent, and Indic literary tradition supplies only the usual web of timeless legendry. At this point, however, epigraphy makes a unique contribution in the form of the first authentic and datable historical documents from India, the edicts of Bindusāra's son and successor Aśoka. As a matter of epigraphic fact, Aśoka ruled all of northern India and a large portion of the south, from Taxila and beyond to Mysore and Kalinga (coast of Orissa and Andhra Pradesh). His 14 rock edicts and seven pillar edicts in numerous versions and copies, plus separate minor texts, are scattered over this expanse-in the Prakrit language of his time and in the Brāhmī script, except for some northwestern examples of the Aramaic-inspired Kharosthi writing. Even a Greek-Aramaic bilingual version was found in 1958 near Kandahār in Afghanistan. Ašoka's edicts are proclamations and ordinances in a Buddhistic spirit, designed to impart good order, morality, and moderation by the Emperor's personal enjoining and example. Particularly notable is the 13th rock edict, which bares the ruler's pangs of conscience over the conquest of Kalinga eight years after his coronation, his continuing sorrow over the cruelties committed, and his pledge to substitute the victory of Buddhist religious law (dhamma) for all earthly conquest.

Aśoka's edicts would rate a mere historiographic footnote for their inconsequential transitoriness, were it not that in the same breath Asoka supplied the very synchronisms that are the main key to ancient Indian chronology. Among his western neighbours he mentioned Amtiyoge (Antiochus II Theos of Syria), Tulamaye (Ptolemy II Philadelphus of Egypt), Antekine (Antigonus II Gonatas of Macedonia), Maka (Magas of Cyrene), and Alikasudaro (Alexander of Epirus or Alexander of Corinth). The dates of these contemporaries circumscribe the time of Aśoka's reign; combined with the earlier Greek synchronisms, they afford a firm foundation for the correlation of Indic and Mediterranean events. The edicts of Aśoka are thus a prime example of the value of inscriptions for historiographic dating and constitute a fixed record unparallelled in ancient Indian tradition. Later periods of Indian history, such as those of the Indo-Scythian and Gupta rulers, are also represented in epigraphic documents of some historical value.

Ancient China. In China also, inscriptions are a means of separating chronological fact from historiographic legend. Nonepigraphic book composition on wood or bamboo strips had an early history in China, beginning in the later 2nd millennium BC; its scope was such that the Ch'in emperor Shih Huang-ti went down in history as a book burner in 213 BC. The San Tai, or three periods of early Chinese history (Hsia, c. 2205-1766 BC; Shang, c. 1766-1122 BC: Chou and Ch'in, c. 1122-206 BC), were long considered by Western scholars purely legendary down to the early Chou period, and the literary documents (such as the Shu Ching or "Classic of History") were dismissed as compilations consisting mostly of successive overlays of little historical value. But the historicity of written records from the later Shang era (c. 1400-1122 BC) is now apparent from the mass of inscribed archeological material found especially in northern Honan Province, These include, in particular, the so-called oracle bones (mostly tortoise shells and scapulae of animals), bearing incised records of royal divination. At the site of the Shang capital, Yin, were discovered inscribed vessels of bronze, bone, pottery, jade, and stone, probably ceremonial in nature and related to official ritual uses such as ancestor worship. The script is a mixture of pictograms, word signs, and phonograms. From the ensuing Chou era, bronze inscriptions of official provenance have likewise been found, especially records of royal largesse. Inscriptions from later periods form a steady but subsidiary source of information beside the larger, nonepigraphic written record.

Ancient Greece. The historically significant epigraphic record of classical Greece differs in many ways from most of those discussed above. Much of it is parallelled by a mature and independent tradition of professional literary historiography. Except for the preclassical Helladic (Mycenaean) period of the 2nd millennium BC (see below), there was no archival tradition, although the bulk of "monumental" records sometimes approximates the same purpose of massive preservation. There was no allimportant power centre and no dominant rulership before Hellenistic and Roman times: thus the geographical scattering of records was extreme, although naturally with some focuses of emphasis such as Athens. Above all, there was continuity from the inception of literacy, with gradual

adventure.

but steady increase in bulk Epigraphically transmitted historiography in Greece is extremely scarce because the probing of past events has passed beyond the stage of dynastically centred and sheltered annalism; an example is the "Marmor Parium" (from the island of Paros and now at Oxford), which contains a chronographic rundown of traditional dates and events of Greek history. Rather than monolithic records of autocracy, there is history in the making by a plethora of tyrannical, oligarchic, or democratic microentities. Treaties of alliance and various other agreements between the multiple city-states-recorded on metal or stone and publicly displayed, or consecrated at such pan-Hellenic sanctuaries as Delphi or Olympia-form an important part of the epigraphic yield. Joint-citizenship covenants, decrees concerning the return of exiles, monetary agreements on coinage and debts, and tribute lists are typical examples. They are supplemented by the records of arbitration of interstate disputes, most often boundary matters, by thirdparty commissions. Thus, when around 240 BC a territorial disagreement arose between Epidaurus and Corinth. the Achaean League appointed a group of 151 Megarians as mediators, and their report survives. Further extensions of such "international" documentation are the proxenia decrees, which amount to letters of patent and resolutions of appreciation issued by one state to a citizen of another for service as proxenos, a kind of honorary consul looking after the interests of the other state's citizens. The extensive colonization efforts by the Greeks around the Mediterranean produced a further kind of political document-regulations governing conditions for emigration and return, citizenship rights of the colonists, and relations between the colony and the mother community. Not all historically meaningful international records are of the monumental type. Greek mercenaries of Pharaoh Psamtik II (ruled 594-589 BC) left their scrawlings on the legs of a colossal statue at Abu Simbel on the upper Nile, proving by their names and dialect that they came from Rhodes and Ionia and were far abroad on foreign

The special circumstances of the Greek epigraphic record

Internal documents of the various Greek states include numerous records of decrees and ordinances, both administrative and legislative. Stereotyped Athenian ones are complemented by variant forms in other localities; most contain a preamble setting forth the date and the officialdom in charge, the circumstances occasioning the action, the decision itself, means and sanctions for its enforcement, and sometimes instructions for providing and affixing the very physical record that has been preserved. Sometimes they amount to formal laws, such as those directed against extravagances in funeral practices.

Financial data of the states were minutely and permanently inscribed on stone, and the accounts thus displayed recorded in detail the receipts, expenditures, and balances of public funds. Very specific reports cover projects of public construction, including both technical and budgetal details, allowing sometimes the integral modern reconstruction of the buildings from the reports alone. The records of the Erechtheum and the Parthenon at Athens are well preserved, as are inventories of military expenditures, especially those of the Athenian navy. Knowledge of the ephebic system at Athens, a paramilitary youth organization, is in the main based on epigraphic material.

The laws

of Gortyn

The only law code in the Greek epigraphic tradition is the laws of Gortyn in central Crete, inscribed on the slabs of a circular wall which, if completely preserved, would have been nearly 100 feet (30 metres) in diameter. The 12 columns of text, each on four layers of stone and some five feet (1.5 metres) high, are about 30 feet (nine metres) in sideways length and contain more than 600 lines of text. being the longest Greek epigraphic monument; parts of some columns of further text survive, the so-called Second Code. The probable date of this inscription is the first half of the 5th century BC. The code deals with such matters as disputed ownership of slaves, rape and adultery, rights of a wife upon divorce or death of husband, disposition of children born after divorce, inheritance, sale and mortgaging of property, ransom, children of mixed marriages, and adoption. While self-contained, it evidently does not represent the entirety of laws; curiously, it stresses those areas of civil law (inheritance, adoption) that are notably lacking in the Hittite Law Code. The uniqueness of this code in the Greek world points up the relative isolation and marginality of the Cretan tradition, with tendencies to codification more reminiscent of Anatolia and the Near East generally.

Ancient Rome. While partly overlapping Greek inscriptions in time and type, those of Rome nevertheless present distinct peculiarities. There is a high measure of standardization in kind and style, despite lingering local traditions in more remote areas. Extensive and excessive use was made of initials and abbreviations, to the point of serious impediments to comprehension; lists of such abbreviations are standard adjuncts to modern handbooks on Latin epigraphy. Stone and bronze were standard material, but there was more use made of bricks, tiles, and terra-cotta, and practices of stamping and signing such matter are of help in identification and dating.

Literary and epigraphic records of early republican Rome are scant and fragmentary. Latin was at the time still largely confined to Rome proper, with Oscan, Etruscan, and colonial Greek spoken and written in much of Italy. With the arrival of extended political power there was little early literacy to fall back on, and historiographic attempts at retrospection ended in epicized myth and legendry (e.g., in Livy). The Greeks on the southern coastal fringe had little truck with the hinterlands of early times. The Etruscan impact on Rome is evident, but shortcomings in discovering epigraphic records of Etruscan city sites (as opposed to necropolises) and in understanding the Etruscan language, limit the historical data derivable from Etruscology. The potential for such illumination is seen from the discovery of gold tablets at Pyrgi in 1964 that contain a dedication in Etruscan and Phoenician by the Etruscan king of Caere, Thefarie Velianas, to the syncretized goddess Uni (Juno) Astarte. Datable to around 500 BC, the text shows Etruscans ruling in the outskirts of Rome, with enough Phoenician or Punic (Carthaginian) maritime presence to warrant symbiotic and syncretistic bilingualism. The vital historical import of such attestations, pieced together with later Greek and Roman historiographic data, is patently manifest.

No historically important epigraphic Latin text from republican Rome antedates the 2nd century BC. The marble Columna Rostrata-found in Rome in 1565 and now at the Palazzo dei Conservatori on the Capitoline Hillrecords a naval victory of Duilius (consul in 260 BC) over the Carthaginians; but the inscription, replete with fake archaism, dates from a restoration effort in early imperial days. The fasti consulares and similar lists afford a summary sequence of consulates, magistratures, and triumphs. The one truly significant epigraphic historical text is the "Res gestae divi Augusti," an autobiographical record of Augustus' rule, which was exhibited in many places but is best known as the Monumentum Ancyranum, from the bilingual (Latin and Greek) version carved on the walls of the Temple of Rome and Augustus at Ankara (Turkey). By the time the epigraphic record became abundant Rome's domination was secure and the political documentation was one of imperial outflow and or local sycophancy. Treaties of republican Rome with foreign powers survive merely in the works of literary historians. Among "internal" documents from republican days are several epigraphic texts of significance: the Senatusconsultum de Bacchanalibus, on a bronze tablet found in 1640 in Bruttium (the "toe" of Italy) and now in Vienna, is a consular edict on Senate authority, regulating Dionysiac outbursts in Italy in 186 BC; pieces of the laws Lex Acilia Repetundarum (123 BC) and Lex Agraria (111 BC) were found in the 16th century on opposite sides of what was once a large bronze tablet; the local laws of the town of Bantia (on the borderlands of Lucania and Apulia in southern Italy) are inscribed on a fragmentary bronze tablet found in 1790 (now in Naples), with a Latin-language text on one side and the longest known Oscan inscription on the other, both datable to the late 2nd century BC; parts of the Lex Cornelia de Viginti Quaestoribus (81 BC) are preserved on a large bronze tablet found at Rome: Julius Caesar's Lex Julia Municipalis of 45 BC was found near Heraclea in Lucania. On the whole, however, the transmission of Roman law, from the earliest fragments to the mature codifications, is nonepigraphic. In later times the flood of administrative decrees increases with the growth of centralized autocracy. Typically Roman epigraphic material of imperial date comprises further building inscriptions, military records, and honorific texts.

The Turkic peoples. The oldest monuments of Turkic languages-inscribed on stones, and datable to the early 8th century AD-were discovered in the late 19th century in southern Siberia around the Yenisev River and in northern Mongolia near the capital of Urga (modern Ulaanbaatar). Deciphered in 1893 by the Danish scholar Vilhelm Thomsen, they provide valuable insights into the history of Central Asia around the 7th century AD. These records of the Turk dynasty (Chinese T'u-chüeh) comprise especially texts found at Kosho-Tsaidam on the Orhon (Orkhon) Gol (river), including also Chinese text. These texts throw light on the nomadic culture of the tribal empire controlled by the Turk dynasty, including shamanism, calendar, customs, and social structure, with strong Chinese influence detectable in the latter. After the decline of the Turk people (c. 745), their successors, the Uighurs, perpetuated for a time the same kind of monumental dynastic epigraphy, the writing system of which is an offshoot of the Aramaic alphabet, presumably mediated by the Iranian-speaking Sogdians of Central Asia. Gradually, however, new scripts took over (especially the so-called Uighur alphabet, of Syriac origin, which was further transmitted to the Mongols and the Manchus) and inscriptional monuments gave way to manuscript records such as those found in Chinese Turkistan (Turfan) in the late 19th century (along with texts in Sanskrit, Sogdian, Tocharian, and other Indo-European idioms), attesting to a coexistence of Buddhist, Manichaean, and Nestorian Christian religious communities. The later Turkish peoples, including the Anatolian Seljugs and Ottomans, had an Islamic book-tradition, to which the inscriptional record is merely incidental.

Texts from republican Rome

The oldest Turkic monuments Runic

monu-

ments

Northern Europe. The advent of writing was slow north of the Alps; it came either from direct expansionary exportation by Greek coastal colonies and the Roman Empire, as in Gaul and the Iberian Peninsula, or indirect inspiration from the same quarter, as in writing in the Irish and British ogham alphabet and the Germanic runes.

Celt-Iberian inscriptions from Spain and Celtic ones from Gaul and Ireland are scarce, mostly brief, and notably devoid of usable historical information, apart from their mere monumental existence and linguistic and onomastic (pertaining to names) content. Occasional items such as the fragmentary Gaulish Calendar of Coligny afford insights into local cultural practices, apart from an over-

whelming trend to romanization.

The runic alphabet-a Germanic alphabet, originally of 24 letters, also called futhark-and its offshoots (the Scandinavian, especially Danish, 16-letter variety from the 9th century AD; and Anglo-Saxon versions, from the 3rd to the 10th centuries AD, also called futhorc) are probably of "North Etruscan" or "Sub-Alpine" Italic inspiration, datable to around 200 BC. The "North Italic" letters of the Germanic text harixasti teiva, "to the god Harigast," on a helmet from Negau (southern Austria) are probably from that time of transmission. Runic inscriptions from the era of migrations, ranging from eastern France through Germany up to Denmark and eastward via Poland to Romania, are supplemented by the later, richer yield from England and Scandinavia. Native Anglo-Saxon runic epigraphy, mostly in Northumbria, Mercia, and Kent, petered out around the 10th century, whereas the Scandinavian tradition (including its enclaves on British soil) endured for several more centuries. Sweden has some 3,000 runic monuments; Norway and Denmark, perhaps 400 each; while Iceland has remarkably few, apparently in inverse proportion to the literary flowering in that colonial outpost. The Vikings left their runic calling cards in far-flung places, including those in the Greek port of Piraeus, on the Black Sea coast, in Varangian Russia, in Scotland, Ireland, and the Isle of Man, and the Orkneys, Hebrides, and Shetland islands; Greenland has its share, but alleged specimens from North America, notably the Kensington Stone from Minnesota, telling of the westward trek of an exploration party from Vinland, are invariably crude latter-day forgeries.

The purposes of runic inscriptions were usually either dedicatory or commemorative, sometimes magic, and frequently sepulchral. The longest, that from Rök in Sweden (725 runes), seems to contain a catalog of epic deeds. possibly those of the Ostrogoth king Theoderic. The prime historical value of runic epigraphs is usually what and where they are, rather than what they depict or record,

Inscriptions as social and cultural records. In the preceding section, inscriptions were evaluated as sources for the presence and migrations of peoples, the existence and chronology of political states, their dynastic histories, foreign relations, internal governance, legal institutions, and official acts. In this section, epigraphy is surveyed for information about how past civilizations lived; their religious beliefs and practices; their business, financial, legal, and social relations; and what shape their aspirations assumed in terms of verbal creativity. The subdivision of civilizations surveyed differs somewhat arbitrarily from the earlier section by the omission of certain areas and the inclusion of Crete and Mycenaean Greece, In fact, Indic and Chinese epigraphic matter discussed above could just as well have fitted the "religious" slot, but its royal character and chronological importance for official history dictated otherwise. Conversely, the Cretan and Mycenaean tablets are purely economic inventories, but they might possibly have been included with history above for the very important historical fact that they prove the ruling presence of Greeks at Knossos during the 2nd millennium BC. The varying degree of importance of epigraphic material in various cultures persists: in Mesopotamia and the ancient Near East its dominance was nearly total; in Egypt it combined with the papyrological dimension; in Crete it was merely a flash in a prehistoric darkness; while in ancient Greece and Rome, it was a supplementary concomitant of the nonepigraphic literary tradition.

Ancient Mesonotamia. Ample specimens of Akkadianlanguage clay-tablet epistolography have been found at several sites, notably Tell el-Amarna in Egypt and Tell al-Hariri on the middle Euphrates (the ancient Mari of c. 1700 BC) The Amarna letters, about 400 of them, were composed in corrupt Akkadian by Canaanite scribes in Syria and Palestine and were largely official in character. The Mari letters, some 5,000 in number, are more illustrative of normal day-to-day written communication in a Mesopotamian milieu proper.

Another aspect of everyday life in ancient Mesopotamia is amply illustrated by thousands of clay tablets of a practical legal nature, as distinct from the formal laws. These archivally preserved records from various periods use Sumerian, Old Akkadian, Babylonian, and Assyrian alike. They detail law suits, court decisions, marriage contracts, divorce proceedings and settlements, sale adoptions (fictitious acts circumventing prohibitions against land sales outside the family), loan agreements, tax receipts, and much else. Commercial inventories, such as those of the Old Assyrian merchant colony at Karum Kanes in central Asia Minor (20th century BC), complete the picture.

Due to the religious sanction of law, legal records were often stockpiled in temple archives. These latter are also the source of more directly cultic texts, such as descriptions of rituals, which come under such headings as "Temple Program for the New Year's Festivals at Babvlon," "Ritual to be Followed by the Kalū (priest) when Covering the Temple Kettle-Drum," "Ritual for the Repair of a Temple," and "Program of the Pageant of the Statue of the God Anu at Uruk." Prayers, lamentations, and hymns in both Sumerian and Akkadian are extant, addressed to deities such as the goddess Ishtar, the moon god Sin, the sun god Shamash, the great triad Anu, Enlil, and Ea, and the Babylonian patron god Marduk. The Sumerian "Lament for the Destruction of Ur" bemoans the city's fall to Elamites and Subarians. Often the king himself is the spokesman in the text. Wisdom literature, such as proverbs and fables (e.g., "Dispute between the Date Palm and the Tamarisk"), poetic meditations, oracles, divination records, omens, and prophecies are further examples of Mesopotamian genres that only epigraphy has preserved.

Sumerian and Akkadian narrative literature is likewise of wholly inscriptional transmission. It contains man's earliest preserved literary creations in the Sumerian sequence, especially the texts from tablets found at Nippur. These include the "Paradise myth" of the god Enki and the goddess Ninhursag in the pure, clean, and bright land of Dilmun; the story of Dumuzi and Enkimdu (the petulant shepherd god versus the peace-loving farmer god, inversely reminiscent of the Cain-Abel antagonism in Genesis but not culminating in murder); "The Deluge" with its Noah-hero Ziusudra; "Inanna's Descent to the Nether World," which prefigures the later Akkadian "Ishtar's Descent"; and the lays of Gilgamesh, which show the Sumerian traditions that were later partly organized and transformed into the Akkadian epic. The latter include "Gilgamesh and Agga of Kish," a story of confrontation between early Sumerian city-states: "Gilgamesh and the Land of the Living"; and "The Death of Gilgamesh," with its haunting parallelistic refrain "he lies, he rises not." The Akkadian Epic of Gilgamesh is divided into 12 tablets, the longest of which is more than 300 lines; this "Flood Tablet" (the 11th) is virtually intact and comes, like almost all Assyrian-language Gilgamesh texts, from the library of Ashurbanipal at Nineveh (7th century BC). From the 2nd millennium there are fragments of a Hittite version from Boğazköy, as well as minor traces of a Hurrian translation. Old Babylonian correspondences to tablets 1-3 and 10 are found on a tablet from Sippar (c. 1800 BC). The 12th tablet is a literal translation from Sumerian, whereas the rest amounts to a self-contained Akkadian epic original, based on Sumerian motifs but with a thrust of its own. The most complete reconstruction involves a combination of Assyrian, Old

Babylonian, and Hittite versions. The other famous Mesopotamian epic, Enuma elish, "When on high," details the story of cosmic creation and of how Marduk became the great god of Babylon; it had The Amarna and Mari letters

The Gilgamesh more immediate cultic attachments because its recitation formed part of the New Year festival.

Further Akkadian literary creation is attested in the epic of Atrahasis, a tale of mankind's punishment through pestilence and flood, preserved in fragmentary Old Babylonian and Assyrian versions. The story of Adapa, found in parts in the Tell el-Amarna archives and the library of Ashurbanipal, is similar to Gilgamesh's quest for immortality. The myth of Zu deals with the theft of the tables of fate and the usurpation of almightiness by the bird god Zu. The legend of Etana, a namesake of the shepherdking who ascended to heaven in the mythical postdiluvian Sumerian dynasty of Kish, recounts in its Old Babylonian and Assyrian recensions the heavenly flight of Etana on the wings of an eagle in order to acquire the magic birth plant that would cure his childlessness. Death-oriented themes appear in the tale of Ishtar's descent, in the story of Nergal and Ereshkigal, and in various netherworld texts associated with the Tammuz myth and liturgy,

Ancient Egypt. The multitude of incidental day-to-day written matter on potsherds and papyrus, preserved by climatological quirks in Egypt, affords insights into the normal living patterns of ordinary people during the pharaonic, the Hellenistic (Ptolemaic), and the Roman periods. More formal records of similar provenance may be described as legal in the widest sense, comprising such objects as land deeds, cadastral inventories (tax surveys), wills, adoption decrees, and trial transcripts. Thus many technicalities of landholding in the Nile Delta during certain ancient periods survive, unwarranted by any normal expectancies of epigraphic preservation elsewhere; only the happenstance of the Creto-Mycenaean records (see below Crete and Mycenaean Greece) has accidentally transmitted

something analogous.

The

accidental

preserva-

Egyptian

tion of

texts

Ritualistic texts are equally abundant, in both monumental and papyrological transmission. Notable among offertory liturgy was the mortuary service to the dead, acted out as a kind of ritual make-believe in which the offering was referred to as the eye of Horus (the sacrificer) being given up on behalf of his father, Osiris (the departed). Ritual drama in general is amply attested in Egyptian religious practice; day-to-day ceremonial in the cult of gods or god-kings (pharaohs) was recorded in the minutest detail. Magic texts include incantations and charms against such dangerous creatures as snakes, scorpions, crocodiles, and lions. Even the buried dead were deemed in need of such protection, and hence the preserved samples are largely of mortuary provenance. An important category of epigraphs is constituted by curses, imprecations, and threats of divine vengeance against enemies, evildoers, and tomb violators in particular. Dream interpretation and oracular inquiry are represented on both monuments and papyri.

Of a more secular nature and on the verge of true literature are moral and didactic writings, particularly during the early Middle Kingdom (began 1938 BC), when a profound social and spiritual crisis seems to have gripped Egypt. Of such kind are "The Admonitions of Ipuwer" (a denunciation of current sin and evil in Hebrew "prophetic" manner), the "Colloquy of a Prospective Suicide with His Own Soul," and especially copious compendia of conventional wisdom, frequently formulated as instructions from a royal or noble father to his son. Some parts offer remarkable parallels to the Hebrew book of Proverbs.

On the same borderline to real literature stand mythical tales, including in particular the myths of creation by the god Atum of Heliopolis and the Memphite patron deity Ptah, whose eminence is reminiscent of the cultic fortunes of Marduk. The Memphite cosmogony, of 1st dynasty provenance, is an abstract one, with Ptah's creation conceived with his "heart" (mind) and "tongue" (word) rather than the usual physical detail. Other mythic tales concern the perils from the netherworld demon Apepi faced by the sun god Re during his nightly journey in his solar boat; the rivalries between Horus and Seth for the succession of Osiris (a patent allegory of the tensions between Lower and Upper Egypt); mortuary texts particularly concerned with the Osiris myth and the prospect of judgment (e.g., the "Protestations of Innocence"), attested both monumentally and on papyri (the Book of the Dead); and pieces designed to bolster the supremacy of specific sites and deities, particularly Amon-Re at Thebes.

Out of the latter tendency emerged hymnic poetry during the 18th and 19th dynasties, triggered by an imperial trend toward unicentrism in government and universal syncretism in religion. The great hymns to Amon-Re were matched during Ikhnaton's "Amarna revolution" by his great Aton-hymn, uncannily reminiscent of the 104th Psalm of the Old Testament. Victory hymns and prayers are further examples of poetic genre, as are purely secular pieces, including several collections of love songs from c. 1300 to 1100 BC, songs of farm workers and herdsmen. and feast songs for entertainment.

In nonreligious literary prose there is preserved the story of Sinuhe, an account of the life of a Middle Kingdom official, his prosperous peregrination in Asia but continued yearning for the homeland, relieved at last by a chance to join the pharaonic court. Papyri and ostraca tell this story in a long succession of attestations through most of the 2nd millennium BC. Of later date (c. 1100 BC) is the "picaresque" narrative of the hieratic-script "Moscow papyrus," detailing the ill-financed mission of a certain Wen-Amon from Karnak to Byblos to buy timber for a ceremonial barge of Amon.

The Hittite Empire. The Boğazköv archives are the unique central storehouse of Hittite records for the duration of that empire (only minor additions have been found elsewhere, such as letters at Tell el-Amarna and Alalakh). The past of other cultures was known from external and nonepigraphic sources before the explorational and excavational discoveries of inscriptions; with the Hittites, however, the record is in one place and in toto.

Boğazköv archives

Much may be learned of everyday life and social relations from legal texts, including the laws themselves. Such matters as family relations, property rights, land tenure, and commodity prices are dealt with in great and sometimes pedantic or amusing detail. More can be learned from gift deeds of land, cadastral lists, and trial records, the latter containing largely depositions of respondents and witnesses in civil suits. Unique in their kind are treatises on the training of racehorses. Astrological omen texts, divination records (hepatoscopy, auspicy, lottery oracles), and dream interpretations abound, patterned largely on Mesopotamian models; rituals of all kinds take up a disproportionate amount of space. Temple foundations and procedures, festival ceremonies, epidemics, impotence, family quarrels, countermagic, royal welfare, birth, insomnia, and the manipulation of deities are among the topics of Hittite ritual; in a class by itself is a funeral ritual for royalty, reminiscent of Homeric practices. Not only the Hittite language but Hattic, Hurrian, Luwian, and Palaic are used in rituals. Another large category is made up of hymns and prayers, most notably those of King Mursilis II, in particular his "plague prayers," in which he confesses sins and begs the storm god for mercy. Other notable examples are the prayer of Muwatallis to the sun god. the vows of Queen Puduhepa to the sun goddess, and the prayer of Kantuzilis with its intimations of mortality. Native Anatolian mythical texts, such as those of the slaying of the dragon Illuvankas and of the disappearance of the god Telipinus, were part of ritual recitation. Other mythical matter points up the crossroads character of Hittite civilization, being made up of Akkadian, Hurrian, and Canaanite themes. Most of the Hittite epigraphic corpus has some connection with religion.

Other countries of the ancient Middle East. Away from the big power centres some quite important sites remain to be identified, such as the Mitannian capital of Wassukkani. Others (e.g., the fortress-town of Carchemish on the upper Euphrates, for some time a Hittite dependency) have yielded notable data, especially royal inscriptions in Hittite hieroglyphs. In particular the French excavations at Ras Shamra on the Syrian coast since 1929 have uncovered the inscriptional and other remains of the small but strategic city-state of Ugarit, which flourished in the 15th-13th centuries BC. Its own vowelless cuneiform alphabet, a radical departure from the Mesopotamian syllabary prototype, denotes an archaic Semitic dialect closely akin to Canaanite. The written documentation of this crossroads

The citystate of Ugarit

community, in a variety of scripts and languages, provides information on the history of the area where Hittite and Egyptian power politics collided. But its most significant epigraphic products have been poetic epics of mythical and heroic scope, which go far to elucidate religious traditions otherwise known mainly from Old Testament bias. The great cycle of Baal and Anath brings to life the pantheon to which belonged also El, Asherah (the Astarte of the Phoenicians), Kothar ("Deft," the craftsman god), and Yamm (the sea god). The tale of Aqhat is also on the borderline of myth, while that of King Keret (or Kret) takes place in a saga world somewhat reminiscent of the Greek Homeric tradition.

Scattered dedicatory inscriptions and papyrus texts shed some light on the lives and practices of the Aramaeanspeaking populations during the 1st millennium BC. From Palestine there are the Hebrew ostraca of Samaria, datable to the reign of Jeroboam II of Israel (8th century BC), which record names, families, and administrative and religious practices. Of equal significance are the ostraca of Lachish in southern Palestine, which probably immediately preceded the Chaldean onslaught of 589 BC. Phoenician texts are scattered around the Mediterranean, and bear witness to an extensive and protracted maritime supremacy.

The Old Persian Achaemenid inscriptions (see above Ancient Iran) are of some value in assessing the state religion of the time, which seems to have been a rather anemic form of official Zoroastrianism. Later monuments from the wider Iranian area help map its complicated religious history, such as the great inscription of the Kuṣāṇa king Kaniska, found at Surkh-Kotal in Afghanistan in 1957 and attesting to the Iranian language and Mithraic cults of ancient Bactria in the 2nd century AD. The Sāsānian religious tradition of the 3rd-7th centuries, with its rigidified formal Zoroastrianism, is mainly of nonepigraphic

The Linear

B script

Crete and Mycenaean Greece. The decipherment of the latest and most copiously attested of the Minoan linear scripts the so-called Linear B, by British cryptologist Michael Ventris in 1953, is a major example of the dramatic impact epigraphic discovery can have on the most varied antiquarian disciplines. It supplied incontrovertible proof that the Mycenaeans on the Greek mainland during the 2nd millennium BC were Greek in language and likewise that Knossos in Crete was a Greek-speaking stronghold at the time of its final destruction (c. 1400 BC). The records from Knossos, Pylos in Messenia, and Mycenae in the Argolid are exclusively perishable inventories on clay tablets, kept in royal palaces or emporia and apparently meant to be discarded or reused annually; thus they record data from the very last year of any given establishment, just before its final destruction in the fire that also accidentally ensured their preservation by baking the clay.

The contents are brief, concise, practical, and quantifying in character. Nevertheless, they reveal an important amount of detail about a civilization that is otherwise accessible only via the testimony of archaeology, iconography, and the poetic memory of early classical Greece across several "dark" centuries. Apart from the philologically invaluable recording of preclassical linguistic forms and proper names, there is the cryptologic evidence of the syllabic writing system, which may yet help bring about a cogent decipherment and linguistic identification of the earlier forms of Cretan writing.

Something of bureaucratic accounting methods can be learned from the system of the tablets. Contents yield lists of personnel; of livestock and agricultural produce; of textiles, vessels, and furniture; of metals and military matériel (swords, corselets, chariots, etc.); as well as records of landholding and of temporal and cultic tribute. The cadastral inventories are significant for the light they shed on the system of land distribution as compared with classical Greece and especially with contemporary practices in adjacent culture areas, such as those recorded in the Hittite Law Code. The religious tributes are revelatory in proving what bold scholarship had merely surmised-that the bulk of the classical Greek deities existed in name and kind already in Mycenaean days. Something of the social order and the system of government can also be incidentally learned.

Classical Greece. Inscriptions in their variety and profusion are an important means of gauging everyday life in classical Greece, especially such more formal aspects as were deserving of recording. This qualification, however, does not prevent some obscene pederastic rock-carvings on the island of Thera from being the earliest epigraphic texts from the classical period (c. 8th century BC), in a form of the alphabet still strongly marked by its Phoenician source.

In a formal vein there is ample documentation of a business, financial, and legal type, such as regulations for building projects, contracts for medical services (e.g., the Cypriot bronze tablet of Idalium, in a peculiar syllabaric script reminiscent of the Cretan and Cypro-Minoan types, used to write both Greek and the uninterpreted Eteocypriot language), collection agreements for defaulted notes, manumission decrees, records of bank deposits (frequently in a temple), and reports of land commissions (especially the Heraclean Tables from southern Italy).

Even in these formal documents it is impossible to keep out reference to religious establishments. Religion was, in fact, big business in classical Greece, and overlap in the records is frequent. Temples were often of the order of corporations, with extensive holdings of real estate and banking operations. The epigraphs of their transactions are coupled with minute records of dedicatory offerings, priest lists, administrative regulations, and ritualistic and liturgical instructions. So much of social life was centred around institutionalized religion that most of its documentation may be included under the latter heading. Dedicatory texts in the widest sense are common, often in verse, such as that by Nikandre of Naxos on a 7th-century-BC statue of Artemis at Delos, a kind of propitiatory offering to the maiden goddess on the occasion of marriage. Similar hexametric or elegiac texts are found as epitaphs, especially for those who perished in war or at sea.

Tomb inscriptions generally are the most numerous of all but tend to be laconic in style and lacking even in purely statistical data. Those from ancillary areas of the Greekspeaking world, such as the non-Greek ones from Lycia, Lydia, and Phrygia in Asia Minor, are sometimes more revealing to the extent that they are interpreted. Thus the Lycian stela of Xanthus, a tomb monument from the 5th century BC, runs to many hundreds of words, including a dozen lines of Greek. The peculiar Lycian system of matrilinear descent is clearly evident in the texts. The Lydian ones include a marble stela from the necropolis of Sardis with a Lydian-Aramaic bilingual epitaph that typically calls down the curse of Artemis of Ephesus on potential violators. Such imprecations are also standard in Phrygian sepulchral epigraphs. Some kinds of deathrelated inscriptions were intentionally buried, such as the curses that consigned the object to the infernal avengers. Another type is seen in the Orphic tablets-texts on thin gold found interred with the remains of devotees of the Orphic salvation religion near Sybaris in southern Italy, near Rome, and at Eleutherna in Crete. They are apparently meant as instructions to the deceased-exhortations to the soul on its progress in the beyond, enjoining the shunning of the spring of Lethe ("Oblivion") and the drinking from that of Mnemosyne ("Memory"), thus securing the end of transmigration of the soul and the attainment of perpetual higher consciousness.

The Orphic texts provide the popular parallel to the Platonic myth of Er in the 10th book of The Republic, where Plato somewhat recast Lethe and Mnemosyne into Ameles ("Unmindfulness") and Anamnesis ("Recollection"). Thus, epigraphy not merely supplements the literary record of Greek civilization but also complements it in important aspects. If papyrology is included, important additions to the preserved portion of classical Greek literature have come from Egypt, especially in the papyri from Oxyrhynchus; these include such otherwise lost treatises as Aristotle's Constitution of Athens and entire dramatic works (e.g., the Dyscolus of Menander).

Ancient Rome. The frequency of Roman inscriptions increased dramatically in direct proportion to the rise of

Earliest

classical

texts

epigraphic

Tomb monuments

605

Roman power; but that same rise brought centralization. stereotyping, and a certain sterility of the more formal parts of the epigraphic record. Much of the bulk is official, unidirectional, and from the top outward. The Greekspeaking parts of the empire continued in many of their ancient ways, and other annexed regions (such as Spain or Gaul) developed their own locally coloured practices. The spread of a variety of exotic religious cults all over the empire, among them Mithraism and Christianity, added a kind of epigraphic underground initially devoid of official sanction and largely unmatched by alternative avenues of preserved written transmission. Popular epigraphy, including such matter as graffiti at Pompeii and other Vulgar Latin inscriptions, provides further counterpoise to the official stereotypes.

From early republican days the Roman written record is very spotty. The earliest text of any length, the Forum inscription from the early 5th century BC, seems to refer to an augural rite (referred to by Cicero and Festus as the juge auspicium) which enjoins the immediate unyoking of beasts of burden that produce excrement. A 4th-century vase (the "Quirinal vase") is apparently a wedding present with an inscribed guarantee by the bride's guardian to use his good offices to further marital concord. Later texts of religious import include the "Song of the Arval Brethren" on a marble tablet found in the Vatican in 1778 (a chant largely reduced to gibberish by age-old ritualistic repetition), records of various other cultic "colleges" (augures; fetiales, or priestly diplomatic representatives; salii, or priests of Mars and Quirinus et al.), and outside of the Latin-speech area especially the seven Umbrian-language bronze tables found at Iguvium (modern Gubbio) in 1444. recording in more than 4,000 words the ritualistic details of a brotherhood (the Fratres Atiedii) that flourished in republican days. Official religion is further seen in many dedications, such as one found on Caelian Hill in Rome in the 18th century, which records the offering of a temple and statue to Hercules by Lucius Mummius in 146 BC in fulfillment of a vow he had made during his conquest of Greece and sack of Corinth, "Unofficial" cults. especially those of Mithra and Jupiter Dolichenus, can be traced and mapped throughout the empire chiefly with the help of dedicatory epigraphs. Sepulchral inscriptions are recorded in overwhelming numbers, not only in Latin but notably also in Etruscan; among the latter is the mummy wrap, a lengthy funeral liturgy inscribed on an apparently Etruscan mummy entombed in Egypt (now in Zagreb). The earliest notable Roman examples are the epitaphs in Saturnian verse on the sarcophagi of the Scipios from the 3rd century BC.

There are many texts of deep sentiment and poetic feeling. Yet the bulk itself is the main source of information because it affords what may be called demographic statistics, including population distribution, occupations, public health, and longevity. The frequent inclusion of the cursus honorum, or career summary of the departed, has similar informational value. Tombs were usually placed under the divine tutelage of the powers of the beyond. Imprecations against violation were common, as were buried curse tablets in Latin and in Oscan (the defixiones). Many of the unofficial inscriptions exhibit substandard degrees of literacy and colloquial features, being thus an important adjunct to the study of the totality of classical Latin and

its subsequent developments. The use of inscriptions. The dating of historical events. Inscriptions are important specimens for chronology because they are often physical objects contemporary in execution with their contents. The dating of the inscription itself frequently yields a trustworthy chronology of its message: a victory stela records something freshly deserving of celebration; an epitaph implies a recent death. Exceptions do exist, which record more or less remote events at a conscious historical remove; archival specimens, for example, and secondhand copies generally lack the contemporaneity of other inscriptions. On the whole, however, external dating is crucial and may be achieved in several ways. Excavated monuments can be chronologized by their archeological context, including stratigraphic analysis and radiocarbon dating of any adjacent remains

of organic matter. The shape of the monument may permit stylistic and iconographic determination. The type and variety of script used, and especially the style of writing, often allow paleographic dating. Thus, the relative age of Hittite texts can be determined by spotting the typical "Old Hittite ductus" of the more ancient period, and the various "scribal hands" of the Linear B tablets have been differentiated with extreme subtlety. Sometimes a radical reform, such as the official adoption by Athens of the Ionic alphabet in 403 BC (replacing the local Attic variety), provides a chronological watershed. Internal evidence of the inscription may yield its own kind of dating, either by synchronism with otherwise known facts or events or in true calendaric fashion. The year is frequently indicated by a king's reign or the tenure of a magistrate. Such stable counting of time as, for example, from Rome's legendary founding in 753 BC, or from creation (5509 BC, according to Christian dating) is rare in inscriptions; it became more of a historian's device during the classical and postclassical periods. In smaller communities, however, especially in Asia Minor, analogous local departures were used (legendary or historical foundation dates or other epoch-making events), with confusing results for latter-day chronologists

The use of inscriptions for the dating of historical events is most pervasive when the historical tradition itself is "timeless," as in ancient India: the entire Indian chronology comes to be anchored around the Asokan inscriptions. Inscriptions also permit a check on the veracity of ancient historians such as Herodotus (dubbed both "father of history" and "father of lies"), as in the case of the Bisitun inscription of Darius. Equally dramatically, the Linear B tablets prove at one stroke that the Greeks were ensconced at Knossos in the 2nd millennium BC and that the bulk of the "Olympian" religion was already theirs at the time. Most significant of all, nothing would be known of the great Hittite Empire during the 2nd millennium BC, were it not for the discovery of its inscriptional archives

The decipherment of ancient languages. Inscriptions as written records are usable only in proportion to their intelligibility. Important epigraphic corpora remain virtually undeciphered; e.g., the "Indus script" from Mohenjo-daro and Harappa (3rd millennium BC), the Carian texts from Asia Minor and by Carian mercenaries in Egypt (1st millennium BC), and the pictographic Mayan "hieroglyphs" from Central America (c. AD 500-1500). Sometimes the writing system is intelligible, as in the case of Etruscan, but understanding remains deficient because the language is otherwise unknown and bilingual keys are lacking or inadequate. Chances for success are best if there are sufficiently extensive bilingual or multilingual copies, of which at least one language is previously understood. Such presence made possible the decipherment of ancient Egyptian (the Rosetta Stone of 196 BC, with hieroglyphic, demotic, and Greek versions). Once the affinity of an underlying language to known idioms is established (e.g., Old Egyptian to Coptic, Old Persian to Avestan and Sanskrit, Akkadian to Hebrew), interpretation can proceed apace. The recovery of Hittite was not a true decipherment because the script was a relatively common variety of syllabic cuneiform. The interpretation was helped by the nature of the writing on the one hand (including intelligible ideograms, while an alphabet yields no such clues), and by the presence of Akkadian-Hittite bilinguals on the other; the soon-recognized Indo-European affinities of the Hittite language afforded further help. The Hittite hieroglyphs were partly deciphered by painstaking internal analysis based on the correct assumption of an underlying dialect akin to Hittite; a bilingual with Phoenician text brought much welcome confirmation. The decipherment of Linear B was a sheer triumph of methodical cryptology, again based on the correct hunch that the hidden language was Greek.

In sum, the decipherment of ancient scripts and the recovery of lost languages are practically identical with the interpretation of previously unintelligible ancient inscriptions, because texts involved are almost exclusively epigraphic. Even when the language is otherwise preserved (as with classical Greek and Latin), inscriptions yield esUndeciepigraphic corpora

Contemporaneity of epigraphy

Epigraphic

collections

sential additional data for its history, dialects, and social diversification.

History of epigraphy. Greek and Latin inscriptions. Inscriptions have commonly elicited the curiosity of posterity, and such ancient Greek historians as Thucydides and Polybius already made scholarly use of them. Sporadic systematic interest in Greek and Latin inscriptions is attested in later ages; e.g., Cola di Rienzo in the 14th century made a collection, and Cyriacus of Ancona (Ciriaco de' Pizzicolli) in the 15th century was a renowned recorder of ancient written monuments on his mercantile travels to Greece, Anatolia, and Egypt. Cyriacus' material formed the nucleus of various compilations in the succeeding centuries, normally on a geographic basis. A rival typological method of publication was launched by Martin Smetius in Leiden in the late 16th century and was followed in the early 17th by a monumental collection of Janus Gruter and Joseph Justus Scaliger. After copious additions of material during the 18th and early 19th centuries, the Corpus Inscriptionum Graecarum was launched by August Böckh in 1815 under the aegis of the Berlin Academy and was completed in four volumes with index (1828-77). The material had by then again outrun the publication, and it was resolved in 1868 to re-edit completely all Attic inscriptions. Ulrich von Wilamowitz-Moellendorff in 1902 took charge of the Inscriptiones Graecae (1873-), which continued where the Corpus Inscriptionum Graecarum left off and included the Corpus Inscriptionum Atticaru, as well as all Greek inscriptions from European Greece (including Magna Graecia in Italy) and Cyprus. Those of Anatolia were left to the Tituli Asiae Minoris of the Vienna Academy, which began with the Lycian-language inscriptions from Lycia in 1901 and continued with the Greek and Latin ones from Lycia in 1920-44. The rest of Greek Anatolia was combed somewhat by the multivolume American series, Monumenta Asiae Minoris Antiqua (since 1928). Inscriptiones Graecae, framed in 14 volumes, has turned partly into a kind of overall umbrella for diverse coverage; volumes 6, 8, 10, much of 11, parts of 12, and 13 were never completed, being preempted by such other large publications as Inschriften von Olympia, Fouilles de Delphes, V. Latyshev's Inscriptiones Antiquae Orae Septentrionalis Ponti Euxini Graecae et Latinae and G. Mikhaylov's Inscriptiones Graecae in Bulgaria Repertae, Inscriptions de Délos, and M. Guarducci's Inscriptiones Creticae. The continuous influx of new material is inventoried and presented in such annual outlets as Supplementum Epigraphicum Graecum (since 1923) and "Bulletin épigraphique" in the Revue des études grecques. Large recent undertakings either supplement or complement the Inscriptiones Graecae, such as The Athenian Tribute Lists (from the American excavations in the Agora) and Inscriptions grecques et latines de la Syrie (six volumes, 1929-67). There are, in addition, numerous more localized or specialized collections.

The Corpus Inscriptionum Latinarum, founded by Theodore Mommsen in Berlin in 1862, comprises 16 volumes fortified with copious supplements; it covers the classical Latin world and is notable for its homogeneity and systematization. Current finds and studies are presented in L'année épigraphique (since 1888). Etruscan inscriptions are less perfectly published in the antiquated Corpus Inscriptionum Etruscarum; many important later finds are included in transcription in M. Pallottino's Testimonia Linguae Etruscae and in M. Fowler and R.G. Wolfe, Materials for the Study of the Etruscan Language (1955; a computerized corpus). Of further relevance to the Roman world are collections of the type of E. Diehl, Inscriptiones Latinae Christianae Veteres; M.J. Vermaseren, Corpus Inscriptionum et Monumentorum Religionis Mithriacae; and Inscriptiones Italiae.

Other inscriptions. R.A.S. Macalister's Corpus Inscriptionum Insularum Celticarum (1945-49) gathers the oghamic and other early texts from Ireland and elsewhere. The runic inscriptions are inventoried in a variety of compilations. The Corpus Inscriptionum Semiticarum, in Paris (since 1881), covers in separate volumes Phoenician, Aramaic, and other speech areas. Urartean texts were collected by C.F. Lehmann-Haupt in Corpus Inscriptionum Chaldicarum (1928-35); the earlier found Hittite hieroglyphic texts, by L. Messerschmidt in the antiquated Corpus Inscriptionum Hettiticarum. The Corpus Inscriptionum Iranicarum, intended to gather the epigraphs of Persia proper (Achaemenid, Seleucid, Parthian, Sāsānid) and of eastern Iran and Central Asia, began in London in 1955. The Corpus Inscriptionum Indicarum has published four volumes since the 1870s, comprising the Aśoka, Indo-Scythian, Gupta, and Kalacuri-Cedi periods, supplemented by the series Epigraphia Indica and South Indian Inscriptions

No equally closed corpora exist for cuneiform and Egyptian documents. The Hittite texts come closest to such organization, issued mainly in two great ongoing series, Keilschrifttexte aus Boghazköi (German Oriental Society) and Keilschrifturkunden aus Boghazköi (Berlin Academy). But mostly the publication is haphazard-as part of excavation records (Keilschrifttexte aus Assur), depending on storage sites (Cuneiform Texts in the British Museum), or on the basis of genres (F. Thureau-Dangin, Rituels accadiens). The same pattern holds true of the Egyptian records

Much epigraphic material is published in excavation reports and in many archeological and antiquarian periodicals; e.g., Hesperia, Journal of Hellenic Studies, Bulletin de correspondance hellénique, Archeologia classica, Studi Etruschi, and Syria. Specifically epigraphic serial publications include Epigraphica (Milan, since 1939), Kadmos (Berlin, since 1962), Zeitschrift für Papyrologie und Epigraphik (Bonn, since 1967), and Chiron (Munich, since 1971).

GENEALOGY

The word genealogy comes from two Greek words-one meaning "race" or "family" and the other "theory" or "science." Thus is derived "to trace ancestry," the science of studying family history. The term pedigree, used to describe a genealogy as set forth in chart or other written form, comes from the Latin pes ("foot") and grus ("crane") and is derived from a sign resembling a crane's foot, used to indicate lines of descent in early west European genealogies. Chart pedigrees, familiar to most people from school history books, include arrow shapes, parallel lines, a crinkled line denoting illegitimacy, and the sign = denoting marriage. Genealogy is a universal phenomenon and, in forms varying from the rudimentary to the comparatively complex, is found in all nations and periods. In this section the history of genealogy will be outlined, followed by an account of the work of modern genealogists, professional and amateur, and as organized

in associations. History of genealogical study. The history of genealogy can be divided most easily into three stages. The first is that of oral tradition; the second, that in which certain pedigrees were committed to writing. The third stage comprises the period from approximately 1500 in western Europe and later in the English-speaking world, during which the whole basis of genealogy widened to such an extent that it is now possible for the majority of people in western Europe to trace their ancestry.

Oral tradition and biblical sources. In the early days of civilization, before written records were made, oral traditions were necessarily important. Without the art of writing, reliance must be placed on memory, aided possibly by mnemonic systems like that of knot arrangements used by the pre-Hispanic Peruvians, or beads employed by the Maori of New Zealand. The ancient Scottish sennachy, or royal bard, could recite the pedigree of the old Scots kings at the latter's inauguration, and the nobles of Peru, who boasted a common descent with the sovereign, were able to preserve their pedigrees despite the complexity resulting from the practice of polygamy. Oral transmission of genealogical information is almost always as a list of names-the lineages of the ancient Irish kings, for example. Events of outstanding importance are occasionally incorporated in such lists.

Numerous Oriental genealogies appear in the Old Tes- Oriental tament. A cursory examination of these will reveal that genealogies they belong to the first and second stages in the history

In southern India the ruling house of the maharajas of Travancore claimed to trace its descent, direct and unbroken, from the old Cera kings of southern India (referred to as independent sovereigns in one of the edicts of Aśoka, the great Mauryan emperor of the 3rd century BC). A claim that inscriptions of the rulers of Travancore have been found from the 9th century AD comes from a statement issued by the secretariat of the maharaia of Travancore. Its reliability may be judged along with the genealogies of princes in northern India shown in Lt. Col. James Tod's monumental work, Annals and Antiquities of Rajasthan (1829, republished 1950). Referring to the lineages of Indian princes as being known since the early centuries BC. Tod wrote, "If, after all, these are fabricated genealogies of the ancient families of India, the fabrication is of ancient date, and they are all they know themselves upon the subject." The very long Oriental genealogies begin as oral pedigrees and were later written down, but they concern only princes or great persons

In Africa the one instance of a claim to very long descent. that of the Emperor of Ethiopia, bears a similarity to Tod's Rajput genealogies. The Emperor is said to descend from the marriage of King Solomon with the Oueen of Sheba. The tradition was written down more than 15 centuries ago; it is therefore older than the history of most European monarchies, but it cannot, of course, be substantiated by

documentary proof.

Under European influence the greater Oriental countries have adopted the practice of keeping systematic records for all citizens. In China, with its ancient system of ancestor worship, long, drawn-out pedigrees, including claims to descent from Confucius, are not unknown. The establishment of the Chinese Republic in 1911 brought with it

registration of vital statistics.

In modern Japan, as might be expected from its thoroughgoing Westernization, the registration of vital statistics is regulated by law. The Family Registration Law of 1947, and later enactments, require a comprehensive registration of a Japanese national from his birth to his death. Such information, however, is kept in local registration offices, and there is no system in Japan for gathering together, recording, and preserving the information in one central place (although of course the results of statistics, such as the number of births, is known to the central authority). Such an exact system of registration covers only the era of modern Japan. The present-day pedigree of the Japanese emperors has a divine origin; it is mainly a string of names, easily recited and memorized, mixed with semifabulous legends and first written down in the early centuries of the Christian Era. It is concerned only

with exalted persons, royal or noble. In the Old Testament there are many genealogies, the object of which is to show descent from Adam, Noah, and Abraham. By the time these genealogies had become part of the Jewish scriptures, the concept of racial purity had reinforced the keeping of family records. Genealogies of Jesus Christ in the New Testament aim at showing his descent from David, the one in St. Luke's Gospel going as far back as Adam, "who was the son of God." The idea of divine origin was reflected everywhere in a wildly polytheistic form among the Gentiles. Almost without exception, the heroes whose genealogies were recited by the bards had their paternity ascribed to the gods, or to persons such as Romulus who were regarded as having become divine. Greek fables abound in stories of great men begotten by gods and mortals.

In Roman genealogies heroes were always descended from gods. Julius Caesar, for example, was supposed to have sprung from the line of Aeneas, and thus from that of Venus. Among the Romans, traditions of descent remained vague even when written. Caesar's murderer, Brutus, was popularly supposed to be of the same family as an ancient Brutus, who had expelled the Tarquins, but no pedigree appears to have existed to substantiate the belief.

Among the northern nations that overwhelmed the western Roman Empire, belief in divine sonship was general.

For Saxon rulers of the English kingdoms it was necessary to be descended from the god Woden.

Early written records. With the invention of writing, the oral became the written tradition. This occurred in Greece and Rome, where genealogies were recorded in poems and in histories. But genealogy did not at this stage become a science, because when writers dealt with it, they did so either incidentally in their narrative or because they were concerned with the family relationships of their gods.

The historian Edward Gibbon's observation that "the proudest families are content to lose in the darkness of the middle ages, the tree of their pedigree" may be challenged in the light of recorded genealogies. The male line of Charlemagne has been traced to St. Arnulf, bishon of Metz, who died about 635. Several royal line descents are traceable to the 6th century, as, in England, is the tree of Louis Mountbatten, 1st Earl Mountbatten. The ancestry of Oueen Elizabeth II goes to Egbert of Wessex (about 825), beyond him to Cerdic (c. 500), and, if another series of names is accepted, to Woden (an actual man later divinized by the Germans), in the 3rd century AD.

Maximum length of genealogies

With the conversion of the barbarians to Christianity the recording of their regal traditions began. Examples occur in Ireland, Wales, and England. It was natural for the first chroniclers, who were mostly monks, to write down the oral pedigrees of the kings in whose realms they lived. Students of the Irish regal pedigrees are prepared to accept two or three generations before the time of St. Patrick (flourished 5th century AD) as genuine, and it is quite probable that name lists of the Irish kings are valid back to the 3rd century AD. Similarly, in Wales, the ancestry of the greatest Welsh families can be traced for a millennium. Among the Anglo-Saxons there were similar bardic pedigrees recorded by monastic scribes, and many of these might have survived but for the destruction of the Old English ruling class during the Norman Conquest. A regular feature of such old pedigrees recorded by monks was an attempt to link them with the genealogies of the Scriptures. In an Anglo-Saxon pedigree of great lengththat of the kings of Wessex (the ancestors of Elizabeth II)-the line is thus traced to Sceaf, "a son of Noah born in the Ark." In the process of working out the connection between scriptural and regal genealogies, the monks adopted a reverse technique to that of the 4th-century-BC Greek mythographer Euhemerus; i.e., they downgraded the old gods to human status.

From roughly 1100 to 1500, the emphasis of genealogists was on pedigrees of royal and noble lines. Claims to a throne, as with the dozen or so claimants to the Scottish crown after the death of Alexander III in 1286 and of his direct heir, Margaret the Maid of Norway in 1290, frequently involved genealogical trees. The truth was sometimes bent to suit some political end, but, on the whole, medieval European records are genealogically valid. This is because they were not primarily intended to supply genealogical information but to record land transactions, taxation, and lawsuits. The facts of family history are incidental and are therefore generally reliable. Exact dates of birth, marriage, and death are rarely given. A man is said to be of age "by Michaelmas 1330.

This period also saw the emergence of pedigrees of lesser folk. Land transactions involved claims in the local courts of the lords. Serfdom gave way to villenage; the latter involved so many days of labour on the lord's demesne and also the inability to move from the estate without the lord's consent. There was strong inducement for a man to prove that he was not a villein and for the bailiff to show that he was. In several parts of England, pedigrees of villeins or persons claimed as such have been worked out over periods of 100-150 years.

It was during the third period in European genealogical history that records that came to include everyone began. This period extends from 1500 to the present. As feudalism gradually gave way, new classes of citizens arose. In England the appearance of a powerful mercantile and business community was reflected in the growth of the middle classes, from which was continually recruited a new nobility and gentry. In turn, owing to the English rule of inheritance by primogeniture and the fact that unlike the

Biblical genealogies Qualifica-

the profes-

genealogist

tions of

sional

continental nobility English nobility has never extended beyond the reigning peer and his wife, the middle classes themselves continually received the younger children of peers and gentry. Two other factors leading to the proliferation of records were the enormous changes caused by the Reformation and the great reemphasis on individual religion and the desire of Renaissance monarchs to have more exact information about all their subjects.

Modern genealogy. Amateurs in the subject of genealogy are almost always actuated by the desire to trace their own family history. In the course of so doing they discover and work with general principles which apply to pedigrees other than their own, though records other than those applicable to their own case do not interest them. The professional genealogist is concerned not with one family but with many, and with the principles of genealogical research which arise from a wide study. As there are no university courses in the subject and therefore no degrees or other certificates of professional proficiency, the profes-

sional must be largely self-taught.

The disciplines required of a professional genealogist include a deep knowledge of the history of the country with which he is concerned and of its neighbours. National history determines the form of national genealogy, and genealogy can illuminate many aspects of national history that might otherwise remain obscure. The Wars of the Roses, for example, are hard to grasp unless genealogical trees showing relationships of the contestants are studied, and the course of the American Revolution is easier to understand when the links between George Washington and his compeers with the old English landed families who overthrew the Stuarts are comprehended. An understanding of the principles of law, especially of land law, the ability to decipher court hand or medieval script, an understanding of heraldry, and an intimate knowledge of the study of surnames and place names are also essential to the genealogist. Variations in surname spelling can be bewildering. The key is in the sound of the name, for a medieval scribe could not ask the illiterate person before him to spell his name.

The main task undertaken by professional genealogists is the tracing of pedigrees for clients, this being the staple of their work. Clients often consult genealogists when they wish to establish their family background, or, when having tried to trace it, they have come to a stop.

The writing of private family histories by professionals is very common. The material has usually been worked out by others who wish it to be checked and written by a professional

Amateur genealogists, as already mentioned, are usually concerned only with their own families. The standard of amateur work varies with the individual, from the truly bad to the excellent.

Amateur genealogical work has increased greatly since 1945. In the United States there has been a long interest in the subject. The New England Historic Genealogical Society, the Augustan Society (based in California) and many state societies are of note. The Mormons (the Church of Jesus Christ of Latter-day Saints) have built up in Salt Lake City, Utah, a microfilm library of genealogical records from Britain and continental Europe, which is probably unequalled. In Canada, Australia, New Zealand. and South Africa the study of genealogy by private persons and by associations is growing rapidly. In England there is a Society of Genealogists, and there are corresponding bodies for Ireland and Scotland. In Denmark there is an International Confederation of Genealogy and Heraldry, which since 1954 has organized international congresses held in many European capitals at intervals of two years. In Czechoslovakia, by way of contrast, the national Genealogical Society has been dissolved, and in general it has not been feasible to obtain genealogical details from Communist countries, though it is probable that changes are now occurring in this respect. Jewish records are in a separate class. With the establishment of the state of Israel in 1948, a very great effort has been made to centralize information about the Jews of continental Europe under the care and direction of The Central Archives for the Study of the Jewish Peoples, in Jerusalem.

In tracing family history, the worker follows certain rules. He works backward from the present. This is an elementary caution constantly put on one side by amateurs, who tend to trace forward from a person of the same name who may well be unrelated. As there cannot in the nature of things be a gap in a pedigree, no assumptions as to relationship can be allowed without very strong reason to accept them. Good and bad features in the ancestry have to be accepted: bastardy has to be allowed for, as well as regal ancestry by legitimate lines. An ancestor's wrongdoing must also be allowed for, though with passage of time this is usually taken in a romantic sense. Registration of birth, marriage, and death first became compulsory in England in 1837. Public records in most other Western countries began at varying dates in the 19th century. Census records are of great importance. They began in the United States as early as 1791; in Britain in 1801 (papers kept only from 1841); and even earlier in French Canada, in 1655-66. Parish registers began in England in 1538, though they are rarely preserved from that date. In most countries they begin later, but in Spain the oldest extant is dated 1394 and there are 1.636 parishes having records prior to 1570. In England, Nonconformist records have been kept by various bodies, and many are now held officially at Somerset House, London, or the Public Record Office. In America the settlers were generally trying to get away from established church and controlling state. They were vigorous individualists who kept careful records of their lives and of the organization of their new communities. Examples of detail in New England records can be seen in many of the 1,600 pedigrees contained in American Families with British Ancestry (500 page suppl, to Burke's Landed Gentry, 1939), in A.M. Burke's Prominent Families of the United States of America, and in the many volumes of family history produced in the United States. Wills are of the utmost importance as a source of genealogical information. Ships' lists of passengers are useful in supplying dates for immigrant ancestors' departure for the New World, but since they do not indicate place of origin, but only the port of departure, the original habitat must be sought elsewhere. Without knowledge of the ancestor's place of origin in the homeland it is useless in

With the aid of the type of record mentioned above, and with help from family Bibles, tombstones, and plaques and brasses in churches, it is as a rule possible for a person of English antecedents to trace some 250-300 years of ancestry. Before the 17th century, everything depends on the social position of the ancestors. Tax records, lawsuits, and purchases and sales of land are the chief sources for tracing a family before 1600. The Pipe Rolls extend from the reign of Henry II (1154-89) to that of Queen Victoria (1837-1901), with an interrupted beginning also in the time of Henry I (1100-35). Monastic records are of great importance as showing grants or ownership of land. The pleas of the crown deal with suits at law and contain much detail about families. There are many Rolls besides those of the Pipe that give a great deal of incidental genealogical information. Inquisitiones post mortem show the position of an heir; i.e., his age and other details. As the centuries are passed, the numbers of those who can prove a descent by the male line dwindle, until by the time of the Norman Conquest scarcely half a dozen pedigrees can be traced in the male line for either Saxon or Norman.

almost all cases to attempt a search.

Regarding deposition of public records, two principles have been followed by archivists: that of centralization and that of diffused local holdings. The former has many obvious advantages and was adopted in Scotland and in Ireland. It has one disadvantage-destruction of the records at one stroke. This happened in Dublin on April 13, 1922, when Irish factions fighting with each other burned most of the Irish records. The second system, by which records are stored in a number of depositories, prevails to a considerable extent in England. Although the Public Record Office, Somerset House, and the British Museum library are places of centralized record, the parish registers remain outside them, scattered in numerous parishes or county offices. County records contain masses of material not to be found in London.

Main genealogical SOUTCES

From the 16th century there has been an increasing accumulation of written material, which deals either exclusively or incidentally with genealogy. William Camden (1551-1623), a learned English antiquary and historian, did much to raise the standards of genealogical research He was the first English writer on surnames, and his work was not resumed for nearly 200 years. Sir William Dugdale, a younger contemporary of Camden, made a beginning with his Antiquities of Warwickshire to the great output of county histories written between the 17th and 19th centuries. The revolution in modern genealogy was the application to its study of canons of historical and literary criticism formulated in Europe from 1800. Their application to genealogy was fairly late, as is illustrated by the fact that the 19th-century English historian Thomas Macaulay, critically perceptive in most other spheres, accepted what amounted to family myths as true genealogy. Later writers, including J.H. Round, W. Farrer, C. Lewis Loyd, C.T. Clay, and the editors of the Complete Peerage, are of the greatest importance. (I GP)

PALEOGRAPHY

Papyrus

Paleography (from Greek palaios, "old," and graphein "to write") is the study of ancient and medieval handwriting. Precise boundaries for the study are hard to define. For example, epigraphy, the study of inscriptions cut on immovable objects for permanent public inspection, is related to paleography. Casual graffiti, sale or election notices as found on the walls of Pompeii, and Christian inscriptions in the Roman catacombs are likewise part of paleographical knowledge. In general, however, paleography embraces writing found principally on papyrus, parchment (vellum). and paper. Today, paleography is regarded as relating to Greek and Latin scripts with their derivatives, thus, as a rule, excluding Egyptian, Hebrew, and Middle and Far Eastern scripts. It is closely linked with diplomatic (see above), the study of forms in which official and private documents are drawn up.

The scientific study of Latin paleography (and diplomatic) dates from 1681, when the French monk Jean Mabillon published De Re Dinlomatica, the first textbook on the subject, while his compatriot Bernard de Montfaucon performed a parallel service for Greek paleography in his Palaeographia Graeca in 1708.

The primary task of the paleographer is to read the writings of the past correctly and to assign a date and place of origin. Close acquaintance with the language of the text is a prerequisite. Help in dating is offered by changes in styles of handwriting and variations from area to area. Abbreviations in texts likewise help in dating and localization.

Types of writing materials. A paleographer must be familiar with writing materials. Any smooth surface able to accept writing has served in the past, notably, pottery fragments, animals' shoulder blades, slabs of wood, bark, cloth, and metal.

The great writing material of the ancient world was papyrus, in use by 3500 BC. In preparing the surface, strips taken from the papyrus reed (byblos) growing in the Nile Delta were laid side by side, while other strips were laid across at right angles, and the whole impregnated with paste. After treatment a fine smooth surface was obtained. Much of the administration of the Roman Empire depended upon papyrus, in the same way that modern bureaucracies depend upon paper. Warfare and a damp climate resulted in an almost total disappearance of papyrus from Europe, though the dry (if war-scarred) sands of Egypt have preserved vast numbers of documents. Papyrus was imported into Europe from Egypt even after the fall of Rome. Chance survivals include charters of Merovingian kings in France (7th century) and business documents (5th-10th centuries) at Ravenna, the old administrative capital of the late Roman Empire.

The other great ancient writing material, still in occasional use today, is parchment, or vellum, the terms being often used interchangeably. Vellum is a term usually applied to skin from a calf (cf. veal, veau), while parchment is an expression often applied to sheepskin or goatskin.

The word parchment is derived from Pergamum in Asia Minor, the ancient centre of its manufacture.

Both papyrus and parchment were expensive and were replaced for everyday use by wax tablets corresponding to today's notebook. Tablets made of wooden blocks were hollowed out and filled with melted often black way Notes were made in the hardened surface. Even documents of permanent significance, such as property conveyances, were made on wax tablets.

Because ancient writing materials were expensive, they were often reused. Papyrus presented difficulties, for ink soon bonded itself firmly into the surface. Parchment could be more readily reused, because it is tougher and can be washed or scraped clean. Many medieval monks, when short of writing materials, took ancient books to pieces. cleaned off the leaves and used them again. The original script can often be brought out under ultraviolet light. Parchments thus cleaned and freshly inscribed are called palimpsests (Greek palin, "again": psēstos, "scraped").

Paper is the third great writing material. In use in China at a remote period, it was employed extensively in the Arab world by the 9th century. Not in common use in Europe until the 14th century, it took over the name of the half-forgotten papyrus.

In the early classical world the standard form of book was the papyrus roll, commonly called biblion, taking its name from the material of which it was made. It consisted of papyrus sheets pasted edge to edge with a slight overlap. The text was set out in columns, drawn up at right angles to the edge of the rolls, and started at the left. The reader unrolled as he went along and at the conclusion was obliged to reroll the book. The roll was an inconvenient form of book, difficult to consult, which probably accounts for the inaccurate quotations found in early literature, caused by an author relying on his memory rather than troubling to unwind a long roll. By the time of Christ, a new form of book was coming into fashion, the codex, or book in the shape in which it is known today. The codex is almost always of parchment, since papyrus cracks when folded. The codex seems first to have been used for notebooks or account books, the conservatism of booksellers and readers ensuring the survival of the roll for centuries. The Christians popularized the codex, using it for the Gospels.

Various instruments have been used for writing. The early Egyptians used a slender rush. From about 300 BC the thicker reed pen was used. The reed was in general use in the Greco-Roman world. Metal pens, copied from the reed, were also employed. For wax tablets a stylus was used, made of wood, bone, ivory, iron, or bronze. In many northern European areas, where reeds suitable for writing purposes are not indigenous, the feather (penna) became the main writing instrument. It was usually stripped of its vanes and the quill alone used.

Lead, used in classical times for ruling guidelines in manuscripts, was used extensively in the Middle Ages for rough notes and annotations in the margins of books.

Ink has been prepared in a variety of ways. In classical times the black discharge of cuttlefish was used, as well as concoctions of soot and gum. In the Middle Ages oak apples were steeped in water with "vitriol" (ferrous sulphate) to produce ink.

Analysis of texts. The essential skill of a paleographer is the ability to recognize the numerous styles of handwriting prevalent in different ages and places. Most European scripts descend from Greek and Roman capital letters, but variations are enormous. It is a European convention that writing starts on the left at the top and works line by line down the page. An eccentricity known as boustrophedon (from Greek boustrophedon, "following the ox furrow"), whereby alternate lines are written backward in mirror writing, occurs chiefly in very ancient inscriptions.

The Greek and Latin alphabets existed originally as capital, or majuscule, letters. The ancient Greek alphabet, as developed in chiselled inscriptions on stone or marble, served without much modification as the alphabet used in literary works written on papyrus rolls. This script, found in the oldest surviving Greek literary papyri of c. 300 BC or earlier, gave way to more rounded and elegant

Form and binding of

Writing implements

Styles of

writing

forms, probably developed in the Greek literary circles of Alexandria. Cursive scripts that were easier to write were developed for everyday use, for business, and to record the acts of the great bureaucracy of Egypt, where the Greeks settled in large numbers. The Greek cursive script and the formal book script greatly influenced each other, as can be seen from a vast series of cursive documents dating from the 4th century BC for about 1,000 years. Because so much material survived, early Greek cursive can be better studied than its Latin counterpart. In Greek cursive manuscripts the everyday life of ordinary people becomes a reality: they pay or fail to pay taxes, buy or sell houses, and harass civil servants with awkward demands.

A very rough division in Greek paleography may be made at around AD 300. The earlier age is called the papyrus period; and the later, the parchment or Byzantine (or Christian) period. The division, however, is imprecise, for parchment was used well before and papyrus long after this date. The change from papyrus to parchment is signalized by three great monuments of paleographical studies, the Vatican, Alexandrine, and Sinai Bibles, all on

parchment and in codex form.

An alphabet of small, or minuscule, letters developed gradually and was in use by the 8th century. Numerous abbreviations exist in Greek manuscripts, though never so many as in Latin. Accents, an additional complexity, were not systematically applied before the 7th century AD.

The ancient Latin alphabet of capitals (quadrata) is found in numberless inscriptions in stone and marble all over the Roman world. How far this alphabet was used for writing books is uncertain, because, though excellently adapted for incision, it is difficult to write. Some specimens of handwriting in quadrata do exist, such as 4th- or 5th-century copies of Virgil, but scholarly opinion largely regards these as abnormal productions. By the 1st century a handsome Latin alphabet existed, called rustic, based on the use of a broad pen or brush. Rustic was used for public inscriptions on walls, as in the sale and election notices found at Pompeii. Although specimens are scarce, it is likely that books were extensively written in this hand in classical times. By the 4th century another Latin alphabet existed, the script known as uncial, in the nature of a rounded form of quadrata. Uncial survived the fall of Rome and from it developed half-uncial, the ancestor of the small letters in use today.

The stately Roman scripts, quadrata, rustic, or uncial, were not used for everyday purposes, and, as in the case of Greek, a cursive, rapidly written hand arose in which letters and business documents were inscribed. This hand is found in graffiti on Pompeian walls and in wax tablets. After the disintegration of the empire, Roman cursive became the ancestor of regional hands in what are now Spain, France, and Italy.

During the flowering of Christianity and art in Ireland (c. 500-c. 1000) a beautiful "insular" script developed, which found its way into England. There, two streams of influence commingled, for from 597 Christian missionaries arrived from Rome and brought in books in uncial script. Both scripts prospered in England, though insular gradually superseded uncial

The most successful of all scripts proved to be Caroline minuscule, which takes its name from the emperor Charlemagne (died 814), patron of scholars and scribes, under whom the script was developed. Despite its inherent superiority and clarity, it did not predominate over regional scripts until the mid-12th century, and the local hand of southern Italy (Beneventan) maintained itself for

In the 12th century, Caroline minuscule, which had undergone moderate developments, started to display more obvious changes. It compressed laterally, while its rounded strokes became stiffer and straighter as it was converted into the so-called Gothic hands-very angular in northern Europe and more rounded in Italy. A revulsion against Gothic took place in scholarly circles in Italy in the 14th and 15th centuries, and a return to models based on Caroline minuscule took place. This revived hand, called Humanistic because humanist scholars used it, was adopted by 15th-century Italian printers, whose type faces ultimately triumphed over the Gothic. (This encyclopaedia is printed in a type scarcely modified from Caroline minuscule.) Meanwhile, Caroline and Gothic scripts had produced cursive hands for quick everyday use, as in the Cursive case of the ancient Greek and Latin alphabets. These cursive scripts were used for the vast mass of business documents written in the Middle Ages.

Abbreviations are the principal problem confronting paleographers. They were extensively used in Roman times by lawyers to avoid repetition of technical terms and formulas. Abbreviations fall into two classes, suspension and contraction. Suspension, omission of the end of a word and indication by a point or sign, was used in Roman public inscriptions-e.g., IMP.(ERATOR). CAES.(AR). Contraction, the omission of letters from the middle of a word and replacement by a sign or some other device, was common among Greek-speaking Jews, who contracted certain sacred or revered names, such as God, Lord, Israel, or David, as a mark of veneration. The Christians followed the practice by contracting their sacred names, such as Jesus and Christos. The great increase in use of abbreviation as a means of saving time and material dates from the 12th century, but some contraction signs are of high antiquity, such as the sign 7 for et (Latin, "and"). Some are quickly written versions of letter groups, such as "+" for est (Latin, "is"), the top dot standing for e, the bottom dot for t, and the stroke being a long or f-shaped s. fallen on its side. The letter r is often omitted, the adjacent vowel being written above the line, as cata for carta ("charter"). In works for semilearned readers, such as romances, abbreviations are often few, but books produced for the learned, such as university textbooks, are heavily loaded with abbreviations. The number of signs and devices in use by the end of the Middle Ages was enormous. More than 13,000 are listed in the standard work. Adriano Cappelli's Lexicon Abbreviaturarum

Dating of books and documents also offers problems. Even when a precise date is given, the dating system of a given time and a given area must be checked because the year began at different times in different territories, and there were even variations in the same country. Calendar reforms initiated in 1582 by Pone Gregory XIII, for example, were not adopted in Protestant England until 1752. If a year of a monarch's reign is given as a date, it is necessary to determine whether the reign is counted from his accession or coronation. Moreover, few books were dated, the dated title page being nonexistent in medieval works, though sometimes a final paragraph, the colophon, supplies a date with the scribe's name and place of work. Important documents, such as English 12th-century royal

charters, are undated. In the absence of dates, inferences are drawn from handwriting, use of abbreviations, and internal evidence. Caution must be used, however; for an elderly scribe may be using a hand learned over half a century before, and work in the same scriptorium or office as a young clerk anxious to show off all the latest tricks and flourishes. Some styles lasted a long time: Caroline minuscule lasted for more than three centuries. Certain kinds of books, such as liturgical volumes, were produced in a highly stylized form for generations, and thus it is often difficult to provide a close date for a late medieval missal (with standard illustrations and marginal decorations) in a mechanical Gothic hand. Internal evidence must be weighed carefully. A given historical event noted in a chronicle will provide an earliest possible date, unless the entry is an interpolation. Evidence for some legal practice or liturgical usage is no safe guide, for legislation on the subject by a king or a pope

may merely be ratification of a long-standing practice. A paleographer must get to know his scribes, for their mannerisms can be highly informative. Nearly 50 different scribes have been distinguished in the English royal Internal chancery in the period 1100-89. First-rate scribes, such as evidence notaries public, provide much information about themselves, giving their names, notarial signs, and information on their authority to act. Even anonymous clerks, who drew up innumerable property conveyances, can be identified by their script over a period of years, and their career

scripts

Abbrevia-

tions

can be traced through developing, mature, and deteriorating handwriting, thereby offering dating evidence.

The provenance (origin) of many manuscripts can be immediately recognized because certain centres developed individual styles. Papal and royal chanceries issued documents of easily identifiable origin, while many monastic scriptoria-for example, that of Canterbury Cathedral in the earlier 12th century-had a virtually private handwrit-

Textual corruptions are another obstacle to correct elucidation. A legal document is certain to have been checked at the time of writing, but one cannot be sure in the case of a literary, philosophical, or theological text, Scribes were fallible, and, if there are no signs of any corrections in a text, then it probably embodies inaccuracies. A popular book, such as Chaucer's works, exists in large numbers of manuscripts, and many manuscripts produce variant readings. If a scribe made a mistake in copying, future scribes using his version are likely to reproduce the error and add others. Sometimes the same muddled passage in a group of manuscripts of a given author can be traced back to damage in an earlier copy, say a section eaten by rodents or impenetrably stained. Whenever convists worked from different and faulty originals, various copies tend to fall into families. A paleographer must bring together various readings in families and decide which is the best reading.

Sometimes a scribe, set to work because he could write a fine hand, did not necessarily possess much knowledge of the language. Such a scribe faced with a text heavily loaded with abbreviations would usually make nonsense of it. Occasionally, a particularly stupid copyist, faced with a master copy in two columns of writing, would copy straight across the top line, then across the second. When he used a different number of words per line, the text was reduced to unintelligibility. In Greek and Roman times there was the difficulty that texts were written continuously, without space between the words. Copyists misread passages. For instance the historian Tacitus reported that some tribesmen went off to guard their own property: ADSVATVTANDA (ad sua tutanda). Some copyist thought "Suatutanda" was a place and this ghost name was perpetuated in geographical works. Later medieval Gothic hands presented a forest of vertical strokes called minims. The letter v rendered as u made two strokes, while i was often left without a dot or at best with a faint hairline. often misplaced. The group of letters ium could be read, as uim, uiui, niui, mui, miu, with many other variations. Accordingly, minim corruption, confusion of vertical strokes, is a term constantly heard in paleographical circles.

Latin and Greek are inflected languages in which the same case and tense endings constantly occur, offering scope for error. Moreover, in biblical, theological, or philosophical texts, the same words abound. For example, in one place in the Gospel According to John there occurs the passage:

Verba quae ego loquor vobis a me ipso non loquor pater autem in me manens.

("The words that I speak . . ."). The eye of a sleepy scribe might slip from the first loquor to the second, whereupon he would go on copying at pater autem, leaving out the second line altogether, a common type of error known as homoioteleuton ("like ending").

Because of the lack of surviving specimens, it is difficult to assess book decoration in classical times, but apparently it was very limited. In the later centuries of the Roman Empire, however, book illustrations were not infrequent. The narrative material in the Bible encouraged illustration. The Irish were foremost in applying decoration to the text in the form of elaboration of capital letters, producing such masterpieces as the Book of Kells (late 7th century), in which Celtic imagination and artistic sense ran riot in elevating the book to an object of outstanding beauty. Some of the greatest creative talent of the Middle Ages was lavished upon books, especially upon those used in worship, such as Bibles, psalters, and missals. When a book cannot be assigned either a date or provenance upon the appearance of the text alone, its style of illumination will often direct the paleographer to a certain monastery in which the carving on capitals or wall paintings may contain the same motifs

Because of the immensely high prices of manuscripts, the question of forgery naturally arises, but it is safe to say that no modern forgery could survive for a moment. A convincing imitation of ancient script is virtually impossible, while the papyrus, parchment, or paper on which it would be written could not stand up to modern scientific inspection. Anything of recent vegetable or animal origin fluoresces brightly under ultraviolet light, to name but one test, William Henry Ireland (died 1835), the Shakespeare forger, used flyleaves from 16th-century books, but his handwriting and non-Shakespearean language gave him away. A modern would-be forger must either copy an existing work, which, in the present state of art history and paleographical study, would be immediately recognized, or be prepared to invent medieval subject matter.

There was fabrication of documents in medieval times on a considerable scale. A monastery might find itself in possession of estates held since remote antiquity but without any title deeds. When some powerful monorch made difficulties, there was a strong inducement to produce the required ancient-looking documents. The borderline between justifying legitimate possession and culpable attempts to gain extra territory or privileges, however, is ill-defined. Monks occasionally descended to falsifications of title deeds and charters of exemption. About 1125 a monk of Soissons on his deathbed confessed to a career of professional forgery for gain and admitted fabricating charters for various monasteries, including Westminster Abbey. Early forgeries, however, give themselves away through such inconsistencies as mentioning bishops of nonexistent sees or embodying legal phrases that came into use generations later or bearing seals when seals were not yet appended to documents.

The modern paleographer has great technical aids: photography since the 19th century and colour photography in the 20th. Ultraviolet light brings out faded handwriting. Microfilm makes the contents of a volume in a far-distant repository available quickly and cheaply.

Sigillography is the study of seals. A sealing is the impression made by the impact of a hard engraved surface on a softer material, such as clay or wax, once used to authenticate documents in the manner of a signature today; the word seal (Latin sigillum; old French scel) refers either to the matrix (or die) or to the impression. Seals are usually round or a pointed oval in shape or occasionally triangular, square, diamond, or shield-shaped.

Medieval matrices were usually made of latten-a kind of bronze-or of silver. Ivory and lead were occasionally used, gold very rarely. Steel was used from the 17th century. Matrices could include intaglio gems. The usual material for the impression was sealing wax, made of beeswax and resin, often coloured red or green. In southern Europe, notably in the papal Curia, lead and occasionally gold were used. Shellac, the wax used today, was introduced in the 16th century.

Seals were used to establish the authenticity of such documents as charters and legal agreements and for the verification of administrative warrants. In southern Europe, early medieval documents were drawn up by notaries and authenticated with their written signa, but this never replaced seals in northern Europe, Forgeries were manufactured as early as the 12th century, indicating how important seals had become. From that time, also, seals were used to close folded documents and thus to guarantee their secrecy. Seals were also used to affirm assent; for example, by a jury. Under the Statute of Cambridge (1388), sealed letters were used in England for the identification of people and their places of origin.

Sigillography is used to assist other historical studies. Many impressions have survived from the medieval period. Those attached to documents are most valuable, because the documents may date their use precisely and the seal may confirm the documents' authenticity. Unattached seals may still provide useful evidence from their inscription or design. Fragmentary seal impressions are often

Purposes of

Decorations

Seals in antiquity. Seals with designs carved in intaglio were used throughout antiquity. They were of two main types-the cylinder and the stamp. The cylinder first appeared in Mesopotamia in the late 4th millennium BC and continued to be used there until the 4th century BC. It was also widespread in Elam, Syria, and Egypt (3rd millennium BC) and in Cyprus and the Aegean (2nd millennium BC). Stamp seals preceded cylinders, first appearing in Mesopotamia in the 5th millennium BC and developing over a period of about 1,500 years until largely replaced by the cylinder in the 3rd millennium. Early stamp seals were also used in Iran, northern Syria, and southeastern Anatolia during the 4th and 3rd millennia; in Anatolia their use was continued in the 2nd millennium by the Hittites. In Mesopotamia the stamp seal gradually came into use again in the 8th-6th centuries, effectively replacing the cylinder by the 3rd century BC. In Egypt the scarab largely replaced the cylinder seal early in the 2nd millennium BC and continued as the main type until replaced by the signet ring in Roman times. In the Aegean, various types of stamp seals were used throughout the 2nd and much of the 1st millennium BC, until in Hellenistic and Roman times the signet ring became dominant.

The uses of ancient seals are known from textual references and ancient sealings, both on lumps of clay and on documents found in excavations. In historical times most prominent citizens, including women, carried their own seals. That the rank or office of the owner was often included in the inscription indicates that many of these may have been official seals. Kings had their own seals, and high officials could hold the king's seal as a mark of

delegated authority.

Uses of

ancient

seals

Seals came into use before the invention of writing for the securing of jars, bales, bags, baskets, boxes, doors, etc., and this use continued throughout ancient times. The method was either to shape clay over the stopper or lid or to make a fastening with cord and place clay around the knot and then impress it with the seal.

The sealing of written documents, of which the two major ancient classes were clay tablets and papyrus scrolls, became regularly established in the latter part of the 3rd millennium BC. The clay tablet was the main vehicle of writing in Mesopotamia, where cuneiform was used into the Christian Era, and this method spread to Elam, Anatolia, Syria, and Egypt; clay tablets were also used in the Aegean Bronze Age. The tablet was inscribed while the clay was soft, and seal impressions were applied at the same time.

The main kinds of sealed cuneiform documents were contracts, accounts, and letters. Contracts were sealed by the contracting parties and by witnesses and commonly encased in clay "envelopes," on which the text was either repeated or summarized and the seals again impressed. Two special kinds of contract were the royal grant to a subject, impressed with the royal seal of the grantor, and the treaty between nations, a number of examples of which have been recovered, some of them bearing impressions of the seals of the royal contracting parties. Account tablets were sealed to authenticate the transfer of goods. A letter was often encased in an "envelope" and the sender's seal impressed on the outside to identify him to the recipient

and, in the case of official letters, to authenticate any commands contained in the letter.

In Egypt, papyrus documents may be assumed from soon after 3000 BC, but surviving evidence dates mostly from the latter part of the 3rd millennium onward. The method of sealing a papyrus document was to roll it into a tube, tie a strand or cord around the centre, and seal a clay lump over the knot. This method continued into the Christian Era, from which time a great number of Greek papyri have survived in Egypt. It was not until the 1st millennium BC that this kind of document, including by then leather and parchment, came into wide use outside Egypt. The spread of this kind of document, on which the space for a seal was small, probably played some part in the gradual replacement of the cylinder by the stamp seal.

No documents or sealings have been discovered from ancient India, but the still undeciphered inscriptions on the seals may include personal names, perhaps of merchants, who could have used the seals in much the same ways as their Near Eastern contemporaries, with whom they are

known to have had commercial contacts.

Since seals were used throughout ancient times and are sufficiently durable to have survived in very large numbers, they form one of the few classes of ancient objects in which a continuous development can be traced. The great majority bear artistic representations, so their chief value is for art history, but, since these include details of environment (plants, animals), equipment (plows, chariots, musical instruments), or dress, they also contribute to cultural history.

Further information is provided by the inscriptions on seals. The existence of rulers known only from king lists may sometimes be confirmed by the discovery of their seals, and in some cases rulers are known only from their seals, which, because they often mention the names of their fathers, the cities that they ruled, and the chief gods that they served, form a valuable historical source. The assembling of tablets and sealings bearing the impressions of private seals can contribute to the reconstruction of business archives and the destinations of traded goods. thus providing valuable material for economic analysis, and far-flung trade contacts can be deduced from foreign seals in excavations (e.g., Indus Valley seals in Babylonia). Personal names are an important source for ethnic analysis, and inscribed seals, because they often name the owner's father and even grandfather, provide material for this as well as for genealogical reconstruction.

Medieval European seals. The connection between Roman and medieval seals lies in the use of seals in the chanceries of the Merovingian and Carolingian kings. Many Ottonian seals had busts of the emperors. Royal seals of medieval type, with the ruler enthroned and bearing his insignia, appear from the 11th century. The use of seals by bishops and nobles became usual at this time and was widespread by the 12th century. By the 13th century, seals were used by all classes, including small landowners; and, by the 14th century, simple seal matrices could be bought ready-made.

The quality of engraving varied greatly. Some delicately designed seals date from the 12th century, such as the silver seal of Isabella of Hainaut, queen of France in 1180-90. The silver equestrian seal of Robert Fitzwalter is a notable example of the 13th century, the period of the finest seal engraving.

The names of several engravers of medieval seals are known: for example, Luke, who engraved the seal of Exeter, and Walter de Ripa, who engraved the first great seal of Henry III of England.

Forms of medieval seals. Seal matrices may be single or double, thus producing an impression on either one or both sides of the wax. Single matrices, the older type, often have a ridge along the back and end in a loop. Double matrices, known from the 11th century onward, are flat, with two to four projecting lugs pierced with holes in which vertical pins keep the halves aligned.

Sealing both sides of the wax makes detaching the seal more difficult, and so in medieval times the reverse was often sealed by a counterseal for greater security. The official seal of an institution was often countersealed by Spread of sealing in medieval

the seal of an official, such as a town by its mayor. Single seals were often fitted with a handle; the most common type was a six-sided cone ending in a trefoil. In some matrices the centre screwed outward, enabling the device to be used without a legend. On many seals the back was marked with a cross to indicate the ton

Seals could be either applied to the surface of a document or appended from it by a strip of material. Application was the earlier system, although papal bulls were always appended. Appended seals appeared in England in the 11th century and in France in the 12th; seals were appended either on a tongue of parchment cut across from the bottom of the document or on a tag of parchment, leather, or silk inserted through a cut in the document. Some documents had many seals. Seals were often protected by woven bags or by boxes of wood, metal, or ivory known as skippets.

The legend, often abbreviated, usually declared the name of the owner or institution; it often began with a cross and the word sigillum, followed by the name in the gentitive case. Latin remained in fashion for inscriptions, though English and French are occasionally found from the 13th century, more frequently on personal seals. On English seals roman capitals were used in the 11th and 12th centuries and Lombardic ones in the 13th and early 14th centuries. Black letter (Gothie script) was first used in England in the 14th century and was quite popular in the 15th century, although Lombardic often continued for capitals. Roman capitals reappeared in the 16th century.

Royal and official seals. The great seal, or seal of majesty fa round seal showing the seated ruler with the royal insignia), first appeared in Europe on the seal of the emperor Henry II of Germany (ruled 1002–24), in France on the seal of Henry I (ruled 1031–60), and in England on the double seal of Edward the Confessor (ruled 1042–66). The seal of William I of England (ruled 1066–87) had the King on one side and an equestrain figure on the other. The kings of France adopted double seals under Louis VIII

(ruled 1137-80).

The legend

The development of lesser royal seals can be illustrated by the growth of English government. Deputed great seals were used for the major legal courts and for France, Ireland, and Wales. The expansion of the kings' affairs caused the addition of smaller, more personal seals, such as the signet. The Chancery did not control these seals, and this freedom led to the evolution of autonomous offices. The privy seal appeared early in the 13th century in the custody of the clerks of the king's chamber. It was soon transferred to the wardrobe clerks, and gradually its importance increased until by the early 14th century the keeper of the privy seal was the third minister of state. The keepership gained further prestige in midcentury, when the great seal was entrusted to the keepers who went abroad with Edward III. As the privy seal grew in importance, the king preferred another small seal for authenticating correspondence and warrants. Under Edward II (ruled 1307-27) there was a secret seal distinct from the privy seal. By 1400 the signet, as the secret seal was then called, was in the charge of the king's secretary. The signet rather than the privy seal became the originating force in administration, and from 1540 there were two secretaries, each with two signets. The privy seal and signet seal were both single armorial seals.

Royal officials had their own seals. Circular admirals' seals, dating from the late 14th century to the 17th century, include a fine group of 15th-century bronze matrices. The seals show ships in great detail, with the sails displaying

the arms of the admiral.

Religious seals. The principal episcopal seal was the seal of dignity, always a pointed oval. From the 11th to the 14th century it usually depicted the standing figure of the bishop, from the 13th century with a canopy above him. In the mid-14th century the standing figure was often replaced by a saint or a religious scene, with the bishop praying beneath—a form that had been used earlier on episcopal counterseals. The seal of Thomas Arundel, archibishop of Canterbury (1396), depicts the martyrdom of Becket in the centre of an elaborate series of niches, with the archibishop below.

Monastic seals, usually double-sided and of high quality,

normally show the buildings of the monastery, religious scenes, or the patron saint. They were distinct from abbots' and priors' seals, which were similar to those of bishops. Notable was the elaborate four-part matrix of Boxgrove Priory (mid-13th century). The seal of Merton Priory (1241), considered the finest English medieval seal, had the Virgin and child on one side with St. Augustine of Hippo on the other.

Papal bulls were doubled-sided lead seals appended to the document on strings. The earliest known is that of Deuxdedit (reigned 615-618). The usual design, with the head of the Apostles Pietra and Paul on one side and the pope's name on the other, first appeared under Paschal II (reigned 1099-1118). Although this style of portrayal of the heads was changed in the Renaissance, the design has not been altered.

Town seals. The possession of a common seal was an important part of a town's independence. Town seals were almost always round and often double. Many towns still possess their original matrices. The earliest in England date from around 1200, when many towns received their charters. The seal of Exeter has been dated to c. 1180. Maritime towns often depicted a ship with a furled saij, inland towns often showed the guildhall or the town itself. The seal of Rochester depicted the Norman castle within a wall. Counterseals often bore the figures of saints. Later medieval town seals were less common and beginning with the 14th century were often single seals.

Commercial seals: Commercial seals in England were considerably increased during the reign of Edward I, when double-sided bronze dies occurred for various customs, subsidies, and the delivery of wool and hides. Their obverse displayed the arms of England, and the reverse had the same device without the shield. The seals of merchants and craftsmen often displayed either merchants' marks or tools connected with their trade.

Personal seals. The earliest class of personal seals was that of greater barons of the L2th century, who used the device of a fully armed equstrian knight. Their shields often provide the earliest evidence for the use of heraldic charges. Some greater barons used a double seal with an equestrian obverse and an armorial reverse. The most usual type of personal seal was a single seal with the arms of the owner. Women's seals were usually pointed ovals and showed the lady standing, sometimes between shields. Nonheraldic personal seals displayed a variety of devices, such as stars, fleurs-de-lis, armorials, and religious subjects. The inscription sometimes indicated the owner, although it may simply have related to the device, as on those that hore the device of a squirrel and the inscription "It krack nuts."

Modern use of seals. The use of seals declined as the use of signatures grew. Personal fob seals were in fashion from the 17th to the early 19th century; often they were gems in gold settings that were carried in the fob or breeches pocket and were used to seal folded private correspondence before the envelope was introduced. States and institutions continued to use seals for the formal fraification of their acts, but few of these seals maintained the medieval vigour of design. (J.Ch.)

medieval vigour of design.

Chines and Japanese seals. The private seals used in Chine ("u-chang) and Japanese seals. The private seals used in China ("u-chang) and Japane (ingvo), commonly square and reading merely "seal of so and so" (XX chin vini), served as a confirmation of signature or a sign to be verified but have not the legal status of a signature. They are made of ivory, wood, or jade. Used by artists and collectors to mark their paintings and books, there is hardly a limit to their fanciful designs and phraseology. A man might own socres of seals, using his many softiquest, especially those suggesting unworldly and rustic tastes. A seal is impressed in red ink—made of cinnabar in water and honey or suspended in sesame oil, hempseed oil, etc.—held ready on a pad of cotton or moss. The characters most often appear in line, but they are sometimes reserved against the inked ground.

The first record of a seal in China is from 544 BC. Actual bronze seals survive from the 5th century BC, and the practice of sealing must be some centuries older. The emblematic characters cast on Shang dynasty bronze vessels

Bishops' and monastic seals "Small"

seals

(13th-11th century BC) imply the use of something like a seal for impressing on the mold. The royal seal and other seals of high office were termed hsi; other seals of rank and appointment were chang. The imperial hsi (called pao beginning in the T'ang period, AD 618-907) was traditionally large and square, made of jade or ivory. The most famous one belonged to Shih Huang-ti (ruled 221-209/ 210 BC); it had as its knob a one-horned dragon and is fabled to have been handed down to the present day.

The official and, no doubt, the personal use of seals began in Japan with the copying of Chinese institutions in the 7th century AD. Both in China and in Japan modern seals generally employ the "small seal" character (chuan and "great" shu), the "great seal" character being reserved in the past for the ruler and high officers. To the historian the importance of the Far Eastern seals is greater in the earlier periods, and in China they yield more information than in Japan. Thus, seals recovered archaeologically throw light on government appointments made in the Han period, particularly in the reign of Han Wu Ti (140-87 BC), when they were tokens of rank given to internal officials and some external client rulers. Gold seals of the "King of the Han Wei-nu county," found near Fukuoka in 1784, and that of the "King of Tien" excavated near K'unming in 1956 have implications of this kind. But in post-Han times the seals have served little if at all as primary historical documents, and in writings on East Asia it is chiefly the art historian who appeals to their testimony in authenticating paintings and calligraphies.

(W.W.)

TEXTUAL CRITICISM

Textual criticism defined

The technique of restoring texts as nearly as possible to their original form is called textual criticism. Texts in this connection are defined as writings other than formal documents, inscribed or printed on paper, parchment, papyrus, or similar materials. The study of formal documents such as deeds and charters belongs to the science known as "diplomatic"; the study of writings on stone is part of epigraphy; while inscriptions on coins and seals are the province of numismatics and sigillography. Textual criticism, properly speaking, is an ancillary academic discipline designed to lay the foundations for the so-called higher criticism, which deals with questions of authenticity and attribution, of interpretation, and of literary and historical evaluation. This distinction between the lower and the higher branches of criticism was first made explicitly by the German biblical scholar J.G. Eichhorn; the first use of the term "textual criticism" in English dates from the middle of the 19th century. In practice the operations of textual and "higher" criticism cannot be rigidly differentiated: at the very outset of his work a critic, faced with variant forms of a text, inevitably employs stylistic and other criteria belonging to the "higher" branch. The methods of textual criticism, insofar as they are not codified common sense, are the methods of historical inquiry. Texts have been transmitted in an almost limitless variety of ways, and the criteria employed by the textual critictechnical, philological, literary, or aesthetic-are valid only if applied in awareness of the particular set of historical circumstances governing each case.

The value of textual criticism

An acquaintance with the history of texts and the principles of textual criticism is indispensable for the student of history, literature, or philosophy. Written texts supply the main foundation for these disciplines, and some knowledge of the processes of their transmission is necessary for understanding and control of the scholar's basic materials. For the advanced student the criticism and editing of texts offers an unrivalled philological training and a uniquely instructive avenue to the history of scholarship; it is broadly true that all advances in philology have been made in connection with the problems of editing texts. To say this is to recognize that the equipment needed by the critic for his task includes a mastery of the whole field of study within which his text lies; for the editing of Homer (to take an extreme case), a period of some 3,000 years. For the general reader the benefits of textual criticism are less apparent but are nevertheless real. Most men are apt to take texts on trust, even to prefer a familiar version,

however debased or unauthentic, to the true one. The reader who resists all change is exemplified by Erasmus' story of the priest who preferred his nonsensical mumpsimus to the correct sumpsimus. Such people are saved from themselves by the activities of the textual critic.

The law of diminishing returns operates in the textual field as in others; improvements in the texts of the great writers cannot be made indefinitely. Yet a surprisingly large number of texts have not yet been edited satisfactorily. This is particularly true of medieval literature, but also of many modern novels. Indeed the basic materials of most textual investigation, the manuscripts themselves. have as yet not all been identified and catalogued, much less systematically exploited. The first edition of the works of Dickens to be founded on critical study of the textual evidence did not begin to appear until 1966, when K. Tillotson's edition of Oliver Twist was published. Reliable principles of Shakespearean editing have begun to emerge only with modern developments in the techniques of analytical bibliography. The Revised Standard Version of the Bible (1952) and the New English Bible (1970) both incorporate readings of the Old Testament unknown before 1947, the year in which early biblical manuscripts-the so-called Dead Sea Scrolls-were discovered in the caves of Oumran.

The materials of the investigation. The premise of the textual critic's work is that whenever a text is transmitted, variation occurs. This is because human beings are careless, fallible, and occasionally perverse. Variation can occur in several ways: through mechanical damage or accidental omission; through misunderstanding due to changes in fashions of writing; through ignorance of language or subject matter; through inattention or stupidity; and through deliberate efforts at correction. The task of the textual critic is to detect and, so far as possible, undo these effects. His concern is with the reconstruction of what no longer exists. A text is not a concrete artifact, like a pot or a statue, but an abstract concept or idea. The original text of Aeschylus' Agamemnon or Horace's Odes has perished; what survives is a number of derived forms or states of the text, approximations of varying reliability preserved by tradition. The critic must reduce these approximations as nearly as possible to the first or original state that they imperfectly represent; or if, as sometimes happens for reasons that will be explained below, no single original can be reconstructed or postulated, he must reduce their number to the lowest possible figure. His methods and the degree of his success will be determined by the nature of the individual problem; i.e., the text itself and the circumstances of its transmission. The range of possible situations is vast, as the following survey indicates. The types of text with which the critic is concerned may be classified broadly under three heads.

Books transmitted in print. For practical purposes it is often assumed that the latest edition of a modern book published during the author's lifetime may be treated as the original. This is a simplification. The actual author's original may have been a manuscript or a typescript or a recording; in the process of publication it has passed through several stages of transmission, including possibly storage in a computer, at any one of which errors have necessarily occurred. Experience teaches that some errors will survive uncorrected in the published version. Further errors are likely to occur if a book is reprinted. Even an edition revised by the author is not to be regarded as textually definitive. Errors committed and overlooked by the author himself may be corrected by the critic in appropriate cases. Special problems are posed by an author's second thoughts, whether preserved in his books and papers or incorporated in editions revised by him; recent research has shown that authorial revision in modern printed books has been underestimated. The extent to which a critic is free to choose between authorial variants on aesthetic grounds is a matter of debate.

Books published before the 19th century pose essentially similar problems in a more intractable form, as may be seen in the case of Shakespeare. No manuscript of any of Shakespeare's plays survives, and there were substantial intervals between the dates of composition and the first

printed versions, in which unauthorized variation clearly occurred. For Shakespeare's plays, indeed, the very concept of an author's original may be misleading. Elizabethan printers clearly had little regard for strict textual accuracy, so that allowance must be made not only for error but for deliberate alteration by compositors; thus the textual criticism of 16th- and 17th-century books must include a study of the practices of early printers.

Books transmitted in manuscript. Nearly all classical and patristic texts, and a great many medieval texts, fall into this category. Every handwritten copy of a book is textually unique, and to that extent represents a separate edition of the text. Whereas the characteristic grouping of printed texts is "monogenous" (i.e., in a straight line of descent), that of manuscript texts is "polygenous" or branched and interlocking. The critic is in principle obliged to establish the relationship of every surviving manuscript copy of a text to every other. The difficulty and indeed the feasibility of this undertaking varies enormously from case to case. The following extremes embrace a wide range of intermediate possibilities. (1) The authority for a text may be a single surviving copy (e.g., Menander, Dyscolus) or a copy that can be shown to be the source of all other copies (e.g., Varro, De Lingua Latina) or an edition printed directly from a copy now lost (e.g., the work of the Roman historian Velleius Paterculus); or a text may be transmitted in scores of copies whose interrelationships cannot be exactly determined (e.g., Claudian, De raptu Proserpinae). (2) The interval between the original and the earliest surviving copies may be very short (e.g., the French medieval poet Chrétien de Troyes) or very long (e.g., the Attic tragedians). (3) A tradition may be "dynamic"-i.e., the text may have been copied and recopied many times even in a short time (e.g., Dante's La divina commedia); or it may be "static"-i.e., the number of transmissional stages even over a long period may have been few (e.g., Epigrammata Bobiensia, a Latin translation of Greek epigrams). (4) A text may be a religious or literary work that was respectfully treated by copyists and protected by an exegetical tradition (e.g., the Bible, the Latin poet Virgil); or a popular book that was exposed to correction, glossing, and amplification by readers (e.g., the Regula magistri ["Rule of the Master," a Latin work related to the Rule of St. Benedict1 and much medieval vernacular literature). (5) A text may have been written and transmitted after the establishment of a scholarly tradition, or it may show signs of "wild" and arbitrary variation dating from an age in which standards of exact verbal accuracy were low. To this extent all Greek books written before the establishment of the Alexandrian library (see below) were exposed to the hazards associated with oral transmission.

Books transmitted orally. Many texts have been orally transmitted, sometimes for long periods, before being committed to writing, and much textual variation may be attributable to this stage of transmission. Often in such cases the critic cannot attempt to construct an "original" but must stop short at some intermediate stage: thus the edited text of Homer means in practice the closest possible approximation to the text as established by the scholars of Alexandria. The length, complexity, and fidelity of oral traditions varies enormously. The text of the old Indian Rigveda was transmitted orally almost without variation from very ancient to modern times, whereas much old French epic and Provençal lyric has descended in variant redactions for which a common source may be postulated but cannot be reconstructed. Sometimes this is attributable not to spontaneous variation but to deliberate reworking, whether by the author, as appears to be the case with the three versions of the English poem Piers Plowman, or by later revisers, as with the four versions of Digenis Akritas (a Greek epic). The distinction, however, is not always easy to draw. These considerations apply to a wide range of texts from ancient Hebrew through Old Norse to modern Russian, but they are especially important for medieval literature. In this field perhaps more than in any other the critic's aims and methods will be dictated by the character of the oral tradition, the stage at which it attained a more or less fixed form in writing, and the attitude of copyists in a

particular genre to precise verbal accuracy. A problem of particular difficulty and importance is posed by the Greek New Testament. Though the text appears to have been transmitted from the first in writing, the textual variations are in many ways analogous to those of an oral tradition, and it is commonly held that the essential task of the critic is not to try to reconstruct the "original" but to isolate those forms of the text that were current in particular centres in the ancient world.

Critical methods. From the preceding discussion it is apparent that there is only one universally valid principle of textual criticism, the formulation of which can be traced back at least as far as the 18th-century German historian A.L. von Schlözer: that each case is special. The critic must begin by defining the problem presented by his particular material and the consequent limitations of his inquiry. Everything that is said below about "method" must be understood in the light of this general proviso. The celebrated dictum of the 18th-century English classical scholar Richard Bentley that "reason and the facts outweigh a hundred manuscripts" (ratio et res ipsa centum codicibus potiores sunt) is not a repudiation of science but a reminder that the critic is by definition one who discriminates (the word itself derives from the Greek word for "judge"), and that no amount of learning or mastery of method will compensate for a lack of common sense. To study the great critics in action is incomparably more instructive than to read theoretical manuals. As the editor of Manilius, A.E. Housman, wrote,

A man who possesses common sense and the use of reason must not expect to learn from treatises or lectures on textual criticism anything that he could not, with leisure and industry, find out for himself. What the lectures and treatises can do for him is to save him time and trouble by presenting to him immediately considerations which would in any case occur to him sooner or later.

Admittedly, the technical advances in textual bibliography mentioned below are not such as would sooner or later occur to any reflective and intelligent person; but bibliography, like paleography, is ancillary to textual criticism proper, and Housman's words are strictly true. What they imply is that good critics are born, not made.

The critical process can be resolved into three stages: (1) recession, (2) examination, and (3) emendation. Though these stages are logically distinct, (2) and (3) are in practice performed simultaneously, and even (1) entails the application of criteria theoretically appropriate to (2) and (3).

Recension. The operation of recension is the reconstructing of the earliest form or forms of the text that can be inferred from the surviving evidence. Such evidence may be internal or external. Internal evidence consists of all extant copies or editions of the text, together with versions in other languages, citations in other authors, and other sources not belonging to the main textual tradition. These witnesses (as they may be called) must be identified, dated, and described, using the appropriate paleographical and bibliographical techniques. They must then be collated; i.e., the variant readings that they contain must be registered by comparison with some selected form of the text, often a standard printed edition. Where the number of witnesses is large, collation may have to be of selected passages. If there is only one witness to a text, collation and recension are synonymous, and the critic passes straight to examination and emendation. Generally, however, he will be faced with two or more witnesses offering variant forms or states of the text.

Collateral evidence as to the transmission of a text may be supplied from sources external to the direct or indirect textual tradition. Thus the ancient biographers throw light on the circumstances in which Virgil's Anneld was published. Inferred textual stages may be dated on the evidence of copying practices at different periods, or by association with a particular scholar, or from entries in medieval library catalogues. Generally speaking, information of this sort will contribute more to the history than to the criticism of the text, but the two fields are intimately connected; and the better the textual history is known, the more reliable the control of the critic over conjectural solutions to specific problems. In the case of

The importance of common sense

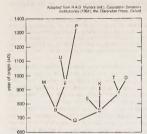

The search for the earliest transmitted form of the text

printed books, such external evidence is as a rule more plentiful; it is often essential, since so much may turn on the accurate dating of editions. Relevant information must be sought in the published and unpublished records of stationers, printers, booksellers, and publishers and in other archival material.

Having assembled his evidence, the critic may proceed, broadly speaking, in one of two different ways, according as he decides to handle the problem of interrelationships

"genealogically" or "textually."

In the "genealogical" or "stemmatic" approach, the attempt to reconstruct an original text here relies on the witnesses themselves regarded as physical objects related to each other chronologically and genealogically; the text and the textual vehicle (the book itself) are treated as a single entity. On the basis of shared variants, chiefly errors and omissions, a family tree of the witnesses (stemma codicum) is drawn up. Those witnesses that repeat the testimony of other surviving witnesses are discarded, and from the agreements of the remainder the text is reconstructed as it existed in the lost copy from which they descend, the "archetype," Thus in the tradition of the 6thcentury monk Cassiodorus' Institutiones the relationships of the manuscripts of the authentic version of the text of Book II may be represented by the accompanying diagram. The Roman letters represent extant manuscripts, and the Greek letters represent the lost manuscripts from

Manuscript genealogy, with Greek letters representing sources upon which known manuscripts (Roman letters) must have been based

which they derive, here arbitrarily dated. The text of the archetype Ω is established by the agreement of B and Σ Since B survives, the readings of MUP, which are derived from it, would be of value only where B had suffered damage after M and B were copied from it. In such cases the text of \beta could be inferred from the agreement of UP and the text of B from the agreement of MB (or MI) or MP). The text of Σ can be inferred from the agreement of SLo or SL or So (or ST or SD) or Lo (or LT or LD). K, being copied from L, would be of value only where L had suffered damage after K was copied from it. An important distinction is here exemplified between "trifid" and "bifid" stemmata. Where there are three independent witnesses to a source, as with Σ , its reading is certified by the agreement of all three or of any two; where there are only two witnesses, as with Ω , and they disagree, the reading of the source cannot be certified. Even in the latter situation, however, the number of possible variants existing in the source would have been reduced to two. Thus in theory the genealogical, or stemmatic, method allows the critic to eliminate from consideration all variants that cannot be traced back to the archetype or earliest inferable textual state

While in principle this method is unassailable, it depends for its practical validity on the assumption that each copyist followed only one model or exemplar and generated only variants peculiar to himself. This is called vertical" transmission, and a tradition of this kind is called "closed." Once the possibility is admitted that a convist used more than one exemplar or (the more probable supposition) copied an exemplar in which variants from another source or sources had been incorporatedi.e., that more than one textual state may coexist in a single witness-the construction of a stemma becomes more complicated and may be impossible. This is called "horizontal" transmission, and a tradition of this kind is called "open" or "contaminated." The practice of critics faced with contamination tends to vary, for historical reasons, from field to field. Editors of classical texts generally adopt a controlled eclecticism, classifying the witnesses broadly by groups according to the general character of their texts and choosing between their readings largely on grounds of intrinsic excellence. Medievalists, following the French scholar Joseph Bédier (see below), sometimes revert to the traditional practice, to which their training may dispose, of selecting a single witness as the main basis of the text. For editors of printed books, contamination is not an important problem.

In the "textual" or "distributional" approach, the text and the textual vehicle are dissociated; the emphasis is on the analysis of the variants themselves and their distribution rather than on the character of the text as presented by individual witnesses. The techniques or models employed include those of statistics, symbolic logic, and biological taxonomy. Two theoretical advantages are suggested for this approach. First, objectivity: no judgments of value are entailed, whereas the genealogical method calls for decisions as to the correctness of readings or textual states. Second, the possibility of mechanization: long and elaborate calculations involving thousands of variants may be performed by a computer. This possibility is especially attractive to New Testament critics, who are confronted with about 5,000 manuscripts of the Greek text as well as versions in other languages and patristic citations. In practice, however, these advantages are to a large extent illusory. An "objective" (i.e., undiscriminating) treatment of all variants in a literary text such as Ovid's Metamorphoses (of which more than 300 manuscripts exist) without regard to their metrical and stylistic quality would be a self-evident waste of time and produce merely confusion. The critic cannot abrogate his critical function, which implies discrimination, at the very beginning of the critical process. Moreover, the preparation or programming of a text for treatment in this way, whether mechanical aids are used or not, is long and laborious, and one must consider whether in a given case the results justify the expenditure of effort. Texts have been transmitted by a combination of purpose and accident that in any particular instance is both unique and unpredictable, and no machine or statistical model exhibits the versatility necessary to unravel the incomplete and tangled skein. Mechanical methods have been most successful in fields other than recension (see below).

Examination. The process of determining whether the transmitted text or any of the transmitted variants of it is "authentic"-i.e., what the author intended-is known as examination. The prior process of recension has reduced the number of textual states having a claim to be considered "authoritative." Many different situations are possible. In a completely closed tradition it is theoretically feasible to reconstruct the archetype with such certainty that only a single form of the text without variants remains to be examined. In practice this is extremely unlikely to be the situation. Usually the critic is faced with pairs (sometimes triplets) of variants, all with a presumptive claim to be considered authoritative. In some traditions he will confront variant versions of the whole text. Where papyri or other early sources independent of the main tradition are available, he may have to reckon with "pretraditional" (i.e., pre-archetypal) variants. The process of examination calls upon the critic's full range of knowledge as well as his innate powers of taste and discrimination. The criteria applied must be those appropriate to the particular author (supposing his identity to be known), the period, the genre, and the particular character of the work. The opposing demands of analogy and anomaly must be weighed according to the circumstances. Many of the older generation of critics based their decisions on aprioristic or rigidly

Analysis variants

Authenticity of a text

Conjec-

tural

emendation analogical principles of elegance and propriety, while the canons of modern criticism are based on historical studies of language and style. It is here that the circularity inherent in the whole operation is most evident, for the linguistic and stylistic criteria employed are themselves based on inductions from texts, probably including the one under examination. There is no escape from this difficulty; as the German philologist Karl Lachmann observed, it is precisely the task of the critic "to tread that circle deftly and warily."

Emendation. The attempt to restore the transmitted text to its authentic state is called emendation. There will usually be a chronological gap, sometimes of several centuries, between the archetype, or earliest inferable state of the text, and the original; nearly all manuscripts of classical authors date from the Middle Ages. The history of the text during the intervening period may be illustrated from external sources; but if examination has convinced the critic that the transmitted text (or its variants) are not authentic, he normally has no recourse but to bridge the gap by conjecture. Conjectural emendation has been defined by the American scholar B.L. Gildersleeve as "the appeal from manuscripts we have to a manuscript that has been lost." Theoretically this definition is acceptable. if we interpret "manuscript" as "source," but in practice the making of conjectures, as distinct from testing them. is intelligent guesswork.

No part of the theory of textual criticism has suffered more from misunderstanding than has conjectural emendation. Such conjectural, or divinatory, criticism has in the past enjoyed a traditional preeminence: Dr. Johnson observed that William Warburton's correction of "good" to "god" in the second act of Hamlet (scene 2, line 182) almost set the critic on a level with the author. That idea is as erroneous as the frame of mind in which the Italian scholar C. Pascal founded the Paravia series of editions in order to purge Latin texts of German conjectures. The best critic is he who discriminates best, whether between

variants or between transmitted text and conjecture. Conjectures as a rule occur to the mind spontaneously or not at all; diagnosis and prescription often present themselves at the same moment. This instinctive process is not under the critic's control, though he can sharpen and regulate it by constant study and observation. The outcome of the process, the emendation itself, can and must be controlled and tested by precisely the same criteria as are used in deciding between variants. This is essentially an exercise in balancing probabilities. These probabilities are historical. The conventional distinction between intrinsic and transcriptional (i.e., paleographical or bibliographical) probability tends to obscure a fundamental historical point. If the transmitted form of the text lies at few removes or a short distance in time from the original, a conjectural solution which violates transcriptional probability is less likely to be correct than if the text has undergone a long and complex process of deterioration. In the latter case the critic may attach little or no importance to transcriptional probability. The critic cannot neglect the study of paleography or bibliography, but he must not give them more than their critical due. What that may be depends on the particular historical circumstances. He will study carefully the rationale of error in manuscripts and books themselves rather than in the schematic classifications of critical manuals; and he will learn from experience to distinguish between the types of error that may be called "psychological" (i.e., those committed by a tired or inattentive copyist, whatever language or instruments he uses) and those contingent on the period and the medium of transmission, whether it be the mouth and the ear, the pen, the hand composing stick, the linotype or typewriter keyboard, the computer or photocopying machine, or the printing press. Two complementary principles originated by the New Testament critics of the 18th century are often cited as aids to decision: utrum in alterum abiturum erat? ("which reading would be more likely to have given rise to the other?") and difficilior lectio potior ("the more difficult reading is to be preferred"). These are no more than useful rules of thumb; it has been suggested that in practice these and other such principles reduce themselves

to the truism melior lectio potior, "the better reading is to be preferred "

From this discussion it is apparent that the traditional opposition between "conservative" and "radical" styles of criticism that has haunted textual criticism since St. Jerome has no meaning. The critic does not attack or defend the transmitted text; he asks himself whether it is authentic. How radically he treats it, and how many conjectural readings he substitutes for transmitted readings, depends not on his temperament but on the nature of the problem. If he has studied the history of textual criticism he will know that as a matter of demonstrable fact nearly all conjectures are wrong, and he will accept that many of his solutions are in the nature of things provisional.

Editorial technique. Critical texts are edited according to conventions that vary with the type of text (classical, medieval, modern) but follow certain general principles. In some cases, as with newly edited papyri and with palimpsests (writing materials re-used after erasure), the edition will take the form of a diplomatic transcript; i.e., the most accurate possible representation of a particular textual form. Generally, however, the editor constitutes his text in accordance with his own judgment on principles explained in his introduction; and he indicates his sources in critical notes (apparatus criticus), preferably at the foot of the page. These notes are usually couched in a special terminology that relies heavily on abbreviation and the use of conventional signs or letters (sigla) to identify the witnesses. In classical and patristic texts the language of the notes is usually Latin. Editorial judgment will be influenced by the presumed needs of readers: in an edition intended for scholars, very corrupt passages are often printed as transmitted and marked with a dagger (†), whereas in an edition for the student or general reader some compromise may be accepted in the interests of readability.

A much-discussed problem is the treatment of "accidentals"-variations in spelling, capitalization, punctuation, and the like. Few if any ancient text traditions preserve reliable evidence of authorial practice in these matters, so that the editor is concerned only with variants that affect the sense; in preparing his text for printing he will adopt modern conventions of presentation and punctuation and a normalized orthography. The same holds good for the majority of medieval texts. Printed texts, however, were generally corrected or seen through the press by the author, or at all events by a contemporary, so that the editor may be reasonably confident of reproducing at least a decent approximation to authorial usage. Whether, or to what extent, he should do so is much debated; opinions differ sharply as to the usefulness of "old-spelling" editions of Shakespeare and other early writers.

History of textual criticism. From antiquity to the Renaissance. Until the 20th century the development of textual criticism was inevitably dominated by classical and biblical studies. The systematic study and practice of the subject originated in the 3rd century BC with the Greek scholars of Alexandria. Literary culture had before that time been predominantly oral, though books were in common use by the 5th century, and many texts had suffered damage because the idea of precise textual accuracy and reproduction was unfamiliar. The aim of the librarians of Alexandria was to collect and catalogue every extant Greek book and to produce critical editions of the most important together with textual and interpretative commentaries. Many such editions and commentaries did in fact appear. Alexandrian editing was distinguished above all by respect for the tradition; the text was constituted from the oldest and best copies available, and conjectural emendation was rigidly confined to the commentary, which was contained in a separate volume. An elaborate battery of critical signs was used to refer from text to commentary. These techniques were applied, though on a less ambitious scale, by Roman scholars to Latin texts. Fidelity to tradition was the chief legacy of ancient textual scholarship to later ages; the copyist was expected to reproduce his exemplar as exactly as he could, and correction was based on comparison with other copies, not on the unaided conjectural sagacity of the scribe. Such was the practice

librarians Alexansance

of the best monastic scriptoria such as that of Tours, or of the best scholars, such as Lupus of Ferrières (fl. 850). From about 1350, however, a change in attitude is evident, particularly in the West. What is often called the revival of learning was in reality a practical movement to enlist the heritage of classical antiquity in the service of the new Christian humanism. In order to make them usable (i.e., readable), texts were corrected freely and often arbitrarily by scholars, copyists, and readers (the three categories being in fact hardly distinguishable). At its best, as seen in the activities of a scholar like Demetrius Triclinius, later medieval and early Renaissance criticism verges on scientific scholarship, but such cases are exceptional. For the most part the correction of texts was a purely subjective display of taste, sometimes right but much more often wrong, and resting as a rule on nothing more solid than a superficial sense of elegance. In consequence, by the 1470s, when the first printed editions (editiones principes) of classical texts began to appear, most Greek and Latin authors were circulating in a textually debased condition, and it was manuscripts of this character that almost always served as copy for the early printers. Very little editing in any real sense of the word was done; the scholars who saw the editiones principes through the press generally confined themselves to superficial improvements.

From Politian to Cobet. This state of affairs entailed that down to the 19th century most critics were engaged not in establishing and emending texts on scientific principles but in correcting, in a necessarily unsystematic fashion, a vulgate or received text (lectio recepta) that was itself the product of an almost entirely haphazard process of variation and conjecture. The situation was aggravated by the fact that the manuscripts themselves, the basic materials of the investigation, were largely inaccessible to scholars. The Italian poet and scholar Politian, unlike most of his contemporaries, was aware that only through the identification and comparison of the best manuscripts could texts be improved; his notes and collations show that he understood the problem correctly as essentially one of control of the sources. What might have been done in this field is shown by his work, cut short by his early death, on the Florentine codex of Justinian's Pandects. Many manuscripts were still privately owned, their very existence unknown to scholars; public libraries were few and published catalogues fewer; travel was difficult, expensive, and often dangerous. It was not until the twin disciplines of diplomatic and paleography were founded by the great Benedictine monks Mabillon and Montfaucon, and developed by their successors, that a critical use of the evidence became possible; and much of the evidence itself did not become available until after the Napoleonic Wars, when most of the private stock of manuscripts passed finally into public collections.

Some advances were taking place, slowly and unsystematically, in both the theory and practice of textual criticism. The history of critical method in this period is most profitably studied in the best editions of the best editors. The accepted method was to correct the text (i.e., the text of the last printed edition) codicum et ingenii ope; i.e., with the aid of the manuscript and printed sources and the critic's own ingenuity. Divination was subordinated to authority, and any reading found in a manuscript or printed text was accounted superior to any conjecture, whatever its intrinsic merits. The first important departure from this pattern is seen in the edition of Catullus by J.J. Scaliger (1577), in which the possibilities of the genealogical method, already understood in principle by Politian and other Renaissance scholars, were exemplified by the demonstration that all the extant copies derived from a lost manuscript, whose orthography and provenance Scaliger was prepared to reconstruct. Almost equally significant was Richard Bentley's edition of Horace (1711), in which for the first time the role of conjecture in the critical and editorial process was recognized and the tradition of producing a corrected version of the text of previous editors was decisively rejected. Bentley's scholarship was greatly admired in the Netherlands, and the editions of the great Dutch Latinists J.F. Gronovius and N. Heinsius were informed by Bentleian principles.

Under his influence there grew up what may be called an Anglo-Dutch school of criticism, the two most typical representatives of which were Richard Porson and C.G. Cobet. Its strength lay in sound judgment and good taste rooted in minute linguistic and metrical study, its weaknesses were an excessive reliance on analogical criteria and an indifference to German science and method. Its influence may still be seen in the empiricism that characterizes much critical work by English scholars.

From Bentley to Lachmann. The decisive influence on the editing of secular texts came from the New Testament critics of the 18th century. The printed text of the Greek New Testament in common use was still essentially that established in 1516 by Desiderius Erasmus. For his edition. produced in great haste, he had used such manuscripts. neither ancient nor good, as chanced to be accessible to him. Superficially revised, this was the text termed in the Elzevier edition of 1633 "now received by all." nunc ab omnibus receptum. Bentley proposed an edition on radical lines in which he engaged to give the text "exactly as it was in the best exemplars at the time of the Council of Nice. So that there shall not be twenty words, nor even particles, difference . . ." This project never materialized. but editions of the Greek text that did not reproduce the textus receptus were published in England by Daniel Mace (1729), William Bowyer, the Younger (1763), and Edward Harwood (1776). On the Continent, meanwhile, New Testament criticism was being developed on scientific and historical lines by a succession of distinguished scholars, notably J.A. Bengel, J.J. Wettstein, J.S. Semler, and J.J. Griesbach. They shaped the genealogical method that was later refined by editors of classical texts. Wettstein also deserves commemoration as the first New Testament critic to use sigla systematically. This was important, since some at least of the deficiencies of classical editions at this time are attributable to the lack of suitable conventions for the presentation of critical information, together with a conservative and belletristic attitude to technical jargon by publishers, scholars, and users of books in general. Though sigla occur sporadically in editions as early as the 16th century and were used by S. Haverkamp in his Lucretius (1725) in something like the modern style, they did not become normal until the second half of the 19th century.

The genealogical, or stemmatic, method of recension has already been described. It is usually associated with the name of the German Karl Lachmann, but it had its origins in the work of J.A. Bengel and his successors, and almost every essential feature of it was already present in the work of Lachmann's precursors such as J.A. Ernesti, F.A. Wolf, K.G. Zumpt, F.W. Ritschl, and J.N. Madvig, Nevertheless Lachmann occupies a central position in the development of textual criticism because of the unusual power and penetration of his scholarship, the range of textual material on which he worked, and his immense contemporary and posthumous influence. His edition of the Greek New Testament (1831; 2nd ed. 1842-50) was intended primarily as a vindication of the principles of Bentley and Bengel and a demonstration that the textus receptus must be finally rejected. Similarly his famous edition of Lucretius (1850) is important as an exemplification of the method in action, since the tradition of Lucretius is peculiarly suitable for the purpose. The demonstration fell short of completeness, for Lachmann had not fully grasped the problem and so failed to exploit the method fully. It has been suggested that Lachmann's best critical work was in his editions of medieval German texts; their influence will be considered below. The Lachmannian model of recension derived added authority from seemingly analogous models in other fields, especially that of comparative philology. As propagated by disciples, notably Moritz

Haupt, it dominated textual studies for half a century, Related developments in the late 19th century. Possibly the most important technical advance in the latter part of the 19th century was the perfection of photography, Instead of travelling in search of his material, the paleographer or critic could now assemble and study it at relatively little expense and without leaving his desk.

During the last quarter of the 19th century the tempo of archaeological discovery in classical and biblical lands The genealogical method of Karl Lachmann

Richard Bentley's influence was vastly increased, and many new texts were unearthed. Some of these were in previously unknown languages, setting new problems of decipherment. Specifically relevant to textual studies are the many Greek papyri recovered from Egypt. These have thrown much light on the history and techniques of ancient book production and scholarship and hence, indirectly, on critical problems. Where the texts they contain are already known, their evidence has tended to emphasize our ignorance of the textual history of classical literature in antiquity itself. Being usually far older than the manuscripts already known, they often illuminate the "pretraditional" state of the text; by sometimes offering readings that agree with those of late and "inferior" medieval copies they justify editors in a policy of cautious eclecticism. Papyrus discoveries have been of particular moment for the text of the New Testament.

Editors of printed texts, having invariably received a classical education (no other being available), had naturally followed, with minor modifications, the methods of classical editing. They would reprint the text of the last edition with such improvements as editorial taste and learning suggested but with no attempt to investigate the sources of the text. Since Lachmann's method was inapplicable to printed texts, this procedure continued until, by the end of the 19th century, the text of Shakespeare, for example, was in a state somewhat analogous to that of most classical writers at the time of the editiones principes. Much of the work of modern Shakespearean editors has consisted of undoing the damage inflicted by their predecessors. The early 20th century saw the rise of a new school of "biblio-textual" criticism, most notably represented by A.W. Pollard, R.B. McKerrow, and W.W. Greg. Its object was to devise a style of recension appropriate to the special circumstances under which early printed texts were produced and propagated, and its methods were those of analytical bibliography. These developments are of direct importance for the criticism and editing of a large range of texts of the 16th, 17th, and 18th centuries, particularly those of the Elizabethan and Jacobean dramatists. They have also engendered a discussion of general methodological interest on the role of bibliographical as opposed to historical and literary criteria in the editorial process. This debate continues.

Critics and editors of medieval texts had also inevitably been influenced by developments in the classical field. Before Lachmann it had been usual to choose a single manuscript as the main basis for an edition. Because of the circumstances in which much medieval literature was composed and transmitted this was not necessarily unscientific, and the surviving bulk of texts was so large as to dictate that approach in many cases if they were to be edited at all. This had been the style of editing followed by the Belgian Jesuits known as Bollandists, the French Benedictines called Maurists, and the Italian scholar L.A. Muratori, and perpetuated in the indispensable Patrologiae Cursus Completus (edition of the Church Fathers) of the French priest Jacques-Paul Migne. At its best it is seen in the editions of medieval Latin chronicles by the 18th-century Oxford antiquary Thomas Hearne, some of which are still standard works. A more scientific approach was adopted in the publications of the Monumenta Germaniae Historica, the later volumes of which (from about 1880) were produced by editors trained in the school of Lachmann. Similarly, editors of vernacular texts followed the lead that Lachmann had given in his editions of such early German poems as the Nibelunge Not (1826) and the Iwein (1827). An important development in the application of the method was due to the medievalists G. Gröber and G. Paris, who first emphasized the significance of common errors. But in the general uncritical enthusiasm for scientific method, the genealogical approach was too often used without regard for the special conditions under which medieval literature has been handed down

Reaction against the genealogical method. Haupt had proclaimed in his lectures that his main object was to teach method. But confidence in method led to its mis-use. The Lachmannian formula of recension was applied to texts, classical as well as medieval, for which it was unsuitable, often with grotesque results. Commonly this

took the form of choosing on "scientific" (i.e., stemmatic) grounds a "best manuscript" (codex optimus) and defending its readings as authoritative even where common sense showed that they could not be authentic. This was the type of editing satirized by A.F. Housman in the brilliant prefaces to his editions of Manilius (1903) and Juvenal (1905) and in many reviews and articles. It flourished chiefly between 1875 and 1900, but the dangers of excessive methodological rigidity had already been foreseen. In 1841 H. Sauppe in his Epistola Critica ad G. Hermannum had emphasized the diversity of transmissional situations and the difficulty or actual impossibility of classifying the manuscripts in all cases. In 1843 Lachmann's pupil O. Jahn, in his edition of Persius, had repudiated the strict application of the genealogical method as unsuitable to the tradition of that poet. The most extreme position was taken by E. Schwartz, who in his edition of Eusebius' Historia ecclesiastica (1909) denied that "vertically" transmitted texts of Greek books existed at all. The limitations of the stemmatic method have subsequently been stressed in a more temperate fashion by other writers. The modern tendency is to acknowledge the validity of the method in principle while recommending a cautious empiricism in its application. For the editor of a contaminated tradition-and most traditions are probably contaminated-the lesson of recent research is that authoritative evidence may survive even in late and generally corrupt or interpolated sources. More radical criticism of the method has come from me-

dievalists. In 1913 and again in 1928 the French scholar J. Bédier attacked the stemmatic method because the stemmata it produced for medieval texts almost invariably had only two branches. Subsequent investigation has shown that Bédier overrated the inherent improbability of this situation, and it is generally agreed that his criticisms had to do with improper application rather than with the method itself. The point taken by H. Quentin (1922) has already been mentioned; that the method entails argument in a circle, since it relies on the identification of errors at the beginning of a process designed to lead to that very end. This objection, more cogent in theory than in practice, applies with greater force to medieval than to classical texts. The linguistic and stylistic canons of classical Greek and Latin are relatively strict and well defined, whereas the vocabulary, grammar, and usage of many medieval authors (especially when an oral prehistory is in question) is often not certain enough to allow reliable discrimination between variant and error. Classical texts, moreover, have passed through a series of bottlenecks in their history, which have simplified editorial problems by eliminating a high proportion of the evidence (cf. the remarks on papyri above). With a few exceptions, such as the commentary of Servius, only one version of each text remains to be reconstructed, whereas many medieval texts are extant in several redactions that cannot be winnowed by the stemmatic method so as to leave only one. Quentin's own method, which depended on the comparison of variants in groups of three, without prejudice as to their correctness, has not been generally adopted. It is immensely laborious and does not in practice possess the objectivity that its inventor claimed for it. Bédier and Quentin have, however, done good service to textual criticism in enjoining caution. The best critics in all fields now agree in rejecting the "logical" (i.e., the illogical) application of any method if the results conflict with common sense, and in stressing the necessity of judging variant readings and forms of a text on their intrinsic merits in the light of the information available.

Mechanical methods: Quentin also gave a lead to later investigators in calling attention to the possibility of basing recension on the variants themselves, and the more sophisticated methods of Greg (1927). Archibald Hill (1950). Vinton Dearing (1959), and J. Froger (1968) may be seen as a continuation of his work. It has already been suggested that methods of this type, so far as recension is concerned, have been of primarily theoretical interest. But the use of mechanical and computing techniques in this field is in its infancy, and assessment must be provisional. Certain practical applications seem to have proved them

Bédier and Quentin

selves. Mechanical aids to collation have been successfully used in editing Shakespeare and Dryden. Computer storage and analysis of texts can provide information about authorial usage, such as stylistic and metrical patterns, and facilitate the production of concordances. These aids are more relevant to conjectural emendation (as shown by their application to the Dead Sea Scrolls) and the "higher" criticism (e.g., determination of authenticity) than to the recension of texts. The formula or machine that will do the critic's essential work for him still awaits discovery; the best texts are produced by the best scholars, whatever their method or lack of method. Lachmann observed that the establishment of a text according to its tradition is a strictly historical undertaking. Twentieth-century research into the composition and transmission of ancient, medieval, and modern texts has confirmed the truth of his pronouncement.

BIBLIOGRAPHY

Historiography: C.V. LANGLOIS and C. SEGNOBOS, Introduction aux stude historiques (1898; Eng. trans., Introduction to the Study of History, 1898); HAROLD TEMPERLEY (ed.). Selected Essays of J.B. Bury (1903), expined 1964); JAMES T. SHOTWELL, The History of History of Historia Witing, 2 vol. (1942); ROBIN G. On Russian historiography, there is no satisfactory general survey in English. The following can be useful for particular periods or historians. Anatole G. Mazour, Modern Russian Historiography, 2nd ed. (1988), Alexanders S. vucinnel, Science in Russian Culture: A History to 1860 (1963); and Richadd PIPES (Urans), Karamirin's Memoir on Ancient and Modern Russia (1966); JOHN S. CURTISS (ed.), Essays in Russian and Soviet History, in Honor of Gerold Tanquary Robinson (1962), especially on Semevsky, ALAN D. FERGUSON and ALFRED LEVIN (eds.), Essays in Russian History: A Collection Dedicated to George Vernadsky (1964); JOHN KEFF and LILIANA BRISHY (eds.), Contemporary History in the Soviet Mirror (1964).

FRANZ ROSENTHAL, A History of Muslim Historiography, 2nd rev. ed. (1968).

WILLIAM G. BEASLEY and E.G. PULLEYBLANK, Historians of China and Japan (1961); CHARLES S. GARDNER, Chinese Traditional Historiography (1938, reprinted 1961).

Archaeology: Good general introductions to the aims and methods of archaeology are LEONARD WOOLLEY, Digging Up the Past (1930), SIR MORTIMER WHEELER, Archaeology from the Earth (1954), and GRAHMER CLARK, Archaeology and Son Clark (1957). For the history of archaeology and its relation to the development of anthropology, see C.W. CERAM,

Götter, Gräber und Gelehrte (1949; Eng. trans., Gods, Graves and Scholars, 1951); G. BIBBY, The Testimony of the Spade (1956); and GLYN DANIEL, A Hundred and Fifty Years of Archaeology (1974). Anthologies of archaeological writings that relate both to the history of the subject and its present methods are many. The following are recommended: R.F. HEIZER, The Archaeologist at Work (1959), and Man's Discovery of his Past. 2nd ed. (1970); and JACQUETTA HAWKES, The World of the Past (1963). For the development of American archaeology, see G. WILLEY and G. SABLOFF, The History of American Archaeology (1973). Special aspects of the development of archaeology are dealt with in D. BROTHWELL and E. HIGGS, Science in Archaeology, 2nd ed. (1969); GEORGE F. BASS, Archaeology Under Water (1967); W.F. LIBBY, Radiocarbon Dating, 2nd ed. (1955); KEN-NETH HUDSON, A Social History of Archaeology (1981): MYRA SHACKLEY, Environmental Archaeology (1981); and M.G.L. BAIL-LIE, Tree-Ring Dating in Archaeology (1982)

Chronology: JAMES C. MACDONALD, Chronologies and Calendars (1897); ALFRED E. STAMP, Methods of Chronology (1933); R.L. POOLE, Studies in Chronology and History, collected and ed. by A.L. POOLE (1934, reprinted 1969).

On the astronomical basis of Chinese calendrical systems, see JOSEPH NEEDHAM, Science and Civilisation in China, vol. 3, pp. 390-408 (1959). A standard reference for conversion between Chinese and Western calendars is MATHIAS TCHANG, Synchronismes chinois (1905).

ROBERT SEWELL and S.B. DIKSHITA. The Indian Calendar (1896), describes the various systems of calendar in India, with tables of concordance and a useful index, ROBERT SEWELL, The Siddhants and the Indian Calendar (1924), a Study of the Hindu astronomical system as a basis for the traditional calendar, SWAMEANNI PILLA, An Indian Ephemeris, 6 vol. (1922), tables of concordance of Hindu, Muslim, and modern calendars, IEAR FILLIDZAT, Notions de chronologie, "In 10218 RENOU and JEAN FILLIDZAT, India classique, vol. 2 (1953), a general summary and list of different reas used in India.

RESTRUCTION AND PRINCE THE Calendars of Ancient Egypt (1950), a basis work providing valid solutions to most of the problems and assistance providing valid solutions to most of the problems and masses II. "I. Near Easters Naul, 16: 30-43 (1957), an analysis of the more important lunar dates of the New Kingdom, M.B. ROWTON, "Manethe's Date for Ramesses II." J. Egyptian Archaeol, 34:57-74 (1948), and "Comparative Chronology at the Time of Dynasty XIV. "J. Near Eastern Stud, 19:15-22 (1960), two articles that deal with the date for the accession of Ramest II (1900 or 1304 es); PISIK BORNING, LIMERSUMERY STUDIES OF THE STRUCTION OF THE OF THE STRUCTI

The most complete general work on the chronology of Western Asia, including Mesopotamia, is pe_vAn DER MER. The Chronology of Ancient Western Asia and Egypt, 2nd rev. ed. (1955); however, it should be used with caution. For the general chronology of ancient Western Asia, with special reference to Mesopotamia, see M.B. Rowron in The Cambridge Ancient History, 3rd ed., vol. 1, pp. 193–237 (1970), and the extensive literature quoted there (up to 1959). For a distribution of the Cambridge Ancient Mesopotamia, see M.B. Rowron in The Cambridge Ancient Mesopotamia, and Near Eastern Chandles and Near Eastern Near Eastern New York Near Eastern New York Ne

B. RATNER, Seder Olam Rabba: Die grosse Weltchronik (1897), the authoritative edition, carefully annotated and with a detailed introduction, of the oldest rabbinic chronology extending

from the earliest records to the first century of the current era. E MAHER, Hamblach for platcher Chromologic (1916), the only comprehensive work on Jewish cashes on the subject and summarizing most previous works on the subject. S. ZETLIN, Megillat Taanil As a Source for Jewish Chromologic and History in the Hellenistic and Roman Periods (1922), removes all discrepancy in I and II Maccabees' and Josephus' chromological data in the Hamomonean phase of Jewish history, thus reinvesting their statements with historical significance and authority.

and dudusty, when the service and Roman Chronology Calendars and Yacra in Classical Antiquity (1972), a lundamental work, HENRY TONIS CLISSICAL PROPERTY (1974), a such as the service of Greek Chronology; W. Kubitscher, Fast: Hellenic, 3 vol. (1834), still useful in providing the sources for the framework of Greek Chronology; W. Kubitscher, Grundriss der autiken Zeitzechnung (1928), the standard handbook but unreliable; A. E. SAWULE, Profenser Chronology (1962); E.J. BICKERMAN, Chronology of the Ancient World (1968), a summary survey to be used judiciously; w. Des Boek, Laconian Studies, pt. 1, "The Struggle for the Chronological Pattern" (1954), on ancient attempts to systematize archaec chronology; A.G. WOODHEAD, The Greeks in the West, pp. 69-72 (1962), on dates in the archaic period.

E.J. BICKERMAN, Chronology of the Ancient World (1968), an excellent short manual, unfortunately marred by a number of factual errors, AGNES KIRSOPP MICHES, The Calendar of the Roman Republic (1967), contains much valuable information on chronology as well as the calendar—probably the best book ever written on the Roman calendar; F.K. GINZEL, Handhuch der mathematischen und technischen Chronologie das Zeitrechnungswesen der Völker, 3 vol. (1906–14), the standard work of reference on its subject.

LESS ON THE Mordinch der mathematischen und technischen Chromologie dus Zeitsechungswesen der Volker, 3 vol. (1906– 14), still the fundamental work; IACK FINEGAN, Handbook of Bible Chronology (1964), the best for its subject, E.J. BICKER-MAN, Chronology of the Ancient World (1968), very thorough and complete.

AL-BILVII, The Chronology of Ancient Nations. Eng. trans. by C. EDWARD SACHAU (1879), useful source material on the Muslim knowledge of chronology down to the 10th century An; see especially pp. 16–82. For actual tables of Muslim chronological information and comments, the following may be consulted: E. LACOINE, Tables de concluder: Marchael et al. (1871), C.L. IDELER, Handback et al. (1872), C.L. IDELER, Handback et al. (1872), and C.L. IDELER, Handback et al. (1872), and C.L. IDELER, Handback et al. (1872), and C.L. Roskovorti, The Islamic Dynastics (1967). See also articles on calendar, chronology, and "Hidja" in the Encyclopaedia of Islam. An extensive collection of conversion tables is given in FRANK PARSE (ed.), The Book of Calendars (1982).

3.G. MORLEY, "An Introduction to the study of the Maya Hieroglyphs," Bull. U.S. Bur Am. Ethnol., no. 57 (1915, reprinted 1968), a clear exposition of Maya chronology, J. ERIC S. THOMPSON, Maya Chronology: The Correlation Question (1935) and Maya Heroglyphic Writing. Introduction (1935, negrot 1971); H.J. SPINDEN, The Reduction of Maya Dates (1924), a presentation of earlier correlation). L. SATTERHWAITE and E.K. RALPH, "New Radiocarbon Dates and the Maya Correlation Problem," Am. Antiq. 2, 2616–518 (1960).

Diplomatics: HARRY BRESSLAU, Handbuch der Urkundenlehre für Deutschland und Italien, 2nd ed., vol. 1 (1912), vol. 2, pt. 1 (1914), vol. 2, pt. 2, ed. by H.W. KLEWITZ (1931, all reprinted 1958, with separate index), although somewhat out of date, still the best handbook by far for Germany and Italy; OSWALD REDLICH, Die Privaturkunden des Mittelalters (1911, reprinted 1967), an excellent work on the private documents of the Middle Ages; LEO SANTIFALLER, Beitrage zur Geschichte der Beschreibstoffe im Mittelalter, pt. 1 (1953), the most up-to-date account of the history of writing materials during the Middle Ages; FRANZ DOLGER and JOHANNES KARAYANNOPULOS, Byzantinische Urkundenlehre die Kaiserurkunden (1968), the only study of the documents of the Byzantine emperors; C.R. CHENEY, The Study of the Medieval Papal Chancery (1966), an excellent general survey of modern research; R.L. POOLE, Lectures on the History of the Papal Chancery down to the Time of Innocent III (1915), the best book in English on this subject, though now out of date; PETER HERDE, Beitrage zum päpstlichen Kanzlei- und Urkundenwesen im 13. Jahrhundert, 2nd ed. (1967); and Audientia litterarum contradictarum, vol. (1970), on papal letters of justice; WILHELM ERBEN, Die Kaiser- und Königsurkunden des Mittelalters in Deutschland, Frankreich und Italien (1907, reprinted 1967), an excellent supplement to Bresslau on the imperial and royal documents of the Middle Ages in Germany. France, and Italy; GEORGES TESSIER, Diplomatique royale française (1962), the best and most up-to-date handbook on the royal French diplomatic; ALAIN DE BOUARD, Manuel de diplomatique française et pontificale (1929), a handbook on French and papal diplomatic;

F.M. STENTON, The Latin Charters of the Anglo-Saxon Period (1955), a good brief survey on research since the 18th century; P.H. SAWYER, Anglo-Saxon Charters (1968), the most up-to-date annotated list and bibliography; R.C. VAN CAENEGEM, Royal Writs in England from the Conquest to Glanvill (1959), the best book on writs; V.H. GALBRAITH, An Introduction to the Use of the Public Records (1934) and Studies in the Public Records (1948), two works especially useful for the later periods; C.R. CHENEY, The Records of Medieval England (1956) and English Bishops' Chanceries 1100-1250 (1950); T.F. TOUT, Chapters in the Administrative History of Medieval England, 6 vol. (1920-33), the basic work on the subject, including the chancery; HARRY BRESSLAU, "International Beziehungen im Urkundenwesen des Mittelalters," Archiv für Urkundenforschung, 6:19-76 (1918), the only survey on international relations in the documentary system of the Middle Ages; HORST ENZENSBERGER, Beiträge zum Kanzlei- und Urkundenwesen der normannischen Herrscher Unteritaliens und Siziliens (1971), the most up-todate account of the chancery and documents of the Norman rulers in southern Italy and Sicily; H.O. MEISNER, Archiva-lienkunde vom 16. Jahrhundert bis 1918 (1969), the best study of records from the 16th century through 1918 for central Europe, especially Germany; CHARLES CARTER, The Western European Powers, 1500-1700 (1971), a very useful survey on archives and their records. All the cited works have comprehensive bibliographies, with some of them also containing bibliographies of editions and facsimiles of documents. H. THOMAS HICKER-SON, Archives and Manuscripts: An Introduction to Automated Access (1981), discusses specific concern of the contemporary archives business

Epigraphy: J.B. PRITCHARD (ed.), Ancient Near Eastern Texts Relating to the Old Testament, 3rd ed. (1969), gives translations of inscriptional material, especially from Egypt, Mesopotamia, Palestine, and Asia Minor. J. FRIEDRICH, Entzifferung verschollener Schriften und Sprachen (1954; Eng. trans., Extinct Languages, 1957), deals especially with the decipherment of inscriptions, while his Kleinasiatische Sprachdenkmäler (1932), transliterates a variety of epichoric texts from Asia Minor, R.G. KENT, Old Persian, 2nd ed. rev. (1953), is a comprehensive work including grammar, texts, and lexicon. w. HINZ, Altiranische Funde und Forschungen (1969), includes a number of important recent inscriptional finds from ancient Iran. J. BLOCH, Les Inscriptions d'Asoka (1950), gives texts and translations of all Asokan epigraphs; whereas R.B. PANDEY, Historical and Literary Inscriptions (1962), provides a transliterated selection of later Indic epigraphy as well. L. DEROY, Initiation à l'épigraphie mycénienne (1962), provides a comprehensive survey of the study of Mycenaean tablets. E.S. ROBERTS, An Introduction to Greek Epigraphy, 2 vol. (1887-1905), remains the classic compendium of its kind; while more recent, shorter surveys of its subject are found in G. KLAFFENBACH, Griechische Epigraphik (1957); and A.G. WOODHEAD, The Study of Greek Inscriptions (1959). A more elaborate recent treatment is that of M. GUARDUCCL Epigrafia greca, 2 vol. (1967-69). The Cretan laws have been sumptuously edited and commented in R.F. WILLETTS. "The Law Code of Gortyn," Kadmos, suppl. 1 (1967). The old standard works on Latin inscriptions, J.E. SANDYS, Latin Epigraphy, 2nd ed. rev. (1927); and R.L.V. CAGNAT, Cours d'épigraphie latine, 3rd ed. (1898), are updated only in such summary surveys as R. BLOCH, L'épigraphie latine, 3rd ed. (1964). The elaborate edition of the principal Umbrian inscription by J.W. POULTNEY, The Bronze Tables of Iguvium (1959), gives text, translation, grammar, extensive commentary, and facsimiles of the tables themselves. R.W.V. ELLIOTT, Runes: An Introduction (1959), is especially thorough on the side of British runes; while w. KRAUSE, Runen (1970), is a compact but comprehensive survey of the entire field of runology.

Genealogy: For an outline of the sources and methods of procedure, see L.G. PINE, Heraldry and Genealogy, 4th ed. (1974). Also useful is A.J. WILLIS, Genealogy for Beginners, 3rd. ed. (1976). J. UNETT, Making a Pedigree, 2nd ed. (1961), contains information on medieval records. G. HAMILTON ED-WARDS, In Search of Ancestry (1966), is a larger work with more detail, especially on naval and military sources. On American genealogy, see G.H. DOANE and J.B. BELL, Searching for Your Ancestors: The How and Why of Genealogy, 5th ed. (1980); and J.S. SWEET, Genealogy and Local History: An Archival and Bibliographical Guide, 2nd rev. ed. (1959). See also L.G. PINE. American Origins (1960, reprinted 1980), on sources for genealogical research in Europe, and The Genealogist's Encyclopedia (1969). A good starting point in genealogical quests is P. WILLIAM FILBY, American and British Genealogy and Heraldry. A Selected List of Books, 3rd ed. (1983).

Paleography: The most comprehensive work, certainly in English, is still E. MAUNDE THOMPSON, An Introduction to Greek and Latin Palaeography (1912). Also valuable, and in print, is his shorter version, Handbook of Greek and Latin Palaeography (1893, reprinted 1966). For Greek paleography, see B.A. VAN GRONINGEN, Short Manual of Greek Palaeography, 3rd rev. ed. (1963); and C.H. ROBERTS, Greek Literary Hands, 350 B.C. A.D. 400 (1956). The article "Handwriting" in C.G. CRUMP and E.F. JACOB (eds.), The Legacy of the Middle Ages (1926), is an important account of Latin book hands. Essential for the study of abbreviations in medieval Europe is ADRIANO CAPPELLI, Lexicon abbreviaturarum: dizionario di abbreviature latine ed italiane, 6th ed. (1961). A standard textbook for medieval English cursive hands is CHARLES JOHNSON and HILARY JENKINSON, English Court Hand A.D. 1066 to 1500 (1915), continued in Jenkinson's Later Court Hands in England from the Fifteenth to the Seventeenth Century (1927), L.C. HECTOR. The Handwriting of English Documents, 2nd ed. (1966), contains a valuable introduction to the paleography of English administrative manuscripts. Very many classical, biblical, and liturgical texts have now been published in facsimile, often with colour plates. Large collections in facsimile comprise E.A. LOWE, Codices latini antiquiores, 12 vol. (1934-71); CHARLES SAMARAN and ROBERT MARICHAL, Catalogue des manuscrits en écriture latine, portant des indications de date (1959-); BERTRAM COLGRAVE (ed.), Early English Manuscripts in Facsimile (1951-); and the "Oxford Palaeographical Handbooks," a series designed to deal with various aspects of the subject, such as C.H. ROBERTS (see above); C.E. WRIGHT, English Vernacular Hands from the Twelfth to the Fifteenth Centuries (1960); M.B. PARKES, English Cursive Book Hands, 1250-1500 (1969); and T.A.M. BISHOP, English Caroline Minuscule (1971), See also MARC DROGIN, Medieval Calligraphy, Its History and Technique (1980); and DONALD JACKSON, The Story of Writing (1981).

Sigillography: The best general account is SIR HILARY JEN-KINSON, Guide to Seals in the Public Record Office (1954). JOSEPH H. ROMAN, Manuel de sigillographie française (1912), is a longer study mainly on French seals. The basic catalog for European seals and impressions is WALTER DE GRAY BIRCH, Catalogue of Seals in the Department of Manuscripts in the British Museum, 6 vol. (1887-1900). Seal matrices are discussed by ALEC B. TONNOCHY in the Catalogue of British Seal-Dies in the British Museum (1952). ALFRED B. WYON, The Great Seals of England from the Earliest Period to the Present Time (1887), provides a systematic and well-illustrated account of English Great Seals. A full discussion of Classical seal use, with bibliography and occasional reference to Near Eastern sources, is given in the article "Signum," by WENGER in Pauly-Wissowa Real-Encyclopädie, vol. 2, col. 2361-2448 (1923); and details of use in the Aegean and Greece are conveniently given in JOHN BOARDMAN, Greek Gems and Finger Rings (1970). No adequate study exists of the uses of seals in ancient western Asia. See at present, however, ELENA CASSIN, "Le Sceau: un fait de civilisation dans la Mésopotamie ancienne," Annales, pp. 742-751 (1960); and M.I. ROSTOVTSEFF, "Seleucid Babylonia: Bullae and Seals of Clay with Greek Inscriptions," Yale Classical Studies 3:1-114 (1932). A very full bibliography of ancient Eastern seal publications from which information on use may be gleaned is given by HANS H. VON DER OSTEN in Ancient Oriental Seals in the Collection of Mr. Edward T. Newell, pp. 168-190 (1934); and in Altorientalische Siegelsteine der Samm-lung Hans Silvius von Aulock, pp. 156-219 (1957), but no more recent convenient bibliography exists; systematic study of use must depend mainly on the examination of scaled texts. For Egypt, P.E. NEWBERRY, Scarab-Shaped Seals (1907), provides a brief account, now much in need of revision. Books on Chinese and Japanese seals deal mainly with those of painters, calligraphers, and collectors. ROBERT H. VAN GULIK, Chinese Pictorial Art As Viewed by the Connoisseur (1958), has the most illuminating discussion of the artist's use of seals. See also VICTORIA CONTAG and WANG CHI-CH'IEN, Seals of Chinese Painters and Collectors of the Ming and Ch'ing Periods, rev ed. (1966); and CH'EN CHIH-MAI, Chinese Calligraphers and Their Art (1966).

Textual criticism: For oral transmission the fundamental work is H.M. and N.K. CHADWICK, The Growth of Literature, 3 vol. (1932-40, reprinted 1969). Classical, biblical, and medieval texts are all covered (but somewhat unevenly) by H. HUNGER et al., Geschichte der Textüberlieferung der antiken und mittelalterlichen Literatur, 2 vol. (1961-64). For classical texts in general the best introduction is L.D. REYNOLDS and N.G. WILSON, Scribes and Scholars (1968); more specialized are A.C. CLARK, The Descent of Manuscripts (1918); and A. DAIN, Les manuscrits, 2nd rev. ed. (1964). For special areas, see B.A. VAN GRONINGEN, Traité d'histoire et de critique des textes grecs (1963); R.D. DAWE, The Collation and Investigation of Manuscripts of Aeschylus (1964); R. RENEHAN, Greek Textual Criticism: A Reader (1969); L. HAVET, Manuel de critique verbale appliquée aux textes latins (1911), an exhaustive catalogue raisonné of scribal error; E.G. TURNER, Greek Papyri: An Introduction (1968), important for the history of Greek texts in antiquity. For biblical texts, in addition to Hunger (op. cit.), the standard work on the New Testament is B.M. METZGER,

The Test of the New Testament, 2nd ed. (1968). For patristic tests an excellent case study sating important general issues is M. BEYNOT, The Tradition of Manuscripts: A Study in the Transmission of St. Ceptron's Traditist (1961). For medieval tests a good exposition of typical problems may be found in Dys.a. AVALE, "Die Liederhandschriften und die Texthrifts," in Hunger (op. cit.), 2:733–290, see also J.A. ASHER, "Truth and Fiction: The Text of Medical Manuscripts," Aumia, 2:56–16 (1966). For printed books the standard work is F. BOWER, Bibliography and Textual Criticism (1964); while a sueful collection of essays may be found in O.M. BAKER and W. BANES con Literature. J'700 to the Present (1960).

For the history of the stemmatic method and the contribution of Lachmann, s. TIMPANARO, La genesi del metodo del Lachmann (1963), is definitive. For its application, P. MAAS, Textual Criticism (Eng. trans. 1958), an austere theoretical exposition; and G. PASQUALI, Storia della tradizione e critica del testo, 2nd ed. (1952), brilliant but discursive, are complementary and fundamental. The reaction to the stemmatic method may be studied in H. QUENTIN, Mémoire sur l'établissement du may be studied in B. QUENTIN, Memorite Suf Testansseriem, use treated de la Viaguate (1922). Essais de critique textuelle-excludique (1926); J. BUEKE SEVERS, "Quentifi S' Thoory of Textual Criticism," English Inst. Annual 1911, pp. 65-93 (1942); J. BEDIER, "La tradition manuscrite du Lai de L'Ombre: Reflexions sur Part d'éditer les anciens textes," Romania, 54:161-96, 321-56 (1928). A. CASTELLANI, Bédier avait-il raison? (1957); W.W. GREG, The Calculus of Variants (1927); A.A. HILL, "Some Postulates for Distributional Study of Texts," Stud. in Bibliphy., 3:63-95 (1950). For further discussion of these developments, see w.p. shepard, "Recent Theories of Textual Criticism," Mod. w.p. shepard, "Recent Theories of Textual Criticism," Mod. Philol., 28:129–141 (1930); J. Andrieu, "Principes et recherches en critique textuelle," in Mémorial des études latines... J. Marouzeau, pp. 458–74 (1943); E.B. Ham, "Textual Criticism Marouzeau, pp. 458–14 (1943); E.B. HAM, "Textual Criticism

and Common Sense," Romance Philol, 12:198–215 (1959). For mechanized techniques, see V.A. DEARING, A Manual of Tex-tual Analysis (1959), 1. FROGER, La critique des textes et son automatisation (1968). For the taxonomic approach, see 1.6. GRIFFITH, "A Taxonomic Study of the Manuscript Tradition of Juvenal," Mux. Heb., 25:101–138 (1968); "Numerical Taxonomy and Some Primary Manuscripts of the Gospels," J. Theol. Stud., 20:390–406 (1969).

For classical texts on textual criticism the standard works are still. o. STAMEN, Editionsteenhie, 2nd ed. (1914), and A. DELATTE and A. SEVERYNS, Emploi des signes critiques (1938). For medieval texts, see A. DONDANIS, "Abbreviations latines et signes raccommandés pour l'apparat critique des éditions des textes médievaux, "Bul ed is acc. in: pour l'étude de la control de l'acc. L'acc

Many of the works cited above include discussion of general principles of textual criticism. In addition, the following works critically cited to the desired principle of textual criticism. In addition, the following work critical (1921), sound emphasis on the roles of probability and common sense; A.E. HOUSMAN, "The Application of Thought to Textual Criticism," Proc. Class. 4stoc., 1867–84 (1922), a brilliant polemic against hard-and-fast "rules" of criticism; 1, and Textual Criticism; 2, and 4, B. McDONALD, "The Textual Criticism," in Oxford Classical Dictionary, 2nd ed. (1970), a sound exposition for classical students. ISROM E. McCARN, A Critique of Modern Textual Criticism (1983), is a study of the role of non-literary contexts in textual criticism.

Hitler reviewing troops on the eastern front, 1939.

Hitler's father, Alois (born 1837), was illegitimate. For a time he bore his mother's name, Schicklgruber, but by 1876 he had established his family claim to the surname Hitler. Adolf never used any other surname.

EARLY LIFE AND RISE TO POWER

After his father's retirement from the state customs service, Adolf Hitler spent most of his childhood in Linz, the capital of Upper Austria. It remained his favourite city throughout his life, and he expressed his wish to be buried there. Alois Hitler died in 1903 but left an adequate pension and savings to support his wife and children. Although Hitler feared and disliked his father, he was a devoted son to his mother, who died after much suffering in 1907. With a mixed record as a student, Hitler never advanced beyond a secondary education. After leaving school, he visited Vienna, then returned to Linz, where he dreamed of becoming an artist. Later, he used the small allowance he continued to draw to maintain himself in Vienna. He wished to study art, for which he had some facilities, but he twice failed to secure entry to the Academy of Fine Arts. For some years he lived a lonely and isolated life, earning a precarious livelihood by painting postcards and advertisements and drifting from one municipal hostel to another. Hitler already showed traits that characterized his later life: loneliness and secretiveness, a bohemian mode of everyday existence, and hatred of cosmopolitanism and of the multinational character of Vienna.

In 1913 Hitler moved to Munich. Screened for Austrian military service in February 1914, he was classified as unfit because of inadequate physical vigour; but when World War I broke out he immediately volunteered for the German army and joined the 16th Bavarian Reserve Infantry Regiment, He served throughout the war, was wounded in October 1916, and was gassed two years later. He was hospitalized when the conflict ended. During the war, he was continuously in the front line as a headquarters runner; his bravery in action was rewarded with the Iron Cross, Second Class, in December 1914, and the Iron Cross, First Class (a rare decoration for a corporal), in August 1918. He greeted the war with enthusiasm, as a great relief from the frustration and aimlessness of civilian life. He found discipline and comradeship satisfying and was confirmed in his belief in the heroic virtues of war.

Discharged from the hospital amid the social chaos that followed Germany's defeat, Hitler took up political work in Munich in May-June 1919. As an army political agent, he joined the small German Workers' Party in Munich (September 1919). In 1920 he was put in charge of the party's propaganda and left the army to devote himself to improving his position within the party, which in that year was renamed the Nationalsozialistische Deutsche Arbeiterpartei (Nazi). Conditions were ripe for the development of such a party. Resentment at the loss of the war and the severity of the peace terms added to the economic woes and brought widespread discontent. This was especially sharp in Bavaria, due to its traditional separatism and the region's popular dislike of the republican government in Berlin. In March 1920 a coup d'état by a few army officers attempted in vain to establish a right-wing government.

Munich was a gathering place for dissatisfied former servicemen and members of the Freikorps, which had been organized in 1918-19 from units of the German army that were unwilling to return to civilian life, and for political plotters against the republic. Many of these joined the Nazi Party. Foremost among them was Ernst Röhm, a staff member of the district army command, who had joined the German Workers' Party before Hitler and who was of great help in furthering Hitler's rise within the party. It was he who recruited the "strong arm" squads used by Hitler to protect party meetings, to attack socialists and communists, and to exploit violence for the impression of strength it gave. In 1921 these squads were formally organized under Röhm into a private party army, the SA (Sturmabteilung). Röhm was also able to secure protection from the Bavarian government, which depended on the local army command for the maintenance of order and which tacitly accepted some of his terrorist tactics

Conditions were favourable for the growth of the small party, and Hitler was sufficiently astute to take full advantage of them. When he joined the party, he found it ineffective, committed to a program of nationalist and socialist ideas but uncertain of its aims and divided in its leadership. He accepted its program but regarded it as a means to an end. His propaganda and his personal ambition caused friction with the other leaders of the party. Hitler countered their attempts to curb him by threatening resignation, and because the future of the party depended on his power to organize publicity and to acquire funds, his opponents relented. In July 1921 he became their leader with almost unlimited powers. From the first he set out to create a mass movement, whose mystique and power would be sufficient to bind its members in loyalty to him. He engaged in unrelenting propaganda through the party newspaper, the Völkischer Beobachter ("Popular Observer," acquired in 1920), and through meetings whose audiences soon grew from a handful to thousands. With his charismatic personality and dynamic leadership, he attracted a devoted cadre of Nazi leaders, men whose names today live in infamy-Alfred Rosenberg, Rudolf Hess, Hermann Göring, and Julius Streicher.

Military World

Leader of the Nazi Party

Munich Putsch

The climax of this rapid growth of the Nazi Party in Bavaria came in an attempt to seize power in the Munich (Beer Hall) Putsch of November 1923, when Hitler and General Erich Ludendorff tried to take advantage of the prevailing confusion and opposition to the Weimar Republic to force the leaders of the Bavarian government and the local army commander to proclaim a national revolution. In the melee that resulted, the police and the army fired at the advancing marchers, killing a few of them Hitler was injured, and four policemen were killed. Placed on trial for treason, he characteristically took advantage of the immense publicity afforded to him. He also drew a vital lesson from the Putsch-that the movement must achieve power by legal means. He was sentenced to prison for five years but served only nine months, and those in relative comfort at Landsberg castle. Hitler used the time to dictate the first volume of Mein Kampf, his political autobiography as well as a compendium of his multitudinous

Mein Kampf

Hitler's ideas included inequality among races, nations, and individuals as part of an unchangeable natural order that exalted the "Arvan race" as the creative element of mankind, According to Hitler, the natural unit of mankind was the Volk ("the people"), of which the German people was the greatest. Moreover, he believed that the state existed to serve the Volk-a mission that to him the Weimar German Republic betrayed. All morality and truth were judged by this criterion; whether it was in accordance with the interest and preservation of the Volk. Parliamentary democratic government stood doubly condemned. It assumed the equality of individuals that for Hitler did not exist and supposed that what was in the interests of the Volk could be decided by parliamentary procedures. Instead, Hitler argued that the unity of the Volk would find its incarnation in the Führer, endowed with perfect authority. Below the Führer the party was drawn from the Volk and was in turn its safeguard.

The greatest enemy of Nazism was not, in Hitler's view, liberal democracy in Germany, which was already on the verge of collapse. It was the rival Weltanschauung, Marxism (which for him embraced social democracy as well as communism), with its insistence on internationalism and economic conflict. Beyond Marxism he believed the greatest enemy of all to be the Jew, who was for Hitler the incarnation of evil. There is debate among historians as to when anti-Semitism became Hitler's deepest and strongest conviction. As early as 1919 he wrote, "Rational anti-Semitism must lead to systematic legal opposition. Its final objective must be the removal of the Jews altogether." In Mein Kampf, he described the Jew as the "destroyer of culture," "a parasite within the nation," and "a menace.

During Hitler's absence in prison, the Nazi Party languished as the result of internal dissension. After his release. Hitler faced difficulties that had not existed before 1923. Economic stability had been achieved by a currency reform and the Dawes Plan had scaled back Germany's World War I reparations. The republic seemed to have become more respectable. Hitler was forbidden to make speeches, first in Bavaria, then in many other German states (these prohibitions remained in force until 1927-28). Nevertheless, the party grew slowly in numbers, and in 1926 Hitler successfully established his position within it against Gregor Strasser, whose followers were primarily in

Alliance with Alfred Hugenberg

northern Germany. The advent of the Depression in 1929, however, led to a new period of political instability. In 1930 Hitler made an alliance with the Nationalist Alfred Hugenberg in a campaign against the Young Plan, a second renegotiation of Germany's war reparation payments. With the help of Hugenberg's newspapers, Hitler was able for the first time to reach a nationwide audience. The alliance also enabled him to seek support from many of the magnates of business and industry who controlled political funds and were anxious to use them to establish a strong right-wing, antisocialist government. The subsidies Hitler received from the industrialists placed his party on a secure financial footing and enabled him to make effective his emotional appeal to the lower middle class and the unemployed, based on the proclamation of his faith that Germany would awaken from its sufferings to reassert its natural greatness. Hitler's dealings with Hugenberg and the industrialists exemplify his skill in using those who sought to use him. But his most important achievement was the establishment of a truly national party (with its voters and followers drawn from different classes and religious groups),

unique in Germany at the time. Unremitting propaganda, set against the failure of the government to improve conditions during the Depression. produced a steadily mounting electoral strength for the Nazis. The party became the second largest in the country. rising from 2.6 percent of the vote in the national election of 1928 to more than 18 percent in September 1930. In 1932 Hitler opposed Hindenburg in the presidential election, capturing 36.8 percent of the votes on the second ballot. Finding himself in a strong position by virtue of his unprecedented mass following, he entered into a series of intrigues with conservatives such as Franz von Papen, Otto Meissner, and President Hindenburg's son, Oskar, The fear of communism and the rejection of the Social Democrats bound them together. In spite of a decline in the Nazi Party's votes in November 1932, Hitler insisted that the chancellorship was the only office he would accept. On January 30, 1933, Hindenburg offered him the chancellorship of Germany. His cabinet included few Nazis at that point.

Hitler's personal life had grown more relaxed and stable with the added comfort that accompanied political success. After his release from prison, he often went to live on the Obersalzberg, near Berchtesgaden. His income at this time was derived from party funds and from writing for nationalist newspapers. He was largely indifferent to clothes and food but did not eat meat and gave up drinking beer (and all other alcohols). His rather irregular working schedule prevailed. He usually rose late, sometimes dawdled at his

desk, and retired late at night. At Berchtesgaden, his half sister Angela Raubal and her two daughters accompanied him. Hitler became devoted to one of them, Geli, and it seems that his possessive jealousy drove her to suicide in September 1931. For weeks Hitler was inconsolable. Some time later Eva Braun, a shop assistant from Munich, became his mistress. Hitler rarely allowed her to appear in public with him. He would not consider marriage on the grounds that it would hamper his career. Braun was a simple young woman with few intellectual gifts. Her great virtue in Hitler's eves was her unquestioning loyalty, and in recognition of this he legally married her at the end of his life.

DICTATOR, 1933-39 Once in power, Hitler established an absolute dictatorship. He secured the president's assent for new elections. The Reichstag fire, on the night of February 27, 1933 (apparently the work of a Dutch Communist, Marinus van der Lubbe), provided an excuse for a decree overriding all guarantees of freedom and for an intensified campaign of violence. In these conditions, when the elections were held (March 5), the Nazis polled 43.9 percent of the votes. On March 21, the Reichstag assembled in the Potsdam Garrison Church to demonstrate the unity of National Socialism with the old conservative Germany, represented by Hindenburg. Two days later the Enabling Bill, giving full powers to Hitler, was passed in the Reichstag by the combined votes of Nazi, Nationalist, and Centre party deputies (March 23, 1933). Less than three months later all non-Nazi parties, organizations, and labour unions ceased to exist. The disappearance of the Catholic Centre party was followed by a German Concordat with the Vatican in July.

Hitler had no desire to spark a radical revolution. Conservative "ideas" were still necessary if he was to succeed to the presidency and retain the support of the army; moreover, he did not intend to expropriate the leaders of industry, provided they served the interests of the Nazi state. Ernst Röhm, however, was a protagonist of the "continuing revolution"; he was also, as head of the SA, distrusted by the army. Hitler tried first to secure Röhm's support for his policies by persuasion. Hermann Göring and Heinrich Himmler were eager to remove Röhm, but Hitler hesitated until the last moment. Finally, on June 29, 1934, he

Eva Braun

Planning

eastward

expansion

reached his decision. On the "Night of the Long Knives," Röhm and his lieutenant Edmund Heines were executed without trial, along with Gregor Strasser, Kurt von Schleicher, and others. The army leaders, satisfied at seeing the SA broken up, approved Hitler's actions. When Hindenburg died on August 2, the army leaders, together with Papen, assented to the merging of the chancellorship and the presidency-with which went the supreme command of the armed forces of the Reich. Now officers and men took an oath of allegiance to Hitler personally. Economic recovery and a fast reduction in unemployment (coincident with world recovery, but for which Hitler took credit) made the regime increasingly popular, and a combination of success and police terror brought the support of 90 percent of the voters in a plebiscite.

Hitler devoted little attention to the organization and running of the domestic affairs of the Nazi state. Responsible for the broad lines of policy, as well as for the system of terror that upheld the state, he left detailed administration to his subordinates. Each of these exercised arbitrary power in his own sphere; but by deliberately creating offices and organizations with overlapping authority, Hitler effectively prevented any one of these particular realms from ever becoming sufficiently strong to challenge his

own absolute authority.

Foreign policy claimed his greater interest. As he had made clear in Mein Kampf, the reunion of the German peoples was his overriding ambition. Beyond that, the natural field of expansion lay eastward, in Poland, the Ukraine, and the U.S.S.R .- expansion that would necessarily involve renewal of Germany's historic conflict with the Slavic peoples, who would be subordinate in the new order to the Teutonic master race. He saw fascist Italy as his natural ally in this crusade. Britain was a possible ally, provided it abandon its traditional policy of maintaining the balance of power in Europe and limit itself to its interests overseas. In the west France remained the natural enemy of Germany and must, therefore, be cowed or subdued to make expansion eastward possible.

Before such expansion was possible, it was necessary to remove the restrictions placed on Germany at the end of World War I by the Treaty of Versailles. Hitler used all the arts of propaganda to allay the suspicions of the other powers. He posed as the champion of Europe against the scourge of Bolshevism and insisted that he was a man of peace who wished only to remove the inequalities of the Versailles Treaty. He withdrew from the Disarmament Conference and from the League of Nations (October 1933), and he signed a nonaggression treaty with Poland (January 1934). Every repudiation of the treaty was followed by an offer to negotiate a fresh agreement and insistence on the limited nature of Germany's ambitions. Only once did the Nazis overreach themselves; when Austrian Nazis, with the connivance of German organizations, murdered Chancellor Engelbert Dollfuss of Austria and attempted a revolt (July 1934). The attempt failed, and Hitler disclaimed all responsibility. In January 1935 a plebiscite in the Saarland, with a more than 90 percent majority, returned that territory to Germany. In March of the same year, Hitler introduced conscription. Although this action provoked protests from Britain, France, and Italy, the opposition was restrained, and Hitler's peace diplomacy was sufficiently successful to persuade the British to negotiate a naval treaty (June 1935) recognizing Germany's right to a considerable navy. His greatest stroke came in March 1936, when he used the excuse of a pact between France and the Soviet Union to march into the demilitarized Rhineland-a decision that he took against the advice of many generals. Meanwhile the alliance with Italy. foreseen in Mein Kampf, rapidly became a reality as a result of the sanctions imposed by Britain and France against Italy during the Ethiopian war. In October 1936, a Rome-Berlin axis was proclaimed by Italian dictator Benito Mussolini; shortly afterward came the Anti-Comintern Pact with Japan; and a year later all three countries joined in a pact. Although on paper France had a number of allies in Europe, while Germany had none, Hitler's Third Reich had become the principal European power.

In November 1937, at a secret meeting of his military

leaders, Hitler outlined his plans for future conquest (beginning with Austria and Czechoslovakia). In January 1938 he dispensed with the services of those who were not wholehearted in their acceptance of Nazi dynamism-Hialmar Schacht, who was concerned with the German economy; Werner von Fritsch, a representative of the caution of professional soldiers; and Konstantin von Neurath, Hindenburg's appointment at the foreign office. In February Hitler invited the Austrian chancellor, Kurt von Schuschnigg, to Berchtesgaden and forced him to sign an agreement including Austrian Nazis within the Vienna government. When Schuschnigg attempted to resist, announcing a plebiscite about Austrian independence, Hitler immediately ordered the invasion of Austria by German troops. The enthusiastic reception that Hitler received convinced him to settle the future of Austria by outright annexation (Anschluss). He returned in triumph to Vienna, the scene of his youthful humiliations and hardships. No resistance was encountered from Britain and France. Hitler had taken special care to secure the support of Italy; as this was forthcoming he proclaimed his undying gratitude to Mussolini.

In spite of his assurances that Anschluss would not affect Germany's relations with Czechoslovakia, Hitler proceeded at once with his plans against that country. Konrad Henlein, leader of the German minority in Czechoslovakia, was instructed to agitate for impossible demands on the part of the Sudetenland Germans, thereby enabling Hitler to move ahead on the dismemberment of Czechoslovakia. Britain's and France's willingness to accept the cession of the Sudetenland areas to Germany presented Hitler with the choice between substantial gains by peaceful agreement or by a spectacular war against Czechoslovakia. The intervention by Mussolini and British prime minister Neville Chamberlain appear to have been decisive. Hitler accepted the Munich Agreement on September 30. He also declared that these were his last territorial demands in Europe.

Only a few months later, he proceeded to occupy the rest of Czechoslovakia. On March 15, 1939, he marched into Prague declaring that the rest of "Czechia" would become a German protectorate. A few days later (March 23) the Lithuanian government was forced to cede Memel (Klaipeda), next to the northern frontier of East Prussia, to Germany.

Immediately Hitler turned on Poland. Confronted by the Polish nation and its leaders, whose resolution to resist him was strengthened by a guarantee from Britain and France, Hitler confirmed his alliance with Italy (the "Pact of Steel," May 1939). Moreover, on August 23, just within the deadline set for an attack on Poland, he signed a nonagression pact with Joseph Stalin's Soviet Union-the greatest diplomatic bombshell in centuries. Hitler still disclaimed any quarrel with Britain, but to no avail; the German invasion of Poland (September 1) was followed two days later by a British and French declaration of war on Ger-

In his foreign policy, Hitler combined opportunism and clever timing. He showed astonishing skill in judging the mood of the democratic leaders and exploiting their weaknesses-in spite of the fact that he had scarcely set foot outside Austria and Germany and spoke no foreign language. Up to this point every move had been successful. Even his anxiety over British and French entry into the war was dispelled by the rapid success of the campaign in Poland. He could, he thought, rely on his talents during the war as he relied on them before.

WORLD WAR II

Germany's war strategy was assumed by Hitler from the first. When the successful campaign against Poland failed to produce the desired peace accord with Britain, he ordered the army to prepare for an immediate offensive in the west. Bad weather made some of his reluctant generals postpone the western offensive. This in turn led to two major changes in planning. The first was Hitler's order to forestall an eventual British presence in Norway by occupying that country and Denmark in April 1940. Hitler took a close personal interest in this daring operation.

Anschluss

Invasion of

From this time onward his intervention in the detail of military operations grew steadily greater. The second was Hitler's important adoption of General Erich von Manstein's plan for an attack through the Ardennes (which began May 10) instead of farther north. This was a brilliant and startling success. The German armies reached the Channel ports (which they had been unable to reach during World War I) in 10 days. Holland surrendered after 4 days and Belgium after 16 days, Hitler held back General Karl von Rundstedt's tanks south of Dunkirk, thus enabling the British to evacuate most of their army. But the Western campaign as a whole was amazingly successful. On June 10 Italy entered the war on the side of Germany. On June 22 Hitler signed a triumphant armistice with the French on the site of the Armistice of 1918.

Hitler hoped that the British would negotiate an armistice. When this did not happen, he proceeded to plan the invasion of Britain, together with the elimination of British air power. At the same time preparations were begun for the invasion of the Soviet Union, which in Hitler's view was Britain's last hope for a bulwark against German control of the continent. Then Mussolini invaded Greece, where the failures of the Italian armies made it necessary for German forces to come to their aid in the Balkans and North Africa. Hitler's plans were further disrupted by a coup d'état in Yugoslavia in March 1941, overthrowing the government that had made an agreement with Germany. Hitler immediately ordered his armies to subdue Yugoslavia. The campaigns in the Mediterranean theatre, although successful, were limited, compared to the invasion of Russia. Hitler would spare few forces from "Operation Barbarossa," the planned invasion of the Sovi-

"Operation

Barba-

rossa*

The attack against the U.S.S.R. was launched on June 22. 1941. The German army advanced swiftly into the Soviet Union, corralling almost three million Russian prisoners, but it failed to destroy its Russian opponent. Hitler became overbearing in his relations with his generals. He disagreed with them about the object of the main attack, and he wasted time and strength by failing to concentrate on a single objective. In December 1941, a few miles before Moscow, a Russian counteroffensive finally made it clear that Hitler's hopes of a single campaign could not be realized

On December 7, the next day, the Japanese attacked U.S forces at Pearl Harbor. Hitler's alliance with Japan forced him to declare war on the United States. From this moment on his entire strategy changed. He hoped and tried (like his idol Frederick II the Great) to break what he deemed was the unnatural coalition of his opponents by forcing one or the other of them to make peace. (In the end, the "unnatural" coalition between Stalin and Winston Churchill and Franklin D. Roosevelt did break up, but too late for Hitler.) He also ordered the reorganization of the

German economy on a full wartime basis.

Meanwhile, Himmler prepared the ground for a "new order" in Europe. From 1933 to 1939 and in some instances even during the first years of the war, Hitler's purpose was to expel the Jews from the Greater German Reich. In 1941 this policy changed from expulsion to extermination. The concentration camps created under the Nazi regime were thereby expanded to include extermination camps, such as Auschwitz, and mobile extermination squads, the Einsatzgruppen. Although Catholics, Poles, homosexuals, Roma (Gypsies), and the handicapped were targeted for persecution, if not outright extermination, the Jews of Germany, Poland, and the Soviet Union were by far the most numerous among the victims; in German-occupied Europe some 6,000,000 Jews were killed during the war. The sufferings of other peoples were only less when measured in their numbers killed.

At the end of 1942, defeat at El-Alamein and at Stalingrad and the American landing in French North Africa brought the turning point in the war, and Hitler's character and way of life began to change. Directing operations from his headquarters in the east, he refused to visit bombed cities or to allow some withdrawals, and he became increasingly dependent on his physician, Theodor Morell, and on the large amounts and varieties of medicines he ingested. Yet Hitler had not lost the power to react vigorously in the face of misfortune. After the arrest of Mussolini in July 1943 and the Italian armistice, he not only directed the occupation of all important positions held by the Italian army but also ordered the rescue of Mussolini, with the intention that he should head a new fascist government. On the eastern front, however, there was less and less possibility of holding up the advance. Relations with his army commanders grew strained, the more so with the growing importance given to the SS (Schutzstaffel) divisions. Meanwhile, the general failure of the U-boat campaign and the bombing of Germany made chances of German victory very unlikely.

Desperate officers and anti-Nazi civilians became ready to Assassinaremove Hitler and negotiate a peace. Several attempts on tion Hitler's life were planned in 1943-44; the most nearly successful was made on July 20, 1944, when Colonel Claus von Stauffenberg exploded a bomb at a conference at Hitler's headquarters in East Prussia. But Hitler escaped with superficial injuries, and, with few exceptions, those implicated in the plot were executed. The reduction of the army's independence was now made complete. National Socialist political officers were appointed to all military

headquarters.

Thereafter, Hitler was increasingly ill; but he did not relax or lose control, and he continued to exercise an almost hypnotic power over his close subordinates, none of whom wielded any independent authority. The Allied invasion of Normandy (June 6, 1944) marked the beginning of the end. Within a few months, eight European capitals (Rome, Paris, Brussels, Bucharest, Sofia, Athens, Belgrade, Helsinki) were liberated by the Allies or surrendered to them. In December 1944 Hitler moved his headquarters to the west to direct an offensive in the Ardennes aimed at splitting the American and the British armies. When this failed, his hopes for victory became ever more visionary, based on the use of new weapons (German rockets had been fired on London since June 1944) or on the breakup of the Allied Powers

After January 1945 Hitler never left the Chancellery in Berlin or its bunker, abandoning a plan to lead a final resistance in the south as the Soviet forces closed in on Berlin. In a state of extreme nervous exhaustion, he at last accepted the inevitability of defeat and thereupon prepared to take his own life, leaving to its fate the country over which he had taken absolute command. Before this, two further acts remained. At midnight on April 28-29 he married Eva Braun. Immediately afterward he dictated his political testament, justifying his career and appointing Admiral Karl Dönitz as head of the state and Josef Goebbels as chancellor.

On April 30 he said farewell to Goebbels and the few others remaining, then retired to his suite and shot himself. His wife took poison. In accordance with his instructions,

their bodies were burned.

Hitler's success was due to the susceptibility of postwar Germany to his unique talents as a national leader. His rise to power was not inevitable; yet there was no one who equalled his ability to exploit and shape events to his own ends. The power that he wielded was unprecedented, both in its scope and in the technical resources at its command. His ideas and purposes were accepted in whole or in part by millions of people, especially in Germany but also elsewhere. By the time he was defeated, he had destroyed most of what was left of old Europe, while the German people had to face what they would later call "Year Zero," 1945. (A.B./W.F.Kn./Ed.)

HITLER'S PLACE IN HISTORY

At the turn of the 21st century more books had been written about Hitler since his death than about Napoleon during the half-century after the latter's demise. Time and distance from the events of World War II have also affected the historical interpretation of Hitler.

There is a general consensus about his historical importance (a term that does not imply a positive judgment). Hitler was principally, and alone, responsible for starting World War II. (This was different from the various responsibilities of rulers and of statesmen who had unleashed

Responsibility for the Holocaust World War I.) His guilt for the implementation of the Holocaust-that is, the shift of German policy from the expulsion to the extermination of Jews, including eventually Jews of all of Europe and of European Russia, is also obvious. Although there exists no single document of his order to that effect, Hitler's speeches, writings, reports of discussions with associates and foreign statesmen, and testimony by those who carried out the actions have often been cited as evidence of his role. Many of his most violent statements were recorded by his minions during his "Table Talks" (including the not entirely authentic "Bormann remarks" of February-April 1945). For example, on January 30, 1939, to celebrate the sixth anniversary of his rule, Hitler told the Reichstag: "Today I will once more be a prophet: If the international Jewish financiers in and outside Europe should succeed in plunging the nations once more in a world war, then the result will not be the Bolshevization of the Earth and thus the victory of Jewry, but the annihilation of the Jewish race in Europe.

In his final will and testament, written just before his suicide in April 1945, he charged the Germans to continue the struggle against the Jews: "Above all, I enjoin the government and the people to uphold the race laws to the limit and to resist mercilessly the poisoner of all nations, inter-

national Jewry."

Despite the immense mass of surviving German documents (and the large volume of his recorded speeches and other statements) Hitter was, as he himself said on a few occasions, a secretive man; and some of his views and decisions differed at times from his public expressions.

For a long time historians and other commentators took it for granted that Hitler's wishes and ambitions and ideology were clearly (and frighteningly) set forth in Mein Kampf, In the first, autobiographical, portion of Mein Kampf, however, he twisted the truth in at least three matters; his relationship to his father (which was very different from the filial affection he had set forth in Mein Kampf); the conditions of his life in Vienna (which were less marked by abject poverty than he had stated); and the crystallization of his worldview, including his anti-Semitism, during his Vienna years (the evidence now suggests that this crystallization occurred much later; in Munich).

The popular view of Hitler often involves assumptions about his mental health. There has been a tendency to attribute madness to Hitler. Despite the occasional evidences of his furious outbursts. Hitler's cruelties and his most extreme expressions and orders suggest a cold brutality that was fully conscious. The attribution of madness to Hitler would of course absolve him from his responsibility for his deeds and words (as it also absolves the responsibility of those who are unwilling to think further about him). Extensive researches of his medical records also indicate that, at least until the last 10 months of his life, he was not profoundly handicapped by illness (except for advancing symptoms of Parkinson disease). What is indisputable is that Hitler had a certain tendency to hypochondria; that he ingested vast amounts of medications during the war; and that as early as 1938 he convinced himself that he would not live long-which may have been a reason for speeding up his timetable for conquest at that time. It should also be noted that Hitler possessed mental abilities that were denied by some of his earlier critics: these included an astonishing memory for certain details and an instinctive insight into his opponents' weaknesses. Again, these talents increase, rather than diminish, his responsibility for the many brutal and evil actions he ordered and committed.

His most amazing achievement was his uniting the great mass of the German (and Austrian) people behind him. Throughout his career his popularity was larger and deeper than the popularity of the National Socialist Party. A great majority of Germans believed in him until the very end. In this respect he stands out among almost all of the dictators of the 19th and 20th centuries, which is especially impressive when we consider that the Germans were among the best-ducated peoples in the 20th century. There is no question that the overwhelming majority of the German people supported Hilter, though often only passively. Their trust in him was greater than their trust in the Nazi hierarchy. Of course, what contributed to this support

were the economic and social successes, for which he fully took credit, during his early leadership: the virtual disappearance of unemployment, the rising prosperity of the masses, the new social institutions, and the increase of German prestige in the 1930s—achievements unparalleled in the histories of other modern totalitarian dictatorships. In spite of the spiritual and intellectual progenitors of some of his ideas there is no German national leader to whom he may be compared. In sum, he had no forerunners—another difference between him and other dictators.

By 1938 Hitler had made Germany the most powerful and feared country in Europe (and perhaps in the world). He achieved all of this without war (and there are now some historians who state that had he died in 1938 before the mass executions began, he would have gone down in history as the greatest statesman in the history of the German people). In fact, he came very close to winning the war in 1940; but the resistance of Britain (personified by Winston Churchill) thwarted him, Nevertheless, it took the overwhelming, and in many ways unusual, Anglo-American coalition with the Soviet Union to defeat the Third Reich: and there are reasons to believe that neither side would have been able to conquer him alone. At the same time it was his brutality and some of his decisions that led to his destruction, binding the unusual alliance of capitalists and communists, of Churchill and Roosevelt and Stalin together. Hitler thought he was a great statesman, but he did not realize the unconditional contemptibility of what he had unleashed; he thought that the coalition of his enemies would eventually break up, and then he would be able to settle with one side or the other. In thinking thus he deceived himself, though such wishes and hopes were also current among many Germans until the end.

Open and hidden admirers of Hiller continue to exist (and not only in Germany): some of them because of a malign attraction to the efficacy of evil; others because of their admiration of Hiller's achievements, no matter how transitory or brutal. However, because of the brutalities and the very crimes associated with his name, it is not likely that Hiller's reputation as the incarnation of evil will ever change. (J.Lu.)

The Holocaust

The Holocaust (Hebrew: Sho'ah: Yiddish and Hebrew: Hurban ["Destruction"]) was the systematic state-sponsored killing of six million Jewish men, women, and children and millions of others by Nazi Germany and its collaborators during World War II. The Germans called this "the final solution to the Jewish question." The word Holocaust is derived from the Greek holokauston, a translation of the Hebrew word 'olah, meaning a burnt sacrifice offered whole to God. This word was chosen because in the ultimate manifestation of the Nazi killing program-the extermination camps-the bodies of the victims were consumed whole in crematoria and open fires.

Nazi anti-Semitism. Even before the Nazis came to power in Germany in 1933, they had made no secret of their anti-Semitism. As early as 1919, Adolf Hitler had written, "Rational anti-Semitism, however, must lead to systematic legal opposition.... Its final objective must unswervingly be the removal of the Jews altogether." In Mein Kampf ("My Struggle"; 1925-27), Hitler further developed the idea of the Jews as an evil race struggling for world domination. Nazi anti-Semitism was rooted in religious anti-Semitism and enhanced by political anti-Semitism. To this the Nazis added a further dimension: racial anti-Semitism. Nazi racial ideology characterized the Jews as Untermenschen (German: "subhumans"). The Nazis portrayed Jews as a race and not a religious group. Religious anti-Semitism could be resolved by conversion, political anti-Semitism by expulsion. Ultimately, the logic of Nazi racial anti-Semitism led to annihilation.

When Hitler came to power legally on January 30, 1933, as the head of a coalition government, his first objective was to consolidate power and to eliminate political opposition. The assault against the Jews began on April 1 with a boycott of Jewish businesses. A week later the Nazis dismissed Jews from the civil service, and by the end of the month, the participation of Jews in German schools was restricted by a quota, On May 10, thousands or Nazi students, together with many professors, stormed university libraries and bookstores in 30 cities throughout Germany to remove tens of thousands of books written by non-Aryans and those opposed to Nazi ideology. The books were tossed into bonfires in an effort to cleanse German culture of "un-Germanic" writings. A century earlier, Heinrich Heine-a German poet of Jewish origin-had said, "Where one burns books, one will, in the end, burn people." In Nazi Germany, the time between the burning of Jewish books and the burning of Jews was eight years.

As discrimination against Jews increased, German law required a legal definition of a Jew and an Aryan. Promulgated at the annual Nazi Party rally in Nürnberg on September 15, 1935, the Nürnberg Laws-the Law for the Protection of German Blood and German Honour and the Law of the Reich Citizen-became the centerpiece of anti-Jewish legislation and a precedent for defining and categorizing Jews in all German-controlled lands. Marriage and sexual relations between Jews and citizens of "German or kindred blood" were prohibited. Only "racial" Germans were entitled to civil and political rights. Jews were reduced to subjects of the state. The Nürnberg Laws formally divided Germans and Jews, yet neither the word German nor the word Jew was defined. That task was left to the bureaucracy. Two basic categories were established in November: Jews-those with at least three Jewish grandparents-and Mischlinge ("mongrels," or "mixed breeds")-people with one or two Jewish grandparents. Thus, the definition of a Jew was primarily based not on the identity an individual affirmed or the religion he practiced but on his ancestry. Categorization was the first stage of destruction.

Responding with alarm to Hitler's rise, the Jewish community sought to defend their rights as Germans. For those Jews who felt themselves fully German and who had patriotically fought in World War I, the Nazification of German society was especially painful. Zionist activity intensified. "Wear it with pride," journalist Robert Wildest wrote in 1933 of the Jewish identity the Nazis had so stigmatized. Martin Buber led an effort at Jewish adult education, preparing the community for the long journey ahead. Rabbi Leo Baeck circulated a prayer for Yom Kippur (the Day of Atonement) in 1935 that instructed Jews how to behave: "We bow down before God; we stand erect before man." Yet while few, if any, could foresee its eventual outcome, the Jewish condition was increasingly perilous and expected to get worse.

By the late 1930s there was a desperate search for countries of refuge. Those who could get visas and qualify under stringent quotas emigrated to the United States. Many went to Palestine, where the small Jewish community was willing to receive refugees. Still others sought refuge in neighbouring European countries. Most countries, however were unwilling to receive large numbers of refugees.

Responding to domestic pressures to act on behalf of Jewish refugees, U.S. President Franklin D. Roosevelt convened, but did not attend, the Evian Conference on

Nürnberg Laws

resettlement, in Évian-les-Bains, France, in July 1938. In his invitation to government leaders, Roosevelt specified that they would not have to change laws or spend government funds; only philanthropic funds would be used for resettlement. The result was that little was attempted, and less accomplished.

Kristallnacht. On the evening of November 9, 1938, carefully orchestrated anti-lewish violence "crupted" throughout the Reich, which since March had included Austria. Over the next 48 hours rioters burned or damaged more than 1,000 synagogues and ransacked and broke the windows of more than 7,500 businesses. The Nazis arrested some 30,000 Jewish men between the ages of 16 and 60 and sent them to concentration camps. Police stood by as the violence—often the action of neighbours, not strangers—occurred. Firemen were present not to protect the synagogues but to ensure that the flames did not spread to adjacent "Aryam" property. The pogrom was given a quaint name. Kristallhacht ("Crystal Night," or "Night of Broken Glass"). In its aftermath, Jews lost the illusion that they had a future in Germany.

On November 12, 1938, Field Marshall Hermann Göring convened a meeting of Nazi officials to discuss the damage to the German economy from pogroms. The Jewish community was fined one billion Reichsmarks. Moreover, Jews were made responsible for cleaning up the damage. German Jews, but not foreign Jews, were barred from collecting insurance. In addition, Jews were soon denied entry to theatres, forced to travel in separate compartments on trains, and excluded from German schools. These new restrictions were added to earlier prohibitions, such as those barring Jews from earning university degrees, from owning businesses, or from practicing law or medicine in the service of non-Jews. The Nazis would continue to confiscate Jewish property in a program called "Aryanization." Göring concluded the November meeting with a note of irony: "I would not like to be a Jew in Germany!"

Non-Jewish victims of Nazism. While Jews were the primary victims of Nazism as it evolved and were central to Nazi racial ideology, other groups were victimized as well—some for what they did, some for what they refused

to do, and some for what they were.

Political dissidents, trade unionists, and Social Democrats were among the first to be arrested and incarcerated in concentration camps. Under the Weimar government, centuries-old prohibitions against homosexuality had been overlooked, but this tolerance ended violently when the SA (Storm Troopers) began raiding gay bars in 1933. Homosexual intent became just cause for prosecution. The Nazis arrested German and Austrian male homosexuals-there was no systematic persecution of lesbians-and interned them in concentration camps, where they were forced to wear special yellow armbands and later pink triangles. Jehovah's Witnesses were a problem for the Nazis because they refused to swear allegiance to the state, register for the draft, or utter the words "Heil Hitler." As a result the Nazis imprisoned many of the roughly 20,000 Witnesses in Germany. The Nazis also singled out the Roma (Gypsies). They were the only other group that the Nazis systematically killed in gas chambers alongside the Jews.

In 1939 the Germans initiated the T4 Program—framed euphemistically as a "euthanasia" program—for the murder of mentally retarded, physically disabled, and emotionally disturbed Germans who departed from the Nazi ideal of Aryan supremacy. The Nazis pioneered the use of gas chambers and mass crematoria under this program.

Following the invasion of Poland, German occupation policy specially targeted the Iews but also brutalized non-Jewish Poles. In pursuit of Lehensraum ("living space"), Germany sought systematically to destroy Polish society and nationhood. The Nazis killed Polish priests and politicians, decimated the Polish leadership, and kidnapped the children of the Polish elte, who were raised as "voluntary Aryans" by their new German "parents." Many Poles were also forced to perform hard labour on survival diets, de-prived of property and uprooted, and interned in concentration camps.

Nazi expansion and the formation of ghettos. Paradoxically, at the same time that Germany tried to rid itself of

its Jews via forced emigration, its territorial expansions kept bringing more Jews under its control. Germany annexed Austria in March 1938 and the Sudetenland (now in the Czech Republic) in September 1938. It established control over the Protectorate of Bohemia and Moravia (now in the Czech Republic) in March 1939. When Germany invaded Poland on September 1, 1939, the 'Jewshi question' became urgent. When the division of Poland between Germany and the Soviet Union was complete, more than two million more Jews had come under German control. For a time, the Nazis considered shipping the Jews to the island of Madagascar, off the southeast coast of Africa. But as the seas became a war zone and the resources required for such a massive deportation scarce, they discarded the plan as impractical.

On September 21, 1939, Reinhard Heydrich ordered the establishment of the Judenzite ("Jewish Councils"), comprising up to 24 men—rabbis and Jewish leaders. Heydrich's order made these councils personally responsible in "the literal sense of the term" for earrying out German orders. When the Nazis sealed the Warsaw Ghetto, the largest of German-occupied Poland's 400 ghettos, in the fall of 1940, the Jews—then 30 percent of Warsaw's population—were forced into 2.4 percent of the city's area. The ghetto's population reached a density of over 200,000 per sons per square mile (77,000 per square km) and 9.2 per room. Disease, malnutrition, hunger, and poverty took their toll even before the first bullet was first bullet was fresh to the catalogue.

For the German rulers, the ghetto was a temporary measure, a holding pen for the Jewish population until a policy on its fate could be established and implemented. For the Jews, ghetto life was the situation under which they thought they would be forced to live until the end of the war. They aimed to make life bearable, even under the most trying circumstances. When the Nazis prohibited schools, they opened clandestine schools. When the Nazis banned religious life, it persisted in hiding. The Jews used humour as a means of defiance, so too song. They resorted to arms only late in the Nazi sasault.

Historians differ on the date of the decision to murder Jews systematically, the so-called "final solution to the Jewish question." There is debate about whether there was one central decision or a series of regional decisions in response to local conditions, but in either case, when Germany attacked the Soviet Union, its former ally, in June of 1941, the Nazis began the systematic killing of Jews.

SYSTEMATIC KILLING

The Einsatzgruppen. Entering conquered Soviet territories alongside the Wehrmacht (the German armed forces) were 3,000 men of the Einsatzgruppen ("deployment groups"), special mobile killing units. Their task was to murder Jews, Soviet commissars, and Roma in the areas conquered by the army. Alone or with the help of local police, native anti-Semitic populations, and accompanying Axis troops, the Einsatzgruppen would enter a town, round up their victims, herd them to the outskirts of the town, and shoot them. They killed Jews in family units, Just outside Kiev, Ukraine, in the valley of Baby Yar, an Einsatzgruppe killed 33,771 Jews on September 28-29, 1941. In the Rumbula Forest outside the ghetto in Riga, Latvia, 25,000-28,000 Jews died on November 30 and December 8-9. Beginning in the summer of 1941. Einsatzgruppen killed more than 70,000 Jews at Ponary, outside Vilna (now Vilnius) in Lithuania. They slaughtered 9,000 Jews, half of them children, at the Ninth Fort adjacent to Kovno (now Kaunas), Lithuania, on October 28.

The mass shootings continued unabated, with a first wave and then a second. When the killing ended in the face of a Soviet counteroffensive, special units returned to dig up the dead and burn their bodies to destroy the evidence of the crimes. It is estimated that the Einsatzgrappen killed more than one million people, most of whom were Jews.

Historians are divided about the motivations of the members of Einsatgruppen. Christopher Browning describes them as ordinary men in extraordinary circumstances in which conformity, peer pressure, careerism, obedience to orders, and group solidarity gradually overcame moral inhibitions. Daniel Goldhagen sees them as

The Judenräte

Persecution of homosexuals "willing executioners," sharing Hitler's vision of genocidal anti-Semitism and finding their tasks unpleasant but necessary. Both concur that no Einsatzgruppe member faced punishment if he asked to be excused. Individuals had a choice whether to participate or not. Almost all chose to become killers.

The extermination camps. On January 20, 1942, Reinhard Heydrich convened the Wannsee Conference at a lakeside villa in a Berlin suburb to organize the "final solution to the Jewish question." Around the table were 15 men representing government agencies necessary to implement so bold and sweeping a policy. The language of the meeting was clear, but the meeting notes were circumspect: "Another possible solution to the [Jewish] question has now taken the place of emigration, i.e., evacuation to the east.... Practical experience is already being collected which is of the greatest importance in the relation to the future final solution of the Jewish question." Participants understood "evacuation to the east" to mean deportation to killing centres.

In early 1942 the Nazis built extermination camps at Treblinka, Sobibor, and Belzec in Poland. The death camps were to be the essential instrument of the "final solution." The Einsatzgruppen had traveled to kill their victims. With the extermination camps, the process was reversed. The victims traveled by train, often in cattle cars, to their killers. The extermination camps became factories producing corpses, effectively and efficiently, at minimal physical and psychological cost to German personnel. Assisted by Ukrainian and Latvian collaborators and prisoners of war. a few Germans could kill tens of thousands of prisoners each month. At Chelmno, the first of the extermination camps, the Nazis used mobile gas vans. Elsewhere, they built permanent gas chambers linked to the crematoria where bodies were burned. Carbon monoxide was the gas of choice at most camps. Zyklon-B, an especially lethal killing agent, was employed primarily at Auschwitz and

later at other camps.

Auschwitz, perhaps the most notorious and lethal of the concentration camps, was actually three camps in one: a prison camp (Auschwitz I), an extermination camp (Auschwitz II-Birkenau), and a slave-labour camp (Auschwitz III-Buna-Monowitz). Upon arrival, Jewish prisoners faced what was called a Selektion, A German doctor presided over the selection of pregnant women, young children, the elderly, handicapped, sick, and infirm for immediate death in the gas chambers. As necessary, the Germans selected able-bodied prisoners for forced labour in the factories adjacent to Auschwitz where one German company, IG Farben, invested 700,000 million Reichsmarks in 1942 alone to take advantage of forced labour. Deprived of adequate food, shelter, clothing, and medical care, these prisoners were literally worked to death. Periodically, they would face another Selektion. The Nazis would transfer those unable to work to the gas chambers of

While the death camps at Auschwitz and Majdanek used inmates for slave labour to support the German war effort, the extermination camps at Belzec, Treblinka, and Sobibor had one task alone: killing. At Treblinka, a staff of 120, of whom only 30 were SS (the Nazi paramilitary corps), killed some 750,000 to 900,000 Jews during the camp's 17 months of operation. At Belzec, German records detail a staff of 104, including about 20 SS, who killed some 600,000 Jews in less than 10 months. At Sobibor, they murdered about 250,000. These camps began operation during the spring and summer of 1942, when the ghettos of German-occupied Poland were filled with Jews. Once they had completed their missions-murder by gassing, or "resettlement in the east," to use the language of the Wannsee protocols-the Nazis closed the camps. There were six extermination camps, all in German-occupied Poland, among the thousands of concentration and slavelabour camps throughout German-occupied Europe.

The impact of the Holocaust varied from region to region, and from year to year in the 21 countries that were directly affected. Nowhere was the Holocaust more intense and sudden than in Hungary. What took place over several years in Germany occurred over 16 weeks in Hungary. Entering the war as a German ally, Hungary had persecuted its Jews but not permitted their deportation. After Germany invaded Hungary on March 19, 1944, this situation changed dramatically. By mid-April the Nazis had confined Jews to ghettos. On May 15, deportations began, and over the next 55 days, the Nazis deported some 438,000 Jews from Hungary to Auschwitz on 147 trains.

Policies differed widely among Germany's Balkan allies. In Romania it was primarily the Romanians themselves who slaughtered the country's Jews. Toward the end of the war, however, when the defeat of Germany was all but certain, the Romanian government found more value in living Jews who could be held for ransom or used as leverage with the West, Bulgaria permitted the deportation of Jews from neighbouring Thrace and Macedonia, but government leaders faced stiff opposition to the deportation of native Bulgarian Jews.

German-occupied Denmark rescued most of its own Jews by spiriting them to Sweden by sea in October 1943. This was possible partly because the German presence in Denmark was relatively small. Moreover, while anti-Semitism in the general population of many other countries led to collaboration with the Germans, Jews were an integrated part of Danish culture. Under these unique circumstances, Danish humanitarianism flourished.

In France, Jews under Fascist Italian occupation in the southeast fared better than the Jews of Vichy France. where collaborationist French authorities and police provided essential support to the understaffed German forces. The Jews in those parts of France under direct German occupation fared the worst. Although allied with Germany, the Italians did not participate in the Holocaust until Germany occupied northern Italy after the overthrow of the Fascist leader, Benito Mussolini.

Throughout German-occupied territory the situation of Jews was desperate. They had meagre resources and few allies and faced impossible choices. A few people came to their rescue, often at the risk of their own lives. Swedish diplomat Raoul Wallenberg arrived in Budapest on July 9. 1944, in an effort to save Hungary's sole remaining Jewish community. Over the next six months, he worked with other neutral diplomats, the Vatican, and Jews themselves to prevent the deportation of these last Jews. Elsewhere, Le Chambon-sur-Lignon, a French Huguenot village, became

a haven for 5,000 Jews. In Poland, where it was illegal to

aid Jews and where such action was punishable by death,

the Zegota (Council for Aid to Jews) rescued a similar

number of Jewish men, women, and children. Financed by the Polish government in exile and involving a wide range of clandestine political organizations, the Zegota provided hiding places, financial support, and forged identity docu-

Some Germans, even some Nazis, dissented from the murder of the Jews and came to their aid. The most famous was Oskar Schindler, a Nazi businessman, who had set up operations using involuntary labour in German-occupied Poland in order to profit from the war. Eventually, he moved to protect his Jewish workers from deportation to extermination camps. In all occupied countries, there were individuals who came to the rescue of Jews, offering a place to hide, some food, or shelter for days, weeks, or even for the duration of the war. Most of the rescuers did not see their actions as heroic but felt bound to the Jews by a common sense of humanity. Israel later recognized rescuers with honorary citizenship and commemoration at

Yad Vashem, Israel's memorial to the Holocaust. Jewish resistance. It is often asked why Jews did not make greater attempts at resistance. Principally they had no access to arms and were surrounded by native anti-Semitic populations who collaborated with the Nazis or condoned the elimination of the Jews. In essence the Jews stood alone against a German war machine zealously determined to carry out the "final solution." Moreover, the Nazis went to great lengths to disguise their ultimate plans. Because of the German policy of collective reprisal, Jews in the ghettos often hesitated to resist. This changed when the Germans ordered the final liquidation of the ghettos, and residents recognized the imminence of their death.

Jews resisted in the forests, in the ghettos, and even in the

Auschwitz

death camps. They fought alone and alongside resistance groups in France, Yugoslavia, and Russia. As a rule, fullscale uprisings occurred only at the end, when Jews realized the inevitability of impending death. On April 19, 1943, nine months after the massive deportations of Warsaw's Jews to Treblinka had begun, the Jewish resistance, led by 24-year-old Mordecai Anielewicz, mounted the Warsaw Ghetto Uprising. In Vilna partisan leader Abba Kovner, recognizing the full intent of Nazi policy toward the Jews, called for resistance in December 1941 and organized an armed force that fought the Germans in September 1943. In March of that year, a resistance group led by Willem Arondeus, a homosexual artist and author, bombed a population registry in Amsterdam to destroy the records of Jews and others sought by the Nazis. At Treblinka and Sobibor uprisings occurred just as the extermination camps were being dismantled and their remaining prisoners were soon to be killed. This was also true at Auschwitz, where the Sonderkommando ("Special Commando"), the prisoner unit that worked in the vicinity of the gas chambers, destroyed a crematorium just as the killing was coming to an end in 1944.

Concealment and liberation. By the winter of 1944-45, with Allied armies closing in, desperate SS officials tried frantically to evacuate the camps and conceal what had taken place. They wanted no eyewitnesses remaining. Prisoners were moved westward, forced to march toward the heartland of Germany. There were over 50 different marches from Nazi concentration and extermination camps during this final winter of Nazi domination, some covering hundreds of miles. The prisoners were given little or no food and water, and almost no time to rest or take care of bodily needs. Those who paused or fell behind were shot. In January 1945, just hours before the Red Army arrived at Auschwitz, the Nazis marched some 60,000 prisoners to Wodzisław and put them on freight trains to the camps at Bergen-Belsen, Gross-Rosen, Buchenwald, Dachau, and Mauthausen. Nearly one in four died en

In April and May of 1945, American and British forces en route to military targets entered the concentration camps in the west and caught a glimpse of what had occurred. Even though tens of thousands of prisoners had perished, these camps were far from the most deadly. Still, even for the battle-weary soldiers who thought they had already seen the worst, the sights and smells and the emaciated survivors they encountered left an indelible impression. At Dachau they came upon 28 railway cars stuffed with dead bodies. Conditions were so horrendous at Bergen-Belsen that some 28,000 inmates died after they were freed, and the entire camp had to be burned to prevent the spread of typhus. Allied soldiers had to perform tasks for which they were ill-trained: to heal the sick, comfort the bereaved, and bury the dead. As for the victims, liberation was not a moment of exultation. Viktor Frankl, a survivor of Auschwitz, recalled, "Everything was unreal. Unlikely as in a dream. Only later-and for some it was very much later or never-was liberation actually liberating.

The Allies, who had early and accurate information on the murder of the Jews, made no special military efforts to rescue them or to bomb the camps or the railroad tracks leading to them. They felt that only after victory could something be done about the Jewish situation. Warnings were issued, condemnations were made, plans proceeded to try the guilty after the war, but no concrete action was undertaken specifically to halt the genocide. An internal memo to U.S. Secretary of the Treasury Henry Morgenthau, Jr., from his general counsel in January 1944 characterized U.S. State Department ploties as "acquiescence to the murder of the European Jews." In response Morgenthau hepded spur the creation of the War Refugee Board, which made a late and limited effort to rescue endangered Jews, mainly through diplomacy and subterfuse.

Refugee

Board

Displacement of the survivors. Although the Germans killed victims from several groups, the Holocaust is primarily associated with the murder of the Jews. Only the Jews were targeted for total annihilation, and their elimination

was central to Hitler's vision of the "New Germany." The intensity of the Nazi campaign against the Jews continued unabated to the very end of the war and at points even took priority over German military efforts.

took pronty over terman minutary citors. When the war ended, Allied armies found between seven and nine million displaced persons living outside their own countries. More than six million people returned to their native lands, but more than one million refused repatriation. Some had collaborated with the Nazis and feared retaliation. Others feared persecution under the new communist regimes. For the Jews, the situation was different. They had no homes to return to. Their communities had been shattered, their homes destroyed or occupied by strangers, and their families decimated and dispersed. First came the often long and difficult physical recuperation from starvation and malnutrition, then the search for loved ones lost or missing, and finally the question of the future.

Many Jews lived in displaced-persons camps. At first they were forced to dwell among their killers because the Allies did not differentiate on the basis of religion, merely by nationality. Their presence on European soil and the absence of a country willing to receive them increased the pressure on Britain to resolve the issue of a Jewish homeland in British-administered Palestine. Both well-publicized and clandestine efforts were made to bring Jews to Palestine. In fact, it was not until after the establishment of the State of Israel in May 1948 and the liberalization of American immigration laws in 1948 and 1949 (allowing the admission of refugees from Europe) that the problem of finding homes for the survivors was olived.

Trial of the perpetrators. Upon liberating the camps, many Allied units were so shocked by what they saw that they meted out spontaneous punishment to some of the remaining SS personnel. Others were arrested and held for trial. The most famous of the postwar trials occurred in 1945-46 at Nürnberg, the former site of Nazi Party rallies. There, the International Military Tribunal tried 22 major Nazi officials for war crimes, crimes against the peace, and a new category of crimes: crimes against humanity. This new category encompassed "murder, extermination, enslavement, deportation, and other inhumane acts committed against any civilian population...persecution on political, racial, or religious grounds . . . whether or not in violation of the domestic laws of the country where perpetrated." After the first trials, 185 defendants were divided into 12 groups, including physicians responsible for medical experimentation (but not so-called euthanasia), judges who preserved the facade of legality for Nazi crimes, Einsatzgruppe leaders, commandants of concentration camps, German generals, and business leaders who profited from slave labour. The defendants made up, however, a minuscule fraction of those who had perpetrated the crimes. In the eyes of many, their trials were a desperate, inadequate, but necessary effort to restore a semblance of justice in the aftermath of so great a crime. The Nürnberg trials established the precedent, later enshrined by international convention, that crimes against humanity are punishable by

an international tribunal. Over the ensuing half-century, additional trials further documented the nature of the crimes and had a public as well as a judicial impact. The 1961 trial in Jerusalem of Adolf Eichmann, who supervised the deportations of Jews to the death camps, not only brought him to justice but made a new generation of Israelis keenly aware of the Holocaust. The Auschwitz trials held in Frankfurt am Main, West Germany, between 1963 and 1976 increased the German public's knowledge of the killing and its pervasiveness. The trials in France of Klaus Barbie (1987) and Maurice Papon (1996-98) and the revelations of François Mitterrand in 1994 concerning his indifference toward Vichy France's anti-Jewish policy called into question the notion of French resistance and forced the French to deal with the issue of collaboration. These trials also became precedents as world leaders considered responses to other crimes against humanity in places such as Bosnia and

Rwanda.

Legacy of the Holocaust. The defeat of Nazi Germany left a bitter legacy for the German leadership and people.

The Nürnberg

Germans had committed crimes in the name of the German people. German culture and the German leadership-political, intellectual, social, and religious-had participated or been complicit in the Nazi crimes or been ineffective in opposing them. In an effort to rehabilitate the good name of the German people, the Federal Republic of Germany (West Germany) firmly established a democracy that protected the human rights of all its citizens and made financial reparations to the Jewish people in an agreement passed by parliament in 1953. West German democratic leaders made special efforts to achieve friendly relations with Israel. In the German Democratic Republic (East Germany), the communist leaders attempted to absolve their population of responsibility for the crimes, portraying themselves as the victims of the Nazis, and Nazism as a manifestation of capitalism. The first gesture of the postcommunist parliament of East Germany, however, was an apology to the Jewish people. At one of its first meetings in the newly renovated Reichstag building in 1999, the German parliament voted to erect a Holocaust memorial in Berlin. The first state visitor to Berlin after its reestablishment as capital of a united Germany was Israeli Prime

Minister Ehud Barak. At the beginning of the 21st century, the history of the Holocaust continued to be unsettling. The Swiss government and its bankers had to confront their role as bankers to the Nazis and in recycling gold and valuables taken from the victims. Under the leadership of German prime minister Gerhard Schröder, German corporations and the German government established a fund to compensate Jews and non-Jews who worked in German slave labour and forced labour programs during the war. Insurance companies were negotiating over claims from descendants of policyholders killed during the war-claims that the companies denied immediately after the war by imposing prohibitive conditions, such as the presentation of a death certificate specifying the time and place of death of the insured. In several eastern European countries, negotiations addressed Jewish property that the Nazis had confiscated during the war but that could not be returned under the region's communist governments. Artworks stolen during the war and later sold on the basis of dubious records were the subject of legal struggles to secure their return to the original owners or to their heirs. The German government continued to pay reparations-first awarded in 1953-to individual Jews and the Jewish people to acknowledge responsibility for the crimes committed in the name of the German people.

Artistic responses to the Holocaust. Artists the world over and camp survivors themselves have responded to the Holocaust through art. The very existence of Holocaust art can, however, create a sense of unease. Critic Irving Howe has asked, "Can imaginative literature represent in any profound or illuminating way the meanings of the Holocaust? Is 'the debris of our misery' (as one survivor described it) a proper or manageable subject for stories and novels? Are there not perhaps extreme situations beyond the reach of art?" Similarly, philosopher Theodore Adorno has commented that writing poetry after Auschwitz is barbaric. Yet poetry has been written-moving poetry that seeks to come to terms with the tragedy even in the German language-in works by Nelly Sachs and Paul Celan. among others. Gripping work dealing with the horror, pain, and loss of the Holocaust has appeared in every literary genre and in music, film, painting, and sculpture.

Survivors of the Holocaust have produced powerful works that record or reflect on their experiences. Anne Frank's The Diary of a Young Girl (originally in Dutch, 1947), Eli Wiesel's Night (originally in Yiddish, 1956), and works by Primo Levi are some of the most memorable in the field of literature. Paintings and drawings by survivors Samuel Bak, Alice Lok Cahana, and David Olère document the horrors that they experienced in ghettos and death camps. Holocaust survivors have also composed a wide variety of music, including street songs, which gave voice to life in the ghetto; resistance songs, such as Hirsh Glik's "Song of the Partisans" (composed and first performed 1943, published 1953); and classical compositions, such as Ouartet for the End of Time (first performed 1941) by Olivier Messiaen and the opera Der Kaiser von Atlantis oder der Tod dankt ab (first performed 1943; "The Em-

peror of Atlantis or Death Abdicates") by Victor Ullman. Artists of all kinds, regardless of any firsthand experience with the Holocaust, have sought to grapple with this tragedy. George Segal's memorial sculpture, Holocaust, is but one notable example. Visual art in response to the Holocaust includes paintings by Holocaust refugees Marc Chagall and George Grosz and the illustrated story Maus (published in installments 1980-85) by Art Spiegelman, the son of a survivor. Notable musical responses to the Holocaust include Arnold Schoenberg's A Survivor from Warsaw (first performed 1947), Dmitri Shostakovich's 13th Symphony (first performed 1962), which used the text of the poem "Baby Yar" (1961) by Yevgeny Yevtushenko, and works by composers Charles Davidson, Michael Horvitz, and Oskar Morawetz.

Film, too, has been a prime medium for dealing with the Holocaust. Shortly after World War II, several eastern Furopean filmmakers, including Aleksander Ford, Wanda Jakubowska, and Alfred Radok, attempted to capture the experience of Holocaust victims. Some of the most influential films since then include The Diary of Anne Frank (1959), directed by George Stevens; Il Giardino dei Finzi-Contini (1970, The Garden of the Finzi Continis), directed by Vittorio De Sica; the nine-hour documentary Shoah (1985), directed by Claude Lanzmann; Au Revoir les Enfants (1987, Goodbye, Children), directed by Louis Malle; Schindler's List (1993), directed by Steven Spielberg; La Vita è Bella (1997; Life Is Beautiful), directed by Roberto Benigni; and Bent (1997), directed by Sean Mathias and based on Martin Sherman's 1979 play about the Nazi persecution of homosexuals.

CONCLUSION

Today the Holocaust is viewed as the emblematic manifestation of absolute evil. Its revelation of the denths of human nature and the power of malevolent social and governmental structures has made it an essential topic of ethical discourse in fields as diverse as law, medicine, religion, government, and the military.

Many survivors report they heard a final plea from those who were killed: "Remember! Do not let the world forget. To this responsibility to those they left behind, survivors have added a plea of their own: "Never again." Never for the Jewish people. Never for any people. They hope that remembrance of the Holocaust can prevent its recurrence. In part because of their efforts, interest in the event has increased rather than diminished with the passage of time and in fact Holocaust Remembrance days are observed each year in many countries. More than half a century after the Holocaust, institutions, memorials, and museums continue to be built and films and educational curricula created to document and teach the history of the Holocaust to future generations.

General references and histories: ISRAEL GUTMAN (ed.), Encyclopedia of the Holocaust, 4 vol. (1990, reissued 4 vol. in 2, 1995), is a comprehensive and authoritative reference work. A useful reference on the geographic extent of the Holocaust is the UNIT-ED STATES HOLOCAUST MEMORIAL MUSEUM, Historical Atlas of the Holocaust (1996). MICHAEL BERENBAUM (ed.), Witness to the Holocaust (1997), contains 94 basic documents on 21 major themes, from the Nazi rise to power to the Nürnberg trials. MICHAEL R. MARRUS, The Holocaust In History (1987, reissued 1989), offers insights on a variety of historical debates surrounding the Holocaust. MICHAEL BERENBAUM, The World Must Know: The History of the Holocaust as Told in the United States Holocaust Memorial Museum (1993) is a non-technical, illustrated history of the Holocaust. Other general histories of the Holocaust include MARTIN GILBERT, The Holocaust: A History of the Jews of Europe During the Second World War (1986); RAUL HILBERG, The Destruction of the European Jews, rev. and definitive ed., 3 vol. (1985); LENI YAHIL, The Holocaust: The Fate of European Jewry, 1932-45 (1990; originally published in Hebrew, 1987); and SAUL FRIEDLÄNDER, Nazi Germany and the Jews, vol. 1, The Years of Persecution, 1933-39 (1997), the first of two planned volumes.

The perpetrators: For first-hand accounts of the Holocaust from the viewpoint of perpetrators and bystanders, see ERNST KLEE, WILLI DRESSEN, and VOLKER RIESS (eds.), "The Good Old

Compensation

Literature of the Holocaust Days": The Holocaust as Seen by Its Perpetrators and Bystanders, trans. from German (1991; also published as "Those Were the Days": The Holocaust through the Eyes of the Perpetrators and Bystanders, 1993). HELEN FEIN, Accounting for Genocide: National Responses and Jewish Victimization During the Holocaust (1979, reprinted 1984), presents a sociological account of genocide and the social forces that make it possible. DANIEL JONAH GOLDHAGEN, Hitler's Willing Executioners: Ordinary Germans and the Holocaust (1996), is a controversial work exploring the rise of anti-Semitism in Germany and the complicity of ordinary Germans in the Holocaust. For an account of the human impact of the killing process in one Einsatzgruppe, see CHRISTOPHER R. BROWNING, Ordinary Men. Reserve Police Battalion 101 and the Final Solution in Poland (1992, reissued 1998). HENRY FRIED-LANDER, The Origins of Nazi Genocide: From Euthanasia to the Final Solution (1995), traces the development of genocidal policies and techniques in the Nazi T4 Program. GITTA SERENY, Into that Darkness (1974, reprinted 1991), offers a chilling account of prison interviews with Franz Stangl, commandant of Sobibor and Treblinka and a product of the German T4 camps, ROBERT JAY LIFTON, The Nazi Doctors: Medical Killing and the Psychology of Genocide (1986), explores the role and psychology of Nazi physicians, Biographies of Nazi architects of the Holocaust include RICHARD BREITMAN, The Architect of Genocide: Himmler and the Final Solution (1991), and ALAN BULLOCK, Hitler: A Study in Tyranny, completely rev. ed. (1962, reissued 1995), also published in an abridged ed. with the same title (1971, reissued 1991). JOHN LUKACS, The Hitler of History (1997), is less a biography of Hitler and more a review of the way in which historians have treated him.

The victims: ISAIAI TRUNK, Juderrat: The Jewish Council in Eastern Europe under Nozi Occupation (1972, reissued 1996), describes the dilemma facing the Jewish Councils in the ghettos in their efforts to reconcile Jewish needs with Nazi demands. For an account of ghetto life and Jewish resistance to German aggression, see LUCY, S. DAWIDOWICZ, The War Against the Jews,

1933-1945, 10th anniversary ed. (1986, reissued 1990). YIRRAEL CUITMAN (Stata Guttman) and MICHAEL BERENAUM (eds.), Auatomy of the Austchwitz Death Camp (1994, reissued 1998), a collection of essays, considers Auschwitz in content, each of its victim groups, and the inner life of both perpetrators and victims. TEREBECE DE SPERS, The Survivor-An Anadomy of Life in the Death Camps (1976, reissued 1980), considers the experience of extermination camp inmates from a psychological viewpoint. LAWBENCE L. LANGER, Holocaust Testimonies: The Ruins of Memory (1991) explores the power of Holocaust survivors testimonies and memories of their experience. Important firsthand accounts by Holocaust survivors include PRINO LEVI, If This is a Man (1959, originally published in Italian, 1947; also published as Survival in Auschwitz, 1961, reissued 1996, and ELIE WISELI, Night (1960, reissued 1986; originally published in Yiddish, 1956).

Edited volumes containing essays on different aspects of the Holocaust include JOHN K. ROTH and MICHAEL BERENBAUM (eds.), The Holocaust: Religious and Philosophical Implications (1989), on religious and philosophical issues related to the Holocaust; LAWRENCE L. LANGER (ed.), Art from the Ashes (1995), presenting art and literature on the Holocaust; CAROL RITTNER and JOHN K. ROTH (eds.), Different Voices: Women and the Holocaust (1993), on the issue of gender and women's experience of the Holocaust. Works on U.S. government policy on the Holocaust include HENRY L. FEINGOLD, The Politics of Rescue: The Roosevelt Administration and the Holocaust, 1938–1945, expanded and updated ed. (1980), a careful historical review; and DAVID S. WYMAN, The Abandonment of the Jews (1984, reissued 1998), a more critical indictment. TIM COLE, Selling the Holocaust: From Auschwitz to Schindler, How History Is Bought, Packaged, and Sold (1999); and NORMAN G. FINKELSTEIN, The Holocaust Industry: Reflection on the Exploitation of Jewish Suffering (2000), deal with what some people see as the commercialization of Holocaust remembrance.

(Mi.Be.)

The Homeric Epics

he two great epic poems of ancient Greece, the Iliad and the Odyssey, have always been attributed to a shadowy figure by the name of Homer, Little is known of him beyond the fact that his was the name attached in antiquity by the Greeks themselves to the two great poems. That there was an epic poet called Homer and that he played the primary part in shaping the Iliad and the Odyssey-so much may be said to be probable. If this assumption is accepted, then Homer must assuredly be one of the greatest of the world's literary artists.

Homer's

influence

He is also one of the most influential authors in the widest sense, for the two epics provided the basis of Greek education and culture throughout the classical age and formed the backbone of humane education down to the time of the Roman Empire and the spread of Christianity. Indirectly through the medium of Virgil's Aeneid (which was loosely molded after the patterns of the Iliad and the Odyssey), directly through their revival under Byzantine culture from the late 8th century AD onward, and subsequently through their passage into Italy with the Greek scholars who fled westward from the Ottomans, the Homeric epics had a profound impact on the Renaissance culture of Italy. Since then the proliferation of translations has helped to make them the most important poems of the classical European tradition.

It was probably through their impact on classical Greek culture itself that the Iliad and the Odyssey most subtly affected Western standards and ideas. The Greeks regarded the great epics as something more than works of literature; they knew much of them by heart, and they valued them not only as a symbol of Hellenic unity and heroism but also as an ancient source of moral and even practical instruction.

Early references. Implicit references to Homer and quotations from the poems date to the middle of the 7th century BC, Archilochus, Aleman, Tyrtaeus, and Callinus in the 7th century and Sappho and others in the early 6th adapted Homeric phraseology and metre to their own purposes and rhythms. At the same time scenes from the epics became popular in works of art. The pseudo-Homeric "Hymn to Apollo of Delos," probably of late 7th-century composition, claimed to be the work of "a blind man who dwells in rugged Chios," a reference to a tradition about

Restored bust thought to represent Homer, copied from a Greek original, c. 450 BC. In the Sala delle Muse, the Vatican

Homer himself. The idea that Homer had descendants known as "Homeridae," and that they had taken over the preservation and propagation of his poetry, goes back at least to the early 6th century BC. Indeed, it was not long before a kind of Homeric scholarship began: Theagenes of Rhegium in southern Italy toward the end of the same century wrote the first of many allegorizing interpretations. By the 5th century biographical fictions were well under way: the Pre-Socratic philosopher Heracleitus of Ephesus made use of a trivial legend of Homer's death-that it was caused by chagrin at not being able to solve some boys' riddle about catching lice-and the concept of a contest of quotations between Homer and Hesiod (after Homer the most ancient of Greek poets) may have been initiated in the Sophistic tradition. The historian Herodotus assigned the formulation of Greek theology to Homer and Hesiod and claimed that they could have lived no more than 400 years before his own time, the 5th century BC. This should be contrasted with the superficial assumption, popular in many circles throughout antiquity, that Homer must have lived not much later than the Trojan War about which he sang.

The general belief that Homer was a native of Ionia (the central part of the western seaboard of Asia Minor) seems a reasonable conjecture for the poems themselves are in predominantly Ionic dialect. Although Smyrna and Chios early began competing for the honour (the poet Pindar, early in the 5th century BC, associated Homer with both), and others joined in, no authenticated local memory survived anywhere of someone who, oral poet or not, must have been remarkable in his time. The absence of hard facts puzzled but did not deter the Greeks; the fictions that had begun even before the 5th century BC were developed in the Alexandrian era in the 3rd and 2nd centuries BC (when false scholarship as well as true abounded) into fantastic pseudobiographies, and these were further refined by derivative scholars under the Roman Empire. The longest to have survived purports to be by Herodotus himself; but it is quite devoid of objective truth.

Modern inferences. Modern scholars agree with the ancient sources only about Homer's general place of activity. The most concrete piece of ancient evidence is that his descendants, the Homeridae, lived on the Ionic island of Chios. Yet an east Aegean environment is suggested for the main author of the Iliad by certain local references in the poem; that is, to the peak of Samothrace just appearing over the intervening mass of Imbros when seen from the plain of Troy, to the birds at the mouth of the Cayster near Ephesus, to storms off Icaria and northwest winds from Thrace. East Aegean colouring is fainter in the Odyssey, which is set primarily in western Greece; but the poem's vagueness over the position of Ithaca, for example, is not incompatible with the idea of a poet in Ionia elaborating materials derived from the farther side of the Greek world.

Admittedly, there is some doubt over whether the Iliad and the Odyssey were even composed by the same main author. Such doubts began in antiquity itself and depended mainly on the difference of genre (the Iliad being martial and heroic, the Odyssey picaresque and often fantastic), but they may be reinforced by subtle differences of vocabulary even apart from those imposed by different subjects. Aristotle's conception of the Odyssey as a work of Homer's old age is not impossible; but if the Iliad is the earlier of the two (as seems likely from its simpler structure and the greater frequency of relatively late linguistic forms in the Odyssey), then the Odyssey could have been created after its image, and as a conscious supplement, once the example of monumental composition had been given. In any case the similarities of the two poems are partly due Personal

to the coherence of the heroic poetical tradition that lay

Date of the epics

The internal evidence of the poems is of some use in determining when Homer lived. Certain elements of the poetic language, which was an artificial amalgam never exactly reproduced in speech, indicate that the epics were not only post-Mycenaean in composition but also substantially later than the foundation of the first Ionian settlements in Asia Minor of about 1000 BC. The running together of adjacent short vowels and the disappearance of the semivowel digamma (a letter formerly existing in the Greek alphabet) are the most significant indications of this. At the other end of the time scale the development in the poems of a true definite article, for instance, represents an earlier phase than is exemplified in the poetry of the middle and late 7th century. Both stylistically and metrically, the Homeric poems appear to be earlier than the Hesiodic poems, which many scholars place not long after 700 BC. A different and perhaps more precise criterion is provided by datable objects and practices mentioned in the poems. Nothing, except for one or two probably Athenian additions, seems from this standpoint to be later than around 700; on the other hand, the role assigned in the Odyssey to the Phoenicians as traders, together with one or two other phenomena, suggests a date of composition-for the relevant contexts at leastof after 900. A few passages in the Iliad may imply a new form of fighting in close formation, dependent on the development of special armour for foot soldiers (hoplites) after about 750, and references to the Gorgon mask as a decorative motif point in the same direction. It is true that the poems contain many traditional and archaic elements, and their language and material background are a compound of different constituents originating at different dates. It seems, nonetheless, plausible to conclude that the period of composition of the large-scale epics (as distinct from their much shorter predecessors) was the 9th or 8th century, with several features pointing more clearly to the 8th. The Odyssey may belong near the end of this century, the Iliad closer to its middle. It may be no coincidence that cults of Homeric heroes tended to spring up toward the end of the 8th century, and that scenes from the epic begin to appear on pots at just about the same time.

Homer as an oral poet. But even if his name is known and his date and region can be inferred, Homer remains primarily a projection of the great poems themselves. Their qualities are significant of his taste and his view of the world, but they also reveal something more specific about his technique and the kind of poet he was. It has been one of the most important discoveries of Homeric scholarship, associated particularly with the name of an American scholar, Milman Parry, that the Homeric tradition was an oral one-that this was a kind of poetry made and passed down by word of mouth and without the intervention of writing. Indeed Homer's own term for a poet is aoidos, The Odyssey describes two such poets in some detail: Phemius, the court singer in the palace of Odysseus in Ithaca, and Demodocus, who lived in the town of the semi-mythical Phaeacians and sang both for the nobles in Alcinous' palace and for the assembled public at the games held for Odysseus. On this occasion he sings of the illicit love affair of Ares and Aphrodite in a version that lasts for exactly 100 Homeric verses. This and the other songs assigned to these singers-for example, that of the Trojan Horse, summarized in the Odyssey-suggest that ordinary aoidoi in the heroic tradition worked with relatively short poems that could be given completely on a single occasion. That is what one would expect, and it is confirmed by the habits of singers and audiences at other periods and in other parts of the world (the tradition of the poet-singers of Muslim Serbia has provided the most fruitful comparison so far). Whatever the favoured occasion for heroic song-whether the aristocratic feast, the religious festival, or popular gatherings in tavern or marketplace-a natural limitation on the length of a poem is imposed by the audience's available time and interest as well as by the singer's own physique and the scope of his repertoire. Such relatively short songs must have provided the backbone of the tradition inherited by Homer, and

his portraits of Demodocus and Phemius are likely to be accurate in this respect. What Homer himself seems to have done is to introduce the concept of a quite different style of poetry, in the shape of a monumental poem that required more than a single hour or evening to sing and could achieve new and far more complex effects, in literary and psychological terms, than those attainable in the more anecdotal and episoids songs of his predecessors.

Poetic techniques. It can be asked how one can be so confident in classing Homer himself as an oral singer, for if he differed from Phemius or Demodocus in terms of length, he may also have differed radically in his poetic techniques. The very nature of his verse may provide a substantial part of the answer. The style of the poems is "formulaic"; that is, they rely heavily on the use not only of stock enithets and repeated verses or groups of verseswhich can also be found to a much lesser extent in a literate imitator like Virgil-but also on a multitude of fixed phrases that are employed time and time again to express a similar idea in a similar part of the verse. The clearest and simplest instance is the so-called noun-epithet formulas. These constitute a veritable system, in which every major god or hero possesses a variety of epithets from which the choice is made solely according to how much of the verse, and which part of it, the singer desires to use up. Odysseus is called divine Odysseus, manycounseled Odysseus, or much-enduring divine Odysseus simply in accordance with the amount of material to be fitted into the remainder of the hexameter (six-foot) verse. A ship is described as black, hollow, or symmetrical not to distinguish this particular ship from others but solely in relation to the qualities and demands of the rhythmical context. The whole noun-epithet system is both extensive and economical-it covers a great variety of subjects with very little exact reduplication or unnecessary overlap. It would seem that so refined and complex a system could not be the invention of a single poet but must have been gradually evolved in a long-standing tradition that needed both the extension and the economy for functional reasons-that depended on these fixed phrase units because of its oral nature, in which memory, practice, and a kind of improvising replace the deliberate, self-correcting, wordby-word progress of the pen-and-paper composer. Admittedly, the rest of Homer's vocabulary is not as markedly formulaic as its noun-epithet aspect (or, another popular example, as its expressions for beginning and ending a speech). Many expressions, many portions of sentences are individually invented for the occasion, or at least so it seems. Even so, there is a strongly formulaic and readymade component in the artificial language that was used by Homer, including its less conspicuous aspects such as the arrangement of particles, conjunctions, and pronouns. It looks, therefore, as though Homer must have trained

as an ordinary aoidos, who began (like most of the present-day Yugoslav guslari) by building up a repertoire of normal-length songs acquired from already established singers. The greatest heroic adventures of the past must already have been prominent in any repertoire, especially the Panhellenic adventures of the Seven Against Thebes, the Argonauts, and the Achaean attack on Troy. Some aspects of the Trojan War might already have been expanded into songs of unusual length, though one that was still manageable on a single occasion. Yet the process was presumably carried much further in the making of the monumental Iliad, consisting of more than 16,000 verses, which would take four or five long evenings, and perhaps more, to perform. This breakthrough into the monumental, which made exceptional and almost unreasonable demands of audiences, presupposes a singer of quite exceptional capacity and reputation-one who could impose the new and admittedly difficult form upon his listeners by the sheer unfamiliar genius of his song. The 8th century BC was in other respects, too, an era of cultural innovation, not least in the direction of monumentality, and huge temples (like the early temple of Hera in Samos) and colossal funerary vases (like the mixing bowls and amphorae in the so-called Geometric style from the Dipylon cemetery in Athens) may have found a literary analogue in the idea of a vast poetical treatment of the Trojan War. But in an

The poet as aoidos

> The monumental poem

poem

important sense Homer was building upon a tendency of all known oral heroic poetry toward elaboration and expansion. The singer does not acquire a song from another singer by simple memorization. He adjusts what he hears to his existing store of phrases, typical scenes, and themes, and he tends to replace what is unfamiliar to him with something he already knows, or to expand it by adding familiar material that it happens to lack. Every singer in a living oral tradition tends to develop what he acquires. There is an element of improvisation, as well as of memory, in his appropriation of fresh material; and judging by the practice of singers studied from the middle of the 19th century onward in Russia, Serbia, Cyprus, and Crete the inclination to adjust, elaborate, and improve comes naturally to all oral poets.

Cumulative poetic structure. Homer must have decided to elaborate his materials not only in quality but also in length and complexity. All oral poetry is cumulative in essence; the verse is built up by adding phrase upon phrase, the individual description by adding verse upon verse. The whole plot of a song consists of the progressive accumulation of minor motifs and major themes, from simple ideas (such as "the hero sets off on a journey" or "addresses his enemy") through typical scenes (such as assemblies of men or gods) to developed but standardized thematic complexes (such as episodes of recognition or reconciliation). Homer seems to have carried this cumulative tendency into new regions of poetry and narrative; in this as in other respects (for example, in his poetical language) he was applying his own individual vision to the fertile raw material of an extensive and well-known tradition.

The result is much more complex than with an ordinary traditional poem. Understanding the origin and essential qualities of the Iliad or the Odyssey entails trying to sort out not only the separate components of the pre-Homeric tradition but also Homer's own probable contributions. whether distinguishable by their dependence on the monumental idea or by their apparent novelty vis-à-vis the tradition as a whole or by other means. Dialectal and linguistic components must be identified as far as possible-survivals of the Mycenaean language, for example, or words used exclusively in the Aeolian cities of the west coast of Asia Minor, or Athenian dialect forms introduced into the poems after the time of Homer; so must specific references to armour, clothing, houses, burial customs, political geography, and so on, that are likely to be assignable to the Late Bronze Age, the Early Iron Age, or the period of Homer's own activity-at the very least to be taken as relatively early or late within the whole range of the poetic tradition down to Homer. These are the tasks of modern Homeric scholarship. Yet such different forms and ideas in Homer are not conveniently separated into distinct sections of the text, which can therefore be assigned to early or late phases of composition. On the contrary, they may coexist in a single (artificial) linguistic form or a single descriptive phrase. Any member of the tradition, not least Homer himself, may, moreover, have chosen to archaize on one occasion, to innovate on another. One result is that the epics are dubious authorities for the assessment of historical events like the attack on Troy or the status of workers, just as they are ambiguous sources for early Greek grammar or theology. Another is that they are not bound to a single worldview or period or mode of perception; rather, they unite judgments and experiences never seen together in "real" life into a whole that is literary but nevertheless revealing of the underlying structure of human existence.

Stabilizing the text. An important and difficult question, which affects the accuracy of modern Homeric texts, is that of the date when the epics became "fixed"—which means given authoritative written form, since oral transmission is always to some extent fluid. An alphabetic writing system reached Greece in the 9th or early 8th century act; before that was a gap of 200 or 300 years, following the collapse of Mycenaean culture and the disappearance of Linear B writing (with each sign generally representing a syllable), during which Greece seems to have been non-literate. During that interval, certainly, much of the epic tradition was formed. The earliest alphabetic inscriptions

to have survived, a few of them containing brief scraps of hexameter verse, date from around 730 BC. Therefore, if Homer created the Iliad at some time after 750 BC, he could conceivably have used writing to help him. Some scholars think that he did. Others believe that he may have remained nonliterate (since literacy is not normally associated with oral creativity) but dictated the poem to a literate assistant. Still others believe that the poems may have been preserved orally and not too inaccurately at least until the middle years of the following, the 7th, century, when "literature" in the strict sense appeared in the poetry of Archilochus. There are objections to all three theories, but this much can be generally agreed: that the use of writing was in any case ancillary, that Homer behaved in important ways like a traditional oral poet. Some scholars are convinced that certain of the more subtle effects and cross-references of Homer's poetry would be impossible without the ability to consult a written text. That is doubtful; certainly the capacities even of ordinary oral poets in this direction are constantly surprising to habitual literates.

At least it may be accepted that partial texts of the epics were probably being used by the Homeridae and by professional reciters known as rhapsodes (who were no longer creative and had abandoned the use of the lyre) by the latter part of the 7th century BC. The first complete version may well have been that established as a standard for rhapsodic competitions at the great quadrennial festival at Athens, the Panathenaea, at some time during the 6th century BC. Even that did not permanently fix the text, and from then on the history of the epics was one of periodical distortion followed by progressively more effective acts of stabilization. The widespread dissemination of the poems consequent upon the growth of the Athenian book trade in the 5th century and the proliferation of libraries after the 4th was followed by the critical work of the Alexandrian scholar Aristarchus of Samothrace in the 2nd century BC, and much later by the propagation of accurate minuscule texts (notably the famous manuscript known as Venetus A of the Iliad), incorporating the best results of Greco-Roman scholarship, in the Byzantine world of the Middle Ages. Rare portions of either poem may have been added after, but not long after, the main act of composition; the night expedition that results in the capture of the Trojan spy Dolon and that fills the 10th book of the Iliad, some of the underworld scenes in the 11th book of the Odyssey, and much of the ending of the Odyssey after line 296 of the 23rd book (regarded by Aristarchus as its original conclusion) are the most probable candidates on the grounds of structure, language, and style.

Even apart from the possibilities of medium-scale elaboration, the *Iliad* and the *Odyssey* exemplify certain of the minor inconsistencies of all oral poetry, and occasionally the composer's amalgamation of traditional material into a large-scale structure shows through. Yet the overriding impression is one of powerful unity.

The Iliad. The Iliad is not merely a distillation of the whole protracted war against Troy but simultaneously an exploration of the heroic ideal in all its self-contradictoriness-its insane and grasping pride, its magnificent but animal strength, its ultimate if obtuse humanity. The poem is, in truth, the story of the wrath of Achilles, the greatest warrior on the Greek side, that is announced in its very first words; yet for thousands of verses on end Achilles is an unseen presence as he broods among his Myrmidons, waiting for Zeus's promise to be fulfilled-the promise that the Trojans will set fire to the Achaean ships and force King Agamemnon to beg him to return to the fight. Much of the poetry between the first book, in which the quarrel flares up, and the 16th, in which Achilles makes the crucial concession of allowing his friend Patroclus to fight on his behalf, consists of long scenes of battle, in which individual encounters alternate with mass movements of the opposing armies. The battle poetry is based on typical and frequently recurring elements and motifs, but it is also subtly varied by highly individualized episodes and set pieces: the catalog of troop contingents, the formal duels between Paris and Menelaus and Ajax and Hector, Helen's identifying of the Achaean princes, Agamemnon

The story of the Iliad inspecting his troops, the triumph of Diomedes, Hector's famous meeting back in Troy with his wife Andromache, the building of the Achaean wall, the unsuccessful embassy to Achilles, the night expedition, Hera's seduction of Zeus and Poseidon's subsequent invigoration of the Achaeans, Patroclus' death two-thirds of the way through the poem brings Achilles back into the fight, although not before the recovery of Patroclus' body, the making of new divine armour for Achilles, and his formal reconciliation with Agamemnon. In book 22 he kills the deluded Hector; next he restores his heroic status by means of the funeral games for Patroclus; and in the concluding book Achilles is compelled by the gods to restore civilized values and his own magnanimity by surrendering Hector's body to King Priam.

The story of the Odyssey

The Odyssev. The Odyssev tends to be blander in expression and sometimes more diffuse in the progress of its action, but it presents an even more complex and harmonious structure than the Iliad. The main elements are the situation in Ithaca, where Penelope, Odysseus' wife, and their young son, Telemachus, are powerless before her arrogant suitors as they despair of Odysseus' return from the siege of Troy; Telemachus' secret journey to the Peloponnese for news of his father, and his encounters there with Nestor, Menelaus, and Helen; Odvsseus' dangerous passage, opposed by the sea-god Poseidon himself, from Calypso's island to that of the Phaeacians, and his narrative there (from book 9 to book 12) of his fantastic adventures after leaving Troy, including his escape from the cave of the Cyclops, Polyphemus; his arrival back in Ithaca, solitary and by night, at the poem's halfway point, followed by his meeting with his protector-goddess Athena, his elaborate disguises, his self-revelation to the faithful swineherd Eumaeus and then to Telemachus, their complicated plan for disposing of the suitors, and its gory fulfillment. Finally comes the recognition by his faithful Penelope, his recounting to her of his adventures, his meeting with his aged father, Laertes, and the restitution, with Athena's help, of stability in his island kingdom of Ithaca. (See also GREEK LITERATURE: Epic narrative.)

Homer's influence seems to have been strongest in some of the most conspicuous formal components of the poems. The participation of the gods can both dignify human events and make them seem trivial-or tragic; it must for long have been part of the heroic tradition, but the frequency and the richness of the divine assemblies in the Iliad, or the peculiarly personal and ambivalent relationship between Odysseus and Athena in the Odyssey, probably reflect the taste and capacity of the main composer. The many-sidedness of battle, the equivocal realism of death in a hundred forms, must have been developed among Homer's predecessors but can never before have been deployed with such massive and complex effect. In the extended similes the strain of heroic action is relieved by the illuminating intrusion of a quite different and often peaceful contemporary world, in images developed often almost longingly beyond the immediate point of comparison. These similes, in their placing and their detail at least, surely depend on the main composer. And yet, beyond such general intuitions as these, the attempt to isolate his special contributions often becomes self-defeating. The Iliad and the Odyssey owe their unique status precisely to the creative and therefore unanalyzable confluence of tradition and design, the crystalline fixity of a formulaic style and the mobile spontaneity of a brilliant personal vision. "Homer" implies, above all, this fusion.

The result is an impressive amalgam of literary power and refinement. The Iliad and the Odyssey, however, owe their preeminence not so much to their antiquity and to their place in Greek culture as a whole but to their timeless success in expressing on a massive scale so much of the triumph and the frustration of human life. Although all literature must be engaged with that to some degree, epic poems are not where one most expects to find it. But these poems rise above the immediate concerns of heroic battle or the struggle against gods and nature or against monstrous forces, and they do so with the help of a poetical language of great simplicity and subtlety, a rugged and surprisingly variable narrative technique, and a nucleus of remarkable tales set around the Trojan War and its aftermath. Their greatest power lies, perhaps, in their dramatic quality because much of each poem consists of conversation and speeches, in which rhetoric is kept firmly under control and the individual characters emerge as they confront each other and the gods with advice, inquiry, request, resignation, and passion. Achilles, Hector, Menelaus, Ajax, Odysseus, and the others acquire a kind of heroic glow that even Greek tragedy later found hard to emulate. That is the result, in part, of the very archaism of these age-old tales, which the special techniques of monumental composition never attempted to conceal: but it also depends on something that overlaps that archaism, namely a sheer mythic quality imparting to these tales something of the universal validity to which all great literature aspires and which Homer achieved consistently and with an apparent ease that must be deceptive.

ong Kong (Wade-Giles romanization: Hsiangkang; Pinyin: Xianggang) is a special administrative region of China located to the east of the Pearl River (Chu Chiang) estuary on the south coast of China. The region is bordered by Kwangtung province on the north and the South China Sea on the east, south, and west. It consists of Hong Kong Island, originally ceded by China to Great Britain in 1842, the southern part of the Kowloon Peninsula and Stonecutters (Ngong Shuen) Island (now joined to the mainland), ceded in 1860, and the New Territories, which include the mainland area lying largely to the north, together with 230 large and small offshore islands-all of which were leased from China for 99 years from 1898 to 1997. The Chinese-British joint declaration signed on Dec. 19, 1984, paved the way for the entire territory to be returned to China, which occurred July 1, 1997.

Hong Kong has 422 square miles (1,092 square kilometres) of land area, including land reclaimed from the sea, and the area continues to grow as more land is reclaimed. Hong Kong Island and its adjacent islets have an area of only about 35 square miles, while urban Kowloon.

which includes the Kowloon Peninsula south of Boundary Street, and Stonecutters Island measure only about six square miles. The New Territories account for the rest of the area, amounting to more than 90 percent of the total. The Victoria urban district located on the barren rocks of the northwestern coast of Hong Kong Island is the place where the British first landed in 1841, and it has since

been the centre of administrative and economic activities. Hong Kong developed initially on the basis of its excellent natural harbour and the lucrative China trade, particularly opium dealing. It was the expansion of its territory, however, that provided labour and other resources necessary for sustained commercial growth that led to its becoming one of the world's major trade and financial centres. The community remains limited in space and natural resources, and it faces persistent problems of overcrowding, trade fluctuations, and social and political unrest. Nevertheless, Hong Kong has emerged strong and prosperous, albeit with a changed role, as an entrepôt, a manufacturing and financial centre, and a vital agent in the trade and modernization of China.

Physical and human geography

THE LAND

Relief. In sharp contrast to the low-lying areas of the Pearl River delta, but conforming geologically and structurally to the great South China massif, a well-eroded upland region, Hong Kong has rugged relief and marked variations in topography. Structurally the area is an anticline, running northeast-southwest, that was formed toward the latter part of the Jurassic Period (about 150 million years ago). Lava poured into this structure and formed volcanic rocks that were later intruded by an extensive grantite dome. The harbour of Hong Kong was formed by the drowning of the denuded centre of the dome. The surrounding hills on the mainland and on Hong Kong Island are partly capped by volcanic rocks, and steep, scarplike concave slopes lead to the inner harbour.

The area is a partially submerged, dissected upland terrain that rises abruptly to heights of more than 2,950 feet (900 metres); its backbone is made up of a series of ridges, running northeast to southwest, that tie in closely with the structural trend in South China. This trend is clearly observable from the alignment of Lantau Island and the Tolo Channel. From Mount Tai Mo—an 3,140 feet (957 metres) the highest peak in the territory—the series of ridges extends southwestward to Lantau Island, where the terrain rises to 3,064 feet on Lantau Peak and 2,851 feet on Sunset Peak. Extending southeastward from Mount Tai Mo, the Kowloon Peak attains an elevation of 1,975 feet, but there is an abrupt drop to about 650 feet at Devil's Peak. Victoria (Hong Kong) Harbour is well protected by mountains on Hong Kong Island that include Victoria Peak in the west, which rises to 1,810 feet, and Mt. Parker in the east, which reaches a height of about 1,742 feet.

Lowlands of the Hong Kong region, including floodplains, river valleys, and reclaimed land, occupy less than one-fifth of the land. Extensive lowland regions are found only north of Mount Tai Mo, in the Yuen Long and Sheung Shui plains. The urban area that spans the two sides of the harbour, with continued reclamation, takes up only about one-tenth of the level area.

Drainage. Hong Kong lacks a river system of any scope, the only exception being in the north where the Sham Chun River, which forms the boundary between Kwangtung and Hong Kong, flows into Deep Bay after collecting a number of small tributaries. Most of the streams are small, and they generally run perpendicular to the northeast-southwest trend of the terrain. The construction of reservoirs and their catchment systems has reduced the amount of fresh water available downstream.

Soils. In general, Hong Kong's soils are acidic and of low fertility. An exception is the alluvial soils, which are found mainly in the Deep Bay area, where the sediment-laden waters of the Pearl meet saline waters at high tide and slow down to deposit their sediments to form mud flats. Paddy rice farming and, more recently, intending the paddy rice farming and rice farming a

The new

towns

sive vegetable cultivation have modified the alluvial soils. Elsewhere, hill soils, classified as red-yellow podzolic and krasnozem, abound. Under forest, these hill soils have a well-developed profile, with rich topsoil, but, when they are exposed, as is mostly the case, they tend to be thin and lacking in nutrients. Under tropical conditions, sheet and gully erosion is extensive and drastic.

Climate. Hong Kong lies at the northern fringe of the tropical zone. It tropical zone is assonal changes are well marked, however, with hot, humid summers and cool, dry winters. The climate is largely controlled by the pressure systems over the adjacent great Asian landmass and ocan surface. Thus, monsoonal winds blow from the northeast in winter as a result of the cooling of the landmass and the development of a large thermal anticyclone over Inner Mongolia. Southeast winds develop in summer when the North Pacific Ocean heats up more slowly through solar radiation and becomes a high-pressure area.

The mean January and July temperatures are about 60° F (16° C) and 84° F (29° C), respectively. The lowest recorded temperature was 32° F (0° C) in January 1893. and the highest was 97° F (36° C) in August 1900. Frost occasionally occurs on hilltops in winter. The average annual rainfall amounts to about 88 inches (2,220 millimetres), more than half of which falls during the summer months of June, July, and August; only about 10 percent falls from November to March. Tropical cyclones, or typhoons, generally occur between June and October, and, of the 20 to 30 typhoons formed over the western North Pacific and South China Sea each year, an average of five or six may affect Hong Kong. The torrential downpours and strong winds that frequently accompany the typhoons sometimes devastate life and property in Hong Kong and adjacent areas of Kwangtung.

Plant and animal life. Hong Kong is noted for the lushness and great diversity of its plant life. The transitional climate between humid subtropical and warm temperate maritime excludes the most sensitive humid tropical genera due to the cool, dry winter conditions, but many tropical as well as temperate-zone families are represented. Most of the land, except for the heavily eroded badlands, is under tropical herbaceous growth, including mangrove and other swamp cover. The most common forest genus today is Pinus, represented by the native South China red pine and the slash pine, introduced from Australia, Some of the oldest areas of woodland are in the feng-shui wood, or "sacred groves," found in many New Territories villages. These woods consist essentially of native forest trees, some of which are of potential value to the villagers. Centuries of cutting and burning have, however, destroyed much of Hong Kong's original vegetation, leaving only about one-eighth of the land forested. A large portion of Hong Kong's present-day forest cover owes its origin to postwar afforestation programs, which have restored some of the stands of pine, eucalyptus, banyan, casuarina, and palm trees.

Hong Kong's animal life consists of a mixture of mammals adapted to the subtropical environment. Among the few arboreal mammals are two species of nonnative monkeys that flourish in forests of the New Territories, the rhesus macaque and the long-tailed meacque. Tigers are reputed to have once roamed the area, but they are no longer in evidence. The largest remaining carnivores are rare and include the South China red fox, the Chinese leopard cat, the seven-banded civet, and the masked palm civet. Some rat and mouse species typically inhabit scrubland and grassland areas. Birdlife is abundant, and there are numerous species of snakes, lizards, and frogs.

Settlement patterns. The predominantly urban settlements of Hong Kong are typically distributed linearly, following the irregular coastline and transportation routes. The principal urban areas are established on Hong Kong Island and Kowloon Peninsula, where more than half of the total population lives. There, most of the population is concentrated around Victoria Harbour, living on the limited flatland that is being continuously extended by reclamation. Many major streets, especially those on the northern shore of Hong Kong Island, as well as the entire industrial district of Kwun Tong and the eastern portion of Tsim Sha Tsui at the tip of the peninsula, have been built on reclaimed land

In the New Territories north of the Kowloon hills, rural settlements vary from hamlets to small towns. Most of the villages, compactly built and often walled, follow the alignment of the river systems in the low-lying but fertile alluvial floodplains or the major route corridors. Villages of the Cantonese people are located mainly in the flat alluvial regions, whereas villages of the Hakka people usually are found in narrow valleys or on foothills. The fong-shul grove and pond are characteristic of both the Cantonese and Hakka villages; the grove is generally planted on the upslope, or back side, of a village for shade and protection, and the pond is for fish-farming.

A number of new towns have sprung up in the New Territories as a result of the tremendous increase in population there. Among these are Tsuen Wan, Tuen Mun (Castle Peak before 1973), and Sha Tin, which were established in the 1960s and designed to have populations of between 500,000 and 700,000 each. Others, including Tai Po, Fanling, Yuen Long, and, more recently, Tseung Kwon O (Junk Bay), were designated as new towns in the 1970s, with population goals ranging from about 150,000 to 400,000. Thus, the New Territories, where only one-eighth of the population resided in 1961, accounted for nearly half of the total by the mid-1990s, and some four-fifths of the New Territories population was concentrated in the new towns.

True to its original character as a fishing port, Hong Kong has a sizable, though rapidly dwindling, marine settlement. The "boat people," or Tanka as they are locally known, are essentially fisherfolk living on junks and boats, as their ancestors did for centuries before them. They inhabit fishing towns such as Aberdeen, Shau Kei Wan, and Cheung Chau and typhoon shelters in the harbour areas. With the advance of urbanization and the decline of fishing activity, increasing numbers of them are working ashore.

THE PEOPLE

Ethnic composition. The great majority of the population is Chinese by place of origin, the non-Chinese making up only about 2 percent of the total. Non-Chinese groups are split fairly evenly between non-Asians and Asians. British, Americans, Australians, Canadians, and New Zealanders are among the non-Asians, while the Asian minority groups include Japanese, Indians, Pakistanis, and Singaporeans. An overwhelming majority of the Chinese are from Kwangtung province and from Hong Kong itself, while less than 10 percent come from other parts of China, notably Fukien, Shanghai, Chekiang, and Kiangsu, and from Taiwan.

Linguistic composition. Chinese and English are both official languages. Chinese, especially Cantonese in the spoken form, is the common language, however, and is almost universally understood. A variety of dialects and other languages are used among the ethnic minorities. Apart from Cantonese, common dialects, such as Siyi, Chaochow, Hakka, Hoklo, and Tanka, are popularly used within separate native communities of the Kwangtung and Hong Kong Chinese. Groups from other parts of China are also likely to use their own native dialects, and, similarly, the non-Chinese are likely to use their own native languages among themselves. The use of Mandarin Chinese is rising as Hong Kong reintegrates with China.

Religions. The religious persuasions of the people of Hong Kong are as various as their languages and dialects. Among the Chinese, followers of Buddhism and Taoism by far outnumber other groups, and the numerous Buddhist and Taoist temples and monasteries, some centuries old, play an important role in the daily life of the average Chinese. Although each temple is generally dedicated to one or two deities, it is not unusual to find images of a number of other gods or goddesses inside. For a fishing and trading port, the most significant deities are those associated with the ocean and the weather, such as T'ien Hau, the goddess of heaven and protector of seafarers, who is honoured by temples at virtually every fishing harbour. Other leading deities include Kuan-yin (Avalokiteśvara), the Buddhist goddess of mercy; Hung Shing, god of the South Seas and a weather prophet; and Wong Tai Sin, a Taoist saint and deity. Christians constitute some halfmillion people, divided roughly equally between Roman Catholics and some 50 Protestant denominations and sects

Vegetable farm on Pok Toi Chau (Lamma Island).

such as Anglican, Baptist, Lutheran, and Methodist, There are also small numbers of Muslims, Hindus, Sikhs, and Towe

Demographic trends. As in many large urban centres of the world, Hong Kong's population has increased in the late 20th century. Since the 1950s the average annual rate of growth has fluctuated between about 2 and 4 percent. the variations in some degree based on the sporadic flow of immigrants from China, Immigration has been a chief cause of population increase, but it was slowed through changes in immigration policy in 1980 and 1982, and emigration rose from the late 1980s. Birth rates have steadily declined since the late 1950s, the rate of natural increase falling below 1 percent by the 1980s, Life expectancy. however, has been showing a gradual increase. Since the 1950s, the proportion of the population under 15 has decreased rapidly, while that between 15 and 64 has shown a marked increase and the group over 65 has more than doubled. Hong Kong is one of the world's most densely populated places.

THE ECONOMY

With its limited natural resources, Hong Kong depends on imports for virtually all of its requirements, including raw materials, food and other consumer goods, capital goods, and fuel. Under its unique status as an international free port, entrepôt trade, mainly with China, flourished until 1951, when a United Nations embargo on trade with China and North Korea drastically curtailed it. This situation, combined with the need to export and with the availability of cheap labour, led to the establishment of competitive light industries and a transformation of the economy in the early 1960s. The market economy and the laissezfaire policy of the British colonial government provided flexibility for further industrialization and the incentive and freedom, from the late 1960s, to attract foreign investment and financial transactions. In succeeding years, with China adopting a more open foreign policy, entrepôt trade rapidly revived, while Hong Kong-China trade surged. Hong Kong developed not only in manufacturing, trade, and shipping but also as a regional financial centre and as an agent in China's pursuit of modernization. The tertiary (services) sector of the economy now makes up some four-fifths of the gross domestic product (GDP).

Resources. Hong Kong is practically devoid of any significant mineral resources. The mining for graphite and lead at Cham ("Needle") Hill and iron ore at Mount Ma On stopped long ago. Hong Kong is similarly poorly endowed in other natural resources: no commercial timber is produced from its sparse forest cover, and there is no hydroelectric potential from the small and short streams. Indeed, even water has been in serious short supply as a consequence of the limited areal extent, the steep terrain, and the lack of catchment areas. In spite of the many reservoirs, which were built mostly before World War II, and several giant projects, such as the water desalinization plant at Castle Peak and the Plover Cove and the High Island reservoirs, which are enclosed sea areas, the bulk of water consumed is piped in from Kwangtung province.

Agriculture and fishing. Only 6 percent of Hong Kong's land area is arable, and another 2 percent is under fishponds. Since the 1950s about one-third of the agricultural land has been lost to other uses. The growing season is year-round, however, and several crops a year are possible. Paddy rice cultivation once dominated agricultural land use, but it has practically disappeared, having been surpassed by vegetable and pond fish farming. Other minor uses include the production of fruits, flowers, and crops such as sweet potatoes, taro, yams, and sugarcane.

Marine fishing in the adjacent waters is one of Hong Kong's most important primary activities. Apart from pond fish, a marine fish culture has shown signs of development, notably in the eastern New Territories.

Industry. The rapid development of manufacturing in the 1950s was made possible by immigrant Chinese industrialists, mainly from Shanghai, who brought with them technology and capital. Foreign investments soon began to flow in to tap the huge supply of cheap labour and relatively cheap raw materials available in the surrounding

Stimulus of trade embargo region. Most of the industry has been confined to the urban areas, especially in the densely populated districts of Kowloon. With the development of industrial and other new towns, manufacturing began to disperse into Kwun Tong, Tsuen Wan, Tuen Mun, and others, In 1977 the Hong Kong Industrial Estates Corporation was established to develop and manage industrial estates that would accommodate high-technology industries, first on reclaimed land in Tai Po and later in Yuen Long,

Manufacturing, once the most important sector of the Hong Kong economy, has been overshadowed by the vast service sector; it now constitutes less than one-tenth of the gross domestic product and employs about one-tenth of the labour force. Textile and clothing production is the leading manufacturing activity and contributes about onethird of the value of domestic exports. The electronics industry is the second largest export earner. There are some heavy industries such as shipbuilding and repair and aircraft engineering. Steel rolling, production of machine parts and plastics, and cement manufacturing serve local needs. The tourist industry, which is highly promoted by the government and well catered to by the huge service sector, is another significant part of the economy.

Finance. Since 1969 Hong Kong has emerged as one of the major financial centres of the Asia-Pacific region, despite the fact that it is without the services of a central bank. The regional government delegates the functions of such an institution to certain government offices and selected commercial banks. In addition to the licensed banks in the region, there are representative offices of foreign banks, including registered deposit-taking companies.

Domestic and international currencies are traded at the Hong Kong foreign-exchange market. The stock market attracts investment from both foreign and domestic sources. Some of its major shares are also traded on the London stock market. A gold bullion market, once the world's largest, is operated by the Chinese Gold and Silver Exchange Society. The lack of exchange controls has contributed to the success of Hong Kong as a financial centre.

Trade. Hong Kong's free-trade policy has made the territory one of the world's great centres of trade. There is no tariff on imports, except for some luxury items, such as perfumes, motor vehicles, alcoholic beverages, and tobacco. Hong Kong is dependent upon imported products, which make up about half of the total amount of external trade, the rest being divided between exports and reexports. Apart from trade with other regions of China, Japan supplies the largest percentage of imports, and other major suppliers include Taiwan, the United States, Singapore, South Korea, Germany, and the United Kingdom. Machinery and transport equipment are the largest import categories, followed by consumer goods such as clothing, radios, television sets, stereos, computers, and watches. The third largest group includes raw materials and semimanufactured goods such as synthetic and natural textiles, chemicals, and electronic components. Other significant imported products are foodstuffs and fuels.

China became the main market for Hong Kong's products prior to 1997, and this trade remained predominant after the territory's reintegration. Other major markets include the United States, the United Kingdom, Germany, Taiwan, and Japan. Textiles and clothing are the leading exports. Also important are electrical machinery and appliances, office machinery, photographic apparatus, and a variety of other manufactured items. Reexports constitute a major portion of the goods shipped out of Hong Kong, which developed historically as an entrepôt port.

Transportation. With roadways limited relative to the population, the government has enforced strict limitations on automobile ownership and placed heavy emphasis on the development of public transportation. As a result, the rate of car ownership is low, although it is steadily rising. The majority of the populace makes its daily trips by public transport. Apart from the bus, tram (streetcar), and ferry, the public is also served by a unique minibus service, a rapid transit system, and an electric railway. Buses, however, are the largest carrier, responsible for more than half of the daily public transport trips excluding those by taxi, followed by the combined minibus and maxicab (a regulated form of minibus) service. The precipitous Victoria Peak area is served by one of the oldest transport companies, which operates a cable car system between the peak and the Central District.

International traffic is served by Hong Kong's international airport and its magnificent harbour, and there are good overland linkages with Kwangtung province. The new Hong Kong International Airport on Chek Lap Kok Island opened in 1998. The port of Hong Kong, based at one of the world's finest natural harbours, is renowned for its efficiency and capacity. The capacity of its container terminals at Kwai Chung ranks Hong Kong among the world's largest container ports. Speedy ferry service between Hong Kong and Macau and parts of Kwangtung is provided by various craft, including hydrofoils and hovercraft. Railroad transportation to Kwangtung is provided by the Kowloon-Canton Railway. Electrification of the railway and the growth, along its line, of the new towns of Sha Tin. Tai Po, and Fanling caused a considerable increase in passenger traffic. Externally, the line carries annually millions of tons of freight and head of livestock, as well as passenger traffic between Hong Kong and Kwangtung.

ADMINISTRATION AND SOCIAL CONDITIONS Government. When it was a colony, Hong Kong was administered by a governor, who was appointed by and represented the monarch of the United Kingdom, directed the government, served as the commander in chief, and presided over the two main organs of government, the Executive Council and the Legislative Council. With the resumption of Chinese sovereignty over the territory in July 1997, the Basic Law of the Hong Kong Special Administrative Region (promulgated by the National People's Congress of China in 1990) went into effect. The guiding principle of the Basic Law was the concept of "one country, two systems," under which Hong Kong was allowed to maintain its capitalist economy and to retain a large degree of political autonomy (except in matters of foreign policy and defense) for a period of 50 years.

The Basic Law vests executive authority in a chief executive, who is under the jurisdiction of the central government in Peking (Beijing) and serves a five-year term. Legislative authority rests with a Legislative Council, whose 60 members serve a four-year term; the chief executive, however, can dissolve the council before the end of a term. A 400-member Selection Committee, created by the central government, chose Tung Chee-hwa as the first chief executive. A Provisional Legislative Council was also

chosen, which served for one year after reversion. In May 1998, elections were held for the first formal Legislative Council (whose members served a two-year term), followed by elections for a full four-year term in September 2000. In each election, half the members were chosen by "functional constituencies," drawn from business and professional circles. In 1998, 20 members were elected from geographic constituencies, this number increasing to 24 in 2000. The remaining members-10 in 1998 and six in 2000-were chosen by an 800-member Election Committee, which was to cease functioning in subsequent elections. Ultimately, the chief executive and all council members are to be chosen by universal suffrage.

Civil and criminal law is derived generally from that of the United Kingdom, and the Basic Law states that this system is to be maintained. The highest court in the judiciary is the Court of Final Appeal, headed by a chief justice. This is followed by the High Court (headed by a chief judge) and by district, magistrate, and special courts. The chief executive appoints all judges, although judges of the Court of Final Appeal and the chief judge of the High Court also must be confirmed by the Legislative

Council. Education. Some three-fifths of the schools from kindergarten to secondary are private, and about another third are either subsidized or aided by public funds. The number of public schools in Hong Kong is quite small. Education is compulsory through the junior secondary level. Students finishing primary, junior secondary, and senior secondary education take examinations for allocation of school places at the next higher level.

Housing. Historically, housing has been a major problem in Hong Kong, where space is limited and the number of occupants ever-growing. Changes in the residential environment between the establishment of the colony in 1842 and the Japanese occupation in 1941 were moderate. compared to those that took place in the postwar years. There was no planning in the earlier days of development, except that generally the British lived on the Peak (the area around Victoria Peak), other nationalities in the Mid-Levels (below the Peak), and the wealthy on somewhat higher ground, where the grand garden houses and large mansions remain as landmarks. Most of the Chinese lived on the lowlands surrounding the harbour, where the streets were narrow and the houses made of wood, bricks, and mortar. They lacked not only good natural lighting and ventilation but also piped water and flush toilets. Frequently urban development was the result of plagues, fires, and typhoons rather than comprehensive city planning; and the presence of large numbers of squatters and street sleepers as a result of a shortage of housing has been

a persistent feature.

The limited housing supply was further reduced by the ravages of World War II. In the early postwar years, more than half of all families shared accommodations with others, living in cubicles, bed spaces, and attics and on roofs and verandas and in similar quarters. The colonial government's reluctant involvement in housing provision began with the building of resettlement blocks for fire victims in 1953, but it took real impetus in the early 1960s when the great demand for urban land resulted in the relocation of large numbers of squatters and urban poor. Eventually public housing came to accommodate more than half of the population, most of them living far from the urban core, and with growing numbers settling into the new towns. Land prices and rents have reached extremely high levels.

Health and welfare. The health of the populace is generally good, the result, in part, of an aggressive program of public measures, including the promotion of preventive medicine and personal health services, and a relatively high quality of life. Improving health indexes and a downward trend in the occurrence of major communicable diseases are leading indicators of the state of health in Hong Kong. Most deaths are caused by cancer, heart disease, and cerebrovascular diseases. Hospitals are divided into three groups: government, government-assisted, and private. These are under great pressure to meet the needs of the people. Clinics, some operated by the government, supplement other medical facilities. Boat-borne clinics provide services to some outlying villages.

The social security system is largely limited to emergency relief programs, although there are some allowances for unemployment, old age, and disabilities. The aging of the population, coupled with the extreme crowding, presents increasing problems of elderly care.

CULTURAL LIFE

Cultural milieu and the arts. Hong Kong's is truly a mixed culture. Not only does the territory celebrate festivals and holidays of the East and the West, such as the Dragon Boat Festival, the Mid-Autumn Festival, the Lunar (Chinese) New Year, Christmas, the Western New Year, and others, but it also enjoys hundreds of annual cultural events ranging from traditional Cantonese and other Chinese regional operas and puppet shows to performances of ballet, theatre, and music and exhibitions of paintings and sculptures by nationally and internationally renowned performers and artists. The Hong Kong Arts Festival has become one of Asia's major cultural events, and the Hong Kong Philharmonic Orchestra, the Hong Kong Chinese Orchestra, the Chung Ying Theatre Company, and the City Contemporary Dance Company are among the bestknown local artistic groups. The Hong Kong Conservatory of Music and the Hong Kong Academy of Ballet have been combined into the Hong Kong Academy for Performing Arts.

Scores of motion pictures are produced every year in Hong Kong, many of which attain international fame: some have even started new trends in the art, such as the so-called kung fu films. The Hong Kong International Film Festival, inaugurated in 1977, is a major event, especially for the display of Asian films. Hong Kong is also a regional as well as an international centre in fashion design and in the cutting and design of ornamental diamonds.

Cultural institutions. Apart from the libraries of the major educational institutions. Hong Kong has a system of 25 libraries, including mobile ones. Of the museums, major ones include those specializing in history, art, science and technology, and space. The multifunctional City Hall (a cultural centre) and the Art Centre provide the major gallery, theatrical, and concert facilities. In addition, town halls have been established in the new towns and cultural centres in some districts to serve local communities.

Recreation. Hong Kong's country park system covers two-fifths of the land area, and outdoor recreation in parks is a part of the way of life for many of the people. City dwellers use park areas on the urban fringe for walking, running, and T'ai Chi ch'uan, among other activities, while remoter locations are used for kite flying, picnicking, hiking, cycling, and camping. There are wellorganized programs of recreation and sports at the community level. The Ocean Park, one of the world's largest oceanariums, the Hong Kong Coliseum, a 12,500-seat indoor stadium that is among the largest in Asia, and the Queen Elizabeth Stadium are among the best venues for local and international sports events and musical, cultural, and entertainment programs. For those who can afford it, the many inlets and bays in Hong Kong provide a superb setting for pleasure sailing, waterskiing, canoeing, and other water sports.

Press and broadcasting. A wide-ranging and sophisticated communications network has developed in Hong Kong, reflecting its thriving commerce and international importance. There are some 60 newspapers (in various languages, but mostly Chinese) and the numbers of periodicals run into the hundreds. The territory is in addition the East and Southeast Asian headquarters for most of the major international news services. Broadcast news is provided by several television and radio companies, one of which is government-run. Under the British administration, the press developed largely free from government censorship. Television provides the major source of news and entertainment for the average family, and the Chinese television programs produced are not only for local consumption but also for overseas markets. Hong Kong also ranks as an important centre of publishing and printing: numerous books are published yearly for local consumption, several leading foreign publishers have their regional offices in Hong Kong, and many international magazines are printed in the territory.

For statistical data on Hong Kong, see the Britannica World Data section of the BRITANNICA BOOK OF THE YEAR.

History

EARLY SETTLEMENT

Archaeological remains of pottery, stone implements, rings, and bronzes found on more than 20 sites are Music and theatre

Public housing and the rising Ch'ing, led by the Manchus.

Before the British arrived in the mid-19th cent

Before the British arrived in the mid-19th century, Hong Kong Island had only a small fishing population, with life to recommend it for settlement. It lacked fertile soil and fresh water, was mountainous, and was reputed to be a haunt of pirates. But it was a relatively safe base for the British merchants who in 1821 began to use the fine harbour for the opium trade. The commercial and strategic value of this deep, sheltered harbour, possessing east and west entrances and lying on the main trade routes of Asia, was quickly realized.

After the first Opium War (1839-42), Hong Kong Island was ceded to Britain by the Treaty of Nanking. Not satisfied with only partial control of the harbour, the British forced China, under the Convention of Peking (1860) after the second Opium War (1856-60), to cede Kowloon Peninsula south of what is now Boundary Street and Stonecutters Island. By the Convention of 1898, the New Territories and 235 islands were leased to Britain for 99 years from July 1, 1898. With these additions, Hong Kong's population grew to 120,000 in 1861 and to more than 300,000 by the end of the century.

EVENTS BEFORE AND DURING WORLD WAR II

Since its establishment, Hong Kong, more than other treaty ports, afforded a refuge for people and capital from treaty ports, afforded a refuge for people and capital from China as well as a way station for emigrants destined for China as well as a way station for emigrants destined for China and Hong Kong were free and were responsive to political and economic conditions in China. After the establishment of the Republic of China in 1912, early nationalists sought to abolish all foreign treaty privileges in China. A boycott of foreign goods particularly hurt by Britain, which was well established in China. The campaign soon spread to Hong Kong, where strikes occurred in the 1920s.

When the Sino-Japanese War broke out in 1937, Hong Kong again became a refuge, with thousands of Chinese arriving before the advancing Japanese. With the outbreak of war in Europe in 1939, the position of the colony became even more precarious, and the Japanese attacked and occupied Hong Kong in December 1941. During the war Hong Kong's commerce was impaired; food was scarce, and many residents fled to inland China. The population, which numbered 1,600,000 in 1941, was about 650,000 in 1945 when the Japanese surrendered.

MODERN HONG KONG

Japanese

occupation

British troops returned to the city on Aug. 30, 1945, and civil government was reestablished in May 1946. Hundreds of thousands of Chinese and foreigners returned, joined by refugees from China fleeing the civil war between the Nationalist and Communist armies.

The 1951 United Nations embargo on trade with China and North Korea during the Korean War curtailed the entrepôt trade, the colony's lifeline, and for several years conditions were depressed. Hong Kong began its revival with light industries such as textiles, which were set up by immigrant capitalists, provided needed employment, and became the basis for further industrialization. With much of the development relying on cheap labour, toiling under poor working conditions, labour disputes and social discontent began to spread in the early 1960s. Riots broke out in Hong Kong and Kowloon in May 1967 following a fabour dispute in a plastic-flower factory. The economic and social unrest led to violent political demonstrations, largely inspired by followers of the Cultural Revolution (1966-76) in China. When the situation stabilized toward the end of the 1960s, working and living conditions were improved by labour legislation, government housing projects, and public works programs. Simultaneously, hightechnology industries such as electronics were developed, and the property and financial markets prospered until early 1973, when the stock market collapsed as billions of dollars were drained out of Hong Kong. From the mid-1970s the economy resumed its upward trend as relations with China improved.

In the late 1970s, concern about the future of Hong Kong began to loom large, as British jurisdiction over the leased areas of the New Territories neared the 1997 expiration date. Although the lease applied only to the New Territories, the Chinese government had consistently maintained that the whole of Hong Kong was Chinese territory and that the earlier Hong Kong-British agreements were unequal treaties and were invalid. Initial contacts between the two governments on the matter began in March 1979, but negotiations did not start until late 1982 and continued for two years. Finally, the Chinese-British joint declaration concerning Hong Kong was signed by the heads of the two governments in Peking on Dec. 19, 1984. The agreement stipulated that Hong Kong (including Hong Kong Island, Kowloon, and the New Territories) would revert to China on July 1, 1997. Difficult negotiations ensued between Hong Kong and Peking on the final wording of the document by which Hong Kong would be governed under Chinese sovereignty. Despite some reservations from Hong Kong, the National People's Congress ratified the Basic Law on April 4, 1990, which took effect on July 1, 1997, and established the Hong Kong Special Administrative Region directly under the central government.

The reversion has generally gone smoothly. The elimination of the colonial elected Legislative Council and the imposition of the provisional body was widely criticized, however. The central government's 1999 rejection of a judgment by Hong Kong's highest court on the rights of abode of children born on the mainland to Hong Kong residents also raised questions about the central government's respect for the principle of "one country, two systems." Hong Kong has gradually recovered from the Asian financial crisis of the late 1990s, continuing its shift from manufacturing to services and high tech industries.

For later developments in the history of Hong Kong, see the BRITANNICA BOOK OF THE YEAR.

BIBI IOCD ADIIV

General works. A well-illustrated discussion of geography, history, economy, and society is presented in *Hong Kong* (annual), issued by the Hong Kong Government Information Service, ALAN BIRCH, Y.C. JAO, and ELIZABETH SINN (eds.), Research Maternals for Hong Kong Studies (1994), and IAN SCOTT (complier), Hong Kong (1990), are useful for further research on all aspects of Hong Kong.

Physical and human geography. Geologic studies of Hong Kong include P.M. ALLEN and E.A. STEPHENS, Report on the Geological Survey of Hong Kong, 1967-1969 (1971). An analysis of the political, economic, geographic, and social developments in Hong Kong up to the early 1980s is found in CHI-KEUNG LEUNG. J.W. CUSHMAN, and WANG GUNGWU (eds.), Hong Kong: Dilemmas of Growth (1980). FRANK LEEMING, Street Studies in Hong Kong: Localities in a Chinese City (1977), examines Hong Kong's neighbourhoods. Socioeconomic studies include Hong Kong Social and Economic Trends, 1970-1980 (1981), compiled by the Hong Kong Census and Statistics Department; A.J. YOUNGSON, Hong Kong, Economic Growth and Policy (1982); and SEK HONG NG and DAVID A. LEVIN, Contemporary Issues in Hong Kong Labour Relations (1983). Hong Kong in Search of a Future (1984), ed. by JOSEPH Y.S. CHENG; and NORMAN MINERS, The Government and Politics of Hong Kong, 5th ed., updated by JAMES T.H. TANG (1998), address the politics of the territory.

HIStory. Overviews are provided by JAN MORRIS, Hong Kong (1998); and MING K. CHAN and JOHN D. YOUNG (eds.), Precarious Balance-Hong Kong Between China and Briain; 1842–1922 (1994). China-Britain

Horses and Horsemanship

oologically, the horse is a mammal of the family Equidae. It comprises a single species, Equus ca-I hallus, whose numerous varieties are called breeds. Before the advent of mechanized vehicles, riding on horseback was one of the chief means of transportation. Horsemanship evolved, of necessity, as the art of riding with maximum discernment and a minimum of interference with the horse. Until the 20th century riding was a monopoly of the cavalry, of cowboys and others whose work required riding on horseback, and of the wealthy,

who rode for sport. Although hunting and polo tend to remain sports of the wealthy and the role of the horse in battle has ended, special value is now placed on horse shows of a high standard, in which the most popular event is undoubtedly show jumping. Horsemanship has remained a valued social asset and symbol of prestige, but the opening of many new riding clubs and stables has made riding and horsemanship accessible to a much larger segment of the population.

Riding and horsemanship 651

Utility of the wild horse

In prehistoric times the wild horse was probably first hunted for food. When its domestication took place is unknown, but it certainly was long after the domestication of the dog or of cattle. It is supposed that the horse was first used by a tribe of Indo-European origin that lived in the steppes north of the chain of mountains adjacent to the Black and Caspian seas. Influenced by climate, food, and humans, the horse rapidly acquired its present form.

The relationship of the horse to humans has been unique. The horse is a partner and friend. It plowed fields and brought in the harvest, hauled goods and conveyed passengers, followed game and tracked cattle, and carried combatants into battle and adventurers to unknown lands. It has provided recreation in the form of jousts, tournaments, carousels, and the sport of riding. The influence of the horse is expressed in the English language in such terms as chivalry and cavalier, which connote honour, respect, good manners, and straightforwardness.

The horse is the "proudest conquest of Man," according to the French zoologist Le Comte de Buffon. Its place was at its master's side in the graves of the Scythian kings or in the tombs of the pharaohs. Many early human cultures were centred on possession of the horse. Superstition read meaning into the colours of the horse, and a horse's head suspended near a grave or sanctuary or on the gables of a house conferred supernatural powers on the place. Greek mythology created the centaur, the most obvious symbol of the oneness of horse and rider. White stallions were the supreme sacrifice to the gods, and the Greek general Xenophon recorded that "Gods and heroes are depicted on well-trained horses." A beautiful and well-trained horse was, therefore, a status symbol in ancient Greece. Kings, generals, and statesmen, of necessity, had to be horsemen. The names of famous horses are inseparably linked to those of their famous riders: Bucephalus, the charger of Alexander the Great; Incitatus, foolishly made a senator by the Roman emperor Caligula; El Morzillo, Cortés' favourite horse, to whom the Indians erected a statue; Roan Barbery, the stallion of Richard II, mentioned by Shakespeare; Copenhagen, the Duke of Wellington's horse, which was buried with military honours.

The horse has occupied a special place in the realm of art. From the Stone Age drawings to the marvel of the Parthenon frieze, from Chinese T'ang dynasty tomb sculptures to Leonardo da Vinci's sketches and Verrocchio's Colleoni, from the Qur'an to modern literature, the horse has inspired artists of all ages and in all parts of the world.

The horse

in art

The horse in life has served its master in travels, wars, and labours and in death has provided many commodities. Long before their domestication horses were hunted by primitive tribes for their flesh, and horsemeat is still consumed by people in parts of Europe and in Iceland and is the basis of many pet foods. Horse bones and cartilage are used to make glue. Tetanus antitoxin is obtained from the blood serum of horses previously inoculated with tetanus toxoid. From horsehide a number of articles are manufactured, including fine shoes and belts. The cordovan leather fabricated by the Moors in Córdoba, Spain, was originally made from horsehide. Stylish fur coats are made of the sleek coats of foals. Horsehair has wide use in upholstery, mattresses, and stiff lining for coats and suits; high-quality horsehair, usually white, is employed for violin bows. Horse manure, which today provides the basis for cultivation of mushrooms, was used by the Scythians for fuel. Mare's milk was drunk by the Scythians, the Mongols, and the Arabs.

FORM AND FUNCTION

A mature male horse is called a stallion, the female a mare. A stallion used for breeding is known as a stud. A castrated stallion is commonly called a gelding. Formerly, stallions were employed as riding horses, while mares were kept for breeding purposes only. Geldings were used for work and as ladies' riding horses. Recently, however, geldings generally have replaced stallions as riding horses. Young horses are known as foals; male foals are called colts and females fillies.

Anatomical adaptations. The primitive horse probably stood 12 hands tall (about 120 centimetres, or 48 inches) at the withers, the high point on the back at the base of the neck, and was dun coloured. Domestic horses gone wild, such as the mustangs of western North America, tend to revert to those primitive features under random mating; they generally are somewhat taller (about 15 hands), usually gray, dun, or brownish in colour, and move in herds led by a stallion.

The horse's general form is characteristic of an animal of speed: the long leg bones pivot on pulley-like joints that restrict movement to the fore and aft, the limbs are levered to muscle masses in such a way as to provide the most efficient use of energy, and the compact body is supported permanently on the tips of the toes, allowing fuller extension of the limbs in running (see illustration).

The rounded skull houses a large and complex brain, well developed in those areas that direct muscle coordination. While the horse is intelligent among subhuman animals. it is safe to say that the horse is more concerned with the functioning of its acute sensory reception and its musculature than with mental processes. Though much has been written about "educated" horses that appear to exhibit an ability to spell and count, it is generally agreed that in such cases a very perceptive animal is responding to cues from its master. But this ability is remarkable enough in its own right-for the cues are often given unconsciously by the human trainer, and detection of such subtle signals requires extremely sharp perception.

The horse, like other grazing herbivores, has typical adaptations for plant eating; a set of strong, high-crowned teeth. suited to grinding grasses and other harsh vegetation, and a relatively long digestive tract, most of which is intestine concerned with digesting cellulose matter from vegetation. Young horses have milk (or baby) teeth, which they begin to shed at about age two and a half. The permanent teeth, numbering 36 to 40, are completely developed by age four to five years. In the stallion these teeth are arranged as follows on the upper and lower jaws: 12 incisors that cut and pull at grasses; four canines, remnants without function in the modern horse and usually not found in

2nd phalans nal phalans

(Top) Skeleton of the horse; (bottom) points of the horse.

mares: 12 premolars and 12 molars, high prisms that keep moving out of the jaw to replace the surfaces worn off in grinding food.

Under domestication the horse has diversified into three major types, based on size and build: draft horses, heavy limbed and up to 20 hands high (200 centimetres, or 80 inches); ponies, by convention horses under 14.2 hands high (about 144 centimetres, or 57 inches); and light horses-the saddle or riding horses-which fall in the intermediate size range. Domestic horses tend to be nearsighted, less hardy than their ancestors, and often highstrung, especially thoroughbreds, where intensive breeding has been focused upon speed to the exclusion of other qualities. The stomach is relatively small, and, since much vegetation must be ingested to maintain vital processes. foraging is almost constant under natural conditions. Domestic animals are fed several (at least three) times a day in quantities governed by the exertion of the horse.

Senses. The extremely large eyes placed far back on the elongated head admirably suit the horse for its chief mode of defense: flight. Its long neck and high-set eyes, which register a much wider range than do the eyes of a human being, enable the horse to discern a possible threat even while eating low grasses. Like human vision, the horse's vision is binocular, but only in the narrow area directly forward, and evidence suggests that it does not register colour. While visual acuity is high, the eyes do not have variable focus, and objects at different distances register only on different areas of the retina, which requires tilting movements of the head. The senses of smell and hearing seem to be keener than in human beings. As the biologist George Gaylord Simpson has put it in Horses (1961): "Legs for running and eyes for warning have enabled horses to survive through the ages, although subject to constant attack by flesh eaters that liked nothing better than horse for supper."

Colour and pattern. From the dun of the primitive horse has sprung a variety of colours and patterns, some highly variable and difficult to distinguish. Among the most important colours are black, bay, chestnut (and sorrel), palomino, cream, and white.

The black colour is a true black, although a white face marking (blaze) and white ankles (stockings) may occur. The brown horse is almost black but has lighter areas around the muzzle, eyes, and legs. Bay refers to several shades of brown, from red brown and tan to sandy. Bay horses have a black mane, tail, and (usually) stockings. Chestnut is similar to bay but with none of the bay's black overtones. Lighter shades of chestnut are called sorrel. The palomino horse runs from cream to bronze, with a flaxen or silvery mane and tail. The cream is a diluted sorrel, or very pale yellow, nearly white. White in horses is variable, ranging from aging grays (see below) to albinos with blue eyes and pink skin and to pseudoalbinos with a buff mane or with brown eyes. The chief patterns of the white horse are gray, roan, pinto, and appaloosa. Gray horses are born dark brown or black and develop white hairs as they age, becoming almost all white in advanced years. Roan refers to white mixed with other colours at birth: blue roan is white mixed with black; red roan is mixed white and bay; and strawberry roan is white and chestnut. The pinto is almost any spotted pattern of white and another colour; other names, such as paint, calico, piebald, skewbald, overo, and tobiano, refer to subtle distinctions in type of colour or pattern. Appaloosa is another extremely variable pattern, but the term generally refers to a large white patch over the hips and loin, with scattered irregular dark spots.

Nutrition. The horse's natural food is grass. For stabled horses, the diet generally consists of hay and grain. The animal should not be fed immediately before or after work, to avoid digestive problems. Fresh water is important, especially when the horse is shedding its winter coat, but the animal should never be watered when it is overheated after working. Oats provide the greatest nutritional value and are given especially to foals. Older horses, whose teeth are worn down, or those with digestive troubles, can be provided with crushed oats. Chaff (minced straw) can be added to the oat ration of animals that eat greedily or do not chew the grain properly. Crushed barley is sometimes

cation into three types

substituted in part for oats. Hay provides the bulk of the horse's ration and may be of varying composition according to locale. Mash is bran mixed with water and with various invigorating additions or medications. It may be given to horses with digestive troubles or deficient eating habits. Corn (maize) is used as a fattening cereal, but it makes the horse sweat easily. Salt is needed by the horse at all times and especially when shedding. Bread, carrots, and sugar are tidbits often used to reward an animal by the rider or trainer. In times of poverty horses have adapted to all sorts of food-potatoes, beans, green leaves, and in Iceland even fish-but such foods are not generally taken if other fare is available. A number of commercial feed mixes are available to modern breeders and owners;

these mixes contain minerals, vitamins, and other nutri-

ents and are designed to provide a balanced diet when

supplemented with hay. Behaviour. The horse's nervous system is highly developed and gives proof to varying degrees of the essential faculties that are the basis of intelligence: instinct, memory, and judgment. Foals, which stand on their feet a short while after birth and are able to follow their mothers within a few hours, even at this early stage in life exhibit the traits generally ascribed to horses. They have a tendency to flee danger. They express fear sometimes by showing panic and sometimes by immobility. Horses rarely attack and do so either when flight is impossible or when driven to assault a person who has treated them brutally.

Habit and instinct

Habit governs a large number of their reactions. Instinct, together with a fine sense of smell and hearing, enables them to sense water, fire, even distant danger. An extremely well-developed sense of direction permits the horse to find its way back to its stables even at night or after a prolonged absence. The visual memory of the horse prompts it to shy repeatedly from an object or place where it had earlier experienced fear. The animal's auditory memory, which enabled ancient army horses or hunters to follow the sounds of the bugles, is used in training. When teaching, the instructor always uses the same words and the same tone of voice for a given desired reaction. Intelligent horses soon attach certain movements desired by their trainers to particular sounds and even try to anticipate their rider's wishes.

While instinct is an unconscious reaction more or less present in all individuals of the same species, the degree of its expression varies according to the individual and its development. Most horses can sense a rider's uncertainty, nervousness, or fear and are thereby encouraged to disregard or even deliberately disobey the rider. Highbred animals, which give evidence of greater intelligence than those of low breeding, are capable not only of acts of vengeance and jealousy against their riders but also of expressions of confidence, obedience, affection, and fidelity. They are less willing than a lowbred horse to suffer rough handling or unjust treatment.

Cunning animals have been known to employ their intelligence and physical skill to a determined end, such as opening the latch of a stall or the lid of a chest of oats.

Reproduction and development. The onset of adult sex characteristics generally begins at the age of 16 to 18 months; the horse is considered mature, according to the breed, at approximately three years and adult at five. Fecundity varies according to the breed and may last beyond age 20 with thoroughbreds and to 12 or 15 with other horses. The gestation period is 11 months, 280 days being the minimum in which the foal can be born with expectation to live. As a rule a mare produces one foal per mating, twins occasionally, and triplets rarely. The foal is weaned at six months.

The useful life of a horse varies according to the amount of work it is required to do and the maintenance furnished by its owner. A horse that is trained carefully and slowly and is given the necessary time for development may be expected to serve to an older age than a horse that is rushed in its training. Racehorses that enter into races at the age of two rarely remain on the turf beyond eight. Well-kept riding horses, on the contrary, may be used more than 20 years.

The life span of a horse is calculated at six to seven

times the time necessary for his physical and mental de- Life velopment; that is, 30 to 35 years at the utmost, the rule expectancy being about 20 to 25 years. Ponies generally live longer than larger horses. There are a number of examples of horses that have passed the usual limit of age. The veterinary university of Vienna conserves the skeleton of a thoroughbred mare of 44 years of age. There have been reports made of horses living to the early 60s in age.

Diseases and parasites. Horses are subjected to a number of contagious diseases, such as influenza, strangles, glanders, equine encephalomyelitis, and swamp fever. Their skin is affected by parasites, including certain mites, ticks, and lice. Those with sensitive skin are especially subject to eczemas and abscesses, which may result from neglect or contamination. Sores caused by injuries to the skin from ill-fitting or unclean saddles and bridles are common ailments. The horse's digestive tract is particularly sensitive to spoiled feed, which causes acute or chronic indigestion, especially in hot weather. Worms can develop in the intestine and include the larvae of the botfly, pinworms, tapeworms, and roundworms (ascarids). Overwork and neglect may predispose the horse to pneumonia and rheumatism. The ailment known as roaring is an infection of the larynx that makes the horse inhale noisily; a milder form causes the horse to whistle. Chronic asthma, or "broken wind," is an ailment that is considered to be all but incurable. A horse's legs and feet are sensitive to blows, sprains, and overwork, especially if the horse is young or is worked on hard surfaces. Lameness may be caused by bony growths, such as splints, spavins, and ringbones, by soft-tissue enlargements, known as windgalls, thoroughpins, and shoe boils, and by injury to the hooves. including sand crack, split hoof, tread thrush, and acute or chronic laminitis.

BREEDS OF HORSES

The first intensively domesticated horses were developed in Central Asia. They were small, lightweight, and stocky. In time, two general groups of horses emerged: the southerly Arab-Barb types (from the Barbary coast) and the northerly, so-called cold-blooded types. When, where, and how these horses appeared is disputed. Nevertheless all modern breeds-the light, fast, spirited breeds typified by the modern Arabian, the heavier, slower, and calmer working breeds typified by the Belgian, and the intermediate breeds typified by the Thoroughbred-may be classified according to where they originated (e.g., Percheron, Clydesdale, and Arabian), by the principal use of the horse (riding, draft, coach horse), and by their outward appearance and size (light, heavy, pony).

Light horses. Arabian. Its long history is obscured by legend, but the Arabian breed, prized for its stamina, intelligence, and character, is known to have been developed in Arabia by the 7th century AD. It is a compact horse with a small head, protruding eyes, wide nostrils, marked withers, and a short back. It usually has only 23 vertebrae, while 24 is the usual number for other breeds. Its legs are strong with fine hooves. The coat, tail, and mane are of fine silky hair. While many colours are possible in the breed, gray prevails. The most famous stud farm is in the region of Najd, Saudi Arabia, but many fine Arabian horses are bred in the United States.

Thoroughbred. The history of the English Thoroughbred is a long one. Records indicate that a stock of Arab and Barb horses was introduced into England as early as the 3rd century. Conditions of climate, soil, and water favoured development, and selective breeding was long encouraged by those interested in racing. Under the reigns of James I and Charles I, 43 mares (the Royal Mares) were imported into England, and a record, the General Stud Book, was begun in which are inscribed only those horses that may be traced back to the Royal Mares in direct line, or to only three other horses imported to England: the Byerly Turk (imported in 1689), the Darley Arabian (after 1700), and the Godolphin Barb (also known as the Godolphin Arabian, imported about 1730). The English Thoroughbred has since been introduced to most countries, where it is bred for racing or used to improve local breeds. The Thoroughbred has a small fine head, a

Thoroughbred lineage

deep chest, and a straight back. Its legs have short bones that allow a long easy stride, and its coat is generally bay or chestnut, rarely black or gray.

Asian Asian breeds were strongly influenced by Arabian or Persian breeds, which together with the horses of the steppes produced small, plain-looking horses of great intelligence and endurance. Among them are the Tartar. Kirghis, Mongol, and Cossack horses. A Persian stallion and a Dutch mare produced the Orlov trotter in 1778. named after Count Orlov, the owner of the stud farm where the mating took place.

Anglo-Arab. The Anglo-Arab breed originated in France with a crossing of English Thoroughbreds to pure Arabians. The matings produced a horse larger than the Arabian and smaller than the Thoroughbred, of easy maintenance. and capable of carrying considerable weight in the saddle. Its coat is generally chestnut or bay.

American breeds. The Standardbred, a breed that excels at the pace and trot, ranks as one of the world's finest harness racers. A powerful, long-bodied horse, the Standardbred was developed during the first half of the 19th century and can be traced largely to the sire Messenger, a Thoroughbred imported from Britain in 1788 and mated to various brood mares in New York, New Jersey, and Pennsylvania

The quarter horse was bred for races of a quarter of a mile and is said to descend from Janus, a small Thoroughbred stallion imported into Virginia toward the end of the 18th century. It is 14.2 to 16 hands high, with sturdily muscled hindquarters, essential for the fast departure required in short races. It serves as a polo pony equally well as for ranch work.

The Morgan horse originated from a stallion given to Justin Morgan of Vermont around 1795. This breed has become a most versatile horse for riding, pulling carriages, farm labour, and cattle cutting. It was the ideal army charger. It stands about 15 hands high and is robust, goodnatured, willing, and intelligent. Its coat is dark brown or liver chestnut.

Appaloosa is a colour breed (see above) said to have descended in the Nez Percé Indian territory of North America from wild mustangs, which in turn descended from Spanish horses brought to the New World by explorers. The Appaloosa is 14.2 to 15.2 hands high, of sturdy build

and of most diverse use; it is especially good in farm work. American breeders have also developed several horses that have specialized gaits. These gaited breeds include the American saddle horse, the Tennessee walking horse, and the Missouri fox trotting horse. The American saddle horse has a small head and spectacular high-stepping movements. It is trained for either three or five gaits. The three-gaited horses perform the walk, trot, and canter; the five-gaited horses in addition perform the rack, a quick, high-stepping four-beat gait, and the slow gait, a somewhat slower form of the rack. Since they are used mainly for shows, their hooves are kept rather long, and the muscles of the tail are often clipped so that the base of the tail is carried high. Chestnut and bay are the usual colours. The Tennessee walking horse-a breed derived partially from the Thoroughbred, Standardbred, Morgan, and American saddle horse-serves as a comfortable riding mount used to cover great distances at considerable speed. Its specialty is the running walk, a long and swift stride. Bay is the most common colour. The Missouri fox trotting horse, a breed developed to cover the rough terrain of the Ozark region, is characterized by an unusual gait, called the fox trot, in which the front legs move at a walk while the hind legs perform a trot. The most common colours for this breed are sorrel and chestnut sorrel.

Other light breeds. The English Hackney is a light car-riage horse, influenced by the Thoroughbred, capable of covering distances of 12 to 15 miles (19 to 24 kilometres) per hour at the trot and canter. It measures 15.2 to 15.3 hands high and is appreciated for its high knee action.

The Cleveland Bay carriage horse, up to 17 hands high and generally bay in colour, is similar to the Yorkshire Coach horse. Both breeds are now used for the sport of driving.

Other versatile breeds include the German Holstein,

Representative horse breeds (Top) The Belgian, a heavy breed; (centre) an Indian pony; (bottom) the American saddle horse, a light breed.

Hanoverian, and East Prussian (Trakehner), which serve equally well for riding, light labour, and carriage. These horses, 16 to 18 hands high and of all colours, are now mostly bred for sport.

The Andalusian, a high-stepping, spirited horse, and the small but enduring Barb produced the Lipizzaner, which was named after the stud farm founded near Trieste, Italy, in 1580. Originally of all colours, the Lipizzaner is gray or, now exceptionally, bay. It is small, rarely over 15 hands high, of powerful build but slender legs, and with long silky mane and tail. Intelligence and sweetness of disposition as well as gracefulness destined it for academic horsemanship, notably as practiced at the Spanish Riding School of Vienna.

Heavy breeds. The horses used for heavy loads and

The Appaloosa Originating in the South Tyrol, the Hastlinger is a mountain horse, enduring, robust, and versatile, used for all farm labour, for pulling a carriage or sledge, and for pack hauline. It is rarely over 14.2 hands high and is chestnut

Ponies. Ponies are any horses other than Arabians that are shorter than 14.2 hands. They are generally very sturdy, intelligent, energetic, and sometimes stubborn. The coat is of all colours, mainly dark, and the mane and tail are full. Ponies are used for pulling carriages and puck loads and as children's fiding horses or pets. There are numerous varieties, including the Welsh, Dartmoor, Exmoor, Connemara, New Forest, Highland, Dale, Fell, pony of the Americas, Shetland (under seven hands high), Iceland, and Norwegian. Ponies of the warmer countries include the Indian, Java, Manila, and Argentine. (A.W.P,Ed.)

EVOLUTION OF THE HORSE

with a flaxen mane and tail.

The evolutionary lineage of the horse is among the best documented in all paleontology. The history of the horse family, Equidae, began during the Eocene Epoch, which lasted from about 54,000,000 to 38,000,000 years ago. During the early Eocene there appeared the first ancestral horse, a hoofed, browsing mammal known technically as Hyracotherium but more commonly called eohippus, the "dawn horse." Fossils of eohippus, which have been found in both North America and Europe, show an animal that stood from 4.2 to 5 hands high, diminutive by comparison to the modern horse, with an arched back and raised hindquarters. The legs ended in padded feet with four functional hooves on the forefeet and three on the hindfeet-quite unlike the unpadded, single-hoofed foot of modern equines. The skull lacked the large, flexible muzzle of the modern horse, and the size and shape of the cranium indicate that the brain was far smaller and less complex than that of today's horse. The teeth, too, differed significantly from those of the modern equines. being adapted to a fairly general browser's diet. Echippus was, in fact, so unhorselike that its evolutionary relationship to the modern equines was at first unsuspected. It was not until paleontologists had unearthed fossils of later extinct horses that the link to eohippus became clear.

The line leading from cohippus to the modern horse exhibits the following evolutionary trends increase in size, reduction in the number of hooves, loss of the foot pads, lengthening of the legs, fusion of the independent bones of the lower legs, elongation of the muzzle, increase in the size and complexity of the brain, and the development of crested, high-crowned teeth suited to grazing. This is not to imply that there was a steady, gradual progression in these characteristics leading inevitably from those of cohippus to those of the modern horse. Some of these features, such as grazing dentition, appear abruptly in the features, such as grazing dentition, appear abruptly in the soil record, rather than as the culmination of numerous, gradual changes. Echippus, moreover, gave rise to many now-extinct branches of the horse family, some of which different substantially from the line leading to the modern substantial the four three substantials from the line leading to the modern substantials from the line leading to the modern substantials from the four substantials f

Although cohippus fossils occur in both the Old and New worlds, the subsequent evolution of the horse took place chiefly in North America. During the remainder of the Eocene, the prime evolutionary changes were in dentition. Orchippus, a genus from the middle Eocene, and Epithipus, a genus from the late Eocene, resembled cohippus in size and in the structure of the limbs. But the form of the check teeth—the four premolars and the three molars found in each half of both jaws—had changed somewhat. In cohippus the premolars and molars were clearly distinct, the molars being larger. In Orchippus the fourth premolar

had become similar to the molars, and in Epihippus both the third and fourth premolars had become molar-like. In addition, the individual cusps that characterized the cheek teeth of cohippus had given way in Epihippus to a system of continuous crests or ridges running the length of the molars and molariform premolars. These changes, which represented adaptations to a more specialized browsing diet, were retained by all subsequent ancestors of the modern horse.

Fossils of Mesohippus, the next important ancestor of the modern horse, are found in the early and middle Oligocene of North America (the Oligocene Epoch lasted from about 38,000,000 to 26,000,000 years ago). Mesohippus was far more horselike than its Eocene ancestors—it was larger (averaging about six hands high); the snout was more muzzleike; and the legs were longer and more slender. Mesohippus also had a larger brain. The fourth too on the forefoot had been reduced to a vestige, so that both the forefeet and hindfeet carried three functional toes and a foot pad. The teeth remained adapted to browsing.

By the late Oligocene, Mesohippus had evolved into a somewhat larger form known as Miohippus. The descendants of Miohippus split into various evolutionary branches during the early Miocene (the Miocene Epoch lasted from about 26,000,000 to 7,000,000 years ago). One of these branches, known as the anchitheres, included a variety of three-toed, browsing horses comprising several genera. Anchitheres were successful, and some genera spread from North America across the Bering land bridge into Eurasia.

It was a different branch, however, that led from Miohinpus to the modern horse. The first representative of this line, Parahippus, appeared in the early Miocene. Parahippus and its descendants marked a radical departure in that they had teeth adapted to eating grass. Grasses were at this time becoming widespread across the North American plains, providing Parahippus with a vast food supply. Grass is a much coarser food than succulent leaves and requires a different kind of tooth structure. The cheek teeth developed larger, stronger crests and became adapted to the side-to-side motion of the lower jaw necessary to grind grass blades. Each tooth also had an extremely long crown, most of which, in the young animal, was buried beneath the gum line. As grinding wore down the exposed surface, some of the buried crown grew out. This highcrowned tooth structure assured the animal of having an adequate grinding surface throughout its normal life span. Adaptations in the digestive tract must have occurred as well, but the organs of digestion are not preserved in the fossil record.

The change from browsing to grazing dentition was essentially completed in Merychippus, which evolved from Parahippus during the middle and late Miocene. Merychippus must have looked much like a modern pony. It was fairly large, standing about 10 hands high, and its skull was similar to that of the modern horse. The long bones of the lower leg had become fused; this structure, which has been preserved in all modern equines, is an adaptation for swift running. The feet remained three-toed, but in many species the foot pad was lost, and the two side toes became rather small. In these forms, the large central toe bore the animal's weight. Strong ligaments attached this hoofed central toe to the bones of the ankles and lower leg. providing a spring mechanism that pushed the flexed hoof forward after the impact of hitting the ground. Merychippus gave rise to numerous evolutionary lines during the late Miocene. Most of these, including Hipparion, Neohipparion, and Nannippus, retained the three-toed foot of their ancestors. One line, however, led to the one-toed Pliohippus, the direct predecessor of Equus. Pliohippus fossils occur in the early to middle Pliocene beds of North America (the Pliocene Epoch lasted from about 7,000,000 to 2,500,000 years ago).

Equas—the genus to which all modern equines, including horses, asses, and zebras, belong—evolved from Pliohippus toward the end of the Pliocene. Equus shows even greater development of the spring mechanism in the foot and exhibits straighter and longer cheek teeth. This new form was extremely successful and had spread from Dental adaptations to a grass diet

Trends in the evolution of the horse

The demise of Equus in the Americas

the plains of North America to South America and to all parts of the Old World by the early Pleistocene (the Pleistocene Epoch lasted from about 2,500,000 to 10.-000 years ago). Equus flourished in its North American homeland throughout the Pleistocene; then, about 10,000 to 8,000 years ago, Equus disappeared from North and South America. Scholars have offered various explanations for this disappearance, including the emergence of devastating diseases or the arrival of human populations (which presumably hunted the horse for food). Despite these speculations, the reasons for the demise of Equus in the New World remain uncertain. The submergence of the Bering land bridge prevented any return migration of horses from Asia, and Equus was not reintroduced into its native continent until the Spanish explorers brought horses in the early 16th century.

During the Pleistocene, the evolution of Equus in the Old World gave rise to all the modern members of the genus. The modern horse, Equus caballus, became widespread from central Asia to most of Europe. Local types of horses. all breeds of this single species, undoubtedly developed, and three of these-Przewalski's horse from central Asia. the tarpan from eastern Europe and the Ukrainian steppes. and the forest horse of northern Europe-are generally credited as being the ancestral stock of the domestic horse. According to this line of thinking, Przewalski's horse and the tarpan formed the basic breeding stock from which the southerly "warm-blooded" horses developed, while the forest horse gave rise to the heavy, "cold-blooded" breeds.

Riding and horsemanship

HISTORY

Origins and early history. From the 2nd millennium BC, and probably even earlier, the horse was employed as a riding animal by fierce nomadic peoples of central Asia. One of these peoples, the Scythians, were accomplished horsemen and used saddles. It is also likely that they realized the importance of a firm seat and were the first to devise a form of stirrup. A saddled horse with straps hanging at the side and looped at the lower end is portraved on a vase of the 4th century BC found at Chertomlyk in the Soviet Union. This contrivance may have been used for mounting only, however, because of the danger of being unable to free the foot quickly in dismounting. The Greek historian Strabo said that the indocility of the Scythians' wild horses made gelding necessary, a practice until then unknown in the ancient world. The Sarmatians, superb horsemen who superseded the Scythians, rode bareback, controlling their horses with knee pressure and distribution of the rider's weight.

Among the earliest peoples to fight and hunt on horseback were the Hittites, the Assyrians, and the Babylonians; at the same time (about 1500 BC) the Hyksos, or Shepherd Kings, introduced horses into Egypt and rode them in all their wars. In the 8th and 7th centuries BC, the Scythians brought horses to Greece, where the art of riding developed rapidly, at first only for pleasure. A frieze from the Parthenon in Athens shows Greeks riding bareback, Philip II of Macedon had a body of cavalry in his army, and the army of his son Alexander had separate, organized horse units. In the 4th century BC another Greek historian, Xenophon, wrote his treatise Peri hippikes (On Horsemanship), giving excellent advice on horsemanship. Many of his principles are still perfectly valid. He advocated the use of the mildest possible bits and disapproved of the use of force in training and in riding. The Roman mounted troops were normally barbarian archers who rode without stirrups and apparently without reins, leaving the hands free to use the bow and arrow.

As a general rule almost every item of riding equipment used today originated among the horsemen of the Eurasian steppes and was adopted by the people of the lands they overran to the east, the south, and later the west.

Horseshoes of various types were used by migratory Eurasian tribes about the 2nd century BC, but the nailed iron horseshoe as used today first appeared in Europe about the 5th century AD, introduced by invaders from

the East. One, complete with nails, was found in the tomb of the Frankish king Childeric I at Tournai, Belg.

Attila is said to have brought the stirrup to Europe. Round or triangular iron stirrups were used by the Avars in the 6th century AD, and metal stirrups were used by the Byzantine cavalry. They were in use in China and Japan by about AD 600.

The principle of controlling a horse by exerting pressure on its mouth through a bit (a metal contrivance inserted in the mouth of the horse) and reins (straps attached to the bit held by the rider) was practiced from the earliest times, and bits made of bone and antlers have been found dating from before 1000 BC. The flexible mouthpiece with two links and its variations have been in use down the centuries, leading directly to the jointed snaffle bit of the present day.

Early, stumpy prickspurs have been found in Bohemia on 4th-century-BC Celtic sites.

Military horsemanship. The importance of cavalry increased in the early Middle Ages, and in the 1,000 years that followed, mounted warriors became predominant in battle. Armour steadily became bulkier and heavier, forcing the breeding of more and more massive horses, until the combination rendered maneuverability nearly impossible.

Efforts to overcome this were made at a Naples riding academy in the early 16th century, when Federico Grisone and Giovanni Battista Pignatelli tried to combine classical Greek principles with the requirements of medieval mounted combat. After Xenophon, except for a 14thcentury treatise by Ibn Hudhayl, an Arab of Granada, Spain, apparently no literature on riding was produced until Grisone published his Gli ordini di cavalcare ("The Orders of Riding") in 1550.

The development of firearms led to the shedding of armour, making it possible for some further modifications in methods and training under followers of the school of Pignatelli and Grisone, such as William Cavendish, duke of Newcastle. In 1733 François Robichon de la Guérinière published École de cavalerie ("School of Cavalry"), in which he explained how a horse can be trained without being forced into submission, the fundamental precept of modern dressage. Dressage is the methodical training of a horse for any of a wide range of purposes, excluding only racing and cross-country riding.

Meanwhile, the Spanish Imperial Riding School in Vienna and the French cavalry centre at Saumur aimed at perfecting the combined performance of horse and rider. Their technique and academic seat, a formal riding position or style in which the rider sits erectly, deep in the middle of the saddle, exerted considerable influence in Europe and America during the 18th and 19th centuries and are still used in modern dressage. The head riding master at Saumur, Comte Antoine d'Aure, however, promoted a bold, relaxed, and more natural, if less "correct," style of riding across country, in disagreement with his 19thcentury contemporary François Baucher, a horseman of great ability with formal haute école ("high school") ideas. Classical exercises in the manège, or school for riding, had to make way for simplified and more rational riding in war and the hunt. During this period hunting riders jumped obstacles with their feet forward, their torso back on the horse's haunches, and the horse's head held up.

The horse often leaped in terror. At the turn of the 20th century, Capt. Federico Caprilli, an Italian cavalry instructor, made a thorough study of the psychology and mechanics of locomotion of the horse. He completely revolutionized the established system by innovating the forward seat, a position and style of riding in which the rider's weight is centred forward in the saddle, over the horse's withers. Caprilli wrote very little, but his pupil, Piero Santini, popularized his master's fundamental principles. Except in dressage and showing, the forward seat is the one now most frequently used, especially for jumping.

THE ART OF HORSEMANSHIP

The basic principle of horsemanship is to obtain results in a humane way by a combination of balance, seat, hands, and legs.

Growth of modern technique

Classical horsemanship

Fundamentals. The horse's natural centre of gravity shifts with its every movement and change of gait. Considering that a mounted horse also carries a comparatively unstable burden approximately one-fifth of its own weight, it is up to the rider to conform with the movements of the horse as much as possible.

Before one mounts, the saddle is checked to be sure that it fits both the horse and its rider. Experienced riders position themselves in the saddle in such a way as to be able to stay on the horse and control it. The seat adopted depends on the particular task at hand. A secure seat is essential, giving riders complete independence and freedom to apply effectively the aids at their disposal. Good riders do not overrule the horse, but, firmly and without inflicting pain, they persuade it to submit to their wishes.

The horse's movements. The natural gaits of the horse are the walk, the trot, the canter or slow gallop, and the gallop, although in dressage the canter and gallop are not usually differentiated. A riding horse is trained in each gait and in the change from one to another.

During the walk and the gallop the horse's head moves down and forward, then up and back (only at the trot is it still); riders follow these movements with their hands.

Walk. The walk is a slow, four-beat, rhythmic pace of distinct successive hoof beats in an order such as near (left) hind, near fore, off (right) hind, off fore. Alternately two or three feet may be touching the ground simultaneously. It may be a free, or ordinary, walk in which relaxed extended action allows the horse freedom of its head and neck, but contact with the mouth is maintained; or it may be a collected walk, a short-striding gait full of impulsion, or vigour; or it may be an extended walk of long, unhurried strides.

Trot. The trot is a two-beat gait, light and balanced, the fore and hind diagonal pairs of legs following each other almost simultaneously-near fore, off hind, off fore, and near hind. Riders can either sit in the saddle and be bumped as the horse springs from one diagonal to the other, or they can rise to the trot, post, by rising out of the saddle slightly and allowing more of their weight to bear on the stirrups when one or the other of the diagonal pairs of legs leaves the ground. Posting reduces the impact of the trot on both horse and rider.

Canter. As the horse moves faster, its gait changes into the canter, or ordinary gallop, in which the rider does not rise or bump. It is a three-beat gait, graceful and elegant, characterized by one or the other of the forelegs and both hindlegs leading-near hind, off hind, and near fore practically together, then off fore, followed briefly by complete suspension. Cantering can be on the near lead or the off, depending on which is the last foot to leave the ground. The rider's body is more forward than at the trot. the weight taken by the stirrups.

Gallop. An accelerated canter becomes the gallop, in which the rider's weight is brought sharply forward as the horse reaches speeds up to 30 miles (48 kilometres) an hour. The horse's movements are the same as in the canter. To some authorities, the gallop is a four-beat gait, especially in an extended run.

Other gaits. There are a number of disconnected and intermediate gaits, some done only by horses bred to perform them. One is the rack, a four-beat gait, with each beat evenly spaced in perfect cadence and rapid succession. The legs on either side move together, the hindleg striking the ground slightly before the foreleg. The single foot is similar to the rack but slower. In the pace, the legs on either side move and strike the ground together in a two-beat gait. The fox trot and the amble are four-beat gaits, the latter smoother and gliding.

Training and equipment. Depending on the abilities and inclinations of horse and trainer, training may include such elements as collection (controlled, precise, elevated movement) and extension (smooth, swift, reaching movement-the opposite of collection) at all paces; turns on the forehand (that part of the horse that is in front of the rider) and hindquarters; changing lead leg at the canter; change of speed; reining back, or moving backward; lateral movements; and finally the refinements of dressage, jumping, and cross-country riding.

Communication with the horse is rendered possible by the use of the bit and the aids. The rider signals intentions to the horse by a combination of recognized movements of hands and legs, using several articles of equipment. By repetition the horse remembers this language, understands what is required, and obeys.

Bits. There are several types of bits, including the snaffle, the double bridle, and the Pelham.

The simplest is the snaffle, also called the bridgon. It consists of a single straight or jointed mouthpiece with a ring at each end for the reins. The snaffle is used for racing and frequently for cross-country riding. It is appropriate for preliminary schooling.

The double bridle is used for advanced schooling. It consists of a jointed snaffle and a straight bit placed together in the mouth, first the snaffle, then the bit, both functioning independently and attached to separate reins. The mouthpiece of the bit can have a port or indentation in its centre to give more control. The slightest pull on the bit rein exerts pressure on the mouth.

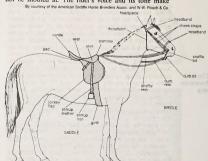

The double

The Pelham is a snaffle with a straight mouthpiece; cheekpieces with rings at the lower ends for curb action; and a curb chain, with which pressure may be applied to the lower outside of the mouth. The Pelham gives control with only slight discomfort and is popular for polo-

Bridles. The bridle is a set of straps that makes the bit secure in the animal's mouth and thus ensures human control by means of the reins (see figure). The upper portion of the bridle consists of the headpiece passing behind the ears and joining the headband over the forehead: the cheek straps run down the sides of the head to the bit, to which they are fastened; in the blind type of driving bridle the blinkers, rectangular or round leather flaps that prevent the animal from seeing anything except what lies in front, are attached to the cheek straps; the noseband passes around the front of the nose just above the nostrils: and the throatlatch extends from the top of the cheek straps underneath the head.

Aids. The principal features of a horse's mentality are acute powers of observation, innate timidity, and a good memory. To a certain extent the horse can also understand. Schooling is based on these faculties, and the rider's aids are applied accordingly. The natural aids are the voice, the hands through the reins and the bit, the legs and heels, and the movement of the rider's weight. The whip, the spur, and devices such as martingales, special nosebands, and reins are artificial aids, so termed in theory, as the horse does not discriminate between natural and artificial.

Horses are easily startled. A good horseman will approach them quietly, speaking to them and patting them to give them confidence. Silence on the part of the rider can even cause disquiet to some horses, but they should not be shouted at. The rider's voice and its tone make

Nomenclature of a modern bridle and English saddle.

The rack gait

a useful aid in teaching a horse in its early schooling to walk, trot, canter, and halt.

To keep the horse alert at all times, the rider's hands keep a light, continual contact with its mouth, even at the halt. The hands are employed together with the legs to maintain contact, to urge the horse forward, to turn, to rein back, and generally to control the forehand. The horse is said to be collected and light in hand when the action of the bit can cause it to flex, or relax, its jaw with its head bent at the poll, or top,

When pressed simultaneously against the flanks, immediately after the hands ease the reins, the legs induce the forward movement of the horse. They are of the greatest importance in creating and maintaining impulsion, in controlling the hindquarters, and for lateral movement.

Riders achieve unity of balance by means of the weight aid, that is, by moving the body in harmony with the movements of the horse, forward, backward, or to the side. Thus, in cantering to the left, the rider leans to the left; or when about to descend a steep slope, the rider stays erect while the horse is feeling for the edge with its forefeet, but as soon as the descent starts the rider leans forward, leaving the hindquarters free to act as a brake and to prevent scraping the back of the horse's rear legs on rough ground. Meanwhile the hands keep the horse headed straight to maintain its balance.

The whip is used chiefly to reinforce the leg aid for control, to command attention, and to demand obedience, but it can be used as a punishment in cases of deliberate rebellion. A horse may show resistance by gnashing its teeth and swishing its tail. Striking should always be on the quarters, behind the saddle girth, and must be immediate since a horse can associate only nearly simultaneous events. This applies equally to rewards. A friendly tone of voice or a pat on the neck are types of reward.

Although normally the leg or the heel, or both, should be sufficient, spurs, which should always be blunt, assist the legs in directing the precision movements of advanced schooling. Their use must be correctly timed.

Martingales are of three types: running, standing, or Irish. The running and standing martingales are attached to the saddle straps at one end and the bit reins or bridle at the other. The Irish martingale, a short strap below the horse's chin through which the reins pass, is used for racing and stops the horse from jerking the reins over its head. As the horse cannot see below a line from the eye to the nostril. it should not be allowed to toss its head back, particularly near an obstacle, as it is liable to leap blindly. A martingale should not be necessary with a well-schooled horse.

The noseband, a strap of the bridle that encircles the horse's nose, may be either a cavesson, with a headpiece and rings for attaching a long training rein, or a noseband with a headstrap, only necessary if a standing martingale is used. A variety of other nosebands are intended for horses that pull, or bear, on the reins unnecessarily.

Seats. The saddle, the length of the stirrup, and the rider's seat, or style of riding, should suit the purpose for which the horse is ridden. The first use of the stirrup is to enable the rider to get on the horse, normally from the near (left) side. With the raised foot in the stirrup the rider should avoid digging the horse in the flank on springing up and should gradually slide into position without landing on the horse's kidneys with a bump. With an excitable horse, the rider may wait, resting on knees and stirrups, until the horse moves forward.

Forward seat. The forward seat, favoured for show jumping, hunting, and cross-country riding, is generally considered to conform with the natural action of the horse. The rider sits near the middle of the saddle, his torso a trifle forward, even at the halt. The saddle is shaped with the flaps forward, sometimes with knee rolls for added support in jumping. The length of the stirrup leather is such that, with continual lower thigh and knee grip, the arch of the foot can press on the tread of the iron with the heel well down. A wide and heavy stirrup iron allows easy release of the foot in case of accidents. The line along the forearm from the elbow to the hands and along the reins to the bit is held straight. As the horse moves forward, so do the rider's hands, to suit the horse's comfort.

Forward seat in jumping.

Dressage seat. In the show and dressage seat the rider sinks deep into the saddle, in a supple, relaxed but erect position above it. The saddle flaps are practically straight so as to show as much expanse of the horse's front as possible. The stirrup leather is of sufficient length for the rider's knee to bend at an angle of about 140 degrees and for the calf to make light contact with the horse's flank, the heel well down, and the toes or the ball of the foot resting on the tread of the stirrup iron. The rider keeps continual, light contact with the horse's mouth; and the intention is to convey an impression of graceful, collected action. In the past this type of saddle, with its straight-cut flaps, was used for hunting and polo, but the forward seat has become more popular for these activities.

Stock saddle. The stock saddle seat is appropriate for ranchers but is also used at rodeos and by many pleasure and trail riders. The saddle, which can weigh as much as 40 pounds (18 kilograms), is designed for rounding up cattle and is distinguished by a high pommel horn for tying a lariat. The rider employs long stirrups and a severe bit that he seldom uses because he rides with a loose rein, guiding his horse chiefly by means of shifting the weight of his body in the saddle. The gaucho roughriders of the Argentine Pampa have adopted a similar seat, using a saddle with a high pommel and cantle. Australian stockmen have used a saddle that has a short flap and is equipped with knee and thigh rolls, or props, which give an extremely secure seat.

Dressage seat in the extended trot.

The use of the whip

Side saddle. Though now not so fashionable, the elegant and classical side-saddle seat was formerly favoured and considered correct by many horsewomen. On the near side the saddle has an upright pommel on which the rider's right leg rests. There is a lower, or leaping, pommel, against which the left leg can push upward when grip is required, and a single stirrup. Although the rider sits with both legs on one side of the saddle, forward action to suit the movement of the horse is feasible in crosscountry riding.

Bareback. Bareback means riding without saddle or blanket, the rider sitting in the hollow of the horse's back and staying there chiefly by balance. It is an uncomfortable seat but less so at the walk and the slow canter. When suffering from saddle galls horses are sometimes ridden bareback for exercise

training was begun early in the 16th century. The international rules for dressage are based on the traditions and practice of the best riding schools in the world. The following is an extract from these rules of the Fédération Équestre Internationale:

Object and general principles.

The object of dressage is the harmonious development of the physique and the ability of the horse. As a result, it makes the horse calm, supple, and keen, thus achieving perfect understanding with its rider. These qualities are revealed by the freedom and regularity of the paces; the harmony, lightness, and ease of the movements; the lightening of the forehand, and the engagement of the hindquarters; the horse remaining absolutely straight in any movement along a straight line, and bending accordingly when moving on curved lines.

The horse thus gives the impression of doing of his own account what is required of him. Confident and attentive, he submits generously to the control of his rider. (Used with permission of the publisher.)

Campagne is the term used for elementary but thorough training, including work on the longeing rein. This long rein, also used for training young or difficult horses, is attached to a headpiece with a noseband called a cavesson. The horse is bitted and saddled and is schooled in circles at the end of the rein. It is an accessory to training from the saddle, which is always best. Basic to campagne is collection: teaching the horse to arch its neck, to shift its weight backward onto its hindquarters, and to move in a showy, animated manner. Other elements of campagne include riding in a straight line, turns, and lateral movements

Haute école is the most elaborate and specialized form of dressage, reaching its ultimate development at the Vienna school in its traditional white Lippizaner horses. Some characteristic haute école airs, or movements, are the pirouettes, which are turns on the haunches at the walk and the canter; the piaffe, in which the horse trots without moving forward, backward, or sideways, the impulse being upward; the passage, high-stepping trot in which the impulse is more upward than forward; the levade,

in which the horse stands balanced on its hindlegs, its

saddle, leaving the legs from the knees down free for impulsion. Contact with the mouth is maintained evenly and continually, the rider conforming with every movement Dressage. Originally intended for military use, dressage as the horse's head goes forward after takeoff and as it is retracted on landing, the hands always moving in line with the horse's shoulder. In order to give complete freedom to

> the hindquarters and to the hocks, the rider does not sit back in the saddle until at least two strides after landing. The horse is a natural jumper, but, if ridden, schooling becomes necessary. Training is started in an enclosed level area by walking the horse, preferably in a snaffle, over a number of bars or poles laid flat on the ground. When the horse has become accustomed to this, its speed is increased. As the horse progresses, the obstacles are

foreless drawn in; the courvet, which is a jump forward

in the levade position; and the croupade, ballotade, and

capriole, a variety of spectacular airs in which the horse

All of these movements are based, perhaps remotely in some instances, on those that the horse performs naturally,

Jumping. The most sensitive parts of the horse when

ridden are the mouth and the loins, particularly in jump-

ing. The rider's hands control the forehand while the legs

act on the hindquarters. As speed is increased the seat is raised slightly from the saddle, with the back straight

and the trunk and hands forward, the lower thighs and

the knees taking the weight of the body and gripping the

jumps and lands again in the same spot.

systematically raised, varied, and spaced irregularly. The object is to teach the horse; (1) to keep its head down; (2) to approach an obstacle at a quiet, collected, vet energetic pace: (3) to decide how and where to take off; and (4) after landing to proceed quietly to the next obstacle. The horse should be confident over every jump before it is raised and should be familiarized with a variety of obstacles.

Only thoroughly trained riders and horses compete. Very strenuous effort is required of the horse, as well as of the rider who does not by any action give the horse the impression that something out of the ordinary is impending. If possible the horse is warmed up by at least a halfhour's walking and trotting before entering the ring. The horse is guided toward the exact centre of every obstacle, the rider looking straight ahead and not looking around after takeoff for any reason, as that might unbalance the horse. The broader the obstacle, the greater the speed of approach. Although a few experienced riders can adjust the horse's stride for a correct takeoff, this should not be necessary with a well-schooled horse. The rider is always made to conform with every action of the horse, the only assistance necessary being that of direction and increasing or decreasing speed according to the obstacle.

RIDING AND SHOWS

Racing on horseback probably originated soon after man first mastered the horse. By the 7th century BC organized mounted games were held at Olympia. The Romans held race meetings, and in medieval Europe tournaments, jousting, and horse fairs were frequent and popular events.

Haute école figures: Lippizaner horses in (left) piaffe and (right) ballotade.

Haute école dressage

Played in Persia for centuries, polo was brought to England from India about 1870. In North America, Western ranch riding produced the rodeo.

Horse associations and pony clubs are today the mainstay of equine sport. They have improved the standards of riding instruction and the competitive activities of dressage, hunter trials, and show jumping. The latter became an important event from 1869, when what was probably the first "competition for leaping horses" was included in the program of an Agricultural Hall Society horse show in London. National organizations such as the British Horse Society, the American Horse Shows Association (AHSA) the Federazione Italiana Sports Equestri, the National Equestrian Federation of Ireland, the Fédération Française des Sports Équestres, and similar groups from about 50 other nations are affiliated with the Fédération Équestre Internationale (FEI), founded in 1921 with headquarters at Brussels, the official international governing body and the authority on the requirements of equitation.

Associa-

clubs

tions and

Horse shows. Horse shows are a popular institution that evolved from the horse sections of agricultural fairs Originally they were informal displays intended to attract buyers and encourage the improvement of every type of horse. Now they are organized and conducted by committees of experts and by associations that enforce uniform rules, appoint judges, settle disputes, maintain records, and disseminate information. Riding contests included in the program have become increasingly important.

Under the auspices of the Royal Dublin Society, an international horse show was first held at Dublin in 1864. It is an annual exhibition of every type of saddle horse, as well as broodmares and ponies. International jumping contests similar to Olympic competition, events for children, and auction sales are held during this five-day show.

The National Horse Show at New York, first held in 1883, is another great yearly event. Held at Madison Square Garden, it lasts several days and includes about 10 different events. Among the most important are the international jumping under FEI rules and the open jumping under AHSA rules. Other shows are held in many sections of the United States.

Horse and pony shows are held regularly in the United Kingdom, the most important being the Richmond Royal Horse Show, the Horse of the Year Show, and the Royal International Horse Show. The latter, an annual event first held in 1907, has flourished under royal patronage and includes international jumping, special items such as the visit of the Spanish Riding School with its Lippizaners in 1953, and a Supreme Riding Horse competition.

In Canada, the Royal Agricultural Winter Fair at Toronto, opened in 1922 and known in Canada as the "Royal," is a major event, and in Australia the Royal Agricultural Society organizes horse shows annually in every state. Other events include the shows at Verona and at the Piazza di Siena in Rome; frequent horse shows in Belgium, France, Germany, and The Netherlands; the winter show in July in Buenos Aires; and the Exhibition of Economic Achievement in Moscow.

Olympic equestrian competition. The FEI organizes and controls the equestrian events at the Olympic Games. Included in each Olympics since the Games at Stockholm in 1912 (equestrian events were also held in 1900), these events are the occasion for keen rivalry and evoke high standards of horsemanship. They comprise a dressage grand prix, a three-day event, and a jumping grand prix, all open to team and individual competition.

The Grand Prix de Dressage involves performance of the walk, trot, canter, and collected paces and several conventional dressage figures and movements, as well as the correct rider's position. Scoring on each item is from a maximum of 10 for excellent down to 1 for very bad.

The three-day event consists of tests in dressage, endurance or cross-country riding, and show jumping. Dressage is on the first day. On the second day there is an endurance test over a course 25 to 35 kilometres (16 to 22 miles) in length, covering swamp roads, tracks, steeplechase obstacles, and cross-country sections. Jumping tests, less strenuous than the Prix des Nations jumping event, are held on the third day.

The Prix des Nations jumping event is a competition involving 13 or 14 obstacles, heights varying between 1.30 and 1.60 metres (51 and 63 inches), and a water jump 4 metres (13 feet) across, over a course with 60 metres (200 feet) between obstacles. Penalties are scored for disobedience, knocking down or touching an obstacle, and for a fall. The rider with the lowest penalty score wins.

In addition to these competitions there is a riding section of the modern pentathlon, also conducted under FEI rules. Competitors must clear, riding a strange horse chosen by lot, 20 obstacles over a course 1,000 metres (3,000 feet) in length. Other international competitions began in the 1950s under the supervision of the FEI. (CFC) BIRLIOGRAPHY

General works: GEORGE G. SIMPSON, Horses (1951, reprinted 1970), a very readable and popular account of the horse family today and through 60,000,000 years of development, with a good bibliography; MARGARET C. SELF, The Horseman's Encyclopedia, rev. ed. (1963, reprinted 1978), an invaluable collection of information on domestic horses. Breed associations issue pamphlets on selected breeds of horses. Human Rights

It is a common observation, and perhaps even a truism, that human beings everywhere desire to live in a world in which their individual and collective well-being is assured. It also is a common observation that this desire often is painfully frustrated as a result of exploitation, oppression, persecution, and other forms of social deprivation. Deeply rooted in these twin observations are the beginnings of what today are called "human rights" and the national and international legal processes that are associated with them.

This article is divided into the following sections:

Historical development of human rights

The expression "human rights" is relatively new, having come into everyday parlance only since the end of World War II. It replaced the phrase "natural rights," which had fallen into disfavour in part because the concept of natural law, to which it was intimately linked, had become a matter of great controversy. It replaced as well the later phrase "the rights of Man," which was not universally understood to include the rights of women.

ORIGINS IN ANCIENT GREECE AND ROME

Most students of human rights trace the origins of the concept to ancient Greece and Rome, where it was closely tied to the natural law doctrines of Stoicism. According to the Stoics, human conduct should be judged according to, and brought into harmony with, the laws of nature. A classic example of this view is given in Sophocles' play Antigone, in which the title character, upon being reproached by King Creon for defying his command not to bury her slain brother, asserted that she acted in accordance with the immutable laws of the gods.

In part because Stoicism played a key role in its formation and spread, Roman law similarly allowed for the existence of a natural law, and with it certain universal rights that extended beyond the rights of citizenship. According to the Roman jurist Ulpian, for example, natural law was that which nature-not the state-assures to all human beings, Roman citizens or not.

It was not until after the Middle Ages, however, that natural law became associated with natural rights. In ancient and medieval times, doctrines of natural law concerned mainly the duties, rather than the rights, of "Man." Moreover, these doctrines recognized the legitimacy of slavery and serfdom and, in so doing, excluded perhaps the most important ideas of human rights as they are understood today-freedom (or liberty) and equality,

In order for human rights to gain general acceptance as natural rights, therefore, certain basic changes in society were necessary, changes of the sort that took place from the decline of European feudalism through the Renaissance. During this period, resistance to religious intolerance and political and economic bondage, the evident failure of rulers to meet their obligations under natural law, and the unprecedented commitment to individual expression and worldly experience all combined to shift the conception of natural law from duties to rights. The teachings of St. Thomas Aguinas and Hugo Grotius on the European continent, as well as the Magna Carta (1215), the Petition of Right of 1628, and the English Bill of Rights (1689) were proof of this change. All testified to the increasingly popular view that human beings are endowed with certain eternal and inalienable rights that were not renounced when humankind "contracted" to enter the social from the primitive state and were not diminished by the claim of "the divine right of kings,"

NATURAL LAW TRANSFORMED INTO NATURAL RIGHTS

The modern conception of natural law as meaning natural rights was elaborated primarily by thinkers of the 17th and 18th centuries. The many scientific and intellectual achievements of the 17th century encouraged a belief in natural law and universal order, and during the 18th century, the so-called Age of Enlightenment, a growing confidence in human reason and in the perfectibility of human affairs led to the more comprehensive expression of this belief. Particularly important were the writings of John Locke-arguably the most important natural law theorist of modern times-and the works of the 18th-century philosophes centred mainly in Paris, including Montesquieu, Voltaire, and Jean-Jacques Rousseau, Locke argued in detail that certain rights self-evidently pertain to individuals as human beings; that chief among them are the rights to life, liberty (freedom from arbitrary rule), and property; that, upon entering civil society, humankind surrendered to the state-pursuant to a "social contract"only the right to enforce these natural rights and not the rights themselves; and that the state's failure to secure these rights gives rise to a right to responsible, popular revolution. The philosophes, building on Locke and others, vigorously attacked religious and scientific dogmatism, intolerance, censorship, and social and economic restraints. They sought to discover and act upon universally valid principles governing nature, humanity, and society, including the inalienable "rights of Man," which they treated as a fundamental ethical and social gospel.

Not surprisingly, this liberal intellectual ferment exerted a profound influence in the Western world of the late 18th and early 19th centuries. Together with the Revolution of 1688 in England and the resulting Bill of Rights, it provided the rationale for the wave of revolutionary agitation that swept the West, most notably in North America and France. Thomas Jefferson, who had studied Locke and Montesquieu, gave poetic eloquence to their ideas the Declaration of Independence proclaimed by the 13 American colonies on July 4, 1776: "We hold these truths to be selfevident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the Pursuit of Happiness." Similarly, the Marquis de Lafayette, who won the close friendship of George Washington and who shared the hardships of the American War of Independence, imitated the pronouncements of the English and American revolutions in the Declaration of the Rights of Man and of the Citizen of August 26, 1789, proclaiming that "men are born and remain free and equal in rights" and that "the aim of every political association is the preservation of the natural and imprescriptible rights of man.'

Ideas of Locke

Natural law

Human

rights in

the 20th

century

In sum, the idea of human rights, though known by another name, played a key role in late 18th- and early 19th-century struggles against political absolutism. It was, indeed, the failure of rulers to respect the principles of freedom and equality that was responsible for this development.

"NONSENSE UPON STILTS":

THE CRITICS OF NATURAL RIGHTS

The idea of human rights as natural rights was not without its detractors, however. In the first place, because it was frequently associated with religious orthodoxy, the doctrine of natural rights became less attractive to philosophical and political liberals. Additionally, because they were conceived in essentially absolutist terms, natural rights were increasingly considered to conflict with one another. Most importantly, the doctrine of natural rights came under powerful philosophical and political attack from both the

Burke, Hume, and Bentham right and the left. In England, for example, conservative political thinkers such as Edmund Burke and David Hume united with liberals such as Jeremy Bentham to condemn the doctrine, the former out of fear that public affirmation of natural rights would lead to social upheaval, the latter out of concern lest declarations and proclamations of natural rights substitute for effective legislation. In his Reflections on the Revolution in France (1790), Burke-a believer in natural law who nonetheless denied that the "rights of Man" could be derived from it-criticized the drafters of the Declaration of the Rights of Man and of the Citizen for proclaiming the "monstrous fiction" of human equality, which, he argued, serves but to inspire "false ideas and vain expectations in men destined to travel in the obscure walk of laborious life," Bentham, one of the founders of Utilitarianism, was no less scornful. "Rights," he wrote, "is the child of law; from real law come real rights; but from imaginary laws, from 'law of nature,' come imaginary rights. . . . Natural rights is simple nonsense; natural and imprescriptible rights (an American phrase) . . . [is] rhetorical nonsense, nonsense upon stilts." Agreeing with Bentham, Hume insisted that natural law and natural rights are unreal metaphysical phenomena.

This assault upon natural law and natural rights intensified and broadened during the 19th and early 20th centuries. John Stuart Mill, despite his vigorous defense of liberty, proclaimed that rights ultimately are founded on utility. The German jurist Friedrich Karl von Savigny, England's Sir Henry Maine, and other "historicalist" legal thinkers emphasized that rights are a function of cultural and environmental factors unique to particular communities. The English jurist John Austin argued that the only law is "the command of the sovereign." And the logical positivists of the early 20th century insisted that the pronouncements of ethics were not cognitively significant. By World War I, there were scarcely any theorists who would defend the "rights of Man" in terms of natural law. Indeed, under the influence of 19th-century German Idealism and parallel expressions of rising European nationalism, there were some-the Marxists, for example-who maintained that rights, from whatever source derived, belong preeminently to communities or whole societies and nations.

THE PERSISTENCE OF THE NOTION

Although the heyday of natural rights proved short, the idea of rights nonetheless endured. The abolition of slavery, the implementation of factory legislation, the rise of popular education and trade unionism, the universal suffrage movement-these and other examples of 19th-century reformist impulses afford ample evidence that the idea was not to be extinguished, even if its conceptual foundations had become a matter of general skepticism. But it was not until the rise and fall of Nazi Germany that the idea of human rights truly came into its own. Many of the atrocities committed by the Nazi regime had been officially authorized by Nazi laws and decrees. This fact convinced many that law and morality cannot be grounded in any purely Idealist, Utilitarian, or other consequentialist doctrine. Certain actions, according to this view, are absolutely wrong, no matter what the cirumstances.

Today, the vast majority of legal scholars and philosophers-particularly in the West-agree that every human being has, at least in theory, some basic rights. Indeed, except for some essentially isolated late 19th-century and early 20th-century demonstrations of international humanitarian concern to be noted below, the last half of the 20th century may fairly be said to mark the birth of the international as well as the universal recognition of human rights. In the treaty charter establishing the United Nations, for example, all member states pledged themselves to take joint and separate action for the achievement of "universal respect for, and observance of, human rights and fundamental freedoms for all without distinction as to race, sex, language, or religion." Similarly, in the Universal Declaration of Human Rights (1948), representatives from many cultures endorsed the rights therein set forth "as a common standard of achievement for all peoples and all nations." And in 1976, the International Covenant on Economic, Social and Cultural Rights and the International Covenant on Civil and Political Rights entered into force and effect.

Defining human rights

To say that there is widespread acceptance of the principle of human rights is not to say that there is complete agreement about the nature and scope of such rights. Among the basic questions that have yet to receive conclusive answers are the following: Whether human rights are to be viewed as divine, moral, or legal entitlements; whether they are to be validated by intuition, culture, custom, so-cial contract, principles of distributive justice, or as prerequisites for happiness; whether they are to be understood as irrevocable or partially revocable; and whether they are to be broad or limited in number and content.

THE NATURE OF HUMAN RIGHTS:

COMMONLY ACCEPTED POSTULATES

Despite this lack of consensus, a number of widely accepted—and interrelated—postulates can assist in the task of defining human rights. Five in particular stand out, though not even these are without controversy.

First, regardless of their ultimate origin or justification, numan rights are understood to represent both individual and group demands for political power, wealth, education, and other social goods and benefits, the most fundamental of which is respect and its constituent elements of reciprocal tolerance and mutual forberance in the pursuit of all other goods. Consequently, human rights imply claims against persons and institutions impeding the achievement of these goods, as well as standards for judging the legitimacy of these goods, as well as standards for judging the legitimacy of laws and traditions. At bottom, human rights upualify state sovereignty and power, sometimes expanding the latter even while circumscribing the former.

Second, human rights are commonly assumed to refer, in some vague sense, to "fundamental" as distinct from "nonessential" goods or benefits. In fact, some theorists go so far as to limit human rights to a single core right or two—for example, the right to life or the right to equal freedom of opportunity. The tendency is to emphasize "basic needs" and to rule out "mere wants."

Third, reflecting varying environmental circumstances, differing worldviews, and inescapable interdependencies between goods and benefits, human rights refer to a wide continuum of claims, ranging from the most justiciable to the most aspirational. Human rights partake of both the legal and the moral orders, sometimes indistinguishably. They are expressive of both the "is" and the "ought" in human affairs.

Fourth, most assertions of human rights—though arguably not all—are qualified by the limitation that the rights of any particular individual or group in any particular instance are restricted as much as is necessary to secure the comparable rights of others and the aggregate common interest. Given this limitation, human rights are sometimes designated prima facile rights, so that ordinarily it makes little or no sense to think of them in absolutist terms.

Finally, human rights are understood to be quintessentially universal in character, in some sense equally pos-

Universal nature of human rights sessed by all human beings everywhere, including in certain instances even the unborn. In stark contrast to the divine right of kings and other such conceptions of privilege, human rights extend in theory to every person on Earth

without regard to merit or need, simply for being human. In several critical respects, however, all of these postulates raise more questions than they answer. Granted that human rights qualify state power, do they also qualify private power? If so, when and how? What does it mean to say that a right is fundamental? What is the value of embracing non-justiciable rights as part of the jurisprudence of human rights? When and according to what criteria does the right of one person or group of people give way to the right of another? What happens when individual and group rights collide? How are universal human rights determined? Are they a function of culture or ideology, or are they determined according to some transnational consensus? If the latter, a regional consensus? A global consensus? And if a regional or global consensus, how exactly would it be ascertained, and how would it be reconciled with the right of nations and peoples to self-determination? Is the existence of universal human rights incompatible with the notion of national sovereignty? Should supranational institutions have the power to nullify local, regional, and national laws on capital punishment, "honor killing," veil wearing, female genital cutting, and other practices? How would such a situation comport with Western conceptions of democracy and representative government? In other words, however accurate, the five foregoing postulates are fraught with questions about the content and legitimate scope of human rights and about the priorities, if any, that exist among them. Like the issue of the origin and justification of human rights, all five are controversial.

THE CONTENT OF HUMAN RIGHTS: THREE "GENERATIONS" OF RIGHTS

Like all normative traditions, the human rights tradition is a product of its time. Therefore, to understand better the debate over the content and scope of human rights and the priorities claimed among them, it is useful to note the dominant schools of thought that have informed the human rights tradition since the beginning of modern times.

Particularly helpful in this regard is the notion of "three generations of human rights" advanced by the French jurist Karel Vasak. Inspired by the three normative themes of the French Revolution, they are: the first generation of civil and political rights (liberte); the second generation of economic, social, and cultural rights (segalite); and the third generation of solidarity rights (fraternite). Vasak's model is, of course, a simplified expression of an extremely complex historical record, and it is not intended to suggest a linear process in which each generations are cumulative, overlapping, and, it is important to note, interdependent.

Liberté: civil and political rights. The first generation of civil and political rights derives primarily from the 17thand 18th-century reformist theories noted above-i.e., those associated with the English, American, and French revolutions. Infused with the political philosophy of liberal individualism and the related economic and social doctrine of laissez-faire, the first generation conceives of human rights more in negative ("freedoms from") than positive ("rights to") terms; it favours the abstention over the intervention of government in the quest for human dignity. Belonging to this first generation, thus, are rights such as those set forth in Articles 2-21 of the Universal Declaration of Human Rights, including freedom from gender, racial, and equivalent forms of discrimination; the right to life, liberty, and the security of the person; freedom from slavery or involuntary servitude; freedom from torture and from cruel, inhuman, or degrading treatment or punishment; freedom from arbitrary arrest, detention, or exile; the right to a fair and public trial; freedom from interference in privacy and correspondence; freedom of movement and residence; the right to asylum from persecution; freedom of thought, conscience, and religion; freedom of opinion and expression; freedom of peaceful assembly and association; and the right to participate in government, directly or through free elections. Also included are the right to own property and the right not to be deprived of it arbitrarily, which were fundamental to the interests fought for in the American and French revolutions and to the rise of capitalism.

It should be noted that these and other first-generation rights do not correspond completely to the idea of "negative" rights. The right to security of the person, to a fair and public trial, to asylum from persecution, and to free elections, for example, manifestly cannot be assured without some affirmative government action. What is constant in this first-generation conception is the notion of liberty, a shield that safeguards the individual—alone and in association with others—against the abuse of political authority. This is the core value. Featured in the constitution of almost every country in the world and dominating the majority of international declarations and covenants adopted since World Warl II, this essentially Western liberal conception of human rights is sometimes romanticized as a triumph of Hobbesian—Lockean individualism over Heeglian statism.

Égalité: economic, social, and cultural rights. The second generation of economic, social, and cultural rights finds its origins primarily in the socialist tradition that was foreshadowed among the Saint-Simonians of early 19thcentury France and variously promoted by revolutionary struggles and welfare movements that have taken place since. In large part, it is a response to the abuses of capitalist development and its underlying, essentially uncritical, conception of individual liberty that tolerated, even legitimated, the exploitation of working classes and colonial peoples. Historically, it is a counterpoint to the first generation of civil and political rights, with human rights conceived more in positive than in negative terms and requiring more the intervention than the abstention of the state for the purpose of assuring equitable distribution of the goods and benefits involved. Illustrative are some of the rights set forth in Articles 22-27 of the Universal Declaration of Human Rights, such as the right to social security; the right to work and to protection against unemployment; the right to rest and leisure, including periodic holidays with pay; the right to a standard of living adequate for the health and well-being of self and family; the right to education; and the right to the protection of one's scientific, literary, and artistic production.

But in the same way that all the rights embraced by the first generation of civil and political rights cannot properly be designated "negative rights," so all the rights embraced by the second generation of economic, social, and cultural rights cannot properly be labeled "positive rights." For example, the right to free choice of employment, the right to form and to join trade unions, and the right freely to participate in the cultural life of the community (found in Articles 23 and 27) do not inherently require affirmative state action to ensure their enjoyment. Nevertheless, most of the second-generation rights do necessitate state intervention because they subsume demands more for material than for intangible goods and benefits. Second-generation rights are, fundamentally, claims to social equality. Partly because of the comparatively late arrival of socialist-communist and compatible "Third World" influence in the normative domain of international affairs, however, the internationalization of these rights has been relatively slow in coming; and with free-market capitalism in ascendancy under the banner of "globalization" at the turn of the 21st century, it is not likely that these rights will come of age any time soon. On the other hand, as the social inequities created by unregulated capitalism become more and more evident over time and are not accounted for by sex or race discrimination, it is probable that the struggle for secondgeneration rights will grow and mature. This tendency is already apparent in the evolving European Union.

Fraternité: solidarity rights. Finally, the third generation of solidarity rights is best understood as a product of both the rise and the decline of the nation-state in the last half of the 20th century. Of the six rights in this group, three reflect the emergence of "Third World" nationalism and its "revolution of rising expectation"—Le, its demand for a global redistribution of power, wealth, and other important goods and benefits: the right to political, economic, social, and cultural self-determination; the right to economic and and cultural self-determination; the right to economic and

"Positive"

"Negative" rights social development; and the right to participate in and benefit from "the common heritage of mankind" (shared Earth-space resources; scientific, technical, and other information and progress; and cultural traditions, sites, and monuments). The other three third-generation rights-the right to peace, the right to a healthy and sustainable environment, and the right to humanitarian disaster reliefsuggest the impotence or inefficiency of the nation-state in certain critical respects

Collective rights

All six of these rights tend to be posed as collective rights requiring the concerted efforts of all social forces, to a substantial degree on a planetary scale. Nevertheless, each of them also manifests an individual dimension. For example, while it may be said to be the collective right of all countries and peoples (especially developing countries and non-self-governing peoples) to secure a "new international economic order" that would eliminate obstacles to their economic and social development, so also may it be said to be the individual right of every person to benefit from a developmental policy that is based on the satisfaction of material and nonmaterial human needs. It is also important to note that the majority of these rights are more aspirational than justiciable in character, and their status as international human rights norms remains ambiguous.

"INTERGENERATIONAL CONFLICT":

LEGITIMACY AND PRIORITY

Liberté versus égalité. The fact that human rights have been defined so broadly should not be taken to imply that the three generations of rights are equally acceptable to everyone. Nor should it suggest that they or their separate elements have been greeted with equal urgency. The debate about the nature and content of human rights reflects, after all, a struggle for power and for favoured conceptions of the "good society."

First-generation proponents, for example, are inclined to exclude second- and third-generation rights from their definition of human rights altogether (or, at best, to label them as "derivative"). In part this is because of the complexities involved in putting these rights into operation. First-generation rights are viewed as more feasible because they stress the absence over the presence of government, and feasibility is transformed into a prerequisite of a comprehensive definition of human rights, so that aspirational claims to entitlement are deemed not to be rights at all. The most forceful explanation, however, is more ideologically or politically motivated. Persuaded that egalitarian claims against the rich, particularly where collectively espoused, are unworkable without a severe decline in liberty and equality, first-generation proponents, inspired by the natural law and laissez-faire traditions, are partial to the view that human rights are inherently independent of organized society and are individualistic.

Conversely, second- and third-generation defenders often look upon first-generation rights, at least as commonly practiced, as insufficiently attentive to material-especially "basic"-human needs and, indeed, as instruments in the service of unjust social orders, hence constituting a "bourgeois illusion," Accordingly, if they do not place firstgeneration rights outside their definition of human rights, they tend to assign such rights a low status and to treat them as long-term goals that will come to pass only after the imperatives of economic and social development have been met, to be realized gradually and fully achieved only sometime vaguely in the future.

This liberty-equality and individualist-collectivist debate, it must be added, was especially evident during the Cold War, reflecting the tensions that then existed between Liberal and Marxist conceptions of sovereign public order. Different conceptions of rights contain the potential for challenging the legitimacy and supremacy not only of one another but, more importantly, of the sociopolitical systems with which they are most intimately associated.

The relevance of custom and tradition. With the end of the Cold War, however, the debate took on a more North-South character and was supplemented by a cultural-relativist critique that eschewed the universality of human rights doctrines, principles, and rules on the grounds that they were Western in origin and therefore of limited rele-

vance in non-Western settings. The viewpoint underlying this assertion-that the scope of human rights in any given society is fundamentally determined by local, national, or regional customs and traditions-may seem problematic. especially when one considers that the idea of human rights and many of its precepts are found in all the great philosophical and religious traditions. Nevertheless, the historical development of human rights demonstrates that it cannot be wholly mistaken. Nor is it surprising that it should emerge soon after the end of the Cold War. First prominently expressed at an Asian preparatory meeting to the second UN World Conference on Human Rights convened in Vienna in June 1993, it reflected the end of a bipolar system of alliances that had discouraged independent foreign policies and minimized cultural and political differences among countries allied to the same superpower. Against the backdrop of increasing human rights interventionism on the part of the UN, regional organizations, and deputized coalitions of states (as in Bosnia-Herzegovina, Somalia, Liberia, Rwanda, and Haiti, for example), the viewpoint served as a functional equivalent of the doctrine of respect for national sovereignty and territorial integrity, a doctrine whose influence had been declining not only in human rights affairs but also in affairs related to national security, economics, and the environment. As a consequence, there remains sharp disagreement about the legitimate scope of human rights and about the priorities that are claimed among them.

Inherent risks of the debate. On final analysis, however, this legitimacy-priority debate can be misleading. Although useful for pointing out how notions of liberty and individualism have been used to rationalize the abuses of capitalism and how notions of equality, collectivism, and culture have been alibis for authoritarian governance, in the end it risks obscuring at least three essential truths that must be taken into account if the contemporary worldwide human rights movement is to be objectively understood.

First, one-sided characterizations of legitimacy and priority are very likely, at least over the long term, to undermine the credibility of their proponents and the defensibility of the rights they regard as preeminently important. Second, such characterizations do not accurately reflect reality. In the real world, essentially individualistic societies tolerate, and even promote, certain collectivist values, and essentially communal societies tolerate, and even promote, certain individualistic values.

Finally, none of the international human rights instruments currently in force or proposed says anything about the legitimacy or priority of the rights they address, save possibly in the case of rights that by international covenant are stipulated to be "nonderogable" and therefore, arguably, more fundamental than others (e.g., freedom from arbitrary or unlawful deprivation of life). To be sure, some disagreements about legitimacy and priority can derive from differences of definition (e.g., what is "torture" or "inhuman treatment" to one may not be to another). Similarly, disagreements also can arise when treating the problem of implementation. For example, some insist first on certain civil and political guarantees, whereas others defer initially to conditions of material well-being. Such disagreements, however, reflect differences in political agendas and have little if any conceptual utility. As indicated by numerous resolutions of the UN General Assembly and the Declaration and Programme of Action of the 1993 Vienna World Conference on Human Rights, there is a growing consensus that human rights form an indivisibile whole and that the protection of human rights should not be a matter of purely national jurisdiction. The extent to which the international community actually protects the rights it prescribes, on the other hand, is a different matter.

International human rights enforcement

TREATIES, DECLARATIONS, AND AGREEMENTS

BEFORE WORLD WAR II

Ever since ancient times, but especially since the emergence of the modern state system, the Age of Discovery, and the accompanying spread of industrialization and European culture throughout the world, there has developed,

The end of the Cold War Inter-

national

Law of

Human

Rights

fair treatment.

With the exception of occasional treaties to secure the protection of Christian denominations, it was not until the start of the 19th century that active international concern for the rights of nationals began to make itself felt. Then, in the century and a half before World War II, several noteworthy efforts to encourage respect for nationals by international means began to shape what today is called the International Law of Human Rights.

Throughout the 19th and early 20th centuries, numerous military operations and diplomatic representations, not all of them with the purest of motives but performed nonetheless in the name of "humanitarian intervention" (a customary international law doctrine), undertook to protect oppressed and persecuted minorities in the Ottoman Empire and in Syria, Crete, various Balkan countries, Romania, and Russia. Paralleling these actions, first at the Congress of Vienna (1814-15) and later between the two world wars, a series of treaties and international declarations sought the protection of certain racial, religious, and linguistic minorities in central and eastern Europe and in the Middle East. During the same period, the movement to combat and suppress slavery and the slave trade found expression in treaties involving the major commercial powers, beginning with the Treaty of Paris (1814) and culminating in the International Slavery Convention (1926).

In addition, toward the end of the 19th century and continuing well beyond World War II, the community of nations, inspired largely by persons associated with what is now the International Committee of the Red Cross, concluded a series of multilateral declarations and agreements designed to temper the conduct of hostilities, protect the victims of war, and otherwise elaborate the humanitarian law of war (now commonly referred to as "international humanitarian law"). At about the same time, first with two multilateral labour conventions concluded in 1906 and subsequently at the initiative of the International Labour Organisation (ILO; established in 1919), a reformist-minded international community embarked upon a variety of collaborative measures directed at the promotion of human rights. These included not only fields traditionally associated with labour law and labour relations but alsomainly after World War II-such core human rights concerns as forced labour, discrimination in employment and occupation, freedom of association for collective bargaining, and equal pay for equal work.

Finally, during the interwar period, the Covenant establishing the League of Nations (1919)-though not formally recognizing "the rights of Man" and failing to lay down a principle of racial nondiscrimination as requested by Japan-nevertheless committed the League's members to several human rights goals: fair and humane working conditions; the execution of agreements regarding traffic in women and children; the prevention and control of disease in matters of international concern; and the just treatment of indigenous colonial peoples. Also, the victorious powers-who as "mandatories" were entrusted by the League with the tutelage of colonies formerly governed by Germany and Turkey-accepted responsibility for the wellbeing and development of the inhabitants of those territories as "a sacred trust of civilization." This arrangement was later carried over into the trusteeship system of the United Nations.

As important as these efforts were, however, it was not until after the war—and the Nazi atrocities accompanying it—that active concern for human rights truly came of age internationally. In the proceedings of the International

Military Tribunal at Nürnberg in 1945-46, German high officials were tried not only for "crimes against peace" and "war crimes" but also for "crimes against humanity" committed against civilian populations, even if the crimes were in accordance with the laws of the country where perpetrated. Although the tribunal, whose establishment and rulings subsequently were endorsed by the UN General Assembly, applied a cautious approach to allegations of crimes against humanity, it nonetheless made the treatment by a state of its own citizens the subject of international criminal process. The ad hoc international criminal tribunals established in 1993-94 for the prosecution of serious violations of international humanitarian law in the former Yugoslavia and Rwanda, as well as the permanent International Criminal Court created in 1998, are its first heirs on the international plane. In June 2001 the International Criminal Tribunal for Yugoslavia took custody of former Yugoslav president Slobodan Milošević and charged him with war crimes and crimes against humanity for actions allegedly committed by Serbian forces in Kosovo in 1999.

HUMAN RIGHTS IN THE UNITED NATIONS

The Charter of the United Nations (1945) begins by reaffirming a "faith in fundamental human rights, in the dignity and worth of the human person, in the equal rights of men and women and of nations large and small." It states that the purposes of the UN are, among other things, "to develop friendly relations among nations based on respect for the principle of equal rights and self-determination of peoples . . . [and] to achieve international co-operation . . in promoting and encouraging respect for human rights and for fundamental freedoms for all without distinction as to race, sex, language, or religion." In addition, in two key articles all members "pledge themselves to take joint and separate action in cooperation with the Organization" for the achievement of these and related purposes. It should be noted, however, that a proposal to ensure the protection as well as the promotion of human rights was explicitly rejected at the Charter-drafting San Francisco conference establishing the UN. Moreover, the Charter expressly provides that nothing in it "shall authorize the United Nations to intervene in matters which are essentially within the domestic jurisdiction of any state," except upon a Security Council finding of a "threat to the peace, breach of the peace, or act of aggression." Although typical of major constitutive instruments, the Charter is conspicuously given to generality and vagueness in its human rights clauses, among others.

Thus, not surprisingly, the reconciliation of the Charter's human rights provisions with the history of its drafting and its "domestic jurisdiction" clause has given rise to legal and political controversy. Some authorities have argued that, in becoming parties to the Charter, states accept no more than a nebulous promotional obligation toward human rights and that, in any event, the UN has no standing to insist on human rights safeguards in member states. Others have insisted that the Charter's human rights provisions. being part of a legally binding treaty, clearly involve some element of legal obligation; that the "pledge" made by states upon becoming party to the Charter consequently represents more than a moral statement; and that the "domestic jurisdiction" clause does not apply because human rights no longer can be considered matters "essentially within the domestic jurisdiction" of states.

When all is said and done, however, it is clear from the actual practice of the UN that the problem of resolving these opposing contentions has proved less formidable than the statements of governments and the opinions of scholars would suggest. Neither the Charter's drafting history nor its "domestic jurisdiction" clause—nor, indeed, its generality and vagueness in respect of human rights—has prevented the UN from evaluating and responding to specific human rights situations—e.g., as in the Security Council's imposition of a mandatory arms embargo against South Africa in 1977 and its authorization of the use of military force to end human rights abuses in Somalia and Haiti in the early 1990s. Of course, governments usually are protective of their sovereignty, or domestic juvally

Protection versus promotion of human rights

Human rights goals of the League of Nations

> Intervention in Somalia and Haiti

risdiction. Also, the UN organs responsible for the promotion and protection of human rights suffer from most of the same disabilities that afflict the UN as a whole, in particular the absence of supranational authority and the presence of divisive power politics. Hence, it cannot be expected that UN actions in defense of human rights will be, normally, either swift or categorically effective. Indeed, on the basis of the historical record to date, it may fairly be said that serious UN efforts at human rights implementation are often thwarted, not least at the hands of the major powers. In 1999, for example, opposition by Russian and China prevented the Security Council from agreeing on forceful measures to end the persecution by Serbia of ethnic Albanians in the province of Kosovo, prompting the United States and other members of the North Atlantic Treaty Organization (NATO) to take matters into their own hands through a massive bombing campaign against Serbian targets. Nevertheless, assuming some political will, the legal obstacles to UN enforcement of human rights are not insurmountable

Primary responsibility for the promotion and protection of human rights under the UN Charter rests in the General Assembly and, under its authority, in the Economic and Social Council (ECOSOC), the Commission on Human Rights, and the UN High Commissioner for Human Rights (UNHCHR). The UN Commission on Human Rights, an intergovernmental subsidiary body of ECOSOC that met for the first time in 1947, serves as the UN's central policy organ in the human rights field. The UNHCHR, a post created by the General Assembly in 1993, is the official principally responsible for implementing and coordinating UN human rights programs and projects, including overall supervision of the UN's Geneva-based Centre for Human Rights, a bureau of the UN Secretariat,

UN Commission on Human Rights and its instruments. For the first 20 years of its existence (1947-1966), the UN Commission on Human Rights concentrated its efforts on setting human rights standards. Together with other UN bodies such as the ILO, the UN Educational, Scientific and Cultural Organization (UNESCO), the UN Commission on the Status of Women, and the Commission on Crime Prevention and Criminal Justice, it has drafted standards and prepared a number of international human rights instruments. Among the most important of these have been the Universal Declaration of Human Rights (1948), the International Covenant on Economic, Social and Cultural Rights (1966), and the International Covenant on Civil and Political Rights together with its Optional Protocols (1966; 1989). Collectively known as the "International Bill of Human Rights," these three instruments serve as touchstones for interpreting the human rights provisions of the UN charter. Also central have been the International Convention on the Elimination of All Forms of Racial Discrimination (CERD; 1965), the Convention on the Elimination of All Forms of Discrimination against Women (CEDAN; 1979), the Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (1984), and the Convention on the Rights of the Child (1989), each elaborating on provisions of the International Bill of Human Rights.

The Commission continues to perform this standard-setting role. Beginning in 1967, however, it was specifically authorized to deal with violations of human rights, and since then it has set up elaborate mechanisms and procedures to investigate alleged violations of human rights and otherwise monitor compliance by states with international human rights law. Thus, much of the work of the Commission is now investigatory, evaluative, and advisory in character. It annually establishes a working group to consider and make recommendations concerning alleged "gross violations" of human rights referred to it by its Sub-Commission on Prevention of Discrimination and Protection of Minorities. Also, on an ad hoc basis, the commission appoints Special Rapporteurs, Special Representatives, Special Committees, and other envoys to examine human rights situations and report back to the Commission. These fact-finding and implementation mechanisms and procedures were the focus of the Commission's attention during the 1970s and '80s. In the 1990s the Commission increasingly turned to economic, social, and cultural rights, including the right to development and the right to an adequate standard of living. Particular attention has been paid to the rights of minorities, indigenous peoples, women, and children.

The UN High Commissioner for Human Rights. Appointed by the secretary-general in a regular rotation of geographic regions and approved by the General Assembly, the UN High Commissioner for Human Rights (UN-HCHR) serves a fixed term of four years with the possibility of renewal for an additional four-year term. The first high commissioner, José Ayala Lasso of Ecuador, took office in April 1994 and was temporarily succeeded by Ralph Zacklin of the United Kingdom in 1997-98. Mary Robinson, former president of Ireland, was the second high commissioner. Among other duties, the high commissioner is charged by the General Assembly with promoting and protecting all civil, political, economic, social, and cultural rights; providing advisory services and technical and financial assistance in the field of human rights to states that request them; coordinating human rights promotion and protection activities throughout the UN system, including education and public information programs; and enhancing international cooperation for the promotion and protection of human rights.

The Universal Declaration of Human Rights. The catalog of rights set out in the Universal Declaration of Human Rights, which was adopted without dissent by the General Assembly on Dec. 10, 1948, is scarcely less than the sum of most of the important traditional political and civil rights of national constitutions and legal systems, including equality before the law; protection against arbitrary arrest; the right to a fair trial; freedom from ex post facto criminal laws; the right to own property; freedom of thought, conscience, and religion; freedom of opinion and expression; and freedom of peaceful assembly and association. Also enumerated are such economic, social, and cultural rights as the right to work, the right to form and join trade unions, the right to rest and leisure, the right to a standard of living adequate for health and well-being, and the right to education.

The Universal Declaration, it should be noted, is not a treaty. It was meant to proclaim "a common standard of achievement for all peoples and all nations" rather than enforceable legal obligations. Nevertheless, the Universal Declaration has acquired a status juridically more important than originally intended, and it has been widely used, even by national courts, as a means of judging compliance with human rights obligations under the UN Charter.

The International Covenant on Civil and Political Rights and its Optional Protocols. The civil and political rights guaranteed by the International Covenant on Civil and Political Rights, which was opened for signature on Dec. 19, 1966, and entered into force on March 23, 1976, incorporate almost all those proclaimed in the Universal Declaration, including the right to nondiscrimination, though not the right to own property and the right to asylum. The Covenant also designates several rights that are not listed in the Universal Declaration, among them the right of all peoples to self-determination and the right of ethnic, religious, or linguistic minorities to enjoy their own culture, to profess and practice their own religion, and to use their own language. To the extent that the Universal Declaration and the Covenant overlap, however, the latter is understood to explicate and help interpret the former.

In addition, the Covenant calls for the establishment of a Human Rights Committee to study reports submitted by the state parties on measures they have adopted to give effect to the rights recognized in the Covenant. For state parties that have expressly recognized the competence of the Committee in this regard, the Committee also may respond to allegations by one state party that another state party is not fulfilling its obligations under the Covenant, If the Committee is unable to resolve the problem, the matter is referred to an ad hoc conciliation commission, which eventually reports its findings on all questions of fact, plus its views on the possibilities of an amicable solution. State parties that become party to the Covenant's first Optional Protocol further recognize the competence of the Human

Juridical status of the Universal Declaration

The "International Bill of Human Rights"

Abolition of the

death

penalty

Rights Committee to consider and act upon communications from individuals claiming to be victims of Covenant violations. Other treaty-based organs within the UN system that are empowered to consider grievances from individuals are the Committee on the Elimination of Racial Discrimination and the Committee on Torture.

The Covenant's Second Optional Protocol is aimed at abolishing the death penalty worldwide. Adopted in 1989 and entered into force in 1991, it has been favourably received in most of the countries of western Europe and

many countries in Latin America.

The International Covenant on Economic, Social and Cultural Rights. Just as the International Covenant on Civil and Political Rights elaborates upon most of the civil and political rights enumerated in the Universal Declaration of Human Rights, so the International Covenant on Economic, Social and Cultural Rights elaborates upon most of the economic, social, and cultural rights set forth in the Universal Declaration: the right to work; the right to just and favourable conditions of work; trade union rights; the right to social security; rights relating to the protection of the family; the right to an adequate standard of living; the right to health; the right to education; and rights relating to culture and science. Unlike its companion International Covenant on Civil and Political Rights, however, this covenant generally is not geared toward immediate implementation, the state parties having agreed only "to take steps" toward "achieving progressively the full realization of the rights recognized in the ... Covenant," and then subject to "the maximum of [their] available resources." One obligation, however, is subject to immediate application: the prohibition of discrimination in the enjoyment of the rights enumerated on grounds of race, colour, sex, language, religion, political or other opinion, national or social origin, property, and birth or other status. Also, the international supervisory measures that apply to the Covenant oblige the state parties to report to the UN Economic and Social Council on the steps they have adopted and the progress they have made in achieving the realization of the enumerated rights.

Other UN human rights conventions and declarations. Numerous other human rights treaties drafted under UN auspices address a broad range of concerns, including the prevention and punishment of the crime of genocide; the humane treatment of military and civilian personnel in time of war; the status of refugees; the protection and reduction of stateless persons; the abolition of slavery, forced labour, and discrimination in employment and occupation; the suppression and punishment of the crime of apartheid; the elimination of discrimination in education; the promotion of the political rights of women; the protection of minorities and indigenous peoples; and the promotion of equality of opportunity and treatment among migrant workers. In addition to overseeing human rights treaties, the UN also adopts declarations, in the form of resolutions, aimed at promoting human rights. Although technically not binding on member states in the sense of a treaty, such declarations may nevertheless create strong expectations about authority and control. Perhaps the bestknown examples subsequent to the Universal Declaration are the Declaration on the Granting of Independence to Colonial Countries and Peoples (1960) and the Declaration on Principles of International Law concerning Friendly Relations and Co-operation among States in accordance with the Charter of the United Nations (1970). Other declarations have addressed the rights of disabled persons; the elimination of all forms of intolerance and of discrimination based on religion or belief; the right of peoples to peace; the right to development; the rights of persons belonging to national or ethnic, religious, and linguistic minorities; and the elimination of violence against women.

HUMAN RIGHTS AND THE HELSINKI PROCESS

After World War II, international concern for human rights was evident at the global level outside the UN as well as within it, most notably in the proceedings and aftermath of the Conference on Security and Co-operation in Europe (CSCE), convened in Helsinki, Finland, on July 3, 1973, and concluded there (after continuing deliberations in

Geneva) on August 1, 1975. Attended by representatives of 35 governments-including the NATO countries, the Warsaw Pact nations, and 13 neutral and nonaligned European states-the Conference had as its principal purpose a mutually satisfactory definition of peace and stability between East and West, previously made impossible by the Cold War. In particular, the former Soviet Union wished to gain recognition of its western frontiers as established at the end of World War II (which ended without the conclusion of an omnibus peace treaty). The West, with no realistic territorial claims of its own, sought concessions primarily on security requirements and human rights.

The Final Act of the conference, the importance of which is reflected in its having been signed by almost all of the principal governmental leaders of the day, begins with a Declaration on Principles Guiding Relations between Participating States, in which the "Participating States" solemnly declare "their determination to respect and put into practice," alongside other "guiding" principles, ' spect [for] human rights and fundamental freedoms, including the freedom of thought, conscience, religion or belief" and "respect [for] the equal rights of peoples and their right to self-determination." It was hoped that this declaration would mark the beginning of a liberalization of

authoritarian regimes.

From the earliest discussions, however, it was clear that the Helsinki Final Act was not intended as a legally binding instrument, "Determination to respect" and "put into practice" were treated as moral commitments only; the Declaration of Principles was said not to prescribe international law; and nowhere did the participants provide for enforcement machinery. On the other hand, the Declaration of Principles, including its human rights principles, was always viewed as being at least consistent with international law; and in providing for periodic follow-up conferences, it made possible a unique negotiating process ("the Helsinki process") to review compliance with its terms, thus creating expectations concerning the conduct of the "Participating States." In these ways it proved to be an important force in the collapse of the Iron Curtain and the transformation of eastern Europe.

The Helsinki process served also to establish a mechanism for the evolution of the CSCE in the 1990s from a forum for discussion to an operational institution. In 1994 the CSCE was renamed the Organization for Security and Cooperation in Europe (OSCE), and its principal organs and bureaus now include an Office for Democratic Institutions and Human Rights, a Conflict Prevention Centre, a High Commissioner on National Minorities, and a Court of Conciliation and Arbitration. These offices have been increasingly pressed into service to alleviate major deprivations of human rights, particularly those arising from ethnic conflicts. In addition, the Vienna Human Dimension Mechanism and the Moscow Human Dimension Mechanism provide a preliminary formal means of raising resolving disputes about violations of human rights commitments, including the possibility of on-site investigation by independent experts. It should be noted, however, that all these mechanisms bespeak an essentially interstate process; neither individuals nor NGOs have access to them except indirectly as suppliers of information and conveyors of political pressure. They thus contrast markedly with the individual complaint procedures that are available within the UN and in regional human rights systems.

REGIONAL DEVELOPMENTS

Action for the international promotion and protection of human rights has proceeded at the regional level in Europe, the Americas, Africa, the Middle East, and, to a minor extent, Asia. Only the first three of these regions, however, have created enforcement mechanisms within the framework of a human rights charter.

European human rights system. On Nov. 4, 1950, the Council of Europe agreed to the European Convention for the Protection of Human Rights and Fundamental Freedoms, the substantive provisions of which are based on a draft of what is now the International Covenant on Civil and Political Rights. Together with its 11 additional protocols, this convention, which entered into force on SepHelsinki Final Act

tember 3, 1953, represents the most advanced and successful international experiment in the field to date. Over the years, the enforcement mechanisms created by the Convention have developed a considerable body of case law on questions regulated by the Convention, which the state parties typically have honoured and respected. In some European states the provisions of the Convention are deemed to be part of domestic constitutional or statutory law. Where this is not the case, the state parties have taken other measures to make their domestic laws conform with their obligations under the Convention.

Notwithstanding these successes, a significant streamlining of the European human rights regime took place on Nov. 1, 1998, when Protocol No. 11 to the Convention entered into force. Pursuant to the protocol, the enforcement mechanisms created by the Convention, the European Commission of Human Rights and the European Court of Human Rights, were merged into a reconstituted court, which was now empowered to hear individual (as opposed to interstate) petitions or complaints without the prior approval of the local government. The court's decisions are final and binding on the state parties to the Convention.

A companion instrument to the European Convention is the European Social Charter (1961) and its additional protocol (1988). In contrast to the adjudicatory enforcement procedures of the European Convention, the charter's provisions are implemented through an elaborate system of control based on progress reports to the various commit-

tees and organs of the Council of Europe. Inter-American human rights system. In 1948, concurrent with its establishment of the Organization of American States (OAS), the Ninth Pan-American Conference adopted the American Declaration on the Rights and Duties of Man, which, unlike the Universal Declaration of the UN, set out the duties as well as the rights of individual citizens. In 1959, a meeting of the American Ministers for Foreign Affairs created the Inter-American Commission on Human Rights, which has since undertaken important investigative activities. Finally, in 1969, the Inter-American Specialized Conference on Human Rights adopted the American Convention on Human Rights, which, among other things, established the Inter-American Court of Human Rights, which sits in San José, Costa Rica. Of the 26 western hemispheric states that so far have signed the convention, only the United States has yet to ratify it.

The core structure of the Inter-American human rights system is similar to that of its European counterpart. Nevertheless, some noteworthy differences exist, and three stand out in particular. First, reminiscent of the American Declaration on the Rights and Duties of Man, the American convention details individual duties as well as individual rights. Second, the American convention, unlike the European convention prior to Protocol No. 11, gives primary consideration to individual rather than interstate petitions or complaints. Finally, both the Inter-American Commission and the Inter-American Court operate beyond the framework of the American convention. The commission is as much an organ of the OAS Charter as of the American convention, and its powers and procedures can vary significantly depending on which body authorizes its activities. The court, though primarily an organ of the convention, has jurisdiction to interpret human rights provisions of other treaties, including the OAS Charter.

African human rights system. In 1981, the Eighteenth Assembly of Heads of State and Government of the Organization of African Unity (OAU) adopted the African Charter on Human and Peoples' Rights. Also known as the "Banjul Charter" for having been drafted in Banjul, Gambia, it entered into force on October 21, 1986, and boasts

the vast majority of the states of Africa as parties. Like its American and early European counterparts, the African Charter provides for a human rights commission, which has both promotional and protective functions. There is no restriction on who may file a complaint with it. In contrast to the European and American procedures, however, concerned states are encouraged to reach a friendly settlement without formally involving the investigative or conciliatory mechanisms of the Commission. Also, the African Charter does not call for a human rights court. African customs and traditions, it has been said, emphasize mediation, conciliation, and consensus rather than the adversarial and adjudicative procedures that are common to Western legal systems. Nevertheless, owing largely to political changes wrought by the end of the Cold War, planning for an African Court of Human Rights was begun in the late 1990s. As envisioned, the Court would not replace the Commission but would supplement and reinforce its mandate.

Four other distinctive features of the African charter are noteworthy. First, it provides for economic, social, and cultural rights as well as civil and political rights. In this respect it resembles the American convention and differs from the European convention. Second, in contrast to both the European and American conventions, it recognizes the rights of groups in addition to the family, women, and children. The aged and the infirm are accorded special protection also, and the right of peoples to self-determination is elaborated in the right to existence, equality, and nondomination. Third, it uniquely embraces the third-generation, or "solidarity," rights to economic, social, and cultural development and to national and international peace and security. Finally, it is to date the only treaty instrument to detail individual duties as well as individual rights-to the family, society, the state, and the international African community. In view of the turmoil that beset northern and sub-Saharan Africa at the end of the 20th century, it is fair to say that the African human rights system is still in its infancy.

Middle Eastern and Asian human rights systems. The Permanent Arab Commission on Human Rights, founded by the Council of the League of Arab States in September 1968, has been occupied primarily with the rights of Arabs living in Israeli-occupied territories. Functioning more to promote than to protect human rights, at the end of the 1990s it had yet to bring a proposed Arab Convention on Human Rights to a successful conclusion. Nevertheless, work by other intergovernmental and nongovernmental bodies manifested a continuing desire to establish human rights protection mechanisms in the Middle East, Building on the Universal Islamic Declaration of Human Rights (1981) and the Cairo Declaration on Human Rights in Islam (1990), the League of Arab States approved an Arab Charter on Human Rights in September 1994. The Charter provides for periodic reports to the league's Human Rights Committee by state parties and for an independent Committee of Experts apparently empowered to request and study reports and submit its own findings to the Human Rights Committee. No other institutions or procedures for monitoring human rights are specified in the Charter, however. More than in most other regions of the world (except Asia), the states of the Middle East were greatly divided over the need to enforce human rights law and the desirability of achieving a true regional system for

the promotion and protection of human rights. In Asia, despite efforts by NGOs and the United Nations, the states of the region were at best ambivalent-and at worst hostile-to human rights issues, thus precluding agreement on almost all regional human rights initiatives. In early 1993, anticipating the Vienna World Conference on Human Rights later that year, a conference of Asia-Pacific NGOs adopted an Asia-Pacific Declaration of Human Rights, and in 1997 another meeting of NGOs adopted an Asian Human Rights Charter. Both of these initiatives supported the universality and indivisibility of human rights. However, whereas the first initiative called for the creation of a regional human rights regime, the second-seemingly in deference to the cultural diversity and vastness of the region-urged instead the establishment of national human rights commissions and so-called "People's Tribunals," which would be based more on moral and spiritual foundations rather than on legal ones. The states of Asia were slow to respond to these recommendations. Their positions were indicated at a UN-sponsored workshop in 1996, where the 30 participating states concluded that "it was premature . . . to discuss specific arrangements relating to the setting up of a formal human rights mechanism in the Asian and Pacific region." The same states agreed, however, to "[explore] the options available and the process necThe Arab Charter

The Asian Human Rights Charter

The African Charter

European

Social

Charter

essary for establishing a regional mechanism." It remained to be seen whether the economic and political crises that beset Asia at the end of the 20th century would stimulate regional efforts to ensure greater respect for human rights.

INTERNATIONAL HUMAN RIGHTS IN DOMESTIC COURTS

Using domestic courts to clarify and safeguard international human rights is a new and still evolving approach to human rights advocacy. In addition to the inevitable interpretative problems involved in applying norms that are fashioned in multicultural settings, the approach is also burdened by controversial theories about the interrelation of national and international law and by numerous procedural difficulties. To be sure, considerable progress has been made, as perhaps best evidenced in the far-reaching decision handed down by the U.S. Court of Appeals for the 2nd Circuit in Filartiga v. Pena-Irala in 1980, in which the court held that the international prohibition of torture must be honoured in U.S. courts. More recently, in 1998-99, the United Kingdom's highest tribunal, the Law Lords of the British House of Lords, captured international attention when, in response to an extradition request by a Spanish court, it upheld the arrest in England of former Chilean President Augusto Pinochet on charges of torture and conspiracy to commit torture in violation of international treaty law. In so doing, it established the precedent that former heads of state do not enjoy immunity from prosecution, at least for systematic human rights crimes.

Human rights at the turn of the 21st century

Whatever the current attitudes and policies of governments, the reality of popular demands for human rights, including both greater economic justice and greater political freedom, is beyond debate. A deepening and widening concern for the promotion and protection of human rights on all fronts, hastened by the self-determinist impulse of a postcolonial era, is now unmistakably woven into the fabric of contemporary world affairs.

Substantially responsible for this progressive development has been the work of the United Nations, its allied agencies, and such regional organizations as the Council of Europe, the Organization of American States, and the Organization of African Unity. Also contributing to this development, particularly since the 1970s and '80s, have been five other salient factors; (1) the public advocacy of human rights as a key aspect of national foreign policies; (2) the emergence and spread of civil society on a transnational basis, primarily in the form of activist nongovernmental human rights organizations such as Amnesty International and Human Rights Watch; (3) a worldwide profusion of teaching and research devoted to the study of human rights; (4) the work of large UN conferences in areas such as children's rights, population, social development, women's rights, human settlements, and food production and distribution; and (5) a mounting intellectual and political challenge from feminists regarding not only the rights of women worldwide but also what they regard as the myths defining humane governance generally.

To be sure, because the application of international human rights law depends for the most part on the voluntary consent of nations, formidable obstacles attend the endeavours of human rights policy makers, activists, and scholars. Human rights conventions continue to be undermined by the failure of states to ratify them and by emasculating reservations and derogations; by self-serving reporting systems that outnumber objective complaint procedures; and by poor financing for the implementation of human rights prescriptions. In short, though a palpable concern for the advancement of human rights is here to stay, the mechanisms for the enforcement of human rights are still in their infancy.

The role of

the classics

Humanism

he word humanism has been freely applied to a variety of beliefs, methods, and philosophies that place central emphasis on the human realm. Most frequently, however, the term is used with reference to a system of education and mode of inquiry that developed in northern Italy during the 14th century and later spread through Europe and England. Alternately known as "Renaissance humanism," this program was so broadly and profoundly influential that it is one of the chief reasons why the Renaissance is viewed as a distinct historical period. Indeed, though the word Renaissance is of more recent coinage, the fundamental idea of that period as one of renewal and reawakening is humanistic in origin But humanism sought its own philosophical bases in far earlier times and, moreover, continued to exert some of its power long after the end of the Renaissance.

This article is divided into the following sections:

ORIGIN AND MEANING OF THE TERM HUMANISM

The ideal of humanitas. The history of the term humanism is complex but enlightening. It was first employed (as humanismus) by 19th-century German scholars to designate the Renaissance emphasis on classical studies in education. These studies were pursued and endorsed by educators known, as early as the late 15th century, as umanisti: that is, professors or students of classical literature. The word umanisti derives from the studia humanitatis, a course of classical studies that, in the early 15th century, consisted of grammar, poetry, rhetoric, history, and moral philosophy. The studia humanitatis were held to be the equivalent of the Greek paideia. Their name was itself based on the Latin humanitas, an educational and political ideal that was the intellectual basis of the entire movement. Renaissance humanism in all its forms defined itself in its straining toward this ideal. No discussion, therefore, of humanism can have validity without an understanding of humanitas.

Humanitas meant the development of human virtue, in all its forms, to its fullest extent. The term thus implied not only such qualities as are associated with the modern word humanity-understanding, benevolence. compassion, mercy-but also such more aggressive characteristics as fortitude, judgment, prudence, eloquence, and even love of honour. Consequently the possessor of humanitas could not be merely a sedentary and isolated philosopher or man of letters but was of necessity a participant in active life. Just as action without insight was held to be aimless and barbaric, insight without action was rejected as barren and imperfect. Humanitas called for a fine balance of action and contemplation, a balance born not of compromise but of complementarity. The goal of such fulfilled and balanced virtue was political in the broadest sense of the word. The purview of Renaissance humanism included not only the education of the young but also the guidance of adults (including rulers) via philosophical poetry and strategic rhetoric. It included not only realistic social criticism but also utopian hypotheses, not only painstaking reassessments of history but also bold reshapings of the future. In short, humanism called for the comprehensive reform of culture, the transfiguration of what humanists termed the passive and ignorant society of the "dark" ages into a new order that would reflect and encourage the grandest human potentialities. Humanism had an evangelical dimension. It sought to project humanitas from the individual into the state at large.

The wellspring of humanitas was classical literature. Greek and Roman thought, available in a flood of rediscovered or newly translated manuscripts, provided humanism with much of its basic structure and method. For Renaissance humanists, there was nothing dated or outworn about the writings of Plato, Cicero, or Livy. Compared with the typical productions of medieval Christianity, these pagan works had a fresh, radical, almost avant-garde tonality. Indeed, recovering the classics was to humanism tantamount to recovering reality. Classical philosophy, rhetoric, and history were seen as models of proper method-efforts to come to terms, systematically and without preconceptions of any kind, with perceived experience. Moreover, classical thought considered ethics qua ethics, politics qua politics: it lacked the inhibiting dualism occasioned in medieval thought by the often conflicting demands of secularism and Christian spirituality. Classical virtue, in examples of which the literature abounded, was not an abstract essence but a quality that could be tested in the forum or on the battlefield. Finally, classical literature was rich in eloquence. In particular (since humanists were normally better at Latin than they were at Greek) Cicero was considered to be the pattern of refined and copious discourse. In eloquence humanists found far more than an exclusively aesthetic quality. As an effective means of moving leaders or fellow citizens toward one political course or another, eloquence was akin to pure power. Humanists cultivated rhetoric, consequently, as the medium through which all other virtues could be communicated and fulfilled.

Humanism, then, may be accurately defined as that Renaissance movement which had as its central focus the ideal of humanitas. The narrower definition of the Italian term umanisti notwithstanding, all the Renaissance writers who cultivated humanitas, and all their direct "descendants," may be correctly termed humanists.

Other uses. It is small wonder that a term as broadly allusive as humanism should be subject to a wide variety of applications. Of these (excepting the historical movement described above) there are three basic types: humanism as classicism, humanism as referring to the modern concept of the humanities, and humanism as human-centredness. Accepting the notion that Renaissance humanism was

The studia humani-tatis

The

pursuit of

reading

simply a return to the classics, some historians and philologists have reasoned that classical revivals occurring anywhere in history should be called humanistic. St. Augustine, Alcuin, and the scholars of 12th-century Chartres have thus been referred to as humanists. In this sense the term can also be used self-consciously, as in the New Humanism movement in literary criticism led by Irving Babbitt and Paul Elmer More in the early 20th century.

The word humanities, which like the word umanisti derived from the Latin studia humanitatis, is often used to designate the nonscientific scholarly disciplines: language, literature, rhetoric, philosophy, art history, and so forth. Thus it is customary to refer to scholars in these fields as humanists and to their activities as humanistic.

Humanism and related terms are frequently applied to modern doctrines and techniques that are based on the centrality of human experience. In the 20th century the pragmatic humanism of Ferdinand C.S. Schiller, the Christian humanism of Jacques Maritain, and the movement known as secular humanism, though differing from each other significantly in content, all show this anthropocentric emphasis.

Not only is such a large assortment of definitions confusing, but the definitions themselves are often redundant or impertinent. There is no reason to call all classical revivals humanistic when the word classical suffices. To say that professors in the many disciplines known as the humanities are humanists is to compound vagueness with vagueness, for these disciplines have long since ceased to have or even aspire to a common rationale. The definition of humanism as anthropocentricity or human-centredness has a firmer claim to correctness. For obvious reasons, however, it is confusing to apply this word to classical

BASIC PRINCIPLES AND ATTITUDES

Underlying the early expressions of humanism were principles and attitudes that gave the movement a unique character and would shape its future development.

Classicism. Early humanists returned to the classics less with nostalgia or awe than with a sense of deep familiarity, an impression of having been brought newly into contact with expressions of an intrinsic and permanent human reality. Petrarch, the acknowledged founder of the humanistic movement, dramatized his feeling of intimacy with the classics by writing "letters" to Cicero and Livy, Coluccio Salutati remarked with pleasure that possession of a copy of Cicero's letters would make it possible for him to talk with Cicero. Niccolò Machiavelli would later immortalize this experience in a letter that described his own reading habits in ritualistic terms:

Evenings I return home and enter my study; and at its entrance I take off my everyday clothes, full of mud and dust, and don royal and courtly garments; decorously reattired, I enter into the ancient sessions of ancient men. Received amicably by them, I partake of such food as is mine only and for which I was born. There, without shame, I speak with them and ask them about the reason for their actions; and they in their humanity respond to me.

Machiavelli's term umanità ("humanity") means more than kindness; it is a direct translation of the Latin humanitas. Machiavelli implies that he shared with the ancients a sovereign wisdom of human affairs. He also describes that theory of reading as an active and even aggressive pursuit that was common among humanists. Possessing a text and understanding its words were not enough; analytic ability and a questioning attitude were necessary before a reader could truly enter the councils of the great. These councils, moreover, were not merely serious and ennobling; they held secrets available only to the astute, secrets the knowledge of which could transform life from a chaotic miscellany into a crucially heroic experience. Classical thought offered insight into the heart of things. In addition, the classics suggested methods by which, once known, human reality could be transformed from an accident of history into an artifact of will. Antiquity was rich in examples, actual or poetic, of epic action, victorious eloquence, and applied understanding. Carefully studied and well employed, classical rhetoric could implement enlightened policy, while classical poetics could carry enlightenment into the very souls of men. In a manner that might seem paradoxical to more modern minds, humanists associated classicism with the future.

Realism. Early humanists shared in large part a realism that rejected traditional assumptions and aimed instead at the objective analysis of perceived experience. To humanism is owed the rise of modern social science, which emerged not as an academic discipline but rather as a practical instrument of social self-inquiry. Humanists avidly read history, taught it to their young, and, perhaps most importantly, wrote it themselves. They were confident that proper historical method, by extending across time their grasp of human reality, would enhance their active role in the present. For Machiavelli, who avowed to treat of men as they were and not as they ought to be, history would become the basis of a new political science. Similarly, direct experience took precedence over traditional wisdom, Leon Battista Alberti's dictum that an essential form of wisdom could be found only "at the public marketplace, in the theatre, and in people's homes" would be echoed by Francesco Guicciardini:

I, for my part, know no greater pleasure than listening to an old man of uncommon prudence speaking of public and political matters that he has not learnt from books of philosophers but from experience and action; for the latter are the only genuine methods of learning anything.

Renaissance realism also involved the unblinking examination of human uncertainty, folly, and immorality, Petrarch's honest investigation of his own doubts and mixed motives is born of the same impulse that led Giovanni Boccaccio in the Decameron to conduct an encyclopaedic survey of human vices and disorders. Similarly critical treatments of society from a humanistic perspective would be produced later by Erasmus, More, Castiglione, Rabelais, and Montaigne. But it was typical of humanism that this moral criticism did not, conversely, postulate an ideal of absolute purity. Humanists asserted the dignity of normal earthly activities and even endorsed the pursuit of fame and the acquisition of wealth. The emphasis on a mature and healthy balance between mind and body, first implicit in Boccaccio, is evident in the work of Giannozzo Manetti, Francesco Filelfo, and Paracelsus; it is embodied eloquently in Montaigne's final essay, "Of Experience." Humanistic tradition, rather than revolutionary inspiration, would lead Francis Bacon to assert in the early 17th century that the passions should become objects of systematic investigation. The realism of the humanists was, finally, brought to bear on the Roman Catholic Church, which they called into question not as a theological structure but as a political institution. Here as elsewhere, however, the intention was neither radical nor destructive. Humanism did not aim to remake humanity but rather to reform social order through an understanding of what was basically and inalienably human.

Critical scrutiny and concern with detail. Humanistic realism bespoke a comprehensively critical attitude. Indeed, the productions of early humanism constituted a manifesto of independence, at least in the secular world. from all preconceptions and all inherited programs. The same critical self-reliance shown by Coluccio Salutati in his textual emendations and Boccaccio in his interpretations of myth was evident in almost the whole range of humanistic endeavour. It was cognate with a new specificity, a profound concern with the precise details of perceived phenomena, that took hold across the arts and the literary and historical disciplines and would have profound effects on the rise of modern science. The increasing prominence of mathematics as an artistic principle and academic discipline was a testament to this development.

The emergence of the individual and the idea of the dignity of man. These attitudes took shape in concord with a sense of personal autonomy that first was evident in Petrarch and later came to characterize humanism as a whole. An intelligence capable of critical scrutiny and self-inquiry was by definition a free intelligence; the intellectual virtue that could analyze experience was an integral part of that more extensive virtue that could, according to many humanists, go far in conquering fortune. The History and experience

Petrarch's

greatest

influence

emergence of Renaissance individualism was not without its darker aspects. Petrarch and Alberti were alert to the sense of estrangement that accompanies intellectual and moral autonomy, while Machiavelli would depict, in The Prince, a grim world in which the individual must exploit the weakness of the crowd or fall victim to its indignities. But happy or sad, the experience of the individual had taken on a heroic tone. Parallel with individualism arose, as a favourite humanistic theme, the idea of the dignity of man. Backed by medieval sources but more sweeping and insistent in their approach, spokesmen such as Petrarch, Manetti, Valla, and Ficino asserted man's earthly preeminence and unique potentialities. In his noted De hominis dignitate oratio ("Oration on the Dignity of Man"), Giovanni Pico della Mirandola conveyed this notion with unprecedented vigour. Humanity, Pico asserted, had been assigned no fixed character or limit by God but instead was free to seek its own level and create its own future. No dignity, not even divinity itself, was forbidden to human aspiration. Pico's radical affirmation of human capacity shows the influence of Ficino's recent translations of the Hermetic writings. Together with the even holder 16thcentury formulations of this position by Paracelsus and Giordano Bruno, the Oratio betrays a rejection of the early humanists' emphasis on balance and moderation; it suggests the straining toward absolutes that would characterize major elements of later humanism.

Active virtue. The emphasis on virtuous action as the goal of learning was a founding principle of humanism and (though sometimes sharply challenged) continued to exert a strong influence throughout the course of the movement. Salutati, the learned chancellor of Florence whose words could batter cities, represented in word and deed the humanistic ideal of an armed wisdom: that combination of philosophical understanding and powerful rhetoric which alone could effect virtuous policy and reconcile the rival claims of action and contemplation. In De ingenuis moribus et liberalibus studiis ("On the Manners of a Gentleman and Liberal Studies"), a treatise that influenced Guarino Veronese and Vittorino da Feltre, Pietro Paolo Vergerio maintained that just and beneficent action was the purpose of humanistic education; his words were echoed by Alberti in Della famiglia ("On the Family"):

As I have said, happiness cannot be gained without good works and just and righteous deeds. . The best works are those that benefit many people. Those are most virtuous, perhaps, that cannot be pursued without strength and nobility. We must give ourselves to manly effort, then, and follow the noblest pursuits.

Matteo Palmieri wrote that

the true merit of virtue lies in effective action, and effective action is impossible without the faculties that are necessary for it. He who has nothing to give cannot be generous. And he who loves solitude can be neither just, nor strong, nor expenenced in those things that are of importance in government and in the affairs of the majority.

Palmieri's philosophical poem, La città di vita ("The City of Life"), developed the idea that the world was divinely ordained to test human virtue in action. Later humanism would broaden and diversify the theme of active virtue. Machiavelli saw action not only as the goal of virtue but also (via historical understanding of great deeds of the past) as the basis for wisdom, Baldassare Castiglione, in his highly influential Libro del cortegiano (Book of the Courtier), developed in his ideal courtier a psychological model for active virtue, stressing moral awareness as a key element in just action. François Rabelais used the idea of active virtue as the basis for anticlerical satire. In his profusely humanistic Gargantua, he has the active hero Friar John save a monastery from enemy attack, while the monks sit uselessly in the church choir, chanting meaningless Latin syllables. John later asserts that, had he been present, he would have used his manly strength to save Jesus from crucifixion, and he castigates the Apostles for betraying Christ "after a good meal." Endorsements of active virtue, as will be shown, would also characterize the work of English humanists from Sir Thomas Elyot to John Milton. They typify the sense of social responsibility, the instinctive association of learning with politics and morality, that stood at the heart of the movement. As Salutati put it, "One must stand in the line of battle, engage in close combat, struggle for justice, for truth, for honour."

EARLY HISTORY

The influence of Petrarch (Francesco Petrarca, 1304-74) was profound and many-sided. As the most prominent man of letters of the 14th century, he promoted the recovery and transcription of classical texts, providing the impetus for the important classical researches of Boccaccio and Salutati. He threw himself into controversies in which he defined a new humanism in contradistinction to what he considered to be the barbaric influence of medieval tradition. He carried on an energetic correspondence that established him as a cultural focal point and would provide, if all his other works were lost, an accurate index of his views and their development. As a theologian (he was an ordained priest) he advanced the view, held by many humanists to follow, that classical learning and Christian spirituality were not only compatible but also mutually fulfilling. As a political apologist, he gave hearty support to Cola di Rienzo's brief revival of the Roman Republic (1347). As a poet, he was the first Renaissance writer to produce a Latin epic (Africa), but he was even more important for his compositions in the vernacular. His Canzoniere provided the model on which the Renaissance lyric was to take shape and the standard by which future productions would be judged. His work established secular poetry as a serious and noble pursuit. His eloquent and forceful presence made him a personal symbol of his own ideas. Crowned with laurel, favoured by rulers, legates, and scholars, he became the human focus for the new interest in classical revival and literary artistry.

It was, however, as a philosophical spokesman that Petrarch exerted his greatest influence on the history of humanism. In his prose works and letters he established many of the positions that would be central to the movement and broached many of the issues that would be its favourite subjects for debate. His idea of the poet as a philosophical teacher and thus as a champion of culture would inspire humanists from Boccaccio to Sidney. His endorsement of the study of rhetoric and his underlying notion of language as an informing principle of the individual and society would become crucial subjects of humanistic discussion and debate. His view of classical culture, not as an undifferentiated element of the past but as an authentic alternative to his own medieval society. was of equal historical importance. Petrarch broke with the past and helped to reestablish the Socratic tradition in Europe by specifying self-knowledge as a primary goal of philosophy. This attitude and his unfailing insistence on moral autonomy were early and important signs of the individualism that would become a Renaissance hallmark. He emphasized human virtue as opposed to fortune, thus setting the stage for numerous famous treatments of this theme. He struggled repeatedly with the dilemma of action versus contemplation, establishing it as a favourite topic for humanistic debate. Petrarch did not invent these subjects, nor does he usually treat them with overwhelming power. His preeminence lies in the fact that he was the first writer since antiquity to assert that they and other human matters were valid issues for philosophical inquiry in and of themselves, and in the energy and eloquence with which he made his work their forum.

Petrarch's influence was immediately apparent in the work of two major Florentine humanists, Giovanni Boccaccio and Coluccio Salutati. A close friend and devoted supporter of Petrarch, Boccaccio (1313-75) not only enlarged upon his preceptor's ideas but also made important humanistic contributions of his own. His Tesside was the first classical epic to have been written in the vernacular and influenced the more famous Italian epics of Ariosto and Tasso. His De genealogia deorum gentilium ("On the Genealogy of the Gods of the Gentiles"), a scholarly interpretive compendium of classical myth, was the first in a long line of Renaissance mythographies; it includes a celebrated defense of poetry as a medium of hidden truth, a stimulant to virtue, and a source of mental health. His most memorable contribution to humanism, however, was

Armed wisdom

Rabelais's Gargantua

Coluccio

Salutati

Boccaccio's probably the famous Decameron. Ostensibly this work is Decameron no more than a collection of 100 tales about love. But subjected to the interpretive scrutiny that Boccaccio himself recommends in De genealogia deorum gentilium, the Decameron takes on a far more serious tone. The opening phrase "Umana cosa è" ("It is a human thing") is deeply thematic, reminding us that the author structured his work on Dante's spiritual epic, La divina commedia. A close reading of the Decameron suggests that in it Boccaccio is trying to establish for the human realm the same sort of comprehensive understanding that Dante established for the life of the spirit. Through moral fable and direct address to the reader, he undertakes a reinterpretation of human experience based not on traditional doctrine but rather on perceived reality. Appealing repeatedly to reason and nature, and constantly implying the superiority of awareness to innocence (which he equates with ignorance), he calls for a moral order built fairly and solidly on the potentialities of human nature. His 10 storytellers, who leave the plague-ravaged and chaotic city of Florence and reestablish themselves at a delightfully landscaped villa, suggest the remaking of culture through disentanglement with the past, unprejudiced analysis, and enlightened imagination. Rightly considered to be the wellspring of Western realism, the Decameron is also a monument to humanism, Though it makes little mention of classical thought, Boccaccio's great work rings with a tone that was even more basic to the humanistic movement; an emphasis on the human capacity for self-knowledge and willed renewal.

Other humanistic elements implicit in Petrarch's thought were developed in the life and work of Coluccio Salutati (1331-1406). Like Petrarch, Salutati collected manuscripts, wrote on morality and politics, and carried on a voluminous correspondence. He was an aggressive and scientific philologist, instrumental in establishing principles of textual criticism that would become key elements of the humanistic method. He was a forceful apologist for the active life, and his theories bore fruit in his own career as chancellor of the Florentine republic. His use of classical eloquence in the service of his state was an early documentation of the humanistic faith in the political power of rhetoric; it led a bitter enemy, Gian Galeazzo Visconti of Milan, to say that a thousand Florentine horsemen had hurt him less than the letters of Coluccio, Salutati was succeeded in the Florentine chancellorship by two scholar-statesmen who reflected his influence, first Leonardo Bruni (1369-1444) and then Gian Francesco Poggio Braccioloni (1380-1459). Bruni was a pioneer in the advocacy of humanistic education, holding that the studia humanitatis shape the perfected man and that the goal of this perfected virtue is political action. His theory of education stressed the importance of practical experience (implicit in the work of Boccaccio) and put heavy emphasis on historical studies. His history of Florence is considered to be the first work of modern historiography; and, under the influence of Emmanuel Chrysoloras (1368-1415), a Byzantine teacher who had lectured at Florence and Pavia, he produced Latin translations of Plato and Aristotle that broke with medieval tradition by reproducing the sense of the Greek prose rather than following it word by word. Poggio, the foremost recoverer of classical texts, was also a moralist, a historian, a brilliant correspondent, and an early scholar of architectural antiquities. His long career, which included service to both church and state and friendships with Salutati, Bruni, Niccolò Niccoli, Guarino, Nicholas of Cusa, Donatello, and Cosimo de' Medici, exemplifies the scope and vitality of Italian humanism. Together these Florentine chancellors. whose active lives spanned almost a century, strengthened and consolidated the humanistic program. Moreover, their leadership strongly influenced the cultural developments that would make 15th-century Florence the most active intellectual and artistic centre in Europe.

As one proceeds with the history of humanism, the following major points about its development in the 14th century ought to be kept in mind. Humanism received its crucial imprint from the work of a single man and thence developed among men who maintained close touch with each other and acknowledged a shared mission. Humanism was not originally an academic movement but rather a program defined and promoted by statesmen and men of letters. Its proclaimed goal was widespread cultural renewal: therefore, it chose its subjects for consideration from the phenomena of human life as lived and adopted the Ciceronian model of philosopher as citizen in preference to the contemplative ideal. The heavy emphasis on civic action is connected with the fact that humanism developed in a republic rather than a monarchy.

By the turn of the 15th century, all of the key elements that came to define humanism were in place except for two: its detailed educational system and what might be called its Greek dimension. The founders of the first humanistic schools were Vittorino da Feltre (1373-1446) and Guarino Veronese (Guarino da Verona, 1374-1460). Vittorino and Guarino were fellow students at the University of Padua at the turn of the century; they are said later to have tutored each other (Guarino as an expert in Greek, Vittorino in Latin) after Guarino had opened the first humanistic school (Venice, c. 1414). Vittorino taught in both Padua (where he was briefly professor of rhetoric) and Venice during the early 1420s. In 1423 he accepted the invitation of Gianfrancesco Gonzaga, marquis of Mantua, to become tutor to the ruling family. At this post Vittorino spent the remaining 22 years of his life. His school, held in a delightful palace that he renamed "La Giocosa," had as its students not only the Gonzaga children (among them the future marquis, Ludovico) but also an increasing number of others, including sons of Poggio, Guarino, and Filelfo. The eminent humanist Lorenzo Valla studied there, as did Federico da Montefeltro, who later promoted humanistic institutions as duke of Urbino. Vittorino's school in Mantua was the first to focus the full power of the humanistic program, together with its implications in other arts and sciences, upon the education of the young. Latin literature, Latin composition, and Greek literature were required subjects of study. Heavy emphasis was placed on Roman history as an educational treasury of great men and memorable deeds. Rhetoric (as taught by Quintilian) was a central topic, not as an end in itself but as an effective means of channeling moral virtue into political action. Vittorino summed up the essentially political thrust of humanistic education as follows:

Not everyone is called to be a physician, a lawyer, a philosopher, to live in the public eye, nor has everyone outstanding gifts of natural capacity, but all of us are created for the life of social duty, all are responsible for the personal influence that goes forth from us.

Other studies at Mantua included music, drawing, astronomy, and mathematics. The meadows around La Giocosa were turned into playing fields. Vittorino's educational policy spoke at once to mind and body, to aesthetic enjoyment and moral virtue. His work embodied a more comprehensive appeal to human perfectibility than had been attempted since antiquity. Humanists were not unaware of the originality and ambitiousness of this project. With reference to a similar program of his own, Guarino's son Battista remarked that "no branch of knowledge embraces so wide a range of subjects as that learning that I have now attempted to describe."

Guarino had learned his Greek in Constantinople under the influence of Chrysoloras, whose dynamic presence had done much to foster Greek studies in Italy. During the course of the 15th century, which saw the famous council of Eastern and Western churches (Ferrara-Florence, 1438-45) and later the fall of Constantinople to the Turks (1453), Italy received as welcome immigrants a number of other eminent Byzantine scholars. George Gemistus Plethon (1355-1450) was a major force in Cosimo de' Medici's foundation of the Platonic Academy of Florence. George of Trebizond (Georgius Trapezuntius, 1395-1484), a student of Vittorino, was a formidable bilingual stylist who wrote important handbooks on logic and rhetoric. Theodore Gaza (c. 1400-75) and Johannes Argyropoulos (1410-90) contributed major translations of Aristotle. John (originally Basil) Bessarion (1403-72), who became a cardinal in 1439, explored theology from a Platonic perspective and sought to resolve apparent conflicts between Platonic and Aristotelian philosophy; his large collection

The humanistic schools

Byzantine influence

of Greek manuscripts, donated to the Venetian senate, became the core of the notable library of St. Mark. This infusion of Byzantine scholarship had a profound effect on Italian humanism. By making Greek texts and commentaries available to Western students, and by acquainting them with Byzantine methods of criticism and interpretation, the teachers from Constantinople enabled Italian humanists to explore the bases of classical thought and to appreciate its greatest monuments, either in the original or in accurate new Latin translations.

THE 15TH CENTURY

As Italian humanism grew in influence during the 15th century, it developed ramifications that connected it with every major field of intellectual and artistic activity. Moreover, the advent of printing at mid-century and the contemporaneous upsurge of publication in the vernacular brought new sectors of society under humanistic influence. These and other cultural impetuses hastened the export of humanistic ideas to the Low Countries, France, England. and Spain, where significant humanistic programs would be in place by the early 16th century. Even as these things were happening, however, other changes were deeply and permanently affecting the character of the movement. The concerns of many major humanists were narrowed by inevitable historical processes of specialization, to the extent that, in a large number of cases, humanism lost its comprehensive thrust and became a predominantly academic or literary pursuit. The political élan of humanism was weakened by the decline of republican institutions in Florence. Ambiguities and paradoxes implicit in the original program developed into open conflicts, dividing the movement into camps and depleting much of its original integrity. But before considering these developments, one might do well to appreciate three 15th-century examples of humanism at its height: the career of Leon Battista Alberti and the humanistic courts at Florence and Urbino. Leon Battista Alberti. The achievement of Leon Battista Alberti (1404-72) testifies to the formative power and exhaustive scope of earlier Italian humanism. He owed his boyhood education to Gasparino da Barzizza (1359-1431), the noted teacher who, with Vergerio, was influential in the development of humanism at Padua, Alberti attended the University of Bologna from 1421 until 1428. by which time he was expert in law and mathematics and so adept at humanistic literary skills that his comedy Philodoxeos was accepted as the newly discovered work of an ancient author. In 1428 he became secretary to Cardi-

nal Albergati, bishop of Bologna, and in 1432 he accepted a similar position in the papal chancery at Rome. His service to the church soon brought him incomes that permanently secured his livelihood, and he spent the remainder of his life at a variety of literary, philosophical, and artistic pursuits so dazzling as to challenge belief. He was a poet, essayist, and biographer. His moral and philosophical works, especially Della famiglia, De iciarchia ("On the Man of Excellence and Ruler of His Family"), and Momus, are humanistic statements that nonetheless bear the mark of a unique individual. He wrote a rhetorical handbook and a grammatical treatise, the Regule lingue Florentine, which bespeaks his strong influence on the rise of literary expression in the vernacular. He contributed an important text on cartography and was instrumental in the development of ciphers. A prominent architect (e.g., the Tempio Malatestiano in Rimini and the facade of Sta. Maria Novella in Florence), he was also an eminent student of all artistic ideas and practices. His three studies-De pictura (On Painting), De statua (On Sculpture), and De re aedificatoria (Ten Books on Architecture)were landmarks in art theory, powerful in developing the "theory of perspective and the idea of "human" space. His theoretical and practical reliance on mathematics (which he considered to be the basic, unifying element of all science) is rightly seen as an important step in the early development of modern method.

Alberti's

writings

Behind these achievements was a man of startling physical prowess and inexhaustible sanguinity. He said outright that an individual could encompass whatever project he truly willed, and his own life bore witness to this radical thesis. In the 19th century Jacob Burckhardt would write of him as a "universal man" of the Renaissance, while his own contemporary Politian described him with wonderment: "It is better to be silent about him than not to say enough." Alberti's theory and practice bore an undeniably humanistic stamp. His passion for mathematics was in all likelihood an outgrowth of the educational program at Padua (Vittorino, himself an avid mathematician, was also a student of Barzizza). His omnivorous pursuit of knowledge recalls Barzizza's conviction that humanitas was the unifying principle of many arts. An advocate of classical erudition in art and architecture as well as in literary activity, he extended into his artistic studies the same sense of precision and specificity that earlier humanists had applied to philology. His sense of human dignity, evident in all his productions, was supported and indeed iustified by a strenuous realism. His advocacy of the vernacular disturbed a number of more doctrinaire humanists, who favoured total Latinity. But this predisposition, rather than a divergence from humanistic principle, was a direct outgrowth of its evangelistic thrust. In short, Alberti uniquely fulfilled the humanistic aspiration for a learning that would comprehend all experience and a philosophical heroism that would renew society.

The Medici and Federico da Montefeltro. The 15th century saw the rise of the Platonic Academy of Florence and the great humanistic courts. Close ties between Poggio and the Medici helped make that ruling family of Florence the new custodians of the humanistic heritage. Cosimo de' Medici (Cosimo the Elder, 1389-1464), who had personally lured the great council of churches from Ferrara to Florence in 1439, became so enamoured of Greek learning that, at the suggestion of Gemistus Plethon. he decided to found a Platonic academy of his own. He amassed a great collection of books, which would form the nucleus of the Laurentian Library. He generously supported the work of scholars, in particular encouraging the brilliant Marsilio Ficino (1433-99) to undertake a complete Latin translation of Plato. Other notable members of the academy were Politian, Cristoforo Landino (1424-1504), and Ficino's own student, Giovanni Pico della Mirandola (1463-94). The Medici family was equally notable in its patronage of the arts, supporting projects by a list of masters that included Brunelleschi, Michelangelo, and Cellini, Cosimo's famous grandson Lorenzo (Lorenzo the Magnificent, 1449-92) was of a thoroughly humanistic disposition. Lorenzo's versatile and energetic nature lent itself equally to politics and philosophy, to martial arts and music. He wrote poetry and literary commentary and formed close ties with Ficino, Pico, and other leading scholars of the academy. He continued his grandfather's lavish patronage of art and learning and was said to have spent half of his city's revenues on the purchase of books alone. Active in many fields, he nonetheless acknowledged the preeminence of the life of the mind. When chided by a friend for sleeping late and not going out to work, Lorenzo replied, "What I have dreamed in one hour is worth more than what you have done in four.'

The influence of humanism was evident in many 15thcentury Italian courts, including Rome itself, which boasted, in Pius II (Enea Silvio Piccolomini, also known as Aeneas Sylvius Piccolomini, 1405-64), a humanist pope. It manifested itself strikingly at Urbino, where Federico da Montefeltro (1422-82) turned an isolated hill town into a treasury of Renaissance culture. Schooled by Vittorino in Mantua. Federico chose warfare as his calling. As a mercenary he gained a reputation for winning his battles and keeping his word, and the fortune he accumulated in fees and prizes became the medium for his city's renewal. He brought architects, artists, and scholars to Urbino and built a great palace whose unadorned exterior concealed magnificent chambers, a graceful courtyard, and a secret garden. Federico was enthusiastically devoted to the collection and preservation of books. His library, described by Vespasiano Bisticci as being even more complete than that of the Medici, contained an army of 30 to 40 scribes who were constantly at work. His own virtues were so notable and diverse as to mark him as a possible model for Rabelais's humanistic giant, Gargantua. Mighty at

The Medici natronage

Federico's library

arms, he was also conscientious in religious observances; supremely powerful, he was nonetheless a modest and courteous companion. Beneath the ivied tranquility of his secret garden stretched an indoor equestrian arena. He commissioned paintings by Piero della Francesca and was the object of humanistic dedications by Poggio, Landino, and Ficino. He kept two organists at court and maintained five men to read the classics aloud at meals. Federico's intellectual accomplishments were impressive. His skill at mathematics shows the influence of Vittorino. He was a good Latinist and as a student of classical history was able to hold his own in conversation with the erudite Pius II. At philosophy Federico was even more astute. Vespasiano wrote that

he began to study logic with the keenest understanding, and he argued with the most nimble wit that was ever seen. After he had heard (Aristotle's) Ethics many times, comprehending it so thoroughly that his teachers found him hard to cope with in disputation, he studied the Politics assiduously. it may be said of him that he was the first of the Signori who took up philosophy and had knowledge of the same. He was ever careful to keep intellect and virtue to the front, and to learn some new thing every day,

Federico's balance and versatility made him, even more than Lorenzo, an example of the humanistic program in action. Baldassare Castiglione, perhaps the most thoughtful of the later Italian humanists, would speak of him as "the light of Italy; there is no lack of living witnesses to his prudence, humanity (umanità), justice, intrepid spirit, (and) military discipline." Castiglione described Federico's residence as seeming to be less a palace than "a city in the form of a palace"; one might say as well that this structure, with its elegant accommodation for every creative human activity, was an architectural image of the humanistic mind.

LATER ITALIAN HUMANISM

The achievement of Alberti, Federico, and the Medici up to Lorenzo may be seen as the effective culmination of Italian humanism, the ultimate realization of its motives and principles. At the same time as these goals were being achieved, however, the movement was beginning to suffer bifurcation and dilution. Even the enthusiastic Platonism of the Florentine academy was, in its idealism and emphasis on contemplation, a significant digression from the crucial humanistic doctrine of active virtue, and Pico della Mirandola himself was politely admonished by a friend to forsake the ivory tower and accept his civic responsibilities. The conflicting extremes to which sincere humanistic inquiry could drive scholars are nowhere more apparent than in the fact that the arch-idealist Pico and the archrealist Machiavelli lived in the same town and at the same time. Castiglione, who had belonged to the court of Federico's son Guidobaldo, would be saddened by its decline and shocked when another of his patrons, the "model" Renaissance prince Charles V, ordered the sack of Rome. To a large extent, the cause of these and other vicissitudes lay in the nature of the movement itself, for that boundless diversity which nourished its strength was also a well of potential conflict. Humanists' undifferentiated acceptance of the classical heritage was also in effect an appropriation of the profound controversy implicit in that heritage. Rifts between Platonists, monarchists, and republicans; positivists and skeptics; idealists and cynics; and historians and poets came to be more and more characteristic of humanistic discourse. Some of these tensions had been clear from the start, Petrarch having been ambiguous in his sentiments regarding action versus contemplation, and Salutati having been not wholly clear about whether he preferred republics to monarchies. But the 15th century, bringing with it the irreconcilable heterogeneity of Greek thought, vastly multiplied and deepened these divisions. Of these schisms, the two that perhaps most deeply influenced the course of humanism were the so-called resverbum ("thing-word") controversy and the split between Platonic idealism and historical realism.

Things and words. Simply put, the res-verbum controversy was an extended argument between humanists who believed that language constituted the ultimate human reality and those who believed that language, though an important subject for study, was the medium for understanding an even more basic reality that lay beyond it. The origin of the controversy lay in the debate in the 5th-4th century BC between the Socratic school, which held that language was an important means of understanding deeper truths, and the Sophistic-rhetorical school, which held that "truth" was itself a fiction dependent on varying human beliefs and therefore that language had to be considered the ultimate arbiter. Petrarch, who had no direct contact with the works of Plato and little detailed knowledge of his ideas, drew on Cicero and St. Augustine in his development of a Christian-rhetorical position, holding that "it is more satisfying (satius) to will the good than to know the truth" and espousing rhetoric as the effective means of convincing people "to will the good."

Origin of

the res-

verbum

contro-

This assertion would critically shape the character of humanism through the Renaissance and beyond. It was never effectively challenged by Renaissance Platonists because, for reasons discussed below, Renaissance Platonists, though strong in Platonic idealism, were weak in Platonic analytical method. The enthronement of language as both subject and object of humanistic inquiry is evident in the important work of Lorenzo Valla (1407-57) and Politian (Angelo Poliziano, 1454-94). Valla spoke of language as a "sacrament" and urged that it be studied scientifically and historically as the synthesis of all human thought. For Valla, the study of language was, in effect, the study of humanity. Similarly, Politian held that there were in fact two dialectics: one of ideas and one of words. Rejecting the dialectic of ideas as being too difficult and abstruse, he espoused the dialectic of words (i.e., philology and rhetoric) as the proper human study. This project would bear fruit in the intensive linguistic-philosophical researches of Mario Nizolio (1498-1575). Though anticipated by Petrarch, the radical emphasis on the primacy of the word constituted a break with the teaching of other early humanists, such as Bruni and Vittorino, who had strongly maintained that the word was of value only through its relationship to perceived reality. Nor did the old viewpoint lack later adherents. In an epistolary debate with Ermolao Barbaro (1454-93), Pico asserted the preeminence of things over words and hence of philosophy over rhetoric: "But if the rightness of names depends on the nature of things, is it the rhetorician we ought to consult about this rightness, or is it the philosopher who alone contemplates and explores the nature of everything?" Appeals of this sort, however, were not to win the day. Philosophical humanism declined because, though rich in conviction, it had failed to establish a systematic relationship between philosophy and rhetoric, between words and things. By the 16th century, Italian humanism was primarily a literary pursuit, and philosophy was left to develop on its own. Despite significant challenges, the division between philosophical and literary studies would solidify in the development of Western culture.

Idealism and the Platonic Academy of Florence. The idealism so prominent in the Florentine academy is called Platonic because of its debt to Plato's theory of Ideas and to the epistemological doctrine established in his Symposium and Republic. It did not, however, constitute a complete appreciation or reassertion of Plato's thought. Conspicuously absent from the Florentine agenda was the analytic method (dialectic), which was Socrates' greatest contribution to philosophy. This major omission cannot be explained philologically, at least after Ficino's work had made the complete Platonic corpus available in clear Latin prose. The explanation lies rather in a specific cast of mind and in a dramatically successful forgery. The major Platonists of the mid-15th century, Plethon, Bessarion, and Nicholas of Cusa (Nicholaus Cusanus, 1401-64), had all concentrated their attention on the religious implications of Platonic thought; and, following them, Marsilio Ficino (1433-99) sought to reconcile Plato with Christ in a pia philosophia ("pious philosophy"). The transcendental goals of these philosophers left little room for the painstaking dialectical method that sifted through the details of perception and language, even though Plato himself had repeatedly alleged that transcendence itself was impos-

Diversification and erosion

sible without this method. Along with Plato, moreover, Ficino had translated into Latin the works of the so-called Hermes Trismegistos. These books, which also emphasized transcendence at the expense of method, laid claim to divine authority and to an antiquity far greater than Plato's. They were, in fact, forgeries from a much later period, and are in many ways typical of the idealized and diluted versions of Plato that are called Neoplatonic, But the academy, and for that matter all the other Platonists of the 15th century, bought them wholesale. The result of these factors was a Platonism sans Platonic method, a philosophy that, straining for absolutes, had little interest in establishing its own basis in reality. Near the end of The Book of the Courtier, Castiglione puts a speech typical of Florentine Platonism in the mouth of his friend, the Platonist Pietro Bembo (1470-1547). As Bembo finishes his oration, a female companion tugs at the hem of his robe and says, "Take care, Master Pietro, that with such thoughts your soul does not forsake your body.

Machiavelli's realism. Niccolò Machiavelli (1469-1527), whose work derived from sources as authentically humanistic as those of Ficino, proceeded along a wholly opposite course. A throwback to the chancellor-humanists Salutati, Bruni, and Poggio, he served Florence in a similar capacity and with equal fidelity, using his erudition and eloquence in a civic cause. Like Vittorino and other early humanists, he believed in the centrality of historical studies, and he performed a signally humanistic function by creating, in La Mandragola, the first vernacular imitation of Roman comedy. His characteristic reminders of human weakness suggest the influence of Boccaccio; and like Boccaccio he used these reminders less as satire than as practical gauges of human nature. In one way at least, Machiavelli is more humanistic (i.e., closer to the classics) than the other humanists, for while Vittorino and his school ransacked history for examples of virtue, Machiavelli (true to the spirit of Polybius, Livy, Plutarch, and Tacitus) embraced all of history, good, evil, and indifferent, as his school of reality. Like Salutati, though perhaps with greater self-awareness, Machiavelli was ambiguous as to the relative merits of republics and monarchies. In both public and private writings (especially the Discorsi sopra la prima deca di Tito Livio ["Discourses on the First Ten Books of Livy"]) he showed a marked preference for republican government, while in The Prince he developed, with apparent approval, a model of radical autocracy. For this reason, his goals have remained unclear.

His methods, on the other hand, were coherent throughout and remain a major contribution to social science and the history of ideas. Like earlier humanists, Machiavelli saw history as a source of power, but, unlike them (and here perhaps influenced by Sophistic and Averroistic thought), he saw neither history nor power itself within a moral context. Rather he sought to examine history and power in an amoral and hence (to him) wholly scientific manner. He examined human events in the same way that Alberti, Galileo, and the new science examined physical events: as discrete phenomena that had to be measured and described before they could be explained and evaluated. To this extent his work, though original in its specific design, was firmly based in the humanistic tradition. At the same time, however, Machiavelli's achievement significantly eroded humanism. By laying the foundations of modern social science, he created a discipline that, though true to humanistic methodology, had not the slightest regard for humanistic morality. In so doing, he brought to the surface a contradiction that had been implicit in humanism all along: the dichotomy between critical objectivity and moral evangelism.

The achievement of Castiglione. Though Italian humanism was being torn apart by the natural development of its own basic motives, it did not thereby lose its native attractions. The humanistic experience, in both its positive and negative effects, would be reenacted abroad. Baldassare Castiglione (1478–1529), whose Book of the Courtier affectionately summed up humanistic thought, was one of its most powerful ambassadors. Alert to the major contradictions of the program, yet intensely appreciative of its brilliance and energy, Castiglione wove its various strains together in a long dialogue that aimed at an equipoise between various humanistic extremes. Ostensibly a treatise on the model courtier, The Book of the Courtier is more seriously a philosophically organized pattern of conflicting viewpoints in which various positions-Platonist and Aristotelian, idealist and cynic, monarchist and republican, traditional and revolutionary-are given eloquent expression. Unlike most of his humanistic forebears, Castiglione is neither missionary nor polemical. His work is not an effort at systematic knowledge but rather an essay in higher discretion, a powerful reminder that every virtue (moral or intellectual) suggests a concomitant weakness and that extreme postures tend to generate their own opposites. The structure of the dialogue, in which Bembo's Platonic ecstasy is balanced by Bibbiena's assortment of earthy jests, is a testament to this intention. While Castiglione's professed subject matter would epidemically inspire European letters and manners of the 16th century his more profound contribution would be echoed in the work of Montaigne and Shakespeare. His work suggests a redefined humanism, a virtue matured in irony and directed less toward knowledge than toward wisdom.

Tasso's Aristotelianism. In 16th-century Italy, humanistic methods and attitudes provided the medium for a kaleidoscopic variety of literary and philosophical productions. Of these, the work that perhaps most truly reflected the original spirit of humanism was the Gerusalemme liberata of Torquato Tasso (1544-95). New humanistic translations of Aristotle during the 15th century had inspired an Aristotelian Renaissance, and the attention of literary scholars focused particularly on the Poetics. In constructing his epic poem, Tasso was strongly influenced by Aristotle's views regarding the philosophical dimension of poetry; loosely paraphrasing Aristotle, he held (in his Apologia) that poetry, by incorporating both particulars and universals, was capable of seeking truth in its perfect wholeness. As a vehicle for philosophical truth, poetry consequently could provide moral education, specifically in such virtues (reinterpreted from a Christian perspective) as Aristotle had described in the Nichomachean Ethics. The Aristotelian Renaissance thus facilitated the revival of one of the chief articles in the original humanistic constitution: the belief in the poet's role as renewer of culture.

NORTHERN HUMANISM

Though humanism in northern Europe and England sprang largely from Italian sources, it did not emerge exclusively as an outgrowth of later Italian humanism. Non-Italian scholars and poets found inspiration in the full sweep of the Italian tradition, choosing their sources from Petrarch to Castiglione and beyond.

Desiderius Erasmus, Erasmus (c. 1466-1536) was the only other humanist whose international fame in his own time compared with Petrarch's. While lacking Petrarch's polemical zeal and spirit of self-inquiry, he shared the Italian's intense love of language, his dislike for the complexities and pretenses of medieval institutions both secular and religious, and his commanding personal presence. More specifically, however, his ideas and overall direction betray the influence of Lorenzo Valla, whose works he treasured. Like Valla, who had attacked biblical textual criticism with a vengeance and proved the so-called Donation of Constantine to be a forgery, Erasmus contributed importantly to Christian philology. Also like Valla, he philosophically espoused a kind of Christian hedonism, justifying earthly pleasure from a religious perspective. But he was most like Valla (and indeed the entire rhetorical "arm" of Italian humanism) in giving philology prominence over philosophy. He described himself as a poet and orator rather than an inquirer after truth. His one major philosophical effort, a Christian defense of free will, was thunderously answered by Luther. Though his writings are a well of good sense, they are seldom profound and are predominantly derivative. In Latin eloquence, on the other hand, he was preeminent, both as stylist and theorist. His graceful and abundant Ciceronian prose (whose principles he set down in De copia verborum et rerum) helped shape the character of European style. Perhaps his most original work is Moriae encomium (The Praise of

The Book of the Courtier

Machia-

writings

velli's

The Praise of Folly

Folly), an elegant combination of satire and poetic insight whose influence was soon apparent in the work of More (to whom it was dedicated) and Rabelais.

The French humanists. Erasmus' associates in France included the influential humanists Robert Gaguin (1433-1501), Jacques Lefèvre d'Étaples (c. 1455-1536), and Guillaume Budé (Guglielmus Budaeus, 1467-1540). Of these three, Budé was most central to the development of French humanism, not only in his historical and philological studies but also in his use of his national influence to establish the Collège de France and the library at Fontainebleau. The influence of Francis I (1494-1547) and his learned sister Margaret of Angoulême (1492-1549) was important in fostering the new learning. The diversity and energy of French humanism is apparent in the activities of the Estienne family of publishers; the poetry of Pierre de Ronsard (1524-85), Joachim du Bellay (c. 1522-60), and Guillaume du Bartas (1544-90); the political philosophy of Jean Bodin (1530-96); the philosophical methodology of Petrus Ramus (Pierre de la Ramée, 1515-72); and the dynamic relationship between humanistic scholarship and church reform (see below, Humanism and Christianity). Hampered by religious repression and compressed more severely in time, the French movement lacked the intellectual fecundity and the programmatic unity of its Italian counterpart. In François Rabelais and Michel de Montaigne, however, the development of humanistic methods and themes resulted in unique and memorable

François Rabelais (c. 1490-1533). Rabelais ranks with Boccaccio as a founding father of Western realism. As a satirist and stylist (in his hands French prose became a free, poetic form), he influenced writers as important as Jonathan Swift, Laurence Sterne, and James Joyce and may be seen as a major precursor of modernism. His five books concerning the deeds of the giant princes Gargantua and Pantagruel constitute a treasury of social criticism, an articulate statement of humanistic values, and a forceful, if often outrageous, manifesto of human rights. Rabelaisian satire took aim at every social institution and (especially in Book III) every intellectual discipline. Broadly learned and unflaggingly alert to jargon and sham, he repeatedly focused on dogmas that fetter creativity, institutional structures that reward hypocrisy, educational traditions that inspire laziness, and philosophical methodologies that obscure elemental reality. His heroes, Gargantua and his son and heir Pantagruel, are figures whose colossal size and appetites (Rabelais's etymology for Pantagruel is "allthirsty") symbolize the nobility and omnivorous curiosity that typified the humanistic scheme. The multifarious educational program detailed in Gargantua is reminiscent of Vittorino, Alberti, and the Montefeltro court; and the utopian Abbey of Thélème, whose gate bears the motto "Do as you please," is a tribute to enlightened will and pleasure in the manner of Valla, Erasmus, and More, Characteristically overstated and never wholly free of irony, Rabelais's work is a far cry from the earnest moral and educational programs of the early humanists. Rather than rebuild society, he seeks to amuse, edify, and refine it. His qualified endorsement of human dignity is based on the healthy balance of mind and body, the sanctity of all true learning, and the authenticity of direct experience. Michel de Montaigne (1533-92). Montaigne's famous Essays are not only a compendious restatement and reevaluation of humanistic motives but also a milestone in the humanistic project of self-inquiry that had been originally endorsed by Petrarch. Scholar, traveler, soldier, and statesman, Montaigne was, like Machiavelli, alert to both theory and practice; but while Machiavelli saw practice as forming the basis for sound theory, Montaigne perceived in human events a multiplicity so overwhelming as to deny theoretical analysis. Montaigne's use of typical humanistic modalities-interpretation of the classics, appeals to direct experience, exclusive emphasis on the human realm, and universal curiosity-led him, in other words, to the refutation of a typical humanistic premise: that knowledge

of the intellectual arts could teach one a sovereign art

of life. In an effort to make his inquiry more inclusive

and unsparing, Montaigne made himself the subject of his

book, demonstrating through hundreds of personal anecdotes and admissions the ineluctable diversity of a single human spirit. His essays, which seem to move freely from one subject or viewpoint to another, are often in fact carefully organized dialectical structures that draw the reader. through thesis and antithesis, stated subject and relevant association, toward a multidimensional understanding of morality and history. The final essay, grandly titled "Of Experience," counsels a mature acceptance of life in all its contradictions. Human dignity, he implies, is indeed possible, but it lies less in heroic achievement than in painfully won self-knowledge. In this sense Montaigne's attitude toward the humanistic tradition is generally similar to that suggested in the work of Castiglione and Rabelais. While effectively taking issue with a number of the more extreme humanistic contentions, he retained and indeed justified the basic attitudes that gave the movement its form.

The English humanists. English humanism flourished in two stages: the first a basically academic movement that had its roots in the 15th century and culminated in the work of Sir Thomas More, Sir Thomas Elvot, and Roger Ascham, the second a poetic revolution led by Sir Philip

Sidney and William Shakespeare.

Though continental humanists had held court positions since the days of Humphrey of Gloucester, English humanism as a distinct phenomenon did not emerge until late in the 15th century. At Oxford William Grocyn (c. 1446-1519) and his student Thomas Linacre (c. 1460-1524) gave impetus to a tradition of classical studies that would permanently influence English culture, Grocyn and Linacre attended Politian's lectures at the Platonic Academy of Florence. Returning to Oxford, they became central figures in a group that included such younger scholars as John Colet (1466/67-1519) and William Lily (1468?-1522). The humanistic contributions of the Oxford group were philological and institutional rather than philosophical or literary. Grocyn lectured on Greek and theology; Linacre produced several works on Latin grammar and translated Galen into Latin. To Linacre is owed the foundation of the Royal College of Physicians; to Colet, the foundation of St. Paul's School, London. Colet collaborated with Lily (the first headmaster of St. Paul's) and Erasmus in writing the school's constitution, and together the three scholars produced a Latin grammar (known alternately as "Lily's Grammar" and the "Eton Grammar") that would be central to English education for decades to come.

In Sir Thomas More (1478-1535), Sir Thomas Elvot (c. 1490-1546), and Roger Ascham (1515-68), English humanism bore fruit in major literary achievement. Educated at Oxford (where he read Greek with Linacre), More was also influenced by Erasmus, who wrote The Praise of Folly (Latin Moriae encomium) at More's house and named the book punningly after his English friend. More's famous Utopia, a kind of companion piece to The Praise of Folly, is similarly satirical of traditional institutions (Book I) but offers, as an imaginary alternative, a model society based on reason and nature (Book II). Reminiscent of Erasmus and Valla, More's Utopians eschew the rigorous cultivation of virtue and enjoy moderate pleasures. believing that "Nature herself prescribes a life of joy (that is, pleasure)" and seeing no contradiction between earthly enjoyment and religious piety. Significantly indebted both to classical thought and European humanism, the Utopia is also humanistic in its implied thesis that politics begins and ends with humanity: that politics is based exclusively on human nature and aimed exclusively at human happiness. Sir Thomas Elyot chose a narrower subject but developed it in more detail. His great work, The Book Named The Governor, is a lengthy treatise on the virtues to be cultivated by statesmen. Born of the same tradition that produced The Prince and The Courtier, The Governor is typical of English humanism in its emphasis on the accommodation of both classical and Christian virtues within a single moral view. Elyot's other contributions to English humanism include philosophical dialogues, moral essays, translations of ancient and contemporary writers (including Isocrates and Pico), an important Latin-English dictionary, and a highly popular health manual. He served

Experience'

Gargantua

Utopia

his country as ambassador to the court of Charles V. Finally, the humanistic educational program set up at the turn of the century was vigorously supported by Sir John Cheke (1514–57) and codified by his student Roger Ascham. Ascham's famous pedagogical manual, *The School-master*, offers not only a complete program of humanistic education but also an evocation of the ideals toward which that education was directed.

Ascham had been tutor to the young princess Elizabeth, whose personal education was a model of humanistic pedagogy and whose writings and patronage bespoke great love of learning. Elizabeth I's reign (1558–1603) saw the last concerted expression of humanistic ideas. Elizabethan humanism, which added a unique element to the history

of the movement, was the product not of pedagogues and philologists but of poets and playwrights.

Elizabeth I

Sidney and Spenser. Sir Philip Sidney (1554-86) was, like Alberti and Federico da Montefeltro, a living pattern of the humanistic ideal. Splendidly educated in the Latin classics at Shrewsbury and Oxford, Sidney continued his studies under the direction of the prominent French scholar Hubert Languet and was tutored in science by the learned John Dee. His brief career as writer. statesman, and soldier was of such acknowledged brilliance as to make him, after his tragic death in battle, the subject of an Elizabethan heroic cult. Sidney's major works, Astrophel and Stella, the Defence of Poesie, and the two versions of the Arcadia, are medleys of humanistic themes. In the sonnet sequence Astrophel and Stella, he surpassed earlier imitators of Petrarch by emulating not only the Italian humanist's subject and style but also his philosophical bent and habit of self-scrutiny. The Defence of Poesie, composed (like Erasmus' Praise of Folly) in the form of a classical oration, reasserts the theory of poetry as moral doctrine that had been articulated by Petrarch and Boccaccio and revived by the Italian Aristotelians of the 16th century. The later or "new" Arcadia is an epic novel whose theoretical concerns include the dualities of contemplation and action, reason and passion, and theory and practice. In this ambitious and unfinished work, Sidney attempts a characteristically humanistic synthesis of classical philosophy, Christian doctrine, psychological realism, and practical politics. Seen as a whole, moreover, Sidney's life and work form a significant contribution to a debate that had been smoldering since the decline of political liberty in Florence in the 15th century. How, it was asked, could humanism be politically active or "civic" in a Europe that was almost exclusively monarchic in structure? Many humanists had counseled retirement from active life, while Castiglione had seen his learned courtier rather as an advisor than as a leader. Sidney and his friend Edmund Spenser (1552/53-1599) sought to resolve this dilemma by creating a form of chivalric humanism. The image (taken on personally by Sidney and elaborated upon by Spenser in The Faerie Queene) of the hero as questing knight suggests that the humanist, even if not empowered politically, can achieve a valid form of activism by refining, upholding, and representing the values of a just and noble court. Spenser's poetic development of this humanistic program was even more specific than Sidney's. In his famous letter to Raleigh, he asserts that his purpose in The Faerie Queene is "to fashion a gentleman or noble person in virtuous and gentle discipline" and describes a project (never to be completed) of presenting his idea of the Aristotelian virtues in twelve poetic books. As with Sidney, however, this moral didacticism is neither self-righteous nor pedantic. The prescriptive content of The Faerie Queene is qualified by a strong emphasis on moral autonomy and a mature sense of the ambiguity of experience

Chapman, Jonson, and Shakespeare. The poetry and drama of Shakespeare's time were a concourse of themes, ancient and modern, continental and English. Prominent among these motives were the characteristic topics of humanism. George Chapman (15597–1634), the translator of Homer, was a forthright exponent of the theory of poetry as moral wisdom, holding that it surpassed all other in-tellectual pursuits. Ben Jonson (1572–1637) described his own humanistic mission when he wrote that a good poet

was able "to inform young men to all good disciplines, inflame grown men to all great virtues, keep old men in their best and supreme state, or, as they decline to childhood, recover them to their first strength" and that the poet was "the interpreter and arbiter of nature, a teacher of things divine no less than human, a master in manners." Jonson, who sought this moral goal both in his tragedies and in his comedies, paid tribute to the humanistic tradition in Cauline, a tragedy in which Cicero's civic eloquence is portrayed in heroic terms.

Shakespeare

Less overtly humanistic, though in fact more profoundly so, was William Shakespeare (1564-1616). Thoroughly versed (probably at his grammar school) in classical poetic and rhetorical practice, Shakespeare early in his career produced strikingly effective imitations of Ovid and Plautus (Venus and Adonis and The Comedy of Errors, respectively) and drew on Ovid and Livy for his poem The Rape of Lucrece. In Julius Caesar, Antony and Cleopatra. and Coriolanus he developed Plutarchan biography into drama that, though Elizabethan in structure, is sharply classical in tone. Shakespeare clearly did not accept all the precepts of English humanism at face value. He grappled repeatedly with the problem of reconciling Christian doctrine with effective political action, and for a while (e.g., in Henry V) seemed inclined toward the Machiavellian alternative. In Troilus and Cressida, moreover, he broadly satirized Chapman's Homeric revival and, more generally, the humanistic habit of idolizing classical heroism. Finally, he eschewed the moralism, rationalism, and self-conscious erudition of the humanists and was lacking as well in their fraternalism and their theoretical bent. Yet on a deeper level he must be acknowledged the direct and natural heir of Petrarch, Boccaccio, Castiglione, and Montaigne. Like them he delighted more in presenting issues than in espousing systems and held critical awareness, as opposed to doctrinal rectitude, to be the highest possible good. His plays reflect an inquiry into human character entirely in accord with the humanistic emphasis on the dignity of the emotions, and indeed it may be said that his unprecedented use of language as a means of psychological revelation gave striking support to the humanistic contention that language was the heart of culture and the index of the soul. Similarly, Shakespeare's unparalleled realism may be seen as the ultimate embodiment. in poetic terms, of the intense concern for specificitybe it in description, measurement, or imitation-endorsed across the board by humanists from Boccaccio and Salutati on. Shakespearean drama is a treasury of the disputes that frustrated and delighted humanism, including (among many others) action versus contemplation, theory versus practice, res versus verbum, monarchy versus republic, human dignity versus human depravity, and individualism versus communality. In treating of these polarities, he generally proceeds in the manner of Castiglione and Montaigne, presenting structures of balanced contraries rather than syllogistic endorsements of one side or another. In so doing, he achieves a higher realism, transcending the mere imitation of experience and creating, in all its conflict and fertility, a mirror of mind itself. Since the achievement of such psychological and cultural self-awareness was the primary goal of humanistic inquiry, and since humanists agreed that poetry was an uncommonly effective medium for this achievement, Shakespeare must be acknowledged as a preeminent humanist.

One cannot leave Shakespeare and the phenomenon of English humanism without reference to a highly important aspect of his later drama. Throughout his career, Shakespeare had shown a keen interest in the concept of art, not only, as a general idea but also with specific reference to his own identity as dramatist. In two of his final plays, The Winter's Tale and The Tempest, he developed this concept into dramatic and thematic structures that had strongly doctrinal implications. Major characters in both plays practice a moral artistry—a kind of humanitas compounded of awareness, experience, imagination, compassion, and craft—that enables them to begule and dominate other characters and to achieve enduring justice. This special skill, which is cognate with Shakespeare's own dramatic art, suggests a hypothetical solution to many of

Giotto

the dilemmas posed in his earlier work. It implies that problems unavailable to political or religious remedy may he solved by creative innovation and that the art by which things are known and expressed may constitute, in and of itself, a valid field of inquiry and an instrument for cultural renewal. In developing this idea of the sovereignty of art. Shakespeare made the final major contribution to a humanistic tradition that will be discussed in the two sections that follow.

HUMANISM AND THE VISUAL ARTS

Humanistic themes and techniques were woven deeply into the development of Italian Renaissance art; conversely, the general theme of "art" was prominent in humanistic discourse. The mutually enriching character of the two disciplines is evident in a variety of areas.

Realism. Humanists paid conscious tribute to realistic techniques in art that had developed independently of humanism. Giotto di Bondone (c. 1266-1337), the Florentine painter responsible for the movement away from the Byzantine style and toward ancient Roman technique, was praised by Vasari as "the pupil of Nature." Giotto's own contemporary Boccaccio said of him in the Decameron that

there was nothing in Nature-the mother and ruling force of all created things with her constant revolution of the heavens-that he could not paint with his stylus, pen, or brush or make so similar to its original in Nature that it did not appear to be the original rather than a reproduction. Many times, in fact, in observing things painted by this man, the visual sense of men would err, taking what was painted to be the very thing itself.

Boccaccio, himself a naturalist and a realist, here subtly adopts the painter's achievement as a justification for his own literary style. So Shakespeare, at the end of the Renaissance, praises Giulio Romano (and himself), "who, had he himself eternity and could put breath into his work, would beguile Nature of her custom, so perfectly he is her ape" (The Winter's Tale). It should be noted that neither Vasari, Boccaccio, nor Shakespeare endorses realistic style as a summum bonum: realism is rather the means for regaining touch with the sovereign creative principle of Nature.

Classicism. Like the humanists, Italian artists of the 15th century saw a profound correlation between classical forms and realistic technique. Classical sculpture and Roman painting were emulated because of their ability to simulate perceived phenomena, while, more abstractly, classical myth offered a unique model for the artistic idealization of human beauty. Alberti, himself a close friend of Donatello and Brunelleschi, codified this humanistic theory of art, using the fundamental principle of mathematics as a link between perceived reality and the ideal. He developed a classically based theory of proportionality between architectural and human form, believing that the ancients sought "to discover the laws by which Nature produced her works so as to transfer them to the works of architecture."

Anthropocentricity and individualism. Humanism and Italian art were similar in giving paramount attention to human experience, both in its everyday immediacy and in its positive or negative extremes. The religious themes that dominated Renaissance art (partly because of generous church patronage) were frequently developed into images of such human richness that, as one contemporary observer noted, the Christian message was submerged. The human-centredness of Renaissance art, moreover, was not just a generalized endorsement of earthly experience. Like the humanists, Italian artists stressed the autonomy and dignity of the individual. High Renaissance art boasted a style of portraiture that was at once humanely appreciative and unsparing of detail. Heroes of culture such as Federico da Montefeltro and Lorenzo de' Medici, neither of whom was a conventionally handsome man, were portrayed realistically, as though a compromise with strict imitation would be an affront to their dignity as individuals. Similarly, artists of the Italian Renaissance were, characteristically, unabashed individualists. The biographies of Giotto, Brunelleschi, Leonardo, and Michelangelo by Giorgio

Vasari (1511-74) not only describe artists who were well aware of their unique positions in society and history but also attest to a cultural climate in which, for the first time, the role of art achieved heroic stature. The autobiographical writings of the humanist Alberti, the scientist Gerolamo Cardano (1501-76), and the artist Benvenuto Cellini (1500-71) further attest to the individualism developing both in letters and in the arts: and Montaigne dramatized the analogy between visual mimesis and autobiographical realism when he said, in the preface to his Essays, that given the freedom he would have painted himself "tout entier, et tout nu" ("totally complete, and totally nude").

Art as philosophy. Italian Renaissance painting, especially in its secular forms, is alive with visually coded expressions of humanistic philosophy. Symbol, structure. posture, and even colour were used to convey silent messages about humanity and nature. Renaissance style was so articulate, and the Renaissance sense of the unity of experience so deeply ingrained, that even architectural structures could be eloquently philosophical. Two features of Federico's palace at Urbino exemplify the profound interrelationship between humanistic principle and Renaissance art. The first feature is architectural. On the ground floor of the palace two private chapels, of roughly the same dimensions, stand side by side. The chapel at the left is a place of Christian worship, while that at the right is dedicated to the pagan Muses. Directly above these chapels is a study, the walls of which are covered with representations (in intarsia) of assorted humanistic heroes: Homer, Plato, Aristotle, Cicero, Virgil, Seneca, Boethius, St. Augustine, Dante, Petrarch, Bessarion, and Federico's revered teacher Vittorino, among others. The message conveyed by the positioning of the three rooms is hard to ignore. Devotion to the opposed principles of Christianity

Federico da Montefeltro, duke of Urbino, with his son Guidobaldo, portrait probably by Pedro Berruguete, 15th century. In the National Gallery of the Marches, Urbino, Italy.

Biography and autobiography

and earthly (pagan) beauty is rendered possible by a humanistic learning (represented by the study) so generous and appreciative as to comprehend both extremes

The second feature is iconographic—a portrait of Federico and his son Guidobaldo (probably by Pedro Berruguete) that occupies a central position on the wall of the study. It depicts the Duke, his full coat of armour partly covered by a courtly robe, sitting and reading. The son stands beside his father's chair, gazing out of the picture toward the viewer's left. An abbot's mitre rests on a shelf in the upper left, while the Duke's helmet sits on the floor in the lower right. Here also a typically humanistic message is evident. The Duke's scholarly attitude and curious attire suggest his triple role as warrior, ruler, and humanist. The two main axes of the picture-the line between mitre and helmet and the line between father and son-converge at the book, symbolizing the central role of humanistic learning in reconciling the concerns of church and state and in conveying humanistic virtue from generation to generation. The boy's outward gaze implies the characteristic direction of humanistic learning; into the world of action The scope and organic wholeness of Federico's humanistic iconography are so striking as to rival great expressions of religious faith. The private heart of his palace concealed, like a genetic code, the principle that had given shape to the edifice and informed the state.

The

arts

"liberal

HUMANISM, ART, AND SCIENCE It is impossible to speak knowledgeably about Renaissance science without first understanding the Renaissance concept of art. The Latin ars (inflected as artis) was applied indiscriminately to the verbal disciplines, mathematics, music, and science (the "liberal arts"), as well as to painting, sculpture, and architecture: it also could refer to technological expertise, to magic, and to alchemy. Any discipline involving the cultivation of skill and excellence was de facto an art. To the Renaissance, moreover, all arts were "liberal" arts in their capacity to "free" their practitioners to function effectively in specific areas. The art of rhetoric empowered the rhetorician to convince; the art of perspective empowered the painter to create visual illusion; the art of physics empowered the scientist to predict the force and motion of objects, "Art," in effect, was no more or less than articulate power, the technical or intellectual analogy to the political power of the monarch and the divine power of the god. The historical importance of this equation cannot be overestimated. If one concept may be said to have integrated all the varied manifestations of Renaissance culture and given organic unity to the period, it was this definition of art as power. With this definition in mind, one may understand why Renaissance humanists and painters assigned themselves such self-consciously heroic roles: in their artistic ability to delight, to captivate, to convince, they saw themselves as enfranchised directors and remakers of culture. One may also understand why a humanist-artist-scientist like Alberti would have seen no real distinction between the various disciplines he practiced. As profoundly interconnected means of understanding nature and humanity, and as media for effective reform and renewal, these disciplines were all components of an encompassing art. A similar point may be made about Machiavelli, who wrote a book about the "art" of warfare and who used history and logic to develop an art of government, or about the brilliant polymath Paracelsus, who spent his whole career perfecting an art that would comprehend all matter and all spirit. With the equation of art and power in mind, finally, one may understand why a revolutionary scientist like Galileo (1564-1642) put classical and medieval science through a winnowing fan, keeping only such components as allowed for physically *reproducible results. Since every Renaissance art aimed for a dominion or conquest, it was completely appropriate that science should leave its previously contemplative role and focus upon the conquest of nature.

Humanism benefited the development of science in a number of more specific ways. Alberti's technological applications of mathematics, and his influential statement that mathematics was the key to all sciences, grew out of his humanistic education at Padua. Vittorino, another

student at Padua, went on to make mathematics a central feature of his educational program. Gerolamo Cardano, a scholar of renowned humanistic skills, made major contributions to the development of algebra. In short, the importance of mathematics in humanistic pedagogy and the fact that major humanists like Vittorino and Alberti were also mathematicians may be seen as contributing to the critical role mathematics would play in the rise of modern science. Humanistic philology, moreover, supplied scientists with clean texts and clear Latin translations of the classical works-Plato, Aristotle, Euclid, Archimedes, and even Ptolemy-that furthered their studies. The richness of the classical heritage in science is often underestimated. Galileo, who considered Archimedes his mentor, also prized the dialogues of Plato, in particular the Meno. The German philosopher Ernst Cassirer has demonstrated the likelihood that Galileo was fond of the Meno because it contained the first statement of the "hypothetical" method, a modus operandi that characterized Galileo's own scientific practice and that would come to be known as one of the chief principles of the New Science. Humanism may also be seen as offering, of itself, methods and attitudes suitable for application in nonhumanistic fields. It might be argued, for example, that the revolutionary social science of Machiavelli and Juan Luis Vives (1492-1540) was due in large measure to their application of humanistic techniques to fields that lay outside the normal purview of humanism. But most of all it was the general spirit of humanism-critical, questing, ebullient, precise, focused on the physical world, and passionate in its quest for results-that fostered the development of the scientific spirit in social studies and natural philosophy.

HUMANISM AND CHRISTIANITY

Though much humanistic activity was specifically Christian in intention, and though the majority of humanists made firm avowals of faith, the relationship between Christianity and humanism is complex and not wholly untroubled. First, humanists from Petrarch onward recognized that the classical (pagan) direction of humanism necessarily constituted, if not a challenge to Christianity. at least a breach in the previous totality of Christian devotion. The Christian truth that had been acknowledged as comprehending all phenomena, earthly or heavenly, now had to coexist with a classical attitude that was overwhelmingly directed toward earthly life. Humanistic efforts to resolve the contradictions implied by these two attitudes were, if one may judge by their variety, never wholly successful. In particular, the extent to which humanistic inquiry led scholars toward the secular realm, and the extent to which humanistic pedagogy concentrated on secular subjects, suggest erosions of the domain of faith. Coluccio Salutati, who urged the young Poggio not to let humanistic enthusiasm take precedence over Christian piety, thereby acknowledged a dualism implicit in the humanistic program and never wholly absent from its historical development.

Second, the humanistic philology that meticulously compared ancient sources and "cleaned up" the texts of important Christian writings was a serious challenge to the authority of the church. With new authorities or refined texts in hand, humanists found fault with established commentaries and questioned traditional interpretations. Valla's arraignment of the Donation of Constantine and Bessarion's discovery that the supposed Dionysius the Areopagite (later called Pseudo-Dionysius) had borrowed some of his material from Plato exemplify the uneasy relationship between humanism and Catholic dogma. Third, the independent and broadly critical attitude innate to humanism could not but threaten the unanimity of Christian belief. Intellectual individualism, which has never been popular in any church, put particular stress on a religion that encouraged simple faith and alleged universal authority. Finally, humanism repeatedly fostered the impulse of religious reform. The humanistic emphasis on total authenticity and direct contact with sources had, as its religious correlative, a desire to obliterate the medieval accretions and procedural complexities that stood between the worshiper and his god. The reform-mindedness of

classical heritage in science

Implicit

impulse of reform

such humanists as Petrarch, Boccaccio, Erasmus, and Rabelais was balanced on the religious side by reformers such as Calvin and Melanchthon, who employed humanistic techniques in their own cause. And the reform movement, while it may have modernized and thus preserved Christianity, rang the death knell for a medieval culture whose essential characteristic had been participation in a universal church.

LATER FORTUNES OF HUMANISM

Shakespeare may be seen as the last major interpreter of the humanistic program. Sir Francis Bacon and John Milton, though formidably adept at humanistic techniques, diverged in their major work from the central current of humanism, Bacon toward natural science, Milton toward theology. If Bacon's rationalism may be seen as a link between humanism and the Enlightenment, his strong emphasis on nature (rather than humanity) as subject matter presaged the permanent separation of the sciences from the humanities. In Milton's theocentricity, on the other hand, lay the Christian distrust (going back, perhaps, to Luther) of humanistic secularism. These epochal divergences, moreover, were complemented by a series of rifts and ramifications within the humanistic movement. The split between philosophy and letters was, over future generations, to be compounded by the development of countless discrete specialties within both fields. Philosophers came more and more to define themselves within narrow boundaries. Creative writers and "critics" took up distinct positions and assumed adversarial relationships. The profound loss of coherence in humane letters was furthered by the gradual decline of Latin as the lingua franca of European intellectuals and the consequent separation of national traditions.

By the 19th century, humanism was such a lost art as to have to be reassembled, like a disjointed fossil, by careful historians. Of course there were exceptions. Jonathan Swift (1667-1745) reasserted humanistic values in a broad-based attack on contemporary institutions, and in Gottfried Wilhelm Leibniz (1646-1716) can be found the serious intention and multifarious curiosity that characterized humanism at its best. Strong humanistic motives may be found in Germany at the turn of the 19th century, particularly in the work of Gotthold Ephraim Lessing (1729-81), Friedrich von Schiller (1759-1805), and Georg Wilhelm Friedrich Hegel (1770-1831); while Johann Wolfgang von Goethe (1749-1832) was perhaps the last individual whose breadth of achievement and sense of the unity of experience lived up to the ideal established by Alberti.

More recently, the mode of inquiry and interpretation developed by the political philosopher Leo Strauss (1899-1973) showed strong signs of the humanistic spirit. But in general the traces of the original program have been scattered. To the modern mind, a "humanist" is a university scholar, walled off from the interdisciplinary scope of the original humanistic program and immune to the active experience that was its basis and its goal. This decline is easy enough to explain. Had there been nothing else, one external factor would have made the cultivation of humanitas, as originally practiced, more and more difficult from the beginning of the 16th century on. The proliferation of published work in all fields, and the creation of many new fields, made increasingly impracticable the development of the comprehensive learning and awareness that were central to the original program. In 1500 the major texts constituting a humanistic education, though numerous, could still be counted; by 1900 they were legion. and people had long ceased agreeing about exactly which ones they were. But problems implicit in the movement were equally responsible for its demise. The characteristic emphases on rhetoric and philology, which gave the The lack of humanistic movement vitality and made it available to countless students of moderate gifts, also betokened its impermanence. Weak in dialectic or any other comprehensively analytic method, the movement had no instrument for self-examination, no medium for self-renewal. By the same token, neither had humanism any valid means of defense against the attackers-scientists, fundamentalists, materialists, and others-who camped in ever larger numbers on its borders. Lacking an integral method, finally, humanism in effect lacked a centre and became prev to an endless series of ramifications. While eloquent humanists rambled through Europe and spread the word about the classics, the method that might have unified their efforts lay, available but unheeded, in texts of Plato and Aristotle. Given this core of rigorous analysis, humanism might (all other challenges notwithstanding) have retained its basic character for centuries. But ironically it might also have failed to attract followers.

Though lacking permanence itself, humanism in large measure established the climate and provided the medium for the rise of modern thought. An impressive variety of major developments in literature, philosophy, art, religion. social science, and even natural science had their basis in humanism or were significantly nourished by it. Important spokesmen in all fields regularly made use of humanistic eloquence to further their causes. More generally, the so-called modern awareness-that sense of alienation and freedom applied both to the individual and to the racederives ultimately, for better or worse, from humanistic sources. But with humanism, as with every other historical subject, one should beware lest valid concern about changes, crises, sources, and influences obscure the even more important issues of human continuity and human value. Whatever its weaknesses and inner conflicts, the humanistic movement was heroic in its breadth and energy, remarkable in its aspirations. For human development in all fields, it created a context of seldom-equaled fertility. Its characteristic modalities of thought, speech, and image lent themselves to the promptings of genius and became the media for enduring achievement. Its moral program formed the basis for lives that are remembered with admiration

BIBLIOGRAPHY

General treatments: The three general studies most helpful in approaching the phenomenon of humanism are EUGENIO GARIN, Italian Humanism: Philosophy and Civic Life in the Renaissance, trans. from the Italian (1965, reprinted 1975); PAUL OSKAR KRISTELLER, Renaissance Thought and Its Sources (1979); and CHARLES TRINKAUS, The Scope of Renaissance Humanism (1983). Garin's book is probably the most unified and incisive treatment of Italian humanism yet produced, while Kristeller and Trinkaus offer extremely well-documented analyses of major issues in the history and historiography of humanism. Other valuable readings include HANS BARON. The Crisis of the Early Italian Renaissance: Civic Humanism and Republican Liberty in an Age of Classicism and Tyranny, rev. ed. (1966); QUIRINUS BREEN, Christianity and Humanism: Studies in the History of Ideas (1968); JACOB BURCKHARDT, The Civilization of the Period of the Renaissance in Italy: An Essay (1878; originally published in German, 1860), available in later English-language editions; DOUGLAS BUSH, The Renaissance and English Humanism (1939, reprinted 1972); ERNST CASSIRER, The Individual and the Cosmos in Renaissance Philosophy (1964, reprinted 1972; originally published in German with appendices, 1927); JACK D'AMICO, Knowledge and Power in the Renaissance (1977); MYRON P. GILMORE. The World of Humanism, 1453-1517 (1952; reprinted 1983); DENYS HAY. The Italian Renaissance in Its Historical Background, 2nd ed. (1977); PAUL OSKAR KRISTELLER, Renaissance Concepts of Man, and Other Essays (1972); EDWARD P. YOUNG, The Medici, 2 vol. (1909, reissued in 1 vol., 1933).

Works of the humanists: Works by the later humanists (c. 1500 and after) and the English poet-humanists mentioned in the article, including Castiglione, Cellini, Elyot, Erasmus, Jonson, Machiavelli, Montaigne, More, Pico della Mirandola,

Rabelais, Shakespeare, Sidney, Spenser, Tasso, and Vasari, are readily available in many modern English editions. For the writings of the earlier humanists, see LEON BATTISTA ALBERTI. The Family in Renaissance Florence, trans, by RENÉE NEU WATKINS (1969); GIOVANNI BOCCACCIO, The Decameron, trans. by MARK MUSA and PETER BONDANELLA (1982), and Boccaccio on Poetry, 2nd ed., ed. and trans. by CHARLES G. OSCOOD (1956, reprinted 1978), a translation of the preface and books 14 and 15 of his De genealogia deorum gentilium; biographies of Dante by Boccaccio and Leonardo Bruni in The Earliest Lives of Dante, trans, by JAMES ROBINSON SMITH (1901, reprinted 1976); letters by Poggio Bracciolini in Two Rengissance Book 1976); tetters by roggio biactonin in 1 wo remassance 1976; Hunters, trans. by PHYLLIS WALTER GOODHART GORDAN (1974); and works by Petrarch, including The Life of Solitude, trans. by JACOB ZEITLIN (1924, reprinted 1978); "On His Own Ignorance and That of Many Others," trans. by HANS NACHOD IN ERNST CASSIRER, PAUL OSKAR KRISTELLER, and JOHN HERMAN RAN-DALL, JR. (eds.), The Renaissance Philosophy of Man (1948. reprinted 1971); and Petrarch's Secret; or, The Soul's Conflict with Passion, trans. by WILLIAM H. DRAPER (1911, reprinted 1978). WILLIAM HARRISON WOODWARD, op. cit., contains valuable translations of works by Vergerio, Bruni, Aeneas Sylvius Piccolomini (Pius II), and Battista Guarino. Sixteenth-century writings that reflect the breadth and vitality of humanistic attitudes are JUAN LUIS VIVES, On Education, wans, by Fos-TER WATSON (1913, reprinted 1971); GIROLAMO CARDANO, The Book of My Life, trans. by JEAN STONER (1930, reprinted 1962); TORQUATO TASSO, Tasso's Dialogues, trans. by CARNES LORD and DAIN A. TRAFTON (1982); and PARACELSUS, Selected Writings, trans. by NORBERT GUTERMAN, 2nd rev. ed. (1958; reissued with a new bibliography, 1969; originally published in German, 1942, ed. by JOLANDE JACOBI).

(RoG)

Hume

avid Hume was an 18th-century Scottish empiricist philosopher, historian, economist, and essayist, who conceived of philosophy as the inductive, experimental science of human nature. Taking the scientific method of the English physicist Sir Isaac Newton as his model and building on the epistemology of the English philosopher John Locke, Hume tried to describe how the mind works in acquiring what is called knowledge. He concluded that no theory of reality is possible; there can be no knowledge of anything beyond experience. Despite the enduring impact of his theory of knowledge, Hume seems to have considered himself chiefly as a moralist.

Hume, oil painting by Allan Ramsay, 1766. In the Scottish National Portrait Gallery, Edinburgh.

For coverage of related topics in the Macropædia and Micropædia, see the Propædia, Part Ten, Division V, especially Section 51.

Early life and works. Hume was the younger son of Joseph Hume, the modestly circumstanced laird, or lord, of Ninewells, a small estate adjoining the village of Chirnside, about nine miles distant from Berwick-upon-Tweed on the Scottish side of the border. David's mother, Catherine, a daughter of Sir David Falconer, president of the Scottish court of session, was in Edinburgh when he was born, on May 7 (April 26, old style), 1711. In his third year his father died. He entered Edinburgh University when he was about 12 years old and left it at 14 or 15, as was then usual. Pressed a little later to study law (in the family tradition on both sides), he found it distasteful and instead read voraciously in the wider sphere of letters. Because of the intensity and excitement of his intellectual discovery, he had a nervous breakdown in 1729, from which it took him a few years to recover

In 1734, after trying his hand in a merchant's office in Bristol, he came to the turning point of his life and retired to France for three years. Most of this time he spent at La Flèche on the Loire, in the old Anjou, studying and writing A Treatise of Human Nature. The Treatise was Hume's attempt to formulate a full-fledged philosophical system. It is divided into three books: book I, on understanding, aims at explaining man's process of knowing, describing in order the origin of ideas, the ideas of space and time, causality, and the testimony of the senses; book II, on the "passions" of man, gives an elaborate psychological machinery to explain the affective, or emotional, order in man and assigns a subordinate role to reason in this mechanism; book III, on morals, describes moral good-

ness in terms of "feelings" of approval or disapproval that a person has when he considers human behaviour in the light of the agreeable or disagreeable consequences either to himself or to others. Although the Treatise is Hume's most thorough exposition of his thought, at the end of his life he vehemently repudiated it as juvenile, avowing that only his later writings presented his considered views. The Treatise is not well constructed, in parts oversubtle, confusing because of ambiguity in important terms (especially "reason"), and marred by willful extravagance of statement and rather theatrical personal avowals. For these reasons his mature condemnation of it was perhaps not entirely misplaced. Book I, nevertheless, has been more read in academic circles than any other of his writings,

Returning to England in 1737, he set about publishing the Treatise. Books I and II were published in two volumes in 1739; book III appeared the following year. The poor reception of this, his first and very ambitious work, depressed him; but his next venture, Essays, Moral and Political (1741-42), won some success. Perhaps encouraged by this, he became a candidate for the chair of moral philosophy at Edinburgh in 1744. Objectors alleged heresy and even atheism, pointing to the Treatise as evidence. Unsuccessful, Hume left the city, where he had been living since 1740, and began a period of wandering: a sorry year near St. Albans as tutor to the mad marquess of Annandale (1745-46); a few months as secretary to Gen. James St. Clair (a member of a prominent Scottish family), with whom he saw military action during an abortive expedition to Brittany (1746); a little tarrying in London and at Ninewells; and then some further months with General St. Clair on an embassy to the courts of Vienna and Turin (1748-49).

Mature works. During his years of wandering Hume was earning the money that he needed to gain leisure for his studies. Some fruits of these studies had already appeared before the end of his travels, viz., a further Three Essays, Moral and Political (1748) and Philosophical Essays Concerning Human Understanding (1748). The latter is a rewriting of book I of the Treatise (with the addition of his essay "On Miracles," which became notorious for its denial that a miracle can be proved by any amount or kind of evidence); it is better known as An Enquiry Concerning Human Understanding, the title Hume gave to it in a revision of 1758. The Enquiry Concerning the Principles of Morals (1751) was a rewriting of book III of the Treatise. It was in these works that Hume expressed his mature thought.

An Enquiry Concerning Human Understanding is an attempt to define the principles of human knowledge. It poses in logical form significant questions about the nature of reasoning in regard to matters of fact and experience, and it answers them by recourse to the principle of association. The basis of his exposition is a twofold classification of objects of awareness. In the first place, all such objects are either "impressions," data of sensation or of internal consciousness, or "ideas," derived from such data by compounding, transposing, augmenting, or diminishing. That is to say, the mind does not create any ideas but derives them from impressions. From this Hume develops a theory of meaning. A word that does not stand directly for an impression has meaning only if it brings before the mind an object that can be gathered from an impression by one of the mental processes mentioned. In the second place, there are two approaches to construing meaning, an analytical one, which concentrates on the "relations of ideas," and an empirical one, which focuses on "matters of fact." Ideas can be held before the mind simply as meanings, and their logical relations to one another can then be detected by rational inspection. The idea of a plane triangle, for example, entails the equality of its internal

Theory of knowledge

Writing the Treatise

angles to two right angles, and the idea of motion entails the ideas of space and time, irrespective of whether there really are such things as triangles and motion. Only on this level of mere meanings, Hume asserts, is there room for demonstrative knowledge. Matters of fact, on the other hand, come before the mind merely as they are, revealing no logical relations; their properties and connections must be accepted as they are given. That primroses are yellow, that lead is heavy, and that fire burns things are facts, each shut up in itself, logically barren. Each, so far as reason is concerned, could be different; the contradictory of every matter of fact is conceivable. Therefore, any demonstrative science of fact is impossible.

Hume's doctrine of causality and belief

Theory of

historical

writing

From this basis Hume develops his doctrine about causality. The idea of causality is alleged to assert a necessary connection among matters of fact. From what impression then, is it derived? Hume states that no causal relation among the data of the senses can be observed, for, when a person regards any events as causally connected, all that he does and can observe is that they frequently and uniformly go together. In this sort of togetherness it is a fact that the impression or idea of the one event brings with it the idea of the other. A habitual association is set up in the mind; and, as in other forms of habit, so in this one, the working of the association is felt as compulsion. This feeling, Hume concludes, is the only discoverable impressional source of the idea of causality.

Hume then considers the process of causal inference, and in so doing he introduces the concept of belief. When a person sees a glass fall, he not only thinks of its breaking but expects and believes that it will break; or, starting from an effect, when he sees the ground to be generally wet, he not only thinks of rain but believes that there has been rain. Thus belief is a significant component in the process of causal inference. Hume then proceeds to investigate the nature of belief, claiming that he was the first to do so. He uses this term in the narrow sense of belief regarding matters of fact. He defines belief as a sort of liveliness or vividness that accompanies the perception of an idea. A belief is more than an idea; it is a vivid or lively idea. This vividness is originally possessed by some of the objects of awareness, by impressions and the simple memory images of them. By association it comes to belong to certain ideas as well. In the process of causal inference, then, an observer passes from an impression to an idea regularly associated with it. In the process the aspect of liveliness proper to the impression infects the idea, Hume asserts. And it is this aspect of liveliness that Hume defines as the essence of belief.

Hume does not claim to prove that the propositions, (1) that events themselves are causally related and (2) that they will be related in the future in the same ways as they were in the past, are false. He firmly believed both of these propositions and insisted that everybody else believed them, will continue to believe them, and must continue to believe them in order to survive. They are natural beliefs, inextinguishable propensities of human nature, madness apart. What Hume claims to prove is that natural beliefs are not obtained and cannot be demonstrated either by empirical observation or by reason, whether intuitive or inferential. Reflection shows that there is no evidence for them and shows also both that we are bound to believe them and that it is sensible or sane to do so. This is Hume's skepticism: it is an affirmation of that tension, a denial not of belief but of certainty.

The Enquiry Concerning the Principles of Morals is a refinement of Hume's thinking on morality, in which he views sympathy as the fact of human nature lying at the basis of all social life and personal happiness. Defining morals and morality as those qualities that are approved (1) in whomsoever they happen to be and (2) by virtually everybody, he sets himself to discover the broadest grounds of the approvals. He finds them, as he found the grounds of belief, in "feelings," not in "knowings." Moral decisions are grounded in moral sentiment. Qualities are valued either for their utility or for their agreeableness, in each case either to their owners or to others. Hume's moral system aims at the happiness of others (without any such formula as "the greatest happiness of the greatest number") and at the happiness of self. But regard for others accounts for the greater part of morality. His emphasis is on altruism: the moral sentiments that he claims to find in human beings, he traces, for the most part, to a sentiment for and a sympathy with one's fellows. It is human nature, he holds, to laugh with the laughing and to grieve with the grieved and to seek the good of others as well as one's own. Two vears after the Enquiry was published, Hume confessed, "I have a partiality for that work"; and at the end of his life he judged it "of all my writings incomparably the best." Such statements, along with other indications in his later writings, make it possible to suspect that he regarded his moral doctrine as his major work. He here writes as a man having the same commitment to duty as his fellows. The traditional view that he was a detached scoffer is deeply wrong: he was skeptical not of morality but of much theorizing about it.

Following the publication of these works, Hume spent several years (1751-63) in Edinburgh, with two breaks in London. An attempt was made to get him appointed as successor to Adam Smith, the Scottish economist (later to be his close friend), in the chair of logic at Glasgow, but the rumour of atheism prevailed again. In 1752, however, Hume was made keeper of the Advocates' Library at Edinburgh. There, "master of 30,000 volumes," he could indulge a desire of some years to turn to historical writing. His History of England, extending from Caesar's invasion to 1688, came out in six quarto volumes between 1754 and 1762, preceded by Political Discourses (1752). His recent writings had begun to make him known, but these two brought him fame, abroad as well as at home. He also wrote Four Dissertations (1757), which he regarded as a trifle, although it included a rewriting of book II of the Treatise (completing his purged restatement of this work) and a brilliant study of "the natural history of religion." In 1762 James Boswell, the biographer of Samuel Johnson, called Hume "the greatest writer in Britain," and the Roman Catholic Church, in 1761, paid him the attention of putting all his writings on the Index, its list of forbidden books.

The most colourful episode of his life ensued; in 1763 he Hume's left England to become secretary to the British embassy in Paris under the Earl of Hertford. The society of Paris accepted him, despite his ungainly figure and gauche manner. He was honoured as eminent in breadth of learning, in acuteness of thought, and in elegance of pen and was taken to heart for his simple goodness and cheerfulness. The salons threw open their doors to him, and he was warmly welcomed by all. For four months in 1765 he acted as chargé d'affaires at the embassy. When he returned to London at the beginning of 1766 (to become, a year later, undersecretary of state), he brought Jean-Jacques Rousseau, the Swiss philosopher connected with the Encyclopédie of Diderot and d'Alembert, with him and found him a refuge from persecution in a country house at Wootton in Staffordshire. This tormented genius suspected a plot, took secret flight back to France, and spread a report of Hume's bad faith. Hume was partly stung and partly persuaded into publishing the relevant correspondence between them with a connecting narrative (A Concise and Genuine Account of the Dispute Between Mr. Hume and Mr. Rousseau, 1766).

In 1769, somewhat tired of public life and of England too, he again established a residence in his beloved Edinburgh, deeply enjoying the company-at once intellectual and convivial-of friends old and new (he never married), as well as revising the text of his writings. He issued five further editions of his History between 1762 and 1773 as well as eight editions of his collected writings (omitting the Treatise, History, and ephemera) under the title Essays and Treatises between 1753 and 1772, besides preparing the final edition of this collection, which appeared posthumously (1777), and Dialogues Concerning Natural Religion, held back under pressure from friends and not published until 1779. His curiously detached autobiography, The Life of David Hume, Esquire, Written by Himself (1777; the title is his own), is dated April 18, 1776. After a long illness he died in his Edinburgh house on Aug. 25, 1776, and was buried on Calton Hill.

reception in Paris

Adam Smith, his literary executor, added to the Life a letter that concludes with his judgment on his friend as "approaching as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit." His distinguished friends, with ministers of religion among them, certainly admired and loved him, and there were younger men indebted either to his influence or to his pocket. The mob had heard only that he was an atheist and simply wondered how such an ogre would manage his dving. Yet Boswell has recounted, in a passage in his Private Papers, that, when he visited Hume in his last illness, the philosopher put up a lively, cheerful defense of his disbelief in immortality.

Significance and influence. That Hume was one of the major figures of his century can hardly be doubted. So his contemporaries thought, and his achievement, as seen in historical perspective, confirms that judgment, though with a shift of emphasis. Some of the reasons for the assessment may be given under four heads:

As a writer. Hume's style was praised in his lifetime and has often been praised since. It exemplifies the classical standards of his day. It lacks individuality and colour, for he was always proudly on guard against his emotions. The touch is light, except on slight subjects, where it is rather heavy. Yet in his philosophical works he gives an unsought pleasure. Here his detachment, levelness (all on one plane), smoothness, and daylight clearness are proper merits. It is as one of the best writers of scientific prose in English that he stands in the history of style.

As a historian. Library catalogs still list Hume as "Hume, David, the Historian." Between his death and 1894, there were at least 50 editions of his History; and an abridgment, The Student's Hume (1859; often reprinted), remained in common use for 50 years. Though now outdated. Hume's History must be regarded as an event of cultural importance. In its own day, moreover, it was an innovation, soaring high above its very few predecessors. It was fuller and set a higher standard of impartiality. His History of England not only traced the deeds of kings and statesmen but also displayed the intellectual interests of the educated citizens, as may be seen, for instance, in the pages on literature and science under the Commonwealth at the end of chapter 3 and under James II at the end of chapter 2. It was unprecedentedly readable, in structure as well as in phrasing. Persons and events were woven into causal patterns that furnished a narrative with the goals and resting points of recurrent climaxes. That was to be the plan of future history books for the general reader.

As an economist. Hume steps forward as an economist in the Political Discourses incorporated in Essays and Treatises as part 2 of Essays Moral and Political. How far he influenced his friend Adam Smith, 12 years his junior, remains uncertain: they had broadly similar principles, and both had the excellent habit of illustrating and supporting these from history. He did not formulate a complete system of economic theory, as did Adam Smith in his Wealth of Nations, but Hume introduced several of the new ideas around which the "classical economics" of the 18th century was built. His level of insight can be gathered from his main contentions; that wealth consists not contentions of money but of commodities; that the amount of money in circulation should be kept related to the amount of goods in the market (two points made by Berkeley); that a low rate of interest is a symptom not of superabundance of money but of booming trade; that no nation can go on exporting only for bullion; that each nation has special advantages of raw materials, climate, and skill, so that a free interchange of products (with some exceptions) is mutually beneficial; and that poor nations impoverish the rest just because they do not produce enough to be able to take much part in that exchange. He welcomed advance beyond an agricultural to an industrial economy as a precondition of any but the barer forms of civilization.

As a philosopher. Hume conceived of philosophy as the inductive science of human nature, and he concluded that man is more a creature of sensitive and practical sentiment than of reason. On the Continent he is seen as one of the few British classical philosophers. For some Germans his importance lies in the fact that Immanuel

Kant conceived his critical philosophy in direct reaction to Hume. Hume was one of the influences that led Auguste Comte, the 19th-century French mathematician and sociologist, to positivism. In Britain his positive influence is seen in Jeremy Bentham, the early 19th-century jurist and philosopher, who was moved to utilitarianism (the moral theory that right conduct should be determined by the usefulness of its consequences) by book III of the Treatise, and more extensively in John Stuart Mill, the philosopher and economist who lived later in the 19th century.

In throwing doubt on the assumption of a necessary link between cause and effect, Hume was the first philosopher of the postmedieval world to reformulate the skepticism of the ancients. His reformulation, moreover, was carried out in a new and compelling way. Although Hume admired Newton, Hume's subtle undermining of causality called in question the philosophical basis of Newton's science as a way of looking at the world, inasmuch as this rested on the identification of a few fundamental causal laws that govern the universe. As a result the positivists of the 19th century were obliged to wrestle with Hume's questioning of causality if they were to succeed in their aim of making science the central framework of human thought. In the 20th century it was Hume's naturalism rather than his skepticism that attracted attention, chiefly among analytic philosophers. Hume's naturalism lies in his belief that philosophical justification could only be rooted in regularities of the natural world. The attraction of this for analytic philosophers was that it seemed to provide a solution to the problems arising from the skeptical tradition that Hume himself, in his other philosophical role, had done so much to reinvigorate.

MAJOR WORKS

PHILOSOPHY AND RELIGION: A Treatise of Human Nature: Being an Attempt to Introduce the Experimental Method of Reasoning into Moral Subjects (1739-40); An Abstract of a Book Lately Published: Entitled, A Treatise of Human Nature, etc., Wherein the Chief Argument of That Book Is Farther Illustrated and Explained (1740); Philosophical Essays Concerning Human Understanding (1748; many later editions entitled An Enquiry Concerning Human Understanding); Four Dissertations (1757); Dialogues Concerning Natural Religion (1779); A Letter from a Gentleman to His Friend Containing Some Observations on Religion and Morality (1745).

POLITICS AND MORALS: Essays, Moral and Political (1741-42); An Enquiry Concerning the Principles of Morals (1751);

Political Discourses (1752). HISTORY: The History of Great Britain (1754-57); The History of England Under the House of Tudor (1759); The History of England from the Invasion of Julius Caesar to the Accession of Henry VII (1762).

OTHER WORKS: A Concise and Genuine Account of the Dispute Between Mr. Hume and Mr. Rousseau (1766); The Life of David Hume, Esquire, Written by Himself (1777)

Recommended modern editions of separate works by Hume include: A Treatise of Human Nature, ed. by L.A. Selby-Bigge, 2nd ed. rev. by P.H. Nidditch (1980); Enquiries Concerning Human Understanding and Concerning the Principles of Morals, ed. by L.A. Selby-Bigge, 3rd ed. rev. by P.H. Nidditch (1975); Dialogues Concerning Natural Religion, ed. by Norman Kemp Smith (1935, reissued 1981); The Natural History of Religion, ed. by A. Wayne Colver (1976); and The History of Great Britain: The Reigns of James I and Charles I, ed. by Duncan Forbes (1970). The best collected edition is The Philosophical Works of David Hume, ed. by T.H. Green and T.H. Grose, new ed., 4 vol. (1882-86, reprinted 1964).

BIBLIOGRAPHY

Biographies: The standard biography is ERNEST C. MOSSNER, The Life of David Hume, 2nd rev. ed. (1980); while JOHN HILL BURTON, Life and Correspondence of David Hume, 2 vol. (1846, reprinted 1983), is not entirely superseded by more recent scholarship. Shorter biographical studies include J.Y.T. GREIG, David Hume (1931, reprinted 1983); and F.H. HEINE-MANN, David Hume, the Man and His Science of Man (1940). J.Y.T. GREIG (ed.), The Letters of David Hume, 2 vol. (1932 reprinted 1983), is supplemented by RAYMOND KLIBANSKY and ERNEST C. MOSSNER (eds.), New Letters of David Hume (1954, reprinted 1983).

Commentaries: An up-to-date introduction to Hume's philosophical ideas is provided by A.J. AYER, Hume (1980). Other useful introductory works are D.G.C. MacNABB, David Hume: His Theory of Knowledge and Morality, 2nd ed. (1966); BARRY STROUD, Hume (1977); and v.c. CHAPPELL (ed.), The Philosophy

Main economics of David Hume (1963), which contains excerpts from Hume's works. More specialized commentanes on Hume's epistemological theory include H.I. P.EICE, Hume's Theory of the External World (1940, reprinted 1983); CONSTANCE MAUND, Hume's Theory of Rowdedge (1937, reprinted 1973); and NORMAN REIM'S MATTI, The Philosophy of David Hume (1941, reprinted 1983). Commentaries that concentrate on Hume's their lettical thought are. DAVID BROILES, The Moral Philosophy of David Hume, R. DAVID BROILES, The Moral Philosophy of David Hume, R. DAVID BROILES, The Moral Philosophy of Belief (1961); RACKIEL M. GARCIAN'S TARRY, Hume's Philosophy of Belief (1961); RACKIEL M. GARCIAN'S TARRY, Hume's Moral Epistemology (1976), and Hume's Theory, Indianes's Moral Epistemology (1976), and Hume's Theory, Indianes's Moral Epistemology (1976), and Hume's Theory, Indianes's Hindle Straings (1965, reprinted 1979), contains excerpts that are well chosen from

Hume's political theory is examined in DUNCAN FORBES, Hume's Philosophical Politics (1975, reprinted 1985); DAVID MILLER, Philosophy and Ideology in Hume's Political Thought (1981, reprinted 1984); O.K. VLACHOS, Essai sur la politique de Hume (1955); and SHIRLEY ROBIN LEFUN, The Pursuit of Certainty: David Hume, Jeremy Bentham, John Stuart Mill, Beartice Webb (1965). Excerpts from Hume's writings on politics, together with a commentary, appear in FREDERICK WATKINS (edd.), Theory of Politics (1951).

RICHARD WOLLHEIM (ed.), Hume on Religion (1963, reissued

1964), contains Hume's most important writings on the subject. More extensive commentaries are provided by J.C.A. GASKIN, Hume's Philosophy of Religion (1978), and ANDRE-LOUIS LEROY, La Critique et la religion chez David Hume (1935), reissued EUGENE ROTWEIN (ed.), Prütings on Economics (1955, reissued

EUGENE ROTWEIN (ed.), Writings on Economics (1955, reissued 1972), a collection of Hume's essays, is a valuable introduction to a somewhat neglected aspect of Hume's social theory. Commentaries that attempt a more synoptic and comprehensive appraisal of Hume's thought include JOHN PASSMORE, Hume's Intentions, 3rd ed. (1980); CHARLES W. HENDEL, Studies in the Philosophy of David Hume (1925, reissued 1983); ANDLÉ-Hume's Philosophy of Hume's Philosophical Development (1973, and IAMES NOXON, Hume's Philosophical Development (1973), and IAMES NOXON, Hume's Philosophical Development (1973, reprinted 1981) 1975).

Bibliographies: T.E. IESSOP, A Bibliography of David Hume and of Scottish Philosophy from Frances Hutchinson to Lord Ballow (1938, reprinted 1983), and ROLAND HALL, Flfly Years of Hume Scholarship (1978), and A Hume Bibliography, from 1930 (1971), WILLIAM B. TODO (ed.), Hume and the Enightenment (1974), contains a bibliographical essay, Hume Studies (semiannual) updates bibliographical information.

(T.E.Je./M.C.)

Humour and Wit

n all its many-splendoured varieties, humour can be simply defined as a type of stimulation that tends to elicit the laughter reflex. Spontaneous laughter is a motor reflex produced by the coordinated contraction of 15 facial muscles in a stereotyped pattern and accompanied by altered breathing. Electrical stimulation of the main lifting muscle of the upper lip, the zygomatic major, with currents of varying intensity produces facial expressions ranging from the faint smile through the broad grin to the contortions typical of explosive laughter.

The laughter and smile of civilized man is, of course, often of a conventional kind, in which voluntary intent substitutes for, or interferes with, spontaneous reflex activity; this article is concerned, however, only with the latter. Once laughter is realized to be a humble reflex, several paradoxes must be faced. Motor reflexes, such as the contraction of the pupil of the eve in dazzling light, are simple responses to simple stimuli whose value to survival is obvious. But the involuntary contraction of 15 facial muscles, associated with certain irrepressible noises, strikes one as an activity without any utilitarian value, quite unrelated to the struggle for survival. Laughter is a reflex but unique in that it has no apparent biological purpose. One might call it a luxury reflex. Its only function seems to be to provide relief from tension.

The second related paradox is a striking discrepancy between the nature of the stimulus and that of the response in humorous transactions. When a blow beneath the kneecap causes an automatic upward kick, both "stimulus" and "response" function on the same primitive physiological level, without requiring the intervention of the higher mental functions. But that such a complex mental activity as reading a comic story should cause a specific reflex contraction of the facial muscles is a phenomenon that has puzzled philosophers since Plato. There is no clear-cut, predictable response that would tell a lecturer whether he has succeeded in convincing his listeners; but, when he is telling a joke, laughter serves as an experimental test. Humour is the only form of communication in which a stimulus on a high level of complexity produces a stereotyped, predictable response on the physiological reflex level. Thus the response can be used as an indicator for the presence of the elusive quality that is called humour-as the click of the Geiger counter is used to indicate the presence of radioactivity. Such a procedure is not possible in any other form of art; and, since the step from the sublime to the ridiculous is reversible, the study of humour provides clues for the study of creativity in general

This article deals with the changing concepts and practice of humour from the time of Aristotle to the influence of the mass media in the contemporary world.

The article is divided into the following sections:

The logic of laughter 682 Laughter and emotion 683 Verbal humour 684 Situational humour 685 Styles and techniques in humour 686 Relations to art and science 686 The humanization of humour 687 Non-Western styles Humour in the contemporary world

THE LOGIC OF LAUGHTER

Bibliography 687

The range of laughter-provoking experiences is enormous. from physical tickling to mental titillations of the most varied kinds. There is unity in this variety, however, a common denominator of a specific and specifiable pattern that reflects the "logic" or "grammar" of humour, as it were. A few examples will help to unravel that pattern.

1. A masochist is a person who likes a cold shower in the morning so he takes a hot one.

2. An English lady, on being asked by a friend what she thought of her departed husband's whereabouts: "Well, I suppose the poor soul is enjoying eternal bliss, but I wish you wouldn't talk about such unpleasant subjects.

3. A doctor comforts his patient: "You have a very serious disease. Of 10 persons who catch it, only one survives. It is lucky you came to me, for I have recently had nine patients with this disease and they all died of it.

4. Dialogue in a French film:

"Sir, I would like to ask for your daughter's hand." "Why not? You have already had the rest."

5. A marguis of the court of Louis XV unexpectedly returned from a journey and, on entering his wife's boudoir, found her in the arms of a bishop. After a moment's hes itation, the marquis walked calmly to the window, leaned out, and began going through the motions of blessing the people in the street.

"What are you doing?" cried the anguished wife. "Monseigneur is performing my functions, so I am

performing his."

Is there a common pattern underlying these five stories? Starting with the last, a little reflection reveals that the marquis's behaviour is both unexpected and perfectly logical-but of a logic not usually applied to this type of situation. It is the logic of the division of labour, governed by rules as old as human civilization. But his reactions would have been expected to be governed by a different set of rules-the code of sexual morality. It is the sudden clash between these two mutually exclusive codes of rules-or associative contexts-that produces the comic effect. It compels the listener to perceive the situation in two self-consistent but incompatible frames of reference at the same time; his mind has to operate simultaneously on two different wavelengths. While this unusual condition lasts, the event is not only, as is normally the case, associated with a single frame of reference but "disociated" with two. The word disociation was coined by the present Disociation writer to make a distinction between the routines of disciplined thinking within a single universe of discourse-on a single plane, as it were-and the creative types of mental activity that always operate on more than one plane. In humour, both the creation of a subtle joke and the recreative act of perceiving the joke involve the delightful mental jolt of a sudden leap from one plane or associative context to another

Turning to the other examples, in the French film dialogue, the daughter's "hand" is perceived first in a metaphorical frame of reference, then suddenly in a literal, bodily context. The doctor thinks in terms of abstract, statistical probabilities, the rules of which are inapplicable to individual cases; and there is an added twist because, in contrast to what common sense suggests, the patient's odds of survival are unaffected by whatever happened before; they are still one against 10. This is one of the profound paradoxes of the theory of probability, and the joke in fact implies a riddle; it pinpoints an absurdity that tends to be taken for granted. As for the lady who looks upon death as "eternal bliss" and at the same time "an unpleasant subject," she epitomizes the common human predicament of living in the divided house of faith and reason. Here again the simple joke carries unconscious overtones and undertones, audible to the inner ear alone.

The masochist who punishes himself by depriving himself of his daily punishment is governed by rules that are a reversal of those of normal logic. (A pattern can be constructed in which both frames of reference are reversed: "A sadist is a person who is kind to a masochist.") But there

is again an added twist. The joker does not really believe that the masochist takes his hot shower as a punishment; he only pretends to believe it. Irony is the satirist's most effective weapon; it pretends to adopt the opponent's ways of reasoning in order to expose their implicit absurdity or viciousness.

The common pattern underlying these stories is the perceiving of a situation in two self-consistent but mutually incompatible frames of reference or associative conexis. It is formula can be shown to have a general validity for all forms of humour and wil, some of which will be discussed below. But it covers only one aspect of humour—its intellectual structure. Another fundamental aspect must be examined—the emotional dynamics that breathe life into that structure and make a person laugh, gugle, or smile.

LAUGHTER AND EMOTION

When a comedian tells a story, he deliberately sets out to create a certain tension in his listeners, which mounts as the narrative progresses. But it never reaches its expected climax. The punch line, or point, acts as a verbal guillotine that cuts across the logical development of the story; it debunks the audience's dramatic expectations. The tension that was felt becomes suddenly redundant and is exploded in laughter. To put it differently, laughter disposes of emotive excitations that have become pointless and must somehow be worked off along physiological channels of least resistance; and the function of the "luxury reflex" is to provide these channels.

A glance at the caricatures of the 18th-century English artists William Hogarth or Thomas Rowlandson, showing the brutal merriment of people in a tavern, makes one realize at once that they are working off their surplus of adrenalin by contracting their face muscles into grimaces. slapping their thighs, and breathing in puffs through the half-closed glottis. Their flushed faces reveal that the emotions disposed of through these safety valves are brutality, envy, sexual gloating. In cartoons by the 20th-century American James Thurber, however, coarse laughter yields to an amused and rarefied smile: the flow of adrenalin has been distilled and crystallized into a grain of Attic salta sophisticated joke. The word witticism is derived from "wit" in its original sense of intelligence and acumen (as is Witz in German). The domains of humour and of ingenuity are continuous, without a sharp boundary: the jester is brother to the sage. Across the spectrum of humour, from its coarse to its subtle forms, from practical joke to brainteaser, from jibe to irony, from anecdote to epigram, the emotional climate shows a gradual transformation. The emotion discharged in coarse laughter is aggression robbed of its purpose. The jokes small children enjoy are mostly scatological; adolescents of all ages gloat on vicarious sex. The sick joke trades on repressed sadism, satire on righteous indignation. There is a bewildering variety of moods involved in different forms of humour, including mixed or contradictory feelings; but whatever the mixture, it must contain a basic ingredient that is indispensable: an impulse, however faint, of aggression or apprehension. It may appear in the guise of malice, contempt, the veiled cruelty of condescension, or merely an absence of sympathy with the victim of the joke-a momentary anesthesia of the heart, as the French philosopher Henri

In the subtler types of humour, the aggressive tendency may be so faint that only careful analysis will detect it, like the presence of salt in a well-prepared dish-which, however, would be tasteless without it. Replace aggression by sympathy and the same situation-a drunk falling on his face, for example-will be no longer comic but pathetic and will evoke not laughter but pity. It is the aggressive element, the detached malice of the comic impersonator, that turns pathos into bathos, tragedy into travesty. Malice may be combined with affection in friendly teasing; and the aggressive component in civilized humour may be sublimated or no longer conscious. But in jokes that appeal to children and primitive people, cruelty and boastful self-assertiveness are much in evidence. In 1961 a survey carried out among American children aged eight to 15 made the researchers conclude that the mortification, dis-

comfort, or hoaxing of others readily caused laughter, but witty or funny remarks often passed unnoticed.

Similar considerations apply to the historically earlier forms and theories of the comic. In Aristolle's view, laughter was intimately related to ugliness and debasement. Cicero held that the province of the ndiculous lay in a certain baseness and deformity. Descartes believed that laughter was a manifestation of joy mixed with surprise or hatred or both. In Francis Bacon's list of what causes laughter, the first place is again given to deformity. One of the most frequently quoted utterances on the subject is this definition in Thomas Hobbes's Levialma (1651):

The passion of laughter is nothing else but sudden glory arising from a sudden conception of some eminency in ourselves by comparison with the infirmity of others, or with our own formerly.

In the 19th century, Alexander Bain, an early experimental psychologist, thought along the same lines:

Not in physical effects alone, but in everything where a man can achieve a stroke of superiority, in surpassing or discomforting a rival, is the disposition of laughter apparent.

In Bergson's view, laughter is the corrective punishment inflicted by society upon the unsocial individual: "In laughter we always find an unavowed intention to humilate and consequently to correct our neighbour." Sir Max Beerbohm, the 20th-century English wit, found "two elements in the public's humour delight in suffering, contempt for the unfamiliar." The American psychologist William McDougall believed that "laughter has been evolved in the human race as an antidote to sympathy, a protective reaction shielding us from the depressive influence of the shortcomings of our fellow men.

However much the opinions of the theorists differ, on this one point nearly all of them agree: that the emotions discharged in laughter always contain an element of aggressiveness. It must be borne in mind, however, that aggression and apprehension are twin phenomena, so much so that psychologists are used to talking of "aggressivedefensive impulses." Accordingly, one of the typical situations in which laughter occurs is the moment of sudden cessation of fear caused by some imaginary danger. Rarely is the nature of laughter as an overflow of redundant tensions more strikingly manifested than in the sudden change of expression on a small child's face from anxious apprehension to the happy laughter of relief. This seems to be unrelated to humour; yet a closer look reveals in it the same logical structure as in the joke; the wildly barking little dog was first perceived by the child in a context of danger, then discovered to be a harmless pup; the tension

has suddenly become redundant and is spilled. Immanuel Kant realized that what causes laughter is "the sudden transformation of a tense expectation into nothing." Herbert Spencer, the 19th-century. Inglish philosopher, took up the idea and attempted to formulate it in physiological terms. "Emotions and sensations tend to generate bodily movements... When consciousness is unawares transferred from great things to small," the "liberated nerve force" will expend itself along channels of least resistance—the bodily movements of laughter. Freud incorporated Spencer's theory of humour into his own, with special emphasis on the release of repressed emotions in laughing, he also attempted to explain why the excess energy should be worked off in that particular way.

According to the best of my knowledge, the grimaces and contortions of the corners of the mouth that characterise laughter to the satisfied and over-statisted nurshing when he drownshy quits the breast. They are physical expressions of the determination to take no more nourishment, an "enough" so to speak, or rather a "more than enough". This primal sense of pleasurable saturation may have provided the link between the smile—that basic phenomenon underlying laughter—and its subsequent connection with other pleasurable processes of de-tension.

In other words, the muscle contractions of the smile, as the earliest expressions of relief from tension, would thereafter serve as channels of least resistance. Similarly, the explosive exhalations of laughter seem designed to "puff away" surplus tension in a kind of respiratory gymnastics, and agitated gestures obviously serve the same function.

Theories of

Laughter as the release of tension

The aggressive element

It may be objected that such massive reactions often seem quite out of proportion to the slight stimulations that provoke them. But it must be borne in mind that laughter is a phenomenon of the trigger-releaser type, where a sudden turn of the tap may release vast amounts of stored emotions, derived from various, often unconscious, sources: repressed sadism, sexual tumescence, unavowed fear, even boredom. The explosive laughter of a class of schoolboys at some trivial incident is a measure of their pent-up resentment during a boring lecture. Another factor that may amplify the reaction out of all proportion to the comic stimulus is the social infectiousness that laughter shares with other emotive manifestations of group behaviour.

Patterns of

Laughter or smiling may also be caused by stimulations association that are not in themselves comic but signs or symbols deputizing for well-established comic patterns-such as Charlie Chaplin's oversized shoes or Groucho Marx's cigar-or catchphrases, or allusions to family jokes. To discover why people laugh requires, on some occasions, tracing back a long, involved thread of associations to its source. This task is further complicated by the fact that the effect of such comic symbols-in a cartoon or on the stage-appears to be instantaneous, without allowing time for the accumulation and subsequent discharge of "expectations" and "emotive tensions." But here memory comes into play, having already accumulated the required emotions in past experiences, acting as a storage battery whose charge can be sparked off at any time: the smile that greets Falstaff's appearance on the scene is derived from a mixture of memories and expectations. Besides, even if a reaction to a cartoon appears to be instantaneous, there is always a process in time until the reader "sees the joke"; the cartoon has to tell a story even if it is telescoped into a few seconds. All of this shows that to analyze humour is a task as delicate as analyzing the composition of a perfume with its multiple ingredients, some of which are never consciously perceived while others, when sniffed in isolation, would make one wince.

In this article there has been a discussion first of the logical structure of humour and then of its emotional dynamics. Putting the two together, the result may be summarized as follows: the "bisociation" of a situation or idea with two mutually incompatible contexts in a person's mind and the resulting abrupt transfer of his train of thought from one context to another put a sudden end to his "tense expectations"; the accumulated emotion, deprived of its object, is left hanging in the air and is discharged in laughter. Upon hearing that the marquis in the story told earlier walks to the window and starts blessing the people in the street, the intellect turns a somersault and enters with gusto into the new game. The malicious and erotic feelings aroused by the start of the story, however, cannot be fitted into the new context; deserted by the nimble intellect, these feelings gush out in laughter like air from a punctured tire.

Separation of thought and emotion

To put it differently: people laugh because their emotions have a greater inertia and persistence than their thoughts. Affects are incapable of keeping step with reasoning unlike reasoning, they cannot "change direction" at a moment's notice. To the physiologist, this is self-evident since emotions operate through the genetically old, massive sympathetic nervous system and its allied hormones, acting on the whole body, while the processes of conceptual thinking are confined to the neocortex at the roof of the brain. Common experience provides daily confirmation of this dichotomy. People are literally "poisoned" by their adrenal humours; it takes time to talk a person out of a mood; fear and anger show physical aftereffects long after their causes have been removed. If man were able to change his moods as quickly as his thoughts, he would be an acrobat of emotion; but since he is not, his thoughts and emotions frequently become dissociated. It is emotion deserted by thought that is discharged in laughter. For emotion, owing to its greater mass momentum, is, as has been shown, unable to follow the sudden switch of ideas to a different type of logic; it tends to persist in a straight line. Aldous Huxley once wrote:

We carry around with us a glandular system which was admirably well adapted to life in the Paleolithic times but is not very well adapted to life now. Thus we tend to produce more adrenalin than is good for us, and we either suppress ourselves and turn destructive energies inwards or else we do not suppress ourselves and we start hitting people. (From Man and Civilization: Control of the Mind, ed. Seymour M. Farber and Roger H.L. Wilson, Copyright 1961, Used with permission of McGraw-Hill Book Company.)

A third alternative is to laugh at people. There are other outlets for tame aggression, such as competitive sports or literary criticism; but they are acquired skills, whereas laughter is a gift of nature, included in man's native equipment. The glands that control his emotions reflect conditions at a stage of evolution when the struggle for existence was more deadly than at present-and when the reaction to any strange sight or sound consisted in jumping, bristling, fighting, or running. As security and comfort increased in the species, new outlets were needed for emotions that could no longer be worked off through their original channels, and laughter is obviously one of them. But it could only emerge when reasoning had gained a degree of independence from the urges of emotion Relow the human level, thinking and feeling appear to form an indivisible unity. Not before thinking became gradually detached from feeling could man perceive his own emotion as redundant and make the smiling admission, "I have been fooled,"

VERBAL HUMOUR

The foregoing discussion was intended to provide the tools for dissecting and analyzing any specimen of humour. The procedure is to determine the nature of the two (or more) frames of reference whose collision gives rise to the comic effect-to discover the type of logic or "rules of the game" that govern each. In the more sophisticated type of joke, the logic is implied and hidden, and the moment it is stated in explicit form, the joke is dead. Unavoidably, the section that follows will be strewn with cadavers.

Max Eastman, in The Enjoyment of Laughter (1936), remarked of a laboured pun by Ogden Nash: "It is not a pun but a punitive expedition." That applies to most puns, including Milton's famous lines about the Prophet Elijah's ravens, which were "though ravenous taught to abstain from what they brought," or the character mentioned by Freud, who calls the Christmas season the "alcoholidays." Most puns strike one as atrocious, perhaps because they represent the most primitive form of humour; two disparate strings of thought tied together by an acoustic knot. But the very primitiveness of such association based on pure sound ("hol") may account for the pun's immense popularity with children and its prevalence in certain types of mental disorder ("punning mania").

From the play on sounds-puns and Spoonerisms-an ascending series leads to the play on words and so to the play on ideas. When Groucho Marx says of a safari in Africa, "We shot two bucks, but that was all the money we had," the joke hinges on the two meanings of the word buck. It would be less funny without the reference to Groucho, which evokes a visual image instantly arousing high expectations. The story about the marquis above may be considered of a superior type of humour because it plays not on mere words but on ideas.

It would be quite easy-and equally boring-to draw up a list in which jokes and witticisms are classified according to the nature of the frames of reference whose collision creates the comic effect. A few have already been mentioned: metaphorical versus literal meaning (the daughter's "hand"); professional versus common sense logic (the doctor); incompatible codes of behaviour (the marquis); confrontations of the trivial and the exalted ("eternal bliss"); trains of reasoning travelling, happily joined together, in opposite directions (the sadist who is kind to the masochist). The list could be extended indefinitely; in fact any two frames of reference can be made to yield a comic effect of sorts by hooking them together and infusing a drop of malice into the concoction. The frames may even be defined by such abstract concepts as "time" and "weather": the absent-minded professor who tries to read the temperature from his watch or to tell the time from the thermometer is comic in the same way as a game of

table tennis played with a soccer ball or a game of rugby played with a table tennis ball. The variations are infinite, the formula remains the same.

Jokes and anecdotes have a single point of culmination. The literary forms of sustained humour, such as the picaresque novel, do not rely on a single effect but on a series of minor climaxes. The narrative moves along the line of intersection of contrasted planes, such as the fantasy world of Don Ouixote and the cunning horse sense of Sancho Panza, or is made to oscillate between them. As a result, tension is continuously generated and discharged in mild amusement.

Comic verce

Satire and

allegory

Comic verse thrives on the melodious union of incongruities, such as the "cabbages and kings" in Lewis Carroll's "The Walrus and the Carpenter," and particularly on the contrast between lofty form and flat-footed content. Certain metric forms associated with heroic poetry. such as the hexameter or Alexandrine, arouse expectations of pathos, of the exalted; to pour into these epic molds some homely, trivial content-"beautiful soup, so rich and green/ waiting in a hot tureen"-is an almost infallible comic device. The rolling rhythms of the first lines of a limerick that carry, instead of a mythical hero such as Hector or Achilles, a young lady from Ohio for a ride make her ridiculous even before the expected calamities befall her. Instead of a heroic mold, a soft lyrical one may also nay off-

. And what could be moister Than tears of an oyster?

Another type of incongruity between form and content yields the bogus proverb: "The rule is: jam tomorrow and jam yesterday—but never jam today." Two contradictory statements have been telescoped into a line whose homely, admonitory sound conveys the impression of a popular adage. In a similar way, nonsense verse achieves its effect by pretending to make sense, by forcing the reader to project meaning into the phonetic pattern of the jabberwocky, as one interprets the ink blots in a Rorschach test.

The satire is a verbal caricature that shows a deliberately distorted image of a person, institution, or society. The traditional method of the caricaturist is to exaggerate those features he considers to be characteristic of his victim's personality and to simplify by leaving out everything that is not relevant for his purpose. The satirist uses the same technique, and the features of society he selects for magnification are, of course, those of which he disapproves. The result is a juxtaposition, in the reader's mind, of his habitual image of the world in which he moves and its absurd reflection in the satirist's distorting mirror. He is made to recognize familiar features in the absurd and absurdity in the familiar. Without this double vision the satire would be humourless. If the human Yahoos were really such evil-smelling monsters as Gulliver's Houyhnhnm hosts claim, then Jonathan Swift's Gulliver's Travels (1726) would not be a satire but the statement of a deplorable truth. Straight invective is not satire; satire must deliberately overshoot its mark.

A similar effect is achieved if, instead of exaggerating the objectionable features, the satirist projects them by means of the allegory onto a different background, such as an animal society. A succession of writers, from the ancient Greek dramatist Aristophanes through Swift to such 20th-century satirists as Anatole France and George Orwell, have used this technique to focus attention on deformities of society that, blunted by habit, are taken for granted.

SITUATIONAL HUMOUR

The coarsest type of humour is the practical joke: pulling away the chair from under the dignitary's lowered bottom. The victim is perceived first as a person of consequence, then suddenly as an inert body subject to the laws of physics: authority is debunked by gravity, mind by matter; man is degraded to a mechanism. Goose-stepping soldiers acting like automatons, the pedant behaving like a mechanical robot, the Sergeant Major attacked by diarrhea, or Hamlet getting the hiccups-all show man's lofty aspirations deflated by his all-too-solid flesh. A similar effect is produced by artifacts that masquerade as humans: Punch

and Judy, jack-in-the-box, gadgets playing tricks on their masters as if with calculated malice.

In Henri Bergson's theory of laughter, this dualism of subtle mind and inert matter-he calls it "the mechanical encrusted on the living"-is made to serve as an explanation of all varieties of the comic. In the light of what has been said, however, it would seem to apply only to one type of comic situation among many others.

From the "bisociation" of man and machine, there is only a step to the man-animal hybrid. Walt Disney's creations behave as if they were human without losing their animal appearance. The caricaturist follows the reverse procedure by discovering horsey, mousy, or piggish features in the human face.

This leads to the comic devices of imitation, impersonation, and disguise. The impersonator is perceived as himself and somebody else at the same time. If the result is slightly degrading-but only in that case-the spectator will laugh. The comedian impersonating a public personality, two pairs of trousers serving as the legs of the pantomime horse, men disguised as women and women as men-in each case the paired patterns reduce each other to absurdity.

The most aggressive form of impersonation is the parody, designed to deflate hollow pretense, to destroy illusion. and to undermine pathos by harping on the weaknesses of the victim. Wigs falling off, speakers forgetting their lines. gestures remaining suspended in the air: the parodist's favourite points of attack are again situated on the line of intersection between the sublime and the trivial.

Playful behaviour in young animals and children is amusing because it is an unintentional parody of adult behaviour, which it imitates or anticipates. Young puppies are droll because their helplessness, affection, and puzzled expression make them appear more "human" than fullgrown dogs; because their growls strike one as impersonations of adult behaviour-like a child in a bowler hat; because the puppy's waddling, uncertain gait makes it a choice victim of nature's practical jokes; because its bodily disproportions-the huge padded paws, Falstaffian belly, and wrinkled brow-give it the appearance of a caricature; and lastly because the observer feels so superior to a puppy. A fleeting smile can contain many logical ingredients and emotional spices.

Both Cicero and Francis Bacon regarded deformity as the most frequent cause of laughter. Renaissance princes collected dwarfs and hunchbacks for their merriment. It obviously requires a certain amount of imagination and empathy to recognize in a midget a fellow human, who, though different in appearance, thinks and feels much as oneself does. In children, this projective faculty is still rudimentary: they tend to mock people with a stammer or a limp and laugh at the foreigner with an odd pronunciation. Similar attitudes are shown by tribal or parochial societies to any form of appearance or behaviour that deviates from their strict norms: the stranger is not really human; he only pretends to be "like us." The Greeks used the same word, barbarous, for the foreigner and the stutterer: the uncouth barking sounds the stranger uttered were considered a parody of human speech. Vestiges of this primitive attitude are still found in the curious fact that civilized people accept a foreign accent with tolerance, whereas imitation of a foreign accent strikes them as comic. The imitator's mispronunciations are recognized as mere pretense; this knowledge makes sympathy unnecessary and enables the audience to be childishly cruel with a clean conscience.

Other sources of innocent laughter are situations in which the part and the whole change roles, and attention becomes focussed on a detail torn out of the functional context on which its meaning depended. When the phonograph needle gets stuck, the soprano's voice keeps repeating the same word on the same quaver, which suddenly assumes a grotesquely independent life. The same happens when faulty orthography displaces attention from meaning to spelling, or whenever consciousness is directed at functions that otherwise are performed automatically. The latter situation is well illustrated by the story of the centipede who, when asked in which order he moved his hundred legs, became paralyzed and could walk no more. The self-conscious, awkward youth, who does not know what to do with his hands, is a victim of the paradox of the centinede.

Comedies have been classified according to their reliance on situations, manners, or characters. The logic of the last two needs no further discussion; in the first, comic effects are contrived by making a situation participate simultaneously in two independent chains of events with different associative contexts, which intersect through coincidence, mistaken identity, or confusions of time and occasion.

Tickling

the visual

arts and

music

Why tickling should produce laughter remained an enigma in all earlier theories of the comic. As Darwin was the first to point out, the innate response to tickling is squirming and straining to withdraw the tickled part-a defense reaction designed to escape attacks on vulnerable areas such as the soles of the feet, armpits, belly, and flank. If a fly settles on the belly of a horse, it causes a ripple of muscle contractions across the skin-the equivalent of squirming in the tickled child. But the horse does not laugh when tickled, and the child not always. The child will laugh only-and this is the crux of the matter-when it perceives tickling as a mock attack, a caress in mildly aggressive disguise. For the same reason, people laugh only when tickled by others, not when they tickle themselves.

Experiments at Yale University on babies under one year revealed the not very surprising fact that they laughed 15 times more often when tickled by their mothers than by strangers; and when tickled by strangers, they mostly cried. For the mock attack must be recognized as being only pretense, and with strangers one cannot be sure. Even with its own mother, there is an ever-so-slight feeling of uncertainty and apprehension, the expression of which will alternate with laughter in the baby's behaviour. It is precisely this element of tension between the tickles that is relieved in the laughter accompanying the squirm. The rule of the game is "let me be just a little frightened so

that I can enjoy the relief."

Thus the tickler is impersonating an aggressor but is simultaneously known not to be one. This is probably the first situation in life that makes the infant live on two planes at once, a delectable foretaste of being tickled by the horror comic. Humour in

Humour in the visual arts reflects the same logical structures as discussed before. Its most primitive form is the distorting mirror at the fun fair, which reflects the human frame elongated into a column or compressed into the shape of a toad. It plays a practical joke on the victim, who sees the image in the mirror both as his familiar self and as a lump of plasticine that can be stretched and squeezed into any absurd form. The mirror distorts mechanically while the caricaturist does so selectively, employing the same method as the satirist-exaggerating characteristic features and simplifying the rest. Like the satirist, the caricaturist reveals the absurd in the familiar; and, like the satirist, he must overshoot his mark. His malice is rendered harmless by the knowledge that the monstrous potbellies and bowlegs he draws are not real; real deformities are not comic but arouse pity.

The artist, painting a stylized portrait, also uses the technique of selection, exaggeration, and simplification; but his attitude toward the model is usually dominated by positive empathy instead of negative malice, and the features he selects for emphasis differ accordingly. In some character studies by Leonardo da Vinci, Hogarth, or Honoré Daumier, the passions reflected are so violent, the grimaces so ferocious, that it is impossible to tell whether the works were meant as portraits or caricatures. If one feels that such distortions of the human face are not really possible, that Daumier merely pretended that they exist, then one is absolved from horror and pity and can laugh at his grotesques. But if one feels that this is indeed what Daumier saw in those dehumanized faces, then they are not comic but tragic.

Humour in music is a subject to be approached with diffidence because the language of music ultimately eludes translation into verbal concepts. All one can do is to point out some analogies: a "rude" noise, such as the blast of a trumpet inserted into a passage where it does not belong,

has the effect of a practical joke; a singer or an instrument out of tune produces a similar reaction; the imitation of animal sounds, vocally or instrumentally, exploits the technique of impersonation; a nocturne by Chopin transposed into hot jazz or a simple street song performed with Wagnerian pathos is a marriage of incompatibles. These are primitive devices corresponding to the lowest levels of humour; more sophisticated are the techniques employed by Maurice Rayel in La Valse, a parody of the sentimental Viennese waltz, or by Zoltán Kodály in the mock-heroics of his Hungarian folk opera, Háry János, But in comic operas it is almost impossible to sort out how much of the comic effect is derived from the book and how much from the music; and the highest forms of musical humour, the unexpected delights of a lighthearted scherzo by Mozart. defy verbal analysis, unless it is so specialized and technical as to defeat its purpose. Although a "witty" musical passage that springs a surprise on the audience and cheats it of its expectations certainly has the emotion-relieving effect that tends to produce laughter, a concert audience may occasionally smile but will hardly ever laugh: the emotions evoked by musical humour are of a subtler kind than those of the verbal and visual variety.

STYLES AND TECHNIQUES IN HUMOUR

The criteria that determine whether a humorous offering will be judged good, bad, or indifferent are partly a matter of period taste and personal preference and partly dependent on the style and technique of the humorist. It would seem that these criteria can be summed up under three main headings: originality, emphasis, and economy,

The merits of originality are self-evident; it provides the essential element of surprise, which cuts across our expectations. But true originality is not very often met either in humour or in other forms of art. One common substitute and for it is to increase the tension of the audience by various techniques of suggestive emphasis. The clown's domain is the rich, coarse type of humour; he piles it on: he appeals to sadistic, sexual, scatological impulses. One of his favourite tricks is repetition of the same situation, the same key phrase. This diminishes the effect of surprise. but it has a tension-accumulating effect; emotion is easily drawn into the familiar channel-more and more liquid is being pumped into the punctured pipeline.

Emphasis on local colour and ethnic peculiarities, such as Scottish or Cockney stories, for example, is a further means to channel emotion into familiar tracks. The Scotsman or Cockney must, of course, be a caricature if the comic purpose is to be achieved. In other words, exaggeration and simplification once more appear as indispensable

tools to provide emphasis.

In the higher forms of humour, however, emphasis tends to yield to the opposite kind of virtue-economy. Economy, in humour and art, does not mean mechanical brevity but implicit hints instead of explicit statementsthe oblique allusion in lieu of the frontal attack, Oldfashioned cartoons, such as those featuring the British lion and the Russian bear, hammered their message in: the modern cartoon usually poses a riddle that the reader must solve by an imaginative effort in order to see the joke.

In humour, as in other forms of art, emphasis and economy are complementary techniques. The first forces the offering down the consumer's throat; the second tantalizes

to whet his appetite.

RELATIONS TO ART AND SCIENCE

Earlier theories of humour, including even those of Bergson and Freud, treated it as an isolated phenomenon, without attempting to throw light on the intimate connections between the comic and the tragic, between laughter and crying, between artistic inspiration, comic inventiveness, and scientific discovery. Yet these three domains of creative activity form a continuum with no sharp boundaries between wit and ingenuity, nor between discovery and art.

It has been said that scientific discovery consists in seeing an analogy where nobody has seen one before. When, in the Song of Solomon, Solomon compared the Shulamite's neck to a tower of ivory, he saw an analogy that nobody had seen before; when William Harvey compared

emphasis. economy

the heart of a fish to a mechanical pump, he did the same; and when the caricaturist draws a nose like a cucumber, he again does just that. In fact, all the logical patterns discussed above, which constitute a "grammar" of humour, can also enter the service of art or discovery, as the case may be. The pun has structural equivalents in the rhyme and in word games, which range from crossword puzzles to the deciphering of the Rosetta Stone, the key to Egyptian hieroglyphic. The confrontation between diverse codes of behaviour may yield comedy, tragedy, or new psychological insights. The dualism of mind and inert matter is exploited by the practical joker but also provides one of the eternal themes of literature: man as a marionette on strings, manipulated by gods or chromosomes. The man-beast dichotomy is reflected by Walt Disney's cartoon character Donald Duck but also in Franz Kafka's macabre tale The Metamorphosis (1915) and in the psychologist's experiments with rats. The caricature corresponds not only to the artist's character portrait but also to the scientist's diagrams and charts, which emphasize the relevant features and leave out the rest.

Synthesis, iuxtaposition, and collision

Contemporary psychology regards the conscious and unconscious processes underlying creativity in all domains as an essentially combinative activity-the bringing together of previously separate areas of knowledge and experience. The scientist's purpose is to achieve synthesis: the artist aims at a juxtaposition of the familiar and the eternal; the humorist's game is to contrive a collision. And as their motivations differ, so do the emotional responses evoked by each type of creativity: discovery satisfies the exploratory drive; art induces emotional catharsis; humour arouses malice and provides a harmless outlet for it. Laughter has been described as the "Haha reaction"; the discoverer's Eureka cry as the "Aha! reaction"; and the delight of the aesthetic experience as the "Ah . . . reaction." But the transitions from one to the other are continuous: witticism blends into epigram, caricature into portrait; and whether one considers architecture, medicine, chess, or cookery, there is no clear frontier where the realm of science ends and that of art begins: the creative person is a citizen of both. Comedy and tragedy, laughter and weeping, mark the extremes of a continuous spectrum, and a comparison of the physiology of laughter and weeping yields further clues to this challenging problem. Such considerations, however, lie beyond the terms of reference of the present

THE HUMANIZATION OF HUMOUR

The San (Bushmen) of the Kalahari desert of South West Africa/Namibia are among the oldest and most primitive inhabitants of the Earth. An anthropologist who made an exhaustive study of them provided a rare glimpse of prehistoric humour:

On the way home we saw and shot a springbok, as there was no meat left in camp. The bullet hit the springbok in the stomach and partly eviscerated him, causing him to jump and kick before he finally died. The Bushmen thought that this was terribly funny and they laughed, slapping their thighs and kicking their heels to imitate the springbok, showing no pity at all, but then they regard animals with great detachment.

But the San remained "in good spirits, pleased with the amusement the springbok had given them." (From Elizabeth Marshall Thomas, The Harmless People; Alfred A. Knopf, New York, 1959.)

Obviously the San, like most primitive people, do not regard animals as sentient beings; the springbok's kicking in his agony appears to them funny because in their view the animal pretends to suffer pain like a human being, though it is incapable of such feelings. The ancient Greeks' attitude toward the stammering barbarian was similarly inspired by the conviction that he is not really human but only pretends to be. The ancient Hebrews' sense of humour seems to have been no less harsh: it has been pointed out that in the Old Testament there are 29 references to laughter, out of which 13 instances are linked with scorn, derision, mocking, and contempt and only two are born of joy.

As laughter emerged from antiquity, it was so aggressive that it has been likened to a dagger. It was in ancient Greece that the dagger was transformed into a quill, dripping with poison at first, then diluted and infused with delightfully lyrical and fanciful ingredients. The 5th century BC saw the first rise of humour into art, starting with parodies of Olympian heroics and soon reaching a peak, in some respects unsurpassed to this day, in the comedies of Aristophanes. From here onward, the evolution of humour in the Western world merges with the history of literature and art

If the overall trend was toward the humanization of humour from primitive to sophisticated forms, there also have been ups and downs reflecting changes in political and cultural climate. George Orwell's satire of the 20th century, for example, is much more savage than that of Jonathan Swift in 18th-century England or of Voltaire in 18th-century France. If the Dark Ages produced works of humorous art, little of it has survived. And under the tyrannies of Hitler in Germany and of Stalin in the Soviet Union, humour was driven underground. Dictators fear laughter more than bombs

Non-Western styles. About non-Western varieties of humour, the Westerner is tempted to repeat the middleaged British matron's remark on watching Cleopatra rave and die on the stage: "How different, how very different from the home life of our dear Queen." Humour thrives only in its native climate, embedded in its native logic; when one does not know what to expect, one cannot be cheated of one's expectations. Hindu humour, for instance, as exemplified by the savage pranks played on humans by the monkey-god Hanuman, strikes the Westerner as particularly cruel, perhaps because the Hindu's approach to mythology is fundamentally alien to the Western mind. The humour of the Japanese, on the other hand, is, from the Western point of view, astonishingly mild and poetical, like weak, mint-flavoured tea:

Japanese humour

The boss of the monkeys ordered his thousands of henchmen to get the moon reflected in the water. They all tried various means but failed and were much troubled. One of the monkeys at last got the moon in the water and respectfully offered it to the boss, saying "This is what you asked for." The boss was delighted and praised him, saying, "What an exploit! You have distinguished yourself!" The monkey then asked, "By the way, master, what are you going to do with this?" "Well, yes... I didn't think of that." (From Karukuchi Ukibyotan, 1751; in R.H. Blyth, Japanese Humour, 1957.)

The following dates from about a century later:

There was once a man who was always bewailing his lack of money to buy saké (rice wine) with. His wife, feeling sorry for him, dutifully cut off some of her hair and sold it to the hairdresser's for twenty-four mon, and bought her husband some saké. "Where on earth did you get this from?" "I sold my hair and bought it." "You did such a thing for me?" The wretched man shed tears, and fondling his wife's remaining hair said, "Yes, and there's another good half-bottle of saké here!" (From Chanoko-mochi, 1856; in Blyth.)

The combination of maudlin tears and brazen selfishness, and the crazy logic of equating the wife's coiffure with a liquid measure of saké, show the familiar Western pattern of the clash of incompatibles, even though transplanted into another culture.

Humour in the contemporary world. Humour today seems to be dominated by two main factors: the influence of the mass media and the crisis of values affecting a culture in rapid and violent transition. The former tends toward the commercialized manufacture of laughter by popular comedians and gags produced by conveyor-belt methods; the latter toward a sophisticated form of black humour larded with sick jokes, sadism, and sex

Fashions, however, always run their course; perhaps the next one will delight in variations on the theme of the monkey boss who, having gained possession of the moon, does not know what to do with it. The only certainty regarding the humour of the future is contained in Dr. Samuel Johnson's dictum: "Sir, men have been wise in many different modes, but they have always laughed in the same way."

BIBLIOGRAPHY. GUILLAUME DUCHENNE (DE BOULOGNE), Le Mécanisme de la physionomie humaine (1862); and JULES-MARIE RAULIN, Le Rire et les exhilarantes: étude anatomique, psy cho-physiologique et pathologique (1900), contain valuable

source material on the study of the physiology of laughter, including experiments by the neurologist Jean-Marin Char-cot and the Nobel laureate Charles Richet, JERBERT SPENCER, in his "The Physiology of Laughter," Essays on Education and Kindred Subjects (1910, reprinted 1977), outlined the tension-relieving function of humour, on which FREUD elaborated in his Wit and Its Relations to the Unconscious (1916, originally published in German, 1905), with special emphasis on infantile and repressed elements. JERNE JERSON, Laughter (1911, reprinted 1937), originally published in French, 1900), is a classic work attempting to derive all types of humour

from the contrast between mind and matter. MAX F. BASTMAN, Enjoyment of Laughter (1986), is unique in that he dense the malicious element in laughter. REGINALD H. BASTM. Japanses Humor, And ed. (1961), throws a delightful sidelight on a different culture. DAVID H. MONRO, Argument of Laughter (1951), erprinted 1963), contains a valuable summary of earlier theories. ARTHUR KORSTLIR, Insight and Outlook (1949, reprinted 1965), and The Act of Creation (1964, reprinted 1976), attempt to present a synthetic theory of humour and its interrelations with art and discovery.

(A.Ko.)

Hungarian Literature

To written evidence remains of the earliest Hungarian literature, but through Hungarian folktales and folk songs elements have survived that can be traced back to pagan times. Also extant, although only in Latin and dating from between the 11th and 14th centuries, are shortened versions of some Hungarian legends relating the origins of the Hungarian people and episodes from the conquest of Hungary and from the Hungarian campaigns of the 10th century.

This article is divided into the following sections:

EARLIEST WRITINGS IN HUNGARIAN

The earliest known written traces of the Hungarian language are mostly proper names embedded in the Latin text of legal or ecclesiastical documents. The first continuous example of the Hungarian language is the Halotti beszéd, a short funeral oration written in about 1200, moving in its simplicity. Many translations from Latin were made in the 13th and 14th centuries, but the only one that has survived, and also the oldest extant poem written in Hungarian, is a free version of a poem by Godefroy de Breteuil. It is known as Omagyar Mária-siralom (c. 1300; "Old Hungarian Lament of the Virgin Mary"). The 14th century also produced translations of the legends of St. Margaret and St. Francis of Assisi. The Jókai codex, which contains the St. Francis legend, was written in about 1440 and is the oldest extant Hungarian codex.

The 15th century saw the first translations from the Bible. The preachers Thomas and Valentine, followers of the Bohemian religious reformer Jan Hus, were responsible for this work, of which the prophetic books, the Psalms, and the Gospels have survived. A great part of the vocabulary, created for the purpose, is still in use. A number of sermons by the Franciscan Pelbárt Temesvári, originally written in Latin, have come down in Hungarian translations. Among other translations are the first Hungarian drama, A három körösztény leányról (c. 1520; On Three Christian Virgins), translated from the Latin original of Hrosvitha; a translation of the legend of St. Catherine of Alexandria; and a translation of the Song of Solomon.

Hungarian literature was not entirely religious. The existence of a history of the Trojan War and of a Hungarian version of the Alexander romance can be inferred from their South Slavic translations. In the 14th century secular literature developed and literary forms were introduced from abroad

RENAISSANCE AND REFORMATION

In 1367 the first Hungarian university was founded, at Pécs. About 100 years later King Matthias I Corvinus established the first Hungarian printing press. The King became known for his library and his patronage of foreign scholars; during his reign Latin literature in Hungary reached its peak in Janus Pannonius, who had been educated in Italy.

The 16th century brought changes. After the Battle of Mohács (1526) the Ottoman Turks occupied a large part of Hungary and the country was split into three. It is in the era of the Reformation that Hungarian national literature really began. Benedek Komjáti, Gábor Pesti, and János Sylvester, all of whom were disciples of the humanist Erasmus, translated parts of the Bible with philological accuracy. Pesti made a very readable translation of Aesop's fables and published a Latin-Hungarian dictionary. Sylvester published the first Hungarian grammar and, to show the adaptability of the vernacular to classical verse forms, wrote the first Hungarian poem in couplets. In 1541 he published a translation of the New Testament.

Hungarian Reforma-

The second half of the 16th century saw the beginnings of Hungarian drama. Comoedia Balassi Menyhárt árultátásáról (1569; "Comedy on the Treachery of Menyhárt Balassi"), a satire by an unknown author, was among the most interesting literary achievements of the Reformation. Péter Bornemisza, the first important Protestant writer in Hungary, gave an entrancing view of Hungarian life, teeming with fresh observations, vivid descriptions, and original comments. His volume Ördögi Kisértetekről (1578; "On the Temptations of the Devil") offered an interesting consideration of moral and sexual problems in the 16th century. A poem of farewell, written on leaving the country, was one of the gems of early Hungarian poetry. His Tragoedia magyar nyelven (1558; "Tragedy in Hungarian"), though based on Sophocles' Electra, is a skillful adaptation of the play in the spirit of humanism.

Perhaps the greatest single literary achievement of the Hungarian Reformation was a translation of the Bible by Gáspár Károlyi and others (1590). The translation played a role in the development of Hungarian similar to that of

the Authorized Version in English.

Up to the 16th century religious literature seems to have fared better than secular literature, in part because secular literature was not written down. The late 16th-century minstrels were more learned than their predecessors and in many cases were driven to their profession by difficult economic conditions. Perhaps the most important was Sebestyén Tinódi, by temperament more historian than poet. He described the wars against the Turks with remarkable accuracy, but his verse was monotonous. Péter Ilosvai Selymes was the author of a romance, Az hires nevezetes Toldi Miklósnak jeles cselekedetiről (1574; "The Story of the Remarkable Nicholas Toldi's Extraordinary and Brave Deeds"), which achieved great popularity in Hungary and served as a basis for a masterpiece by János Arany in the 19th century. This romance was the one original piece in the flow of the mere entertainment literature characteristic of the 16th century, the principal genre of which was the széphistória ("beautiful story"), adapted from western European originals. Perhaps the best was the História egy Árgirus nevű királyfiról (c. 1575; "The Story of the Prince Argirus") by Albert Gergei, from an Italian original but interwoven with Hungarian folklore

A great poet emerged in Bálint Balassi (1554-94), who Bálint at first imitated Petrarch and various Neo-Latin poets but later displayed originality with a cycle of love poems of great beauty and emotional intensity. His songs of war, while reflecting the vicissitudes of fighting the Turk at the borders of the Christian world, celebrate nature and individual bravery in almost hymnlike tones. The poetry of his last years is imbued with a deep religious feeling; the imagery of the poems of his last creative period (the Coelie cycle of love songs as well as his religious verse) is coloured by Mannerism.

THE 17TH CENTURY

In the 17th century Hungary was still divided into three parts. The first, under Turkish rule, played no part in the

Memoire

epistolary

works

development of Hungarian literature. The second, under Habsburg rule, was open to Italian and German Roman Catholic influence; the third, Transylvania, was in close relationship with Dutch and English Protestant thought. The leading Protestant scholar and writer of the 17th century was János Apáczai Csere. His chief work was a Hungarian encyclopaedia in which he endeavoured to sum up the knowledge of his time. The work, published at Utrecht in 1653, marked a development in technical vocabulary.

Effects of the Counter-Reformation. By the end of the 16th century the Counter-Reformation was gaining momentum in western Hungary. A Jesuit cardinal, Péter Pázmány, a master of Hungarian prose, was outstanding as an orator and essayist. His writing was characterized by a vigorous and clear, though far from simple, style, use of popular expressions, and solid argument. His Isteni igazságra vezérlő kalauz (1613; "Guide to Divine Truth") was a refutation of non-Catholic religious doctrines and a

masterpiece of Baroque prose.

Under the influence of the Jesuits, many Hungarian aristocrats returned to the Catholic faith and sent their sons to the Austrian Catholic universities and to Rome. The Italian Baroque, especially the influence of Tasso and Marino, is evident in the work of Miklós Zrínyi, a great Hungarian statesman and military commander. Most of his prose work was an exposition of political and strategic ideas. His greatest literary achievement was an epic, Szigeti veszedelem (1651: "The Peril of Sziget"), in 15 cantos, on the siege in 1566 of Szigetvár, which had been defended against the Turks by Zrínyi's great-grandfather. Though the influence of classical epics is clear, the work remains profoundly original and Hungarian. Another poet of this time, István Gyöngyösi, composed long narrative poems and also many epithalamia, or nuptial poems. He was inventive and handled rhyme with ease, and his work was read widely during the 17th and 18th centuries.

Period of decline. The period between 1700 and about 1770 was a time of decline and slow consolidation in Hungarian literature. Memoirs form what is best in the prose literature of the period. Among the most absorbing are the autobiography of the well-traveled Miklós Bethlen. a leading Transylvanian statesman, and the confessions and memoirs (written in Latin and French, respectively) of Ferenc Rákóczi II, exiled prince of Transylvania and leader of the anti-Habsburg insurrection of 1703-11. The Törökországi levelek ("Letters from Turkey"), written from 1717 to 1758 by Kelemen Mikes, a companion in exile of Rákóczi, were addressed to an imaginary aunt. In choosing the epistolary genre Mikes was inspired by French models, and his work stands out for its excellent style and wry humour. The Metamorphosis Transylvaniae of Péter Apor is a nostalgic reminiscence of Transylvania.

The poetry of this epoch has little to offer. The poems of László Amade were informed by a Rococo taste, both in form and in content; he mainly wrote poetry of gallantry and courtship. Another poet and translator, the versatile Ferenc Faludi, took his expressions from popular language and folk songs.

This period of literary decadence produced notable works only in the fields of history and history of literature. Some of them were written in Latin. Among historians, Mátyás Bél, György Pray, and István Katona are most important. The first historian of Hungarian literature, Dávid Czvittinger, composed the biographies of some 300 Hungarian writers. His work was continued and improved by Péter Bod, whose Magyar Athénás (1766; "Hungarian Athenaeum") deals with more than 500 Hungarian men of letters.

THE PERIOD OF THE ENLIGHTENMENT

The Hungarian Enlightenment was more receptive to French and English ideas than it was productive of original developments. The period between about 1772 and 1825, though immensely important in the development of the Hungarian spirit, produced few writers of the first rank.

With the publication in 1772 of the first literary work by György Bessenyei, a translation (from the French) of Alexander Pope's Essay on Man, the new era began. All of Bessenyei's works served a didactic purpose. His drama Ágis tragédiáia (1772: "The Tragedy of Agis") was a somewhat creaking vehicle for his liberal ideas. His best work, Tariménes utazása (1802-04; "Tarimenes' Journey"), the first real novel in Hungarian, was a bitter attack on everything that was opposed to the Enlightenment. With destructive irony, Bessenyei, an officer of the Hungarian Guards, examined the shortcomings of contemporary society. His personal influence induced several of his fellow officers-for example, Sándor Báróczi and Ábrahám Barcsay-to try to convey the ideas of the Enlightenment in Hungarian to a Hungarian public.

Spurred on by new ideas, but basically traditionalists. József Gvadányi and András Dugonics produced amusing works that were both of some literary merit and popular. Gvadányi's best work, Egy falusi nótáriusnak budai utazása (1790; "The Journey to Buda of a Village Notary"), is a defense of national and traditional values against encroaching foreign ideas. The novel Etelka (1788), by Dugonics, a sentimental love story in a historical setting, was the first Hungarian best-seller. Both Gvadányi and Dugonics used the language of the common people and this was perhaps their greatest merit. Adám Pálóczi Horváth left a collection of 450 poems, a treasure-house

of authentic folk songs.

The end of the 18th century was a period of experiments with poetic language. The pioneers of the use of Greek and Latin metres in Hungarian verse (to which they are eminently suited) were followed by Benedek Virág, who imbued with poetic inspiration verse forms that for his predecessors were merely formal exercises. It fell to Dániel Berzsenyi, who published a single volume of poetry, in 1813, to show what use a great poet could make of classical metre. His ode "A Magyarokhoz" ("To the Hungarians"), his "Fohász" ("Prayer"), and his elegy "A közelitő tél" ("On the Nearing Winter") express the transitoriness of power and of friendship.

The ideas of the Enlightenment were not universally welcomed in Hungary. Traditionalist elements looked with distrust on any imported ideas, and the government was increasingly suspicious of a spirit of intellectual freedom. which it believed had led to the French Revolution and, in Hungary, to the Jacobin conspiracy of Martinovics, crushed in 1794. Several writers went to prison for harbouring radical views. The most talented among them, János Batsányi, secured his place in the history of Hungarian literature by his poem "A Franciaországi változásokra" (1789; "On the Changes in France"), a vigorous warning to all tyrants "to cast their watchful eyes on Paris.

Sentimentalism found its exponents in József Kármán and Gábor Dayka. Kármán's only work of importance, Fanni hagyományai (1794: "The Memoirs of Fanny"), is a novel of sentiment written in the form of letters and diary entries. Very much on the lines of Goethe's Werther, the work nevertheless marks an important step in the history of the Hungarian novel. Dayka, who was a poet, died too young for the full measure of his talent to be realized.

The first important lyric poet since Bálint Balassi was Mihály Csokonai Vitéz, who continued the purely Hungarian poetical tradition. His many songs to a woman named Lilla are a happy blend of playful grace and subtle thoughts. The influence of Rousseau is very noticeable in some of his longer philosophical poems. Alexander Pope's Rape of the Lock served as a source of inspiration for Csokonai's comic epic Dorottya (1804), but Csokonai's poem is original and his context very Hungarian. The language of the poem is vigorous, even vulgar, and the plot is full of hilariously comic situations.

The place of Sándor Kisfaludy in Hungarian literature is secured by his first work, Kesergő szerelem (1801; "Bitter Love"), a lyric cycle depending on a very thin narrative thread. Writing in an elaborate verse form of 12 lines, called the Himfy verse, which he devised himself, Kisfaludy displayed great ingenuity in finding new variations on the theme of unhappy love.

Ferenc Kazinczy, a mediocre poet but an influential man of letters, was the pivot of literary life for about 40 years. For his involvement in the conspiracy of Martinovics he paid with six years' imprisonment. He wanted a literature refined and limpid, neither baroque nor popular, and his

Ferenc Kazinczy

national

theatre

interest was focused on style. He became the head of the neologi, or linguistic innovators, who tried to renew and enrich the Hungarian language so that it could express the most elaborate concepts. The success of the language reform was due, to a large extent, to Kazinczy's efforts.

THE 19TH CENTURY

Romanticism. The literary revival initiated by Kazinczy continued after his death. The literary leadership of Hungary at the beginning of the 19th century was assumed by Károly Kisfaludy when, in 1822, he founded a literary magazine, Aurora, to which all the important writers of the period contributed. He was also the first representative of Romanticism and the first playwright to achieve pop-

While Kisfaludy's tragedies were applauded all over the country, Bánk bán (the bán was a high Hungarian dignitary), one of Hungary's best tragedies, by József Katona, was published in 1821 but, for the time being, was overlooked. Set in the 13th century and written in vigorous prose, the play was a masterful combination of national and individual conflicts, and one of its characters, Tiborc, a poor peasant, has remained ever since a symbol of the oppressed.

Ferenc Kölcsey was a deputy in the Hungarian parliament and a brilliant orator; his literary criticism was of a high standard, though unduly severe. His later poems, which were grave but vigorous in thought and expression. often dealt with national problems; his impressive "Hymnusz" (1823) became the Hungarian national anthem. After Kisfaludy's death, Mihály Vörösmarty became a central figure in literary life, producing writings of value in every genre. In particular he succeeded with a long epic poem Zalán futása (1825; "The Flight of Zalán"), written in a Romantic vein but expressing a concern for contemporary problems. This concern is evident also in many of his best lyric poems and even in his symbolic fairy play Csongor és Tünde (1831; "Csongor and Tünde"

In Hungarian literature, poetry was far ahead of drama, and the novel seemed slow in taking root. Miklós Jósika. a disciple of Sir Walter Scott, was the first successful novelist. His first and best work, the historical novel Abafi (1836), marked a turning point for the genre. József Eötvös, who after the 1848 revolution became a political theorist, produced two of the best novels in 19thcentury Hungarian literature-A falu jegyzője (1845: The Village Notary), a portrait of feudal life in his own time, and Magyarország 1514-ben (1847; "Hungary in 1514"), about György Dózsa's peasants' revolt. They possessed exceptional qualities of characterization, both of individuals and of periods, and were political manifestos in support of the oppressed and against the appalling injustices that led to revolutions-of which Eötvös nevertheless disapproved.

The folk song and ballad collections of János Erdélyi and János Kriza exerted an influence on the further development of Hungarian poetry. "Popular poetry is the only real poetry" was the opinion of Sándor Petőfi, one of the greatest Hungarian poets, whose best poems rank among the masterpieces of world literature. He was an innovator and made a break with conventional subjects and poetic language. His poems are striking in immediacy of perception and directness of language and cover a vast range of subjects. The fervour of his patriotic poems inspired the revolution of 1848. Petőfi's many songs are enchanting in their simplicity, and in this genre he remained unsurpassed.

János Arany shared Petőfi's conviction of the value of popular poetry, but his approach was different, for his subjects were often taken from history and showed deep understanding of the human mind. He had the assurance of one who knew that what he wrote was the language of the people, lifted to a degree never surpassed in Hungarian. His ballads, often romantic, had vigour, conciseness, and uncommon evocative power. His great narrative poems, the Toldi trilogy (1847-79) and Buda halála (1864; The Death of King Buda), reflected eternal human problems; Arany's philosophy appeared through his characters and not in lengthy digressions and was accompanied by subtle humour.

Writers of the late 19th century. The peaks of poetry reached by Petőfi and Arany remained inaccessible to other poets during the rest of the 19th century. Hungary, after being defeated in the war of independence of 1848-49. was ruled from Vienna until 1867. External political pressures on Austria and the willingness of Hungarian society to end passive resistance made possible the Settlement (or Compromise) of 1867, which created the Austro-Hungarian Monarchy. The post-1867 industrial boom and Hungary's fast technological and commercial development produced a mood of complacency that was first broken by László Arany (son of János), whose ironic novel in verse, A délibábok hőse (1873; "The Hero of the Mirages"), is representative of the mood of disillusionment. Another poet, János Vajda, bridged the gap between the romantic populism of Petőfi and fin-de-siècle decadence: a gloomy visionary, with equal propensity for self-pity and selfaggrandizement, he was nevertheless an important innovator in the field of metaphor and poetic imagery.

In 1837 a national theatre was established to produce works of merit, but, with few exceptions, the standard of plays was low. Ede Szigligeti, a prolific playwright, wrote entertaining comedies and created a special genre of plays. the népszinmű, that give an idealized picture of village life but also contain a measure of social criticism. Very different were the plays of Imre Madách, whose masterpiece Az ember tragédiája (1861; The Tragedy of Man) dealt with universal human problems. This poetic drama followed man's destiny from creation through stages of history into a future of a phalanstery (a Utopian commune) and the ultimate extinction of life. The play was first staged in

1883 and remains a favourite with the Hungarian public. The first outstanding novelist, Zsigmond Kemény, displayed, in such novels as Zord idő (1862; "Grim Times"), A rajongók (1858-59: "The Fanatics"), and Féri és nő (1852; "Husband and Wife"), a masterly skill in psychological analysis. His characters' own deeds determined their gloomy ends. Analysis often took the place of action in Kemény's novels, which were therefore difficult to read and not popular. On the other hand, Mór Jókai was a popular Hungarian novelist, an exceptional storyteller able to evoke any epoch and any milieu. His characters were idealized, and his descriptions tended to be brilliant rather than accurate. Among his numerous works (he published more than 200 books in his lifetime) were historical novels on problems of contemporary society. Az arany ember (1873; "That Golden Man"; Eng. trans., Timár's Two Worlds) is one of his best novels. Kálmán Mikszáth was also popular; he recorded with keen observation and sly humour the shortcomings of society but, although a politician and a member of parliament, was little concerned with improvement. Though the principal works of Géza Gárdonyi were published early in the 20th century, they belonged to the 19th century. Egri csillagok (1901; "The Stars of Eger") and A láthatatlan ember (1902; "The Invisible Man"; Eng. trans., Slave of the Huns) were well

During the 19th century, literary life in Hungary became organized to some extent: the Kisfaludy and Petőfi societies, founded in 1836 and 1876, respectively, were particularly influential, though the authority of the Hungarian Academy, founded in 1825, remained unchallenged. The principal critic of the second half of the century was Pál Gyulai. Literary criticism and the history of Hungarian literature attracted some of the best minds, including Jenő Péterfy and Frigyes Riedl.

The last third of the 19th century in Hungary was an era of literary decline in which writers based their work on social and political ideals that were becoming sterile. The great majority of Hungarian writers came from the nobility and lived as part of the middle class; only at the end of the century did lower-middle-class writers come to the fore. The periodical A hét ("The Week"), founded in 1890 by József Kiss, became the organ of a number of gifted writers, including Zoltán Ambrus and Sándor Bródy.

THE 20TH CENTURY

Early years. The year 1906, when Endre Ady burst upon the literary scene with his Uj versek ("New Poems"),

Hungarian novels

marked a turning point. In matters of style Ady was influenced by the French Symbolists, but in content he was concerned with radical political ideas. He rejuvenated the language of Hungarian poetry, introducing new themes and powerful new imagery. His rise was helped by the periodical Nyugat ("The West"), which was launched in 1908 under the editorship of Hugo Ignotus, Miksa Fenyő, and Ernő Osvát. Among poets associated with Nyugat were Mihály Babits, an excellent translator of foreign poetry who became editor in 1929; Dezső Kosztolányi, who wrote with empathy on childhood and death and whose novels and short stories established high standards in narrative prose; and Árpád Tóth and Gyula Juhász, who voiced the distress of the poor and the oppressed in society. A fifth poet. Milán Füst, wrote little, but the dramatic metaphors and sonorous language of the work he did produce made his a lasting influence. In addition to his poetry he wrote an outstanding novel, A feleségem története (1942; "The Story of My Wife").

The prose writers of Nyugat included Zsigmond Môricz, whose tales of provincial life portrayed peasants and gentry; Margit Kaffka, the first major woman writer in Hungary; and Gyula Krúdy, who created a nostalgic dreamworld with his stream-of-consciousness technique.

Writers not connected with Nyugat included the versatile Ferenc Molnár, who, after a promising start as a writer of fiction, began to write cleverly constructed social comedies. A conservative-nationalist group of writers was highly influential before 1918; its principal figure was Ferenc Herczeg, an author of novels and plays. During World War I and the years of revolution that followed, two authors emerged to challenge both the old establishment and Nyugat. These were Laios Kassák, the first significant poet of the Hungarian avant-garde, who also wrote a remarkable autobiography depicting working-class life at the beginning of the century; and Dezső Szabó, whose large, uneven expressionistic novel Az elsodort falu (1919; "The Village That Was Swept Away") combined antiwar sentiment with a romantic cult of the peasantry. First embraced and then rejected by the post-1919 counterrevolution, Szabó is best remembered as a witty though venomous pamphleteer.

The interwar period. The interwar period saw a flowering of Hungarian letters. Although the influence of Nyagad diminished, neither the populist V falasz ("The Response") nor the left-wing Sz ϕ p sz ϕ ("Fine Word") could quite supplant it. The leading poet of the 1920s was L δ nien Szab δ , a master of poetic technique and fine observation, whereas the 1930s were dominated by Attlia J δ ses f, whose experience of alienation and Socialist ideas were expressed in great poetic tableaux and in poems probing the sub-conscious, and by Gyula Illyés, who found inspiration in the life of the peasantry. The poetry of Miklôs Radnôti reached a tragic climax in the serene and polished poems he wrote in the last years of his life.

In Hungary, as elsewhere, the novel became the principal form of literary expression. While Sándor Márai and Lajos Zilahy depicted the life of the bourgeoisie, János Kodolányi, László Németh, and Zsigmond Remenyik exposed the conflicts of the individual with society (often against a background of injustice and misery). Aron Tamási wrote beautifully stylized novels on the life of the Szeklers, an ethnic group of Transvlvania. Tibor Dérv. whose chief work was published only after 1945, wrote realistic novels and a challenging autobiography. The foremost essayist of the period was László Németh, whose A minőség forradalma (1940; "The Revolution of Quality") remained a seminal influence for many years to come. Other essayists and literary historians active in this era included a particularly brilliant writer, Antal Szerb, and Gábor Halász (both died in forced labour camps in 1945) and László Cs. Szabó.

Writing after 1945. The period since 1945, though officially designated one of "Socialist transformation," has seen but little change in writers' traditional orientations and preoccupations. During the first decade, particularly the years 1948-53, many writers were forced into silence by the regime's attempts to introduce Socialist Realism as the only correct style and creative method. After the failure of the 1956 uprising a number of writers were imprisoned, but by the mid-1960s most efforts to enforce ideological purity in the arts were abandoned. Since then there has been comparatively little official intervention in Hungarian literature and the margin of free experimentation has grown. This allowed writers such as Géza Ottlik, Miklós Mészöly, and István Örkény to publish work that showed ways in which the technique of modern fiction could be applied in Hungary. Among the best new authors were György Konrád and Péter Esterházy. Konrád's novels A látogató (1969; The Case Worker), A városalapító (1977; The City Builder), and the unofficially published A cinkos (1982; The Loser) achieved great impact with their dense, poetically structured style and analytical probing into the world of the social caseworker, the planner of new society, and the mental institution. Esterházy's most successful novel to date, Termelési regény (kisssregény) (1979: "Production Novel (a Ssshort [sic] Novel)"), is a grotesque and refreshingly irreverent survey of Hungarian life and society.

Among the adherents of realistic fiction, József Lengyel, who died in 1975, occupied a special place. In his stories (which could not be published until the loosening of restrictions in the early 1960s) he gave a moving testimony of human suffering in Soviet labour camps.

The best poetry was written by Sándor Weöres, whose poetic span ranges from Eastern philosophy to delightful children's verses, and János Pilinszky, an Existentialist Catholic whose most memorable poems deal with the experience of what he called the "universe of camps" produced by World War II. Other noteworthy poets included the urbane Läszlö Kälnoky and István Vas, and Ferene Juhász and Lászlö Nagy, two poets of peasant origin whose work grew out of native tradition to express universal rites and myths of mankind such as marriage, the struggle among generations for power, and cosmic destruction.

Frontier changes since World War I have placed substantial Hungarian minorities in countries outside Hungary, especially in neighbouring Czechoslovakia, Yugoslavia, and Romania. In Romania, for example, where approximately 2,000,000 Hungarians live, the best known Hungarian writer is the playwright and novelist András Süíö. There also has been a large diaspora in the West, where, apart from Marai, the versatile modernist Győző Határ and the post-Romantic poet Győrgy Faludy have the largest following. The Munich-based cultural review Uj láióhatár ("New Horizon") has enjoyed the longest uninterrupted existence among Hungarian periodicals inside or outside of Hungary.

BIBLIOGRAPHY. ALBERT TEZLA, An Introductory Bibliography to the Study of Hungarian Literature (1964), and Hungarian Authors: A Bibliographical Handbook (1970), are annotated sources on items available from major U.S. and European book collections. ANTAL SZERB, Magyar irodalomtörténet, 6th ed. (1978), is an informative history, an earlier edition of which is available also in a German translation: Ungarische Literaturgeschichte, 2 vol. (1975). An exhaustive historical coverage is provided in ISTVÁN SÖTÉR (ed.), A magyar irodalom története, 6 vol. (1964-66). BÉLA POMOGÁTS, Az újabb magyar irodalom, 1945-1981 (1982), is an informative critical study of 20th-century literature. In English, see D. MERVYN JONES, Five Hungarian Writers (1966), which gives a detailed analysis of the works of the writers Miklós Zrínyi, Kelemen Mikes, Mihály Vörösmarty, József Eötvös, and Sándor Petőfi. TIBOR KLAN-ICZAY (ed.), A History of Hungarian Literature (1982; originally published in Hungarian, 1982), provides broad coverage. Ló-RANT CZIGANY, The Oxford History of Hungarian Literature from the Earliest Times to the Present (1984), is a comprehensive chronologically arranged work, with emphasis on the 19th and 20th centuries.

Hungary

ocated in the heart of Europe and occupying part of the Carpathian Basin, Hungary (in full, the Republic of Hungary; Hungarian: Magyar Köztársaság) has an area of 35,919 square miles (93,030 square kilometres). The nation has ethnic and linguistic roots that reach far back into the past. Its boundaries, however, have changed repeatedly over the centuries as events in Europe precipitated the reduction, expansion, and partition of Hungarian territory.

Modern Hungary shares a border to the north with Slovakia, to the northeast with Ukraine, to the east with Romania, to the south with Serbia and Montenegro (the Vojvodina region of Serbia) and Croatia, to the southwest with Slovenia, and to the west with Austria. Budapest, the capital city, which dominates much of national life, is situated on both banks of the Danube (Hungarian: Duna) River just downstream from the Danube Bend.

THE LAND

The Great and Little Alfolds

Relief. Dominating the relief are the great lowland expanses that make up the core of Hungary. The Little Alfold (Little Hungarian Plain, or Kis Alföld) lies in the northwest, fringed on the west by the easternmost extension of the sub-Alps along the border with Austria and bounded on the north by the Danube. The Little Alfold is separated from the Great Alfold (Great Hungarian Plain, or Nagy Magyar Alföld) by a low mountain system extending across the country from southwest to northeast for a distance of 250 miles (400 kilometres). This system, the backbone of the country, is made up of Transdanubia (Dunantul) and the Northern Mountains, separated by the Visegrad Gorge of the Danube. The former is dominated by the Bakony Mountains, with dolomite and limestone plateaus at elevations between 1,300 and 2,300 feet (400 and 700 metres) above sea level interspersed with volcanic peaks; the latter, which consist of volcanic rocks, comprise the Mátra Mountains in the north, reaching a height of 3,327 feet (1,014 metres) at Mount Kékes, the nation's highest peak. Regions of hills reaching elevations of 800 to 1,000 feet lie on either side of the mountain backbone, while to the south and west of Lake Balaton is an upland region of more subdued, loess-covered topography. The Great Alfold covers most of central and southeastern Hungary. Like its northwestern counterpart, it is a basinlike structure filled with fluvial and windblown deposits. Four types of surface may be distinguished: floodplains, composed of river alluvium; alluvial fans, wedge-shaped features deposited at the breaks of slopes where rivers emerge from the mountain rim; alluvial fans overlain by sand dunes: and plains buried under loess, deposits of windblown material derived from the continental interior. These lowlands range in height from about 260 to 660 feet above sea level, with the lowest point at 256 feet, on the southern edge of Szeged, along the Tisza River.

Drainage and soils. Hungary lies within the drainage basin of the Danube. The Danube and two of its tributaries, the Rába and the Drava, are of Alpine origin, while the Tisza and its tributaries, which drain much of eastern Hungary, rise in the Carpathian Mountains to the east.

The Danube floods regularly twice a year, first in early spring and again in early summer. During these phases discharge is up to 10 times greater than that recorded during the low-water periods of autumn and winter. The Tisza forms a floodplain as it flows through Hungary, and large meanders and oxbow lakes marking former channels are typical features. Devastating floods have occurred on the Danube, the Tisza, and their tributaries. About 2,500 miles of levees have been built to protect against floods. The relatively dry climate of the central and eastern areas of the Great Alfold has necessitated the construction of large-scale irrigation systems, mostly along the Tisza River.

There are few lakes in Hungary, and most are small. Lake Balaton, however, is the largest freshwater lake in central Europe, at 231 square miles (598 square kilometres). Lake Fertő (Neusiedler Lake) lies on the Austrian border, and Lake Velence lies southeast of Budapest.

Gray-brown podzolic (leached) and brown forest soils predominate in the forest zones, while rich black-earth, or chernozem, soil has developed under the forest steppe. Sand dunes and dispersed alkali soils are also characteristic. Climate. Because of its situation within the Carpathian Basin, Hungary has a moderately dry continental climate.

Temperatures

The mean annual temperature is about 50° F (10° C). Average temperatures range from 32° to 25° F (0° to 4° C) in January to 64° to 73° F (18° to 23° C) in July. Recorded temperature extremes are 109° F (43° C) in summer and -29° F (-34° C) in winter. In the lowlands, precipitation generally ranges from 20 to 24 inches (500 to 600 millimetres), rising to 24 to 31 inches over higher elevations. The central and eastern areas of the Great Alfold are the driest and the southwestern uplands the wettest part of the country. As much as two-thirds of annual precipitation falls during the growing season.

Plant and animal life. Human activities over the ages have largely destroyed the natural vegetation of Hungary. More than half of the land is regularly cultivated, and a sixth is used for nonagricultural purposes. The remainder comprises meadows and rough pasture and forest and woodland. No part of the country is of sufficient elevation to support natural coniferous forest, beech being the climax species at the highest elevations and oak woodland alternating with scrubby grassland being the climax at lower elevations in the upland regions.

Deer and wild pigs are abundant in the forests at higher elevations, while rodents, hares, partridge, and pheasant inhabit the lowlands. The once numerous varieties of marsh waterfowl survive only in nature reserves. There are diverse species of freshwater fish, including pike, bream, and pike perch. Significant water and air pollution occurs in some of the industrial regions of the country.

Settlement patterns. Traditional regions. Alfold is the largest region of the country. It is divided into two parts: Kiskunság, the area lying between the Danube and Tisza rivers, and Transtisza (Tiszántúl), the region east of the Tisza. The former consists primarily of a mosaic of small landscape elements-sand dunes, loess plains, and floodplains. Kecskemét is the market centre for the region, which is also noted for its isolated farmsteads, known as tanvák. Several interesting groups live there, including the people of Kalocsa and the Matyó, who occupy the northern part of the plain around Mezőkövesd and are noted for hand embroidery and multicoloured costumes. In the generally homogeneous flat plain of the Transtisza region, only the Nyírség region in the northeast presents any form of topographical contrast. Closely connected with this latter area are the Hajdúság and the Hortobágy regions, and all three areas look to Debrecen, the largest city of the plain. The Hortobágy presents an interesting survival of the steppe life of earlier times, since the original Hungarian cattle, horse, and sheep breeds have been preserved there as part of the national heritage.

The Little Alfold, the second major natural region, is situated in the northwest and is traversed by the Danube and Rába rivers and their tributaries. It is more favourably endowed with natural resources than is the Great Alfold; both agriculture and industry are more advanced there. Győr is the major city of the region.

The third major region, Transdanubia, embraces all the country west of the Danube exclusive of the Little Alfold. It is a rolling upland broken by the Bakony and

Mecsek ridges. Lake Balaton is a leading resort area. To the south of the lake are the hills of Somogy, Tolna, and Baranya counties, where Pécs, a mining and industrial city, is the economic and cultural centre. Also found in Transdanubia are the Bakony Mountains, whose isolation, densely forested ridges, small closed basins, and medieval fortresses and monasteries have protected the local inhabitants over the course of many stormy centuries. Although modern industrial towns drawing on the bauxite, manganese, and brown coal resources of the area have sprung up, the cultural centre of Transdanubia is the historic city of Veszprém. In the southern part of the region, north and west of Lake Balaton, are health resorts and centres of wine production, notably Keszthely, Hévíz, Badacsony, and Balatonfüred.

The Northern Mountains, the fourth major geographic region of the country, contain two important industrial areas, the Nógrád and Borsod basins. Agriculture is important, especially viticulture, including the well-known Tokai (Tokay) and Eger vineyards, Tourism is well-developed. and numerous spas and recreation centres are located there. Miskolc is the main economic centre for the region. Urban settlement. Nearly two-thirds of the population

is urban, but the majority of towns in Hungary have populations of less than 40,000. They were functionally, until the late 20th century, vastly overgrown villages rather than towns. About one-third of the urban population lives within the Budapest metropolitan area.

Urban Hungary is dominated by Budapest, which is several times the size of other major cities. It has the largest industrial workforce in the country. The major provincial centres are Miskolc, Debrecen, Szeged, Pécs, and Győr, each of which has a population exceeding 100,000; an economic, cultural, and administrative hinterland that reaches deep into the surrounding countryside; and an expanding industrial capacity. Below the provincial centres in the hierarchy are the traditional market towns, such as Kecskemét, Székesfehérvár, Nyíregyháza, Szombathely, and Szolnok, with new suburbs added to medieval or Baroque town centres. Also worthy of note are the predominantly industrial towns located close to the mineral resources of the Northern Mountains, which, from small beginnings in the late 19th century, have developed into major industrial centres. They include Tatabánya, Salgótarján, and Ózd. In addition, a number of industrial towns were created in the late 20th century on green-field sites as part of deliberate planning policy. These include the metallurgical centre of Dunaújváros on the Danube and the chemical centre of Kazincbarcika in eastern Hungary.

Rural settlement. The distribution of rural population varies widely from one part of the country to another. For historical reasons connected with resettlement following the Turkish occupation in the 16th century, the compact villages of the Great Alfold are small in number but large in size. By comparison, rural settlement in Transdanubia and in the Northern Mountains takes the form of many small nucleated and linear villages. The tanyak tend to be concentrated in the Great Alfold.

population distribu-

Transdanubia Language

THE PEOPLI

Ethnic and religious structure. From its inception in the 11th century, the Kingdom of Hungary was a multiethnic country. Major territorial changes made Hungary ethnically homogenous after World War I, however, and more than nine-tenths of the population is now ethnically Hungarian and speaks Hungarian (Magyar) as its mother tongue. The Hungarian language is classified as a member of the Ugric branch of the Uralic languages; as such it is most closely related to the Ob-Ugric languages, Khanty and Mansi, which are spoken east of the Ural Mountains. It is also related, though more distantly, to Finnish and Estonian, each of which is (like Hungarian) a national language; to the Sami languages of far northern Scandinavia; and, more distantly still, to the Samoyedic languages of Siberia. Ethnic Hungarians are a mix of the Finno-Ugric Magyars and various assimilated Slavic, Turkish, and Germanic peoples. About 3 percent of the population is Gypsy (Rom), and nearly another 5 percent is made up of Slovaks, Romanians, Croats, Germans, and others.

More than two-thirds of the people are Roman Catholic, most of them living in the western and northern parts of the country. About one-fifth of the population is Calvinist (concentrated in eastern Hungary), and relatively smaller groups belong to various Christian denominations (Lutherans, Greek Catholics, Eastern Orthodox, and Unitarians). The Jewish community, which constituted 5 percent of the population before World War II, has represented less than 1 percent of the population since the Holocaust.

Demographic trends. Owing to major changes in Hungary's borders following World War, I, the republic's population decreased to less than eight million. Since then population growth has been rather slow, as both birth and death rates generally declined in the post-World War II years, though the latter returned to prewar levels by the mid-1980s. Life expectancy for women increased consistently from the 1930s; that for men also increased until the 1970s, when the trend reversed, and women now outlive men by about 10 years.

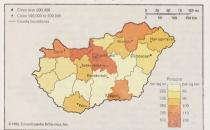

The population reached its peak in 1980 at some 10.7 million, but, because death rates exceeded birth rates, it decreased thereafter. Demographic trends were influenced by the modernization process and by a rate of suicide that was among the highest in the world.

Roughly three million Hungarians live in the neighbouring countries of Romania, Slowakia, Croatia, and Serbia.

Emigration As a consequence of a net overseas emigration of 1.3
million people before World War I and a continuous,
though much smaller, emigration related to major political upheavals in 1918–19, the 1930s, 1944, and 1956,
large Hungarian communities live in North America and
western Europe. After the collapse of communism and the
splintering of Yugoslaviar, roughly 100,000 refugees immigrated to Hungary from Romania and the former Yugoslav federation. Half of them were ethnic Hungarians.

THE ECONOMY

Overview. Hungary remained mostly agrarian until World War II. Beginning in 1948, a forced industrial-

Population density of Hungary.

ization policy based on the Soviet pattern changed the economic character of the country. A centrally planned economy was introduced and millions of new jobs were created in industry (notably for nonworking women) and, later, in services. This was accomplished largely through a policy of forced accumulation: keeping wages low and the prices of consumer goods (as opposed to staples) high made it possible for more people to be employed, and, because consumer goods were beyond their means, most Hungarians put more of their earnings in savings, which became available for use by the government. In the process the proportion of the population employed in agriculture declined from more than half to one-eighth by the 1990s, while the industrial workforce grew to nearly a third of the economically active population by the late 1980s.

Although Soviet-type economic modernization generated rapid growth, it was based on an early 20th-century structural pattern and on outdated technology. The heavy industries of iron, steel, and engineering were given the highest priority, while modern infrastructure, services, and communication were neglected. Moreover, the lack of enterpreneurial interest and market incentives prevented the development of new technologies and high-tech industries, as did Western restrictions (the Coordinating Committee for Multilateral Export Controls) on the export of modern technology to the Soviet bloc

In the late 1960s a mixed economy was introduced in Hungary. Market prices and incentives gradually gained ground, and a partial privatization program was initiated. By the end of the 1980s one-third of the gross domestic product (GDP)—nearly three-fifths of services and more than three-fourths of construction—was being generated by private business. The Hungarian economy, however, failed to meet the challenge of the world economic crisis after 1973. The dramatic price increases for oil and modern technology created a large external trade deficit, which led to increasing foreign indebtedness. Growth slowed down and inflation rose, leading to a period of stagilation.

After 1989 Hungary's emerging market and parliamentary systems inherited a crisis-ridden economy with an enormous external debt and noncompetitive export sectors. Hungary turned to the world market and restructured its foreign trade, but market competition, together with a sudden and radical opening of the country and the abolition of state subsidies, led to further economic decline. Agriculture was drastically affected and declined by half, A large portion of the iron, steel, and engineering sectors, especially in northeastern Hungary, collapsed. Industrial output and GDP decreased by 30 percent and 25 percent, respectively. Unemployment, previously nonexistent, rose to 14 percent in the early 1990s but declined after 1994. By the mid-1990s the economy was again growing, but only moderately. Inflation peaked in 1991 and remained high, at more than 20 percent annually, until the second half of the decade. As a consequence of unavoidable austerity measures that included the elimination of many welfare institutions, most of the population lost its previous security; the number of people living below the subsistence level increased from 10 to about 30 percent of the population between 1988 and 1995. Adjustment to the world economy, however, is evident. Major multinational companies made investments in Hungary that represented more than half of the entire international capital investment in central and eastern Europe in the first half of the 1990s. Modernization of telecommunications also began. and new modern industries (e.g., automobile manufacturing) emerged. Significantly, some 750,000 small-scale, mostly family-owned enterprises were established, while state ownership of businesses declined to roughly onefifth. Another important contributor to economic growth has been a flourishing tourist industry, as the number of foreign tourists reached more than 20 million by the mid-

Resources. The most important natural endowments of Hungary, particularly in its western and central areas, are its fertile soil and abundant water resources (notably Lake Balaton, a major asset for tourism). Half of the country's land is arable, and less than one-fifth is covered by woods. The climate is also favourable for agriculture.

Period of transition Oil and natural gas were discovered in the late 1930s in Transdanubia and during the postwar decades at several localities in the Great Affold. Their share of energy production increased from one-third to one-half between 1970 and 1990; however, Hungary is able to meet only a fraction of its oil requirements with domestic resources.

The country's only significant mineral resources are bauxite—of which Hungary has some of the richest deposits in Europe—manganese, in the Bakony Mountains, and the undeveloped copper and zinc resources at Recsk. Extraction of various metal-bearing ores increased significantly in postwar Hungary, but iron ore is no longer mined. Other minerals that are found include mercury, lead, uranium, perlite, molybdenum, diatomite, kaolin, bentonite, zocilie, and dolomite.

Agriculture. Agriculture's role in the Hungarian economy declined steadily following World War II, dropping from half of the GDP in the immediate postwar period to less than one-tenth by the mid-1990s. Nevertheless, agriculture remains a leading economic sector. Two-thirds of the total area of the country is under cultivation, and Hungary is virtually self-sufficient in food production. Agriculture accounted for nearly one-fourth of Hungarian exports before the economic transition of the 1990s, during which animal stocks decreased by one-third and agricultural output and exports declined by half.

After the initial period of collectivization (1948-61), Hungarian cooperatives incorporated private farming. Private plots comprised roughly one-eighth of a cooperative's land and produced one-third of the country's agricultural output. One-fifth of Hungarian farmland belonged to state farms. Since 1990 the land has been reprivatized. Although farmers are owners of their land, many among the mostly elderly agricultural population remain in reorganized collective farms, producing one-third of agricultural output. Private farms, however, are the norm and produce more than half of the output.

Cereals, primarily wheat and corn (maize), are the republic's most important crops. Other major crops are sugar beets, sunflower seeds, potatoes, and fruit. Viticulture, found in the Northern Mountain region, is also significant. Cattle, sheep, pigs, and poultry are raised in Hungary, but, in response to the government's efforts occupant of the production of animal products, substantial reductions in livestock occurred in the 1990s.

Industry. As a result of the policy of forced industrialization under communism, industry experienced an exceptionally high growth rate until the late 1980s, by which time it constituted two-fifths of GDP. Mining and metallurgy, as well as the chemical and engineering industries, grew in leaps and bounds as the preferred sectors of Hungary's planned economy. Indeed, half of industrial output was produced by these three sectors. Without the implementation of modern technology and an efficient structure, however, Hungarian industry was not prepared to compete in the global economy after the collapse of state socialism. During the first half of the 1990s, industrial employment dropped to one-fourth of the economically active population. Total output declined by nearly onethird, with output in the mining, metallurgy, and engineering industries decreasing by half.

As industry and the Hungarian economy in general underwent restructuring and modernization during the learly 1990s (including the implementation of privatization and the improvement of the quality of goods and services), some industries adapted more successfully to new conditions. Among the industries that regressed least and showed the first signs of growth were the food, tobacco, and wood and paper industries. Of Hungary's traditionally strong sectors, the chemical industry showed the greatest resilience, demonstrating growth again by the mid-1990s after experiencing a large drop in production (25 percent) early in the deeade, Partly through foreign investment, the

machine industry also showed signs of improvement by the mid-1990s. A number of newer industries, including the production and repair of telecommunication equipment and the automobile industry, showed significant growth.

Between 1950 and 1990, electric-power consumption in Hungary increased 10-fold, and by the 1990s more than one-third of industrial output was produced by the energy sector. Because nearly two-thirds of energy consumption is derived from thermal plants burning hydrocarbons (most of which must be imported), nuclear power is growing in importance, accounting for nearly one-fourth of energy production by the early 1990s. As the republic sought to reduce its dependency on foreign oil, a number of power plants were converted from oil to coal. A small percentage of power generation consists of hydroclectricity.

Finance. Under the Soviet-style, single-ter banking system, the National Bank both issued money and monopolized the financing of the entire Hungarian economy, Beginning in 1987, Hungary moved toward a marketoriented, two-tier system in which the National Bank remained the bank of issue but in which commercial banks were established. Foreign investment was permitted, and "consortium" (partly foreign-owned) banks were formed. In 1989 a stock exchange was established. In the 1990, after the collapse of state socialism, the reform process continued with the founding of private banks, the sale of shares in state-owned banks (though most banks remained state-owned), and the enactrement of a law that guaranteed the independence of the National Bank. The currency (forint) also became entirely convertible for business.

Trade. Hungary was a charter member of the Council for Mutual Economic Assistance (Comecon; 1949-91). Under its aegis trade was conducted between the countries of the Soviet bloc on the basis of specialized production, fixed prices, and barter. The Soviet Union was Hungary's most important trading partner, but in the late 1980s and early '90s, as Hungary became increasingly involved in the global market, less than half of the republic's trade remained with Comecon. Unprepared for the competitiveness of global market forces, Hungary accrued a large trade deficit that was covered by foreign loans. In the process the country became heavily indebted and had to use much of its export earnings for repayment. Nevertheless, by the mid-1990s, three-fourths of Hungary's trade was with market economies. Germany became Hungary's most important trading partner, followed by Austria and Italy. In 1994 the republic became an associate member of the European Union, and in 1996 it joined the Organisation for Economic Co-Operation and Development.

By the mid-1990s raw materials, semifinished goods, and spare parts represented more than one-third of exports. About one-fourth of exports were industrial consumer goods and nearly another quarter consisted of agricultural and processed food products. Energy, raw materials, and semifinished products constituted more than half of the total imports. One-fifth of imports were industrial consumer goods, and another fifth consisted of machinery and capital goods (such as motor vehicles, tools, and paper).

Transportation. Railways have long been the centre of Hungary's transportation system. By World War I the country had a modern network that was among the densets in Europe, and it continued to expand regularly until the late 1970s, with electrification beginning the previous decade. When industrial production declined during the transition to a market economy, rail transport of goods dropped sharply, accompanied by significant cutbacks in government subsidies that contributed to the deterioration of the railway infrastructure.

By the mid-1990s road haulage made up an increasing percentage of overall transport of goods. Hungary has more than 18,630 miles (30,000 kilometres) of roads, and expansion of the country's highway system is a priority. Busses are the main form of passenger transportation, with long-distance bus passengers outnumbering rail passengers three to one. The number of privately owned automobiles grew rapidly after the early 1980s.

The Danube, the country's only important transportation waterway, is used primarily for international shipping, via the free port of Csepel. Air transport is limited to interna-

tional flights through Ferihegy International Airport near Budapest, MALÉV, the Hungarian national airline, was founded in 1946.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The modern political system in Hungary was essentially autocratic throughout the 19th and 20th centuries. After World War II the Soviet-style system was introduced, with a leading role for the Communist Party, to which the legislative and executive branches of the government and the legal system were subordinated. Other political parties were abolished. In 1948 the Communist Party and the Social Democratic Party merged to form the Hungarian Workers Party, which was reorganized as the Hungarian Socialist Workers Party (MSzMP) after 1956. Constitutional framework. In 1989 dramatic political reforms accompanied the economic transformation taking place. After giving up its institutionalized leading role, the MSzMP abolished itself and formed the Hungarian Socialist Party (MSzP). In October 1989 a radical revision of the 1949 constitution, which included some 100 changes, introduced a multiparty parliamentary system of representative democracy, with free elections. The legislative and executive branches of the government were separated, and an independent judicial system was created. The revision established a Constitutional Court, elected by the parliament, which reviews the constitutionality of legislation and may annul laws.

Supreme legislative power is granted to the 386-member unicameral National Assembly, which elects the president of the republic, the Council of Ministers, the president of the Supreme Court, and the chief prosecutor. The main organ of state administration is the Council of Ministers, which is headed by the prime minister. The president, who may serve two five-year terms, is commander in chief of the armed forces but otherwise has limited authority. The right of the people to propose referendums is guaranteed.

Parliamentary elections based on universal suffrage for citizens aged 18 years and over are held every four years. Under the mixed system of direct and proportional representation, candidates may be elected as part of national and regional party lists or in an individual constituency. In the latter case candidates must gain an absolute majority in the first round of the elections, or runoff elections must be held. Candidates on territorial lists cannot be elected if their party fails to receive at least 4 percent of the national aggregate of votes for the territorial lists.

Political parties. About 200 political parties were established following the revision of the constitution in 1989, but only six of them became permanent participants in the country's new political life after the first free elections (1990): the Hungarian Democratic Forum, Alliance of Free Democrats, Independent Smallholders' Party, Christian Democratic People's Party, Federation of Young Democrats, and Socialist Party.

Local government. Hungary is divided administratively into 19 counties (megyék), cities, towns, and villages. Budapest has a special status as the capital city (főváros) and is further divided into districts. Local representative governments are responsible for protection of the environment, local public transport and utilities, public security, and various economic, social, and cultural activities. Public administration offices, whose heads are appointed by the minister of the interior, supervise the legality of the operations of local governments.

Judiciary. Justice is administered by the Supreme Court, which provides conceptual guidance for the judicial activity of the Court of the Capital City and the county courts and for the local courts. A chief prosecutor is responsible for protecting the rights of citizens and prosecuting acts violating constitutional order and endangering security.

Armed forces. The Hungarian armed forces consist of ground forces, air and air defense forces, a small navy, the border guard, and police. Military service is compulsory for males over the age of 18 (its length varies according to the branch of service but is typically less than one year). The armed forces are not permitted to cross the state frontiers without the prior consent of parliament,

Education. Schools were nationalized in Hungary in

1948. Attendance of the country's extensive system of preschools and kindergartens is not mandatory, but most children attend. Education is free at all levels. It is compulsory from age 6 to 16 and includes an eight-year general education program, Secondary education, which includes both vocational training and preparation for higher education, became virtually universal by the early 1980s. Hungary's numerous institutions of higher educationwere reorganized after World War II. In addition to major institutions such as Loránd Eötvös University in Budapest. Lajos Kossuth University in Debrecen, Janus Pannonius University of Pécs, and Attila József University in Szeged, there are hundreds of specialized schools and colleges, The Central European University, an institution of postgraduate study, primarily serves students from the former Soviet bloc. Severe budget cuts during the transition period resulted in the reintroduction of tuition for higher education. Those cuts also contributed to the reestablishment of private and church-run schools and threatened the existence of the preschool system.

Health and welfare. Health care improved dramatically under state socialism, with significant increases in the number of physicians and hospital beds in Hungary. By the 1970s free health insurance was guaranteed. Private health care, permitted but limited before the transition period, grew in importance from the early 1990s.

A broad range of social services was provided by the communist government, including child support, extensive maternity leave, and an old-age pension system. This costly welfare system was a heavy burden on the country's budget. At the end of the communist era, Hungary ranked 20th among European nations in terms of per capita GDP, but it was 12th in social insurance spending. Social insurance expenditure, which constituted 4 percent of the republic's GDP in 1950, had risen to one-fifth of the GDP by 1990. The Hungarian system had become one of the most expensive in the world, yet there was considerable resistance to efforts to scale it back. Nevertheless, reform of the system in 1992 made health insurance mandatory but required employers and employees to contribute to that as well as to pension plans.

Housing. Housing shortages were constant in Hungary for years after World War II, despite the million housing units built by the state in urban centres from 1956 to 1985. By the mid-1990s, however, the average number of persons per room in Hungary dropped to roughly one (down from nearly three per room in the immediate postwar period.) Moreover, by the late 1980s electricity was available for nearly the entire population, and running water was available for more than three-fourths of homes. The construction of private homes, which had increased in the 1960s and '70s, constituted more than four-fifths of all construction by the mid-1990s, as housing became part of the market economy.

CULTURAL LIFE

The cultural milieu of Hungary is a result of the diverse mix of genuine Hungarian peasant culture and the cosmopolitan culture of an influential German and Jewish urban population. Both the coffeehouse (as meeting place for intellectuals) and Gypsy music also have had an impact. Cultural life traditionally has been highly political since national culture became the sine qua non of belated nation building from the early 19th century. Theatre, opera, and literature in particular played crucial roles in developing national consciousness. Poets and writers, especially in crisis situations, became national heroes and prophets. Governments also attempted to influence cultural life through subsidy and regulation. During the state socialist era culture was strictly controlled; party interference was influenced by ideological principles, and mass culture was promoted.

Daily life. Genuine traditional culture survived for a long period in an untouched countryside characterized by rootedness. Peasant dress, food, and entertainment, including folk songs and folk dances-the rituals of weddings and Easter and Christmas holidays-continued until the mid-20th century. The drastic (and in the countryside brutal) modernization of the second half of the 20th cenUniversi-

tury nearly destroyed these customs. They were preserved, however, as folk art and tourist entertainment.

Everyday life changed dramatically, as did the family structure. Families became smaller, and ties with extended families driminished. The culture also became less traditional. Clothing styles began to follow the international pattern, and traditional peasant dress was replaced by blue jeans. Folk songs are still occasionally heard, but in daily life they have been replaced by modern rock and pop music. Urban culture, especially in the capital city, is highly cosmopolitan and encompasses the tradition of coffee

house culture. Watching television is a popular pastime. Hungary's most traditional cultural element is its cuisine. Hungarian food is very rich, and red meat is frequently used as an ingredient. Goulash (gulyás), bean soup with smoked meat, and beef stew are national dishes. The most distinctive element of Hungarian cuisine is paprika, a spice made from the pods of chili peppers (Cansicum annuum). Paprika is not native to Hungary-having been imported either from Spain, India by way of the Turks. or the Americas-but it is a fixture on most dining tables in Hungary and an important export, Among Hungary's spicy dishes are halászle, a fish soup, and lecsó, made with hot paprika, tomato, and sausage. Homemade spirits, including various fruit brandies (pálinka), are popular, Before World War II, Hungary was a wine-drinking country, but beer has become increasingly prevalent,

Cuicine

Arts. Traditional folk arts either have disappeared or have become mostly commercialized, and political attempts in the 1930s, '50s, and '70s to preserve them basically failed. Beginning in the 19th century, a national high culture emerged, with literature taking a central role. Ferenc Kazinczy, an advocate of Enlightenment ideas. founded a movement of language reform and promoted literature through his high standard of literary criticism. In his view, literature was a nation-sustaining or even nation-creating force. A newly born literary language was cultivated by Mihály Csokonai Vitéz's rococo poetry and plays. Hungarian drama was born with József Katona's tragedy Bánk Bán. The brothers Károly and Sándor Kisfaludy established the Hungarian novel, and the first Hungarian language newspaper, Hazai Tudósítások, appeared in 1806. Among other important 19th- and early 20th-century literary figures were the poets Sándor Petőfi. János Arany, and Endre Adv. In the Discovery of Hungary series of books written in the 1930s, Gyula Illyés, Ferenc Erdei, and others explored the reality of peasant life. In 1956 writers who had been forced to follow the strict rules of Socialist Realism joined the revolt against the regime; the literary and political contributions of Tibor Déry and István Örkény were particulary significant, Notable among the vounger generation of writers that followed are Péter Nádás and Péter Esterházy,

Most of the important achievements in Hungarian visual arts and music emerged about the turn of the 20th century. The avant-garde painters Lajos Kassák and László Moholy-Nagy elevated Hungarian painting from secondrate romanticism to international significance. Hungarian music achieved worldwide renown with the composer Béla Bartók, a central figure of early 20th-century culture who influenced future generations of Hungarian composers. Musical life and education in Hungary-including the special schools where the method established by Zoltán Kodály is taught-are on par with those of any nation. Many Hungarian musicians have gained international renown as performers, including the conductors Sir Georg Solti and Antal Dorati, the composer and pianist Franz (Ferenk) Liszt, and the pianists Annie Fischer, Zoltán Kocsis, and András Schiff.

From the 1960s Hungarian motion pictures attracted significant international interest. In particular the parabolic films of Miklós Jancsó and István Szabó helped establish the reputation of Hungarian cinema.

Cultural institutions. Following World War II, high culture that previously had been confined to the upper classes was promoted among the masses. A highly subsidized publishing industry fostered reading: the number of books published increased 10-fold between 1938 and 1988. Reading became a regular habit of a third of the

population, and a huge network of more than 15,000 public libraries was established. The main national collections are the Széchényi Library, Ervin Szabé Library, and the libraries of the parliament and the Hungarian Academy of Sciences. Among the most notable of the more than 15,-000 museums and roughly 3,000 cultural centres are the National Gallery, the National Museum, and the Museum of Fine Arts (all in Budapest) and the Christian Museum in Extergom. Museums in Budapest and Pécs house the works of the Hungarian-born artist Victor Vasarely. Government subsidizing of culture virtually ended with the introduction of a market system in the 1990s.

Scholarship and research are both emphasized in Hungary's institutions of higher learning. Following the Soviet model, teaching and research are mutually exclusive. The former is practiced in schools and universities, while the latter is concentrated at the research institute network of the Hungarian Academy of Sciences (established in 1825 and reorganized in 1949). The Academy, with its several dozen research institutes in science, social sciences, and humanities, employs roughly 10,000 researchers and staff.

Hungary has an international reputation for scholarship, with the world's highest per capita rate of Nobel laureates. Because of a lack of funding, however, most of these prizewimers work abroad. Outstanding Hungarian-born scholars include the scientists John von Neumann, Leo Szilárd, Edward Teller, Eugene Wigner, and Albert Szent-György, the social scientist Karl Mannheim, the economist Karl Polanyi, and the philosopher and literary critic György Lukács. In addition, Pál Turán and Péter Erdős are among the world's most renowned mathematicians. Hungarian scholars also have excelled in the disciplines of linguistics (especially historical linguistics), historiography, and literary history.

Recreation. In addition to their observance of the main religious holidays—Christmas, celebrated as a traditional family festivity, and Easter, characterized by merry village grantizuals—Hungarians commemorate the labour movement with a major celebration on May I. Among the traditions of the labour movement reclebration is folk dancing, which, like choral singing, also is practiced by peasant ensembles. The Pilis, Matra, and Bükk mountains are popular vacation destinations for many Hungarians, and a major attraction for the people of Budapes is Margit (Margaret) Island, an urban oasis of gardens and swimming pools in the middle of the Danube.

Hungary has a tradition of success in international sporting competition. It has won a number of world championships and Olympic medals largely because of the overpoliticization of sports in Soviet-bloc nations during the Soviet period. Soccer (association football) is especially opoular, and Hungarian athletes also have enjoved

Lake Balaton from the northwestern shore, near Badacsony Hung.

Scholarship

success in fencing, swimming, table tennis, track and field (athletics), rowing, and weight lifting. Tennis has gained in popularity, especially among the middle class.

Press and broadcasting. Under state socialism the press-about 30 daily newspapers and 1,500 periodicalswas strictly controlled, yet it remained the least restricted in the Soviet bloc. In 1988 press censorship was relaxed. In the first half of the 1990s the number of newspapers increased, but overall circulation declined.

After World War II radio ownership and listening became common. Television appeared only in the late 1950s but soon conquered the country. From the early 1980s almost every household has had a television. There are two main state-run TV channels, and cable and satellite TV are also available. Weekly programming doubled during the 1990s, from about 100 to more than 200 hours. (G.Ba./I.T.B.)

For statistical data on the land and people of Hungary, see the Britannica World Data section in the BRITANNICA BOOK OF THE YEAR.

History

Hungary came into existence when the Magyars, a Finno-Ugric people, occupied the middle basin of the Danube River in the late 9th century AD. Parts of its territory had formed the ancient Roman provinces of Pannonia and Dacia. When Rome lost control of Pannonia at the end of the 4th century, it was occupied first by Germanic tribes, then by Slavs. The subsequent history of Dacia is unrecorded. The central plains had formed the bases of nomadic immigrant peoples from the steppes north of the Black Sea-Huns, Bulgars, Avars-some of whom extended their domination farther afield. The Avars, who dominated the basin in the 7th and 8th centuries, were crushed in about 800 by Charlemagne, whose successors organized the western half of the area in a chain of Slavic vassal "dukedoms." One of these, Croatia, made itself fully independent in 869, while another, Moravia, had openly defied its Carolingian overlord for as long. The Byzantine Empire and Bulgaria exercised loose authority over the south and east of the area.

THE KINGDOM TO 1526

The

history

Magyars

of the

The Árpáds. In 892 the Carolingian emperor Arnulf, attempting to assert his authority over the Moravian duke Svatopluk, called in the help of the Magyars, whose early homes had been on the upper waters of the Volga and Kama rivers; unrecorded causes had driven them southward into the steppes, where they had adopted the life of peripatetic herders. In the 9th century they were based on the lower Don, ranging over the steppes to the west of that river. They then comprised a federation of hordes, or tribes, each under a hereditary chieftain and each composed of a varying number of clans, the members of which shared a real or imagined blood kinship. All clan members were free, but the community included slaves taken in battle or in raids. There were seven Magyar hordes, but other elements were part of the federation, including three hordes of Turkic Khazars (the Kavars). Either because of this fact or perhaps because of a memory of earlier conditions, this federation was known to its neighbours as the On-Ogur (literally, "Ten Arrows"), from the Slavic pronunciation of which the name "Hungarian" is derived.

In 889 attacks by a newly arrived people called the Pechenegs had driven the Magyars and their confederates to the western extremities of the steppes, where they were living when Arnulf's invitation arrived. The band sent to Arnulf reported back that the plains across the Carpathian Mountains would form a suitable new homeland that could be easily conquered and defended from the rear. Having elected as their chief Arpad, the leader of their most powerful tribe, the Magyars crossed the Carpathians en masse, probably in 896, and easily subjugated the peoples of the sparsely inhabited central plain, their first place of settlement. They destroyed the Moravian empire in 906 and in the next year occupied Pannonia, having defeated a German force sent against them. They were then firmly established in the whole centre of the basin, over which their tribes and their associates distributed themselves, Árpád taking the central area west of the Danube for his own tribe. The periphery was guarded by outposts, which were gradually pushed forward, chiefly to the north.

The Christian kingdom. During the next half century the Magyars were chiefly known in Europe for the forays they made across the continent, either as mercenaries in the service of warring princes or in search of booty for themselves-treasure or slaves. Terrifying to others, their mode of life was not always profitable. Their raiding forces suffered a number of severe reverses, culminating in a disastrous defeat at the hands of the German king Otto I in 955 at the Battle of Lechfeld, outside Augsburg (now in Germany). By that time the wild blood of the first invaders was thinning out and new influences, in particular Christianity, had begun to operate. Both the Eastern and Western churches strove to draw them into their orbits. They had established pacific, almost friendly relations with Bavaria. The decisive step was taken by Árpád's great-grandson Géza, who succeeded to the hereditary chief leadership in 972 and reestablished its authority over the tribal chiefs. In 973 he sent an embassy to the Holy Roman emperor Otto II at Quedlinburg (now in Germany), and in 975 he and his family were received into the Western church. In 996 his son, Stephen (István). married Gisella, a Bavarian princess.

Stephen I (997-1038) carried on his father's work. With

the help of Bayarian knights, he crushed his rivals for the headship. Applying to Pope Sylvester II, he received the insignia of royalty from the papacy and was crowned king on Christmas Day, 1000. The event was of immeasurable importance, for not only did Hungary enter the spiritual community of the Western world but it did so without having to recognize the political suzerainty of the Holy Roman Empire. This was possible because Sylvester, who extended papal protection to Hungary, held great sway with the emperor, Otto III, who had once been his pupil. Stephen then effected the conversion of his people to Christianity, establishing a network of archiepiscopal and episcopal sees. Later he crushed the surviving disputants of his authority-notably the Kavars-and, furthering his father's work, organized his state on a system that was to remain for many centuries the essentially unaltered basis of Hungary's political and social structure. The tribes, as units, disappeared, but the fundamental social stratification was not altered. The descendants in the male line of the old conquerors and elements later equated with them remained a privileged class, answerable only to the king or his representative and entitled to appear in general assemblage. Their lands-which at this time, since the economy was mainly pastoral, were held by clans or subclans in semicommunal ownership-were inalienable. except for proved delinquency, and free of any obligation. The only duty required by the state of members of this class was that of military service on call. They were allowed to retain their slaves, although Stephen freed his own. All land not held by this class-then more than half the whole-belonged to the crown, which could donate it at will. The nonservile inhabitants of these lands-e.g., descendants of the pre-Magyar population, manumitted slaves, and invited colonists-were subjects of the crown or of the local landholder,

The whole of this land was divided into counties (megyék), each under a royal official called an ispán (later fő [head] ispán), who represented the king's authority in it, administered its unfree population, and collected the taxes that formed the national revenue, central and local. Each ispán maintained at his vár(fortress) an armed force composed of freemen who took service under him or of persons freed by the king. In Stephen's day there were about 45 such counties.

The early kings. Once St. Stephen (he was canonized in 1083) established his rule, his authority was rarely questioned. He fought few foreign wars and made his long reign a period of peaceful consolidation. But his death in 1038 was followed by a period of internecine dynastic jealousies and intrigue (including murder) that lasted more than a century and a half, with few intervals of stability, before the 30-year reign of Andrew II(1205-35).

Consolidation and expansion. These royal disputes

Conversion to Chris-

A period of disputed succession

701

caused Hungary much harm. Claimants to the throne often invoked foreign help, for which they paid in political degradation or loss of territory; both Peter (1044-46) and Salamon, the son of Andrew I, did homage to the Holy Roman emperor for their thrones; and Samuel Aba's war against Peter's protectors cost Hungary its previous territories west of the Leitha River, while the wars of the 12th century cost it areas in the south. The uncertainty delayed political consolidation, and even Christianity did not take root easily: there was a widespread pagan revolt in 1047 and another in 1063.

Yet the political unity of the country and the new faith somehow survived the earlier troubles, and both were firmly established by Ladislas I (1077-95), one of Hungary's greatest kings, and by Coloman (Kálmán; 1095-1116), who, despite the fact that he had his brother and nephew blinded to secure the throne for his own son, was

a competent and enlightened ruler.

Imported

colonists

Meanwhile, many factors worked for Hungary. After Austria had grown big at the expense of the imperial authority, most of Hungary's neighbours were states of approximately the same size and strength as itself, and the Hungarians lived with them on terms of mutual tolerance and even friendship. The steppes were quiet: the Cumans (Hungarian: Kun), after destroying the Pechenegs there, did not try to go farther, and, after two big raids had been successfully repelled by Ladislas I, they left Hungary in peace. This allowed Hungary to extend its effective frontiers to the Carpathian crest in the north and over Transylvania. Magyar advance guards pushed up the valleys of both areas and were reinforced in the Szepes area and in central Transylvania by imported colonies of Germans (usually called Saxons). In the meantime, colonies of Szeklers (Székely), a people akin to the Magyars who had preceded the latter into the central plains, were settled behind its eastern passes. The county system was extended to both areas, although with modifications in Transylvania, where the Saxons and Szeklers constituted free communities and the whole was placed under a vaivode, or governor. In the south Ladislas I occupied the area between the Sava and Drava rivers; Coloman assumed the crown of Croatia, which then included Bosnia and northern Dalmatia, although this remained a separate "Land of the Hungarian Crown," over which a governor (ban) acted as deputy for the king.

In the interior, too, natural growth and continued immigration swelled the population, which by 1200 had risen to the then large figure of some two million. The rulers of this big, populous state were now important men. After Ladislas' day, German claims to suzerainty over Hungary ceased. In the 12th century the country intervened in its neighbours' affairs as often as they did in Hungary's. Béla III (1173-96), who married a French princess, Margaret Capet, had revenues roughly equal to the income of the king of France. He owned half the land of the kingdom outright and held monopolies of coinage, customs, and mining. While the income of the early kings had been mostly in kind, half of Béla's income was cash, coming from royal monopolies and taxes paid by foreign settlers.

Social and political developments. Meanwhile, the pattern of Hungarian society had been changing. The population of the free class, or "nobles," although frequently reinforced by new admissions to its ranks, probably hardly increased in absolute terms, and certainly grew far less than the unfree population: from perhaps half the total population in 896, they had been reduced to about oneeighth by 1200. Further, as the economy became agricultural, the old clan lands dwindled until only pockets remained. Where the rest had been and in large parts of the old crown lands, which improvident donations had greatly reduced, the land was held in the form of individual estates. The owner of each of these estates was master of the unfree population on it: the nobles had, to a large extent, become a landed oligarchy. Some individual estates were very large, and their owners had come to constitute a "magnate" class, not yet institutionalized or legally differentiated from their poorer co-nobles but far above them in wealth and influence. Although slavery had practically disappeared, the non-nobles were still a

"subject" class. Many of them, including the burghers of the towns (most of which were German foundations) and members of such communities as the Saxons and Szeklers. were protected by special charters and personally free, but even they stood, politically, outside the magic ring of the natio Hungarica.

As a result of Béla's marriage to the sister of the French king, the Hungarian court became a centre of French knightly culture. Western dress and translations of French tales of chivalry appeared. A royal notary, known to future generations as "Anonymous," wrote the history of the conquest of Hungary. The first known work in the Hungarian language, the "Halotti beszéd" ("Funeral Oration"), was part of the otherwise Latin-language Pray-codex written in the early 1190s. Béla also followed a Western model in introducing written documentation of government administrative authority. Moreover, monasteries served as public notaries from the end of the 12th century.

In addition to tents and wooden structures, stone buildings (mostly churches) appeared in the permanent settlements. The cathedral of Pécs, Pannonhalma Apátság (a Benedictine abbey), and the royal palace at Esztergom were the first examples of early Gothic architecture.

Throughout these developments the country had remained an absolutist patrimonial kingship. The king maintained a council of optimates (aristocrats), but his prerogatives were not restricted and his authority remained absolute. A strong king, such as Béla III, could always curb a recalcitrant magnate by simply confiscating his estate. Only the follies and extravagances of the feckless Andrew II evoked a revolt, culminating in 1222 in the issue of the Golden Bull (the eastern European equivalent of the Magna Carta), to which every Hungarian king thereafter had to swear. Its purpose was twofold: to reaffirm the rights of the smaller nobles of the old and new (servientes regis) classes against both the crown and the magnates and to defend those of the whole nation against the crown by restricting the powers of the latter in certain fields and legalizing refusal to obey its unlawful commands (the jus resistendi). Andrew had done much harm by dissipating the royal revenues through his extravagances and by issuing huge grants of land to his partisans. The royal estate gradually melted away as the ispáns and knights became the hereditary owners of the land. Leading aristocratic families like the Abas and Csáks became the unchallenged

Issuance of the Golden

rulers of large parts of the country. The Mongol invasion: the last Arpad kings. Andrew's successor, Béla IV (1235-70), began his reign with a series of measures designed to reestablish royal authority, but his work was soon interrupted by the Mongol invasion. In the spring of 1241 the Mongols overran the country and, before they left it, a year later, had inflicted ghastly devastation. Only a few fortified places and the impenetrable swamps and forests escaped their ravages. The country lost about half its population, the incidence ranging from 60 percent in the Alfold (100 percent in parts of it) to 20 percent in Transdanubia; only parts of Transylvania and the northwest came off fairly lightly. Returned from Dalmatia, where he had taken refuge, Béla, whom his country not unjustly dubbed its second founder, reorganized the army, built a chain of fortresses, and called in new settlers to repopulate the country. He paid special attention to the towns. But he was forced to give some of the magnates practically a free hand on their own estates, and a few families rose to near-sovereign local status. Further, one group of immigrants, a body of Cumans who had fled into Hungary before the Mongols, proved so powerful and so turbulent that to ensure their loyalty Béla had to marry his son, Stephen V, to a Cuman princess. The king attempted to counterbalance the power of the magnates by creating his own army, partly from the Cumans. A newly created "conditional" nobility comprising enobled soldiers and settlers who gained land for military service strengthened the ranks of the lesser nobility. The system of royal estates and judicial power was thereafter transformed in an assembly in which nobles represented their counties.

Stephen died two years after his father's death, after which the country passed under the regency of his widow, the "Cumanian woman," whom the Hungarians detested. Rebuilding under Béla IV

Her son was assassinated and left no legitimate heir, and claims to the throne were made through the female line of the Arpáds. A male heir was found in Italy, and, although the young man's claim to the throne was impugned, Andrew III proved a wise, capable king. With his death in 1301, however, the national dynasty became extinct.

A new Western-style feudal socioeconomic system had emerged in Hungary but it had yet to take root. During the last third of the 13th century Hungarian assimilation into Europe was threatened by the ongoing conflicts between various baronial factions. Moreover, Hungary was still the destination of migrating pagan tribes and the focus of barbarian attacks, and it continued to exhibit the features of a country on the borders of Christian feudal Europe.

Hungary under foreign kings. The extinction of the old dynasty entitled the nation to choose its successor; but the principle of the blood tie was still generally regarded as determinant, and all the candidates for the throne-Wenceslas of Bohemia, Otto of Bavaria, and Charles Robert of the Angevin house of Naples-based their claims on descent from an Arpad in the female line. But all three claimants were foreigners. From that time until its extinction, the kingship of Hungary was invariablywith two exceptions-held by a foreigner, nearly always by one occupying simultaneously at least one foreign throne. This could be to the advantage of Hungary if the king used the resources of those thrones in its service, but he could, alternatively, neglect and exploit Hungary in his other interests and use his power to crush its national freedoms and institutions. Securing the advantages of foreign rule while escaping its dangers was the abiding dilemmaseldom successfully resolved-of Hungarian history.

The Angevin kings. Charles Robert of Anjou (1308-42), still a child when his supporters won out, had no foreign throne and grew up a true Hungarian. He was also a capable man. After reaching manhood, he crushed the most rebellious of the "kinglets" and won over the rest; after this his rule was unquestioned and peaceful at home. The international situation, with Germany distraught by the power struggle between empire and papacy, the Mongolian Tatars grown passive, and the power of Byzantium in full decay, was again favourable to the states of the "middle zone" of eastern Europe and the Balkans; it is no accident that Poland, Hungary, Bohemia, and Serbia all look on the 14th century as their golden age. As this situation favoured Hungary's neighbours, as well as itself, Charles Robert's attempts at expansion were only moderately successful. In the Balkans he made Bosnia his friend and client but lost Dalmatia to Venice and other territories to Serbia and the newly emerged vaivody (province) of Walachia. But he drove Czech and Austrian marauders out of the land and on the whole preserved friendly relations with Austria, Bohemia, and Poland.

Charles's son, Louis (Lajos) I (1342–82), the only Hungarian king on whom his country has bestowed the name "Great," built on his father's foundations. Keeping peace with the West, he repaired his father's losses in the south and surrounded his kingdom with a ring of dependencies

Hungary in 1360.

over which Hungary presided as archiregnum (chief kingdom) in the Balkans, on the lower Danube, and in Galicia. In 1370 he also ascended the throne of Poland, by virtue of an earlier family compact.

Angevin

prosperity

Both Angevin kings owed much to the wealth they derived from the gold mines of Transylvania and northern Hungary, some 35 to 40 percent of which went to the king, enabling him to maintain a splendid court. Spared for two generations from serious invasion or civil war, the country blossomed materially as never before. The population rose to three million and the country contained 49 royal free boroughs, more than 500 smaller towns, and some 26,000 villages. The economy was still mainly rural, but the crafts prospered, trade expanded, and the arts flourished.

The life of the court and the daily life of cities borrowed from western European societies. German settlers and burghers in the cities and the clergy became the main agents of Western culture. The Dominicans built 25 monasteries by the early 14th century and established a theological school in Buda. The Franciscans also established monasteries, as did the Cistercians, Premontstratensians, and Paulines, Romanesque style dominated architecture until the ascendancy of Gothic design in the late 13th century. Cities built impressive churches, such as the Church of Our Blessed Lady (now better known as the Matthias Church) in Buda. The palace of Visegrad, the royal castles of Zólyom and Diósgyör, the miniatures of the Illuminated Chronicle (1360) and the St. George statue in Kolozsvár (1373), together with the earliest codex predominantly in Hungarian (1370) and the finest example of Hungarian poetry, Omagyar Mária-siralom ("Old Hungarian Lament of the Virgin Mary," about 1300), testify to the spread of western European culture. The first universities were established in Pécs (1367) and Obuda (1395), though they were short-lived. Yet, in spite of its advancement Hungary remained a less-developed borderland of Europe.

The rule of the two Angevin kings was essentially despotic, although enlightened. They introduced elements of feudalism into the political, and especially the military, system: each lord was responsible for maintaining his own armed contingent banderium). But the magnates were held firmly in check, and Louis realtimed the rights and privileges of the common nobles and carried further a process, begun in the previous century, under which the counties were developing from "royal" into "noble" institutions, each still under a royal official but administered with a wide measure of autonomy by elected representatives of the local nobility. He also standardized the obligations of the peasants at the figure of one-ninth of their produce to the lord, a tithe to the church, and a house tax forces that was discrete that was discrete that were discrete that was the state.

(porta) that went directly to the state. Sigismund of Luxembourg. The benefits of Louis's rule would have been far greater still had he not wasted much money and many lives on endeavours to secure the throne of Naples for his nephew. His foreign acquisitions served his personal glory more than they did the real interests of his country; much of the imposing edifice collapsed when he died, leaving as heirs only two daughters. Louis had designated the elder, Maria, to succeed him on both his thrones, but the Poles refused to continue the union. They accepted the younger daughter, Hedvig (Polish: Jadwiga). as queen but married her to Jogaila (Polish: Jagiełło) of Lithuania. The Hungarians crowned Maria, whose husband, Sigismund of Luxembourg, became her consort in 1387 and after her death eight years later ruled alone until his own death in 1437. Under Sigismund, matters took a sharp turn for the worse, although he did much for the arts and commerce and, above all, for the towns. Also, like Andrew II, he promoted Hungarian political institutions by creating the need for them. The principle that the consent of representatives of the privileged classes, assembled in the Diet, was necessary for the grant of any subsidy or additional taxation, and even, later, for any legislation, dates from his reign, being made necessary by his extravagance and arbitrariness. His frequent and prolonged absences gave rise to the peculiar Hungarian institution of the palatine, an officer elected jointly by the king and the nation, who represented the king during his absences and also acted as intermediary between him

bitterly felt abuses. The nation, besides hating him for the cruelty he showed at the outset of his reign against the supporters of a rival, resented the absenteeism of his later years, when he occupied himself chiefly with imperial and Bohemian affairs (he was elected German king in 1411 and became titular king of Bohemia in 1419). There was much discontent among the peasants, who were subjected to heavy exactions by the crown and by their masters, the unrest being aggravated by the spread of radical Hussite religious doctrines from Bohemia; there were serious revolts in northern Hungary and Transylvania. Above all, there was the growing danger from the Ottoman Turks, who, though they had already taken Bosnia from Louis, could not threaten Hungary proper while Serbia still stood. But in 1389 the power of Serbia was broken at the Battle of Kosovo, and the danger became urgent. Sigismund organized a crusade that was disastrously defeated at Nicopolis in 1396. Timur (Tamerlane) gave Europe a respite by his attack on the Turkish rear, but

and the nation. But these were only palliatives against

in 1417; thereafter Transylvania and southern Hungary suffered repeated raids.

The

growing

threat

Ottoman

János Hunyadi and Matthias Corvinus. The Ottoman sultan Murad II was preparing a grand assault on Hungary when Sigismund died in 1437, leaving as his heir a daughter, who was married to Albert V of Austria. The country accepted Albert as Sigismund's successor, but only on condition that he not become Holy Roman emperor or reside abroad without permission of the estates. Albert set about organizing the country's defenses but died in 1439, leaving his widow with an unborn child. To avoid an interregnum and a minority, perhaps with a queen, the country elected Władysław III of Poland as king; within two years of his death in battle against the Turks in 1444, they accepted Albert's son, Ladislas V (called Ladislas Posthumus), appointing as his guardian and governor of Hungary the great general János Hunyadi, who had been repelling the renewed Turkish attacks. Hunyadi kept up the defense under increasing difficulties, constantly thwarted by jealous magnates and harassed by the Czech condottiere Jan Jiskra, while Frederick III (first of the Habsburg emperors) encroached on the western provinces.

the advance was resumed in 1415. Walachia submitted

Hunyadi died in 1456 after the recapture of Belgrade from the Turks, Ladislas' maternal uncle, Ulrich of Cilli, aware of the country's devotion to Hunyadi, had the latter's elder son assassinated and his younger son Matthias (Mátvás) Corvinus imprisoned in Prague, Ladislas V himself died suddenly a year later. The country was tired of foreign rule and its agents, and on Jan. 24, 1458, a great concourse of nobles acclaimed Matthias king. He was brought to Buda and crowned amid nationwide rejoicing.

The only national king to reign over all Hungary after the Árpáds, Matthias Corvinus has been seen through something of a golden haze by historians. A true Renaissance prince, he was a fine natural soldier, a first-class administrator, an outstanding linguist, a learned astrologer, and an enlightened patron of the arts and learning. His collections of illuminated manuscripts, pictures, statues, and jewels were famous throughout Europe. Artists and scholars were welcomed at his court, which could vie in magnificence with any other on the continent. Sumptuous buildings sprang up in his capital and other centres.

Politically, too, he represented the ideas of the Renaissance. He listened to his council, convoked the Diet regularly, and enlarged the autonomous powers of the counties. But at heart he was a despot; his real instruments of government were his secretaries, men picked by himself, usually young and often of humble origin. His rule was in the main an efficient and a benevolent one. He simplified · and improved the administration and the laws, enforcing justice with an even hand. The debit side of his rule was the increased taxation imposed by him for his administrative innovations, his collections (which cost his subjects vast sums), and, above all, the mercenary standing army, 30,000 strong (largely composed of the defeated Hussites and known after its commander, "Black John" Haugwitz, as the Black Army), which he kept as part of the royal banderium for use against enemies, at home and abroad.

At first he had much need for such a force; although the Turks were quiescent for a decade, there were discontented magnates, and the Czechs and the Austrians were unquiet neighbours. But, after Matthias had crushed, expelled, or bought off these enemies, had built a chain of fortresses along the southern frontier, and had even reestablished a nominal and, in practice, worthless suzerainty over Bosnia, Serbia, Walachia, and Moldavia, he let himself be drawn into an ever-widening circle of campaigns against Bohemia and Austria. In 1469 he made himself master of Moravia Silesia, and Lusatia, with the title (although this was also borne simultaneously by George of Podebrady) of king of Bohemia, and in 1478 he forced Frederick to cede him Lower Austria and Styria. He argued that his neighbours were untrustworthy and that he could not organize the great crusade against the Turks without the resources of the imperial and Bohemian crowns. But his subjects were unconvinced, and in 1470 a party actually conspired to replace him with a Polish prince. This enterprise collapsed. and Matthias entered on a complex transaction with the new emperor, Maximilian I, under which his illegitimate son John (he had no legitimate issue) was to marry Maximilian's daughter in return for re-cession of the Austrian provinces and Maximilian's recognition of John. But on May 6, 1490, while on his way to the meeting that should have sealed the bargain, Matthias died suddenly, and the whole enterprise collapsed.

Both Sigismund and Matthias attempted to balance baronial power by strengthening the cities, but they were only partly successful. In contrast with western Europe, urbanization remained moderate, with the development of walled cities lagging behind that of western European counterparts. The number of guilds was limited, and the structure of foreign trade reflected economic backwardness: nearly four-fifths of imports consisted of textiles and about one-eighth of metalware. Exports consisted almost entirely of cattle and wine. The most important aspect of urbanization was the rapid growth of agricultural towns. Instead of the approximately 50 families that made up the 20 to 30 portae (taxable units) of the typical village, these oversize peasant settlements (mezöváros) had as many as 500 portae. Moreover, the number of these settlements increased from about 300 in the mid-15th century to about

800 in the early 16th century.

The Jagiellon kings: national decay. The magnates, who did not want another heavy-handed king, procured the accession of Vladislas II, king of Bohemia (Ulászló II in Hungarian history), precisely because of his notorious weakness-he was known as King "Dobre" (meaning "Good" or, loosely, "OK") from his habit of accepting with that word every paper laid before him. The emperor Maximilian contented himself with reoccupying his lost provinces and establishing a sort of paternal patronage over Hungary. This was consolidated in 1515 by an agreement under which Vladislas' son, Louis, married Maximilian's granddaughter Mary, while Louis's sister, Anne, married Maximilian's grandson Ferdinand, who was to succeed to Louis's thrones if Louis died without an heir. The agreement was made without the consent of the Hungarians, and the Diet in 1505 passed a resolution never again to accept a foreign king. The candidate of the "national party" was János Zápolya, vaivode of Transylvania.

Meanwhile, the magnates had disbanded the Black Army (without replacing it) and allowed the country's fortresses to fall into disrepair. Vladislas was their helpless prisoner; he could make no decision without their consent, and his revenues were looted so ruthlessly that he was reduced to selling Matthias' collections. Nearly all of Matthias' reforms were canceled, and the peasants were oppressed grievously. In 1514 there was a peasant uprising that, unlike those that had preceded it, spread nationwide. It was sparked by the call for a crusade against the Ottomans by the papal legate of eastern Europe, Archbishop Tamás Bakócz. Some 20,000 men gathered near Buda in the spring and, led by a Szekler soldier, György Dózsa, moved on the southern border. The rebellious, antilandlord sentiment of these "crusaders" became apparent during their march across the Great Alfold, and Bakócz canceled the campaign. The peasant leaders not only refused to obey

Matthias' despotism

rebellion

Renewed

Ottoman

threat

this order when it reached them in late May but also confronted and defeated the noble's army and burned castles for two months. By mid-July, however, the peasants had been defeated and Dózsa tortured and murdered. The peasants were condemned to perpetual servitude, and their right to free migration was abolished. Although this law was not immediately enforced, it served as the basis for the preservation of serfdom for centuries to come.

When Vladislas died in 1516, his nine-year-old son was proclaimed king as Louis II. The defenses of the kingdom worsened, and in 1521 the new Ottoman sultan, Süleyman I the Magnificent, demanded tribute from Louis; when the demand was rejected, Süleyman took Belgrade. Suddenly alive to the Turkish danger, the magnates voted to reestablish a standing army, but nothing was done to raise it, since each rival faction tried to put the burden of its upkeep on the others. Appeals for help from abroad met with little response. In 1526 the sultan advanced into Hungary. A general call to arms was proclaimed, but the most important forces-those from Transylvania and Croatiawere late in obeying it. Louis, with a force of 16,000 men, moved down the Danube in August and attacked the Turks at Mohâcs. The Hungarian army, heavily outnumbered, was almost annihilated. Louis himself drowned during his flight. Unable to believe that the pitiful array that had met him was Hungary's national army, the sultan advanced with extreme caution. He occupied Buda on September 10 but returned across the Danube by the end of October, taking with him more than 100,000 captives.

THE PERIOD OF PARTITION

Since the sultan had not meant to remain in Hungary, the disaster of Mohács might have been overcome had the king not perished; but, as it was, both Zápolya and Ferdinand of Habsburg (later Holy Roman emperor as Ferdinand I) claimed the throne, and each had supporters in the country. After each had failed to drive his rival out, Zápolya appealed to the sultan, who installed him in Buda, thus limiting Ferdinand's rule to the western third of the country. By a secret agreement-mediated in 1538 by Zápolya's adviser, György Martinuzzi ("Friar George")-Ferdinand was to succeed Zápolya when the older man died. The agreement was upset when, just before Zápolya died, his wife bore a son whom the national party recognized as king. The sultan recognized the infant as king but, more importantly, as his own vassal. Extending his occupation of Buda, the sultan incorporated a great wedge of central and southern Hungary in his own dominions. Ferdinand had to conclude a truce and to pay a tribute in return for recognition of his de facto rule over the territory then held by him. The transaction was completed when in 1566 the sultan formally declared Transylvania an autonomous principality under his own suzerainty; two years later Ferdinand's successor, Maximilian II, was forced to recognize this arrangement and to accept the reduction of Royal Hungary (i.e., that part of Hungary that came under Habsburg rule) to the western fringe of the country, the northwestern mountains, and Croatia. From that time, ruling princes of Transylvania such as István Báthori and later Gábor Bethlen introduced mercantilist economic policies and generated prosperity

The partition of Hungary in 1568

The "age of trisection" was the bleakest in all Hungarian history. Fighting and slave raiding, which went on even in times of nominal peace, reduced the whole south of the country to a wasteland occupied by only a few seminomadic Vlach herdsmen; villages disappeared and fields reverted to swamp and forest. Behind the new frontier the population was partially preserved to supply the garrisons, but the old landholders were replaced by Turkish officials and soldiers who, since their fiefs were not hereditable nor even always long-term, exploited the wretched cultivators. Conditions were relatively tolerable only in those kazalar (districts) managed directly by the Ottoman government. In those districts, most of which lay along the banks of the Tisza River, the people flocked into the great "village towns" that are still a feature of the area. There they enjoyed a measure of protection; but the country between these towns was left virtually empty.

The Turks left Transvlvania relatively unmolested. Martinuzzi devised a constitution based on earlier institutions, consisting, under the prince, of representatives of the three "nations": the Hungarian nobles of the counties, the Saxons, and the Szeklers. Transvlvania was also spared internecine religious strife, when the Roman Catholic, Calvinist, Lutheran, and Unitarian churches agreed to coexist on a basis of equal freedom and mutual toleration. The Greek Orthodox faith of the Romanians, who constituted the rest of the population, was only "tolerated," since the Romanians as such, or even their nobles, did not constitute a "nation."

Royal Hungary and the rise of Transylvania. In the first years after his accession, Ferdinand still hoped to bring the whole kingdom under his rule. He respected its constitution and its institutions and convoked the Diet regularly. But his hopes faded, and, after his succession to the imperial crown in 1558, Royal Hungary became no more than a small outlying annex of his mighty dominions. As it was also an exposed one, without the resources to defend itself, Ferdinand and his successor, Maximilian II, organized a chain of fortresses, mostly garrisoned by German troops, and a defensive "military frontier," inhabited by Serb and Vlach refugees from the Balkans and administered from Vienna. The Hungarians complained that they were being ruled and exploited as a subject people by foreigners, while Vienna looked on them as truculent rebels. Matters grew worse when Maximilian was succeeded by the mentally unbalanced Rudolf II, whose advisers hated Hungary and its traditions; and a religious conflict supervened on the constitutional dispute, for in the preceding half century the Reformation had swept over Hungary.

Religious antagonism played an important part when war between the empire and the Turks broke out again in 1591. In the so-called Fifteen Years' War, imperial troops entered Transylvania, and their commander, George Basta, behaved there (and in northern Hungary) with such insane cruelty toward the Hungarian Protestants that a Transylvanian general, István Bocskay, formerly a Habsburg supporter, revolted. His army of wild herdsmen (haiduks) drove out Basta, and in June 1606 Bocskay concluded with Rudolf the Peace of Vienna, which left him prince of an enlarged Transylvania and also guaranteed the rights of the Protestants of Royal Hungary. He then mediated the Peace of Zsitvatorok (November 1606) between the emperor and the sultan, which kept the territorial status quo but relieved the emperor of his tribute to the sultan.

These two treaties ushered in a new era. The balance of power began to shift from the Turks toward Transvlvania, which entered a half century of prosperity. A scramble for power followed Bocskay's death (1606), but in 1613 the Sublime Porte (the Ottoman government) imposed the election of Gábor Bethlen (1613-29), who proved the most famous of all the princes of Transvlvania. At home Bethlen's rule was thoroughly despotic: through his monopoly of foreign trade and his development of the principality's internal resources, he almost doubled his revenues, devoting the proceeds partly to the unkeep of a sumptuous court, partly to the maintenance of a standing army. Keeping peace with the Porte, he often intervened against the emperor in the Thirty Years' War (1618-48) and safeguarded the rights of the Protestants in Royal

Religious toleration

Reign of Gábor Bethlen

The

Pragmatic

Sanction

Hungary. Under the Treaty of Nikolsburg (Dec. 31, 1621) he retained the title of prince of Transylvania and Hungary (the Porte vetoed his acceptance of the Hungarian crown) and gained a big extension of the principality and a duchy in Silesia, besides further guarantees for the Protestants of Royal Hungary. When Bethlen died suddenly in 1629, his subjects abolished most of his internal reforms, but his successor, György Rákóczi I, maintained the international position of Transylvania, which figured as a sovereign state in the Peace of Westphalia (1648), ending the Thirty Years' War. This Transylvanian support for the Protestants in Royal Hungary, as well as the divisions prevailing among their own members, prevented the Habsburgs from enforcing the Counter-Reformation in Hungary as early and as fully as they did in Austria and Bohemia, Nevertheless, the genius of the cardinal-primate Péter Pázmány won over for Roman Catholicism the majority of the local magnates, who came to form a party attached to the Habsburg cause, which was the more influential because they now formed a separate "table" of the Diet. The nation was thus divided not only between Transylvania and the west but also between the Roman Catholic magnates and their subjects on the one hand and the smaller landowners, many of whom remained Protestants, on the other. In religious matters, the Hungarian Catholic nobles were no more tolerant toward their Protestant fellow countrymen than were the emperor's own German and Czech advisers, although they were not willing to acquiesce in the political centralization championed by the latter.

War and liberation. The Turkish occupation of central Hungary remained a volatile issue, for every Hungarian resented the Habsburgs' policy of leaving the Turks unmolested while pursuing ambitious objectives in the west. This powder keg erupted in 1657 when György Rákóczi II of Transvlvania, who had succeeded his father in 1648. allowed the prospect of obtaining the crown of Poland to seduce him into sending across the Carpathians an expeditionary force, which was annihilated by Tatars. The grand vizier Köprülü Mehmed Pasa, the architect of the Porte's renaissance, led a force against Transvlvania and installed a new puppet prince. Emperor Leopold sent a force against the Turks; but, although the Austrian general Raimondo Montecuccoli defeated the Turks at Szentgotthárd on Aug. 1, 1664, the subsequent Peace of Vasvár recognized all the sultan's gains.

Now even the highest magnates of Royal Hungary plotted to expel the Habsburgs with Turkish and French help, but the conspiracy was betrayed, and Vienna took its revenge, Nobles were executed or lost their estates, and Protestant pastors were sentenced to be galley slaves. In 1673 the constitution was suspended and Hungary placed under a directorate. A young Transylvanian, Imre Thököly, led a revolt that forced Leopold in 1681 to restore the constitution and revoke many of his harshest measures. The Porte, encouraged by Thököly's successes, sent into Hungary a vast army that in 1683 reached Vienna. But the tide ebbed as swiftly as it had advanced. Vienna was relieved and the Turks routed, and the imperial general Prince Eugene of Savoy led a series of campaigns in which all western and central Hungary, with Buda, were cleared of the Turks in 1686. Transylvania was liberated in the years following. By the Treaty of Carlowitz (January 1699), the sultan relinquished all of Hungary except the corner between the Maros and Tisza rivers. (This area was ceded in 1718 but kept until 1779 under Austrian administration as the Bánát of Temesvár.) The military frontier (progressively extended) was kept under a similar regime, and Transylvania was organized as a separate "principality."

HABSBURG RULE, 1699-1918

Habsburg rule to 1867. The emperor, not Hungary, was the victor, for the retreating Turks and the advancing armies of the so-called liberators ravaged the country. In 1687 Leopold reconfirmed the constitution subject to Hungary's acceptance of his dynasty in the male line and to the abolition of the jus resistendi conceded under the Golden Bull of 1222, but the government that followed was another cruel Vienna-centred dictatorship. In 1703 this provoked another rebellion, led by Ferenc Rákóczi II (Thököly's stepson); after eight years of indecisive and fruitless fighting, peace was established by the Treaty of Szatmár (April 1711). On paper, this did little more than confirm what had been agreed in 1687, but the new king, Charles III (Emperor Charles VI), genuinely wanted peace with Hungary, and the worst abuses were now ended.

Charles III and Maria Theresa. Charles's chief concern was to secure the acceptance in Hungary of the Pragmatic Sanction, the imperial decree by which his daughter Maria Theresa was to inherit his dominions. After the Diet accepted the Pragmatic Sanction in 1723, Charles convoked the body only once more, and Maria Theresa, after her coronation in 1740, only twice more-each time to ask for money. Her rule, like her father's, was essentially autocratic. She was severe toward the Protestants, and she allowed her advisers to exclude Hungary from the subsidized industrialization that was bringing wealth to other parts of her dominions. Internal tariff barriers were introduced between the hereditary provinces and Hungary. Imports to Hungary from outside the empire were hindered by high tariffs, but customs for "imports" from Austria and Bohemia were very low. Hungary's exports were all but banned to non-Habsburg lands, and only those agricultural and raw materials that were required in the western part of the monarchy received preferential treatment, Hungary became more dependent on, and subordinate to, Austria than before. Agriculture received some incentives, but the road to industrialization was blocked. Lacking modern credit, entrepreneurial attitude, and strong urban markets. Hungary, unlike Austria and Bohemia, was prevented from entering the preindustrial age.

Maria's rule was not more than severe, even toward the Protestants. Toward the magnates, on whom she lavished many favours, it was positively benign, and she respected the most cherished liberty of the lesser nobles: their exemption from taxation. Exhausted by so many wars and rebellions, the country asked for nothing more, contenting itself with the supreme blessing that her rule brought it an uninterrupted peace that enabled the population to grow once again and the material ravages to be repaired. But a lethargy descended on the country. Political life sank to the parish-pump level, and the towns stagnated. The peasants, into whose conditions the queen introduced some improvements (notably the Urbarial Patent in 1767, which attempted to standardize peasant holdings and obligations), followed their masters in aspiring to nothing more than as much material comfort as could be obtained with a minimum of effort. The national language itself was becoming little more than a peasant dialect, since the language of public administration and the Diet was Latin and of business life was German; and, like the language, the national spirit seemed near moribund.

Joseph II and Leopold II. The nation was shocked out of its lethargy by the accession of Maria Theresa's son, Joseph II, on her death in 1780. Evading the obligation of a king on coronation to swear allegiance to the constitution by not submitting himself to coronation at all (he had the holy crown conveyed to Vienna), Joseph drew Hungary into the Habsburg realm. The counties were transformed into local branches of the state service, taking all their orders from above. German was made the language of government and all education above the elementary level. (A secularized school system had been introduced in 1777.) The land was surveyed in preparation for taxing all estates in it equally. That the position of the peasants was improved pleased them but not their lords. When Joseph fell mortally sick, the country was on the brink of open revolt; on his deathbed he retracted his administrative reforms, but his successor, Leopold II (1790-92), was obliged to restore the ancient constitution and to swear to treat Hungary as a wholly independent kingdom, to be ruled only in accordance with its own laws and customs. Francis I: the reform generation. When Leopold died in

1792, his son, Francis, made the motions of conforming with his coronation oath before slipping back into the old ways. The Diet was convoked simply to supply money and, after 1811, did not convene for 13 years. Social reaction accompanied this political absolutism, and the stranglehold on economic development was not relaxed.

Leaders of

the reform

movement

For many years the Diet, composed either of magnates who identified their interests with those of the court or of landowners who had prospered during the Napoleonic Wars, was as nonprogressive as Francis himself, but in wider circles the spirit of the age had given birth to a great cultural revival that was now bringing forth its first literary fruits, and the new national pride that it embodied was demanding fulfillment of Leopold's promises and an end to the veiled but oppressive dictatorship of Vienna. A great reform movement was set in motion by Gróf (count) István Széchenyi, who proclaimed that the ancient privileges of the nobility were no bastion but a prison. He argued that the servile state of the peasants was degrading and a source of weakness for the nation and also that the system of forced field labour, as well as the nobles' exemption from taxation, was economically harmful even to its supposed beneficiaries. After financial stringency had forced Francis to reconvoke the Diet in 1825, and thereafter to convoke it regularly, doctrines like these were taken up by a whole "reform generation," the most prominent figures of which were the legal expert Ferenc Deák; József, Báró (baron) Eötvös, leader of a small group that opposed breaking with the ruling dynasty; and above all Lajos Kossuth, who largely changed the current of the reform movement by his insistence that social and economic reform could be fully realized only after the achievement of political independence. After Francis had been followed on the throne in 1835 by the luckless Ferdinand-in practice by the government of the two principal ministers, Klemens von Metternich and Anton von Kolowrat-Vienna was driven increasingly onto the defensive and forced to make repeated concessions, especially with respect to the replacement of Latin and German by Magyar as the

The nationalities. This raised a new and painful issue, The population of Hungary, even excluding Croatia, had never been purely Magyar, but the pre-Magyar inhabitants of the plains and the newcomers to them (outside the towns) had quickly become Magyarized; and, while this was not true of the peripheral areas, their populations were relatively sparse. By the end of the 15th century the Slovaks and Ruthenes of the north; the Germans of the free boroughs, the Szepes, and Transylvania; and the Romanians numbered hardly more than 20 to 25 percent of the total. The Magyar majority included almost the entire politically active "noble" class, the non-Magyar recruits to which assimilated most readily. The surviving non-Magyar peasants had neither the wish nor the ability to question the Magyar character of the state, which for its part was uninterested in what languages were spoken by the politically disregarded, unfree populace,

language of the Diet, administration, and education.

Between 1500 and 1800, however, the ethnic composition of the country changed. The most purely Magyar areas were heavily depopulated during the Turkish wars. These losses were accompanied by mass immigrations of Serbs, Croats, and Romanians from the Balkans and later by the introduction by the Austrian government of large numbers of German and other colonists, by 1720 the Magyars numbered only some 35 percent of the total population. By 1780 the figure had risen to nearly 40 percent, but the periphery was still largely non-Magyar. Moreover, as a result of this ethnic colonization, the population of Hungary grew to nine million by the end of the 18th century, more than double the country's population in 1720.

In this environment the ideas of the French Revolution and of nationalism, one of its major consequences, took hold. Hungarians and most of the other ethnic groups discovered their own national identities. From the late 18th century, poetry, drama, fiction, and literary criticism combined to elevate the Hungarian vernacular to the standard of a literary language, partly in response to the forced Germanization by the Habsburgs but even more as part of an international trend that was particularly strong in central Europe. Institutions such as the national library, the national opera, and the Hungarian Academy of Sciences were also part of the linguistic-cultural movement that soon took the form of self-conscious chauvinism and then became an organized political movement.

Revolution, reaction, and "compromise." The Hungar-

ian reformers' opportunity came in the spring of 1848. Inspired by the Revolution of 1848 in Paris, a popular upheaval caused the breakdown of central authority in Vienna. On March 15 (a date celebrated in Hungary ever since), a bloodless revolution led by young intellectuals, including the poet Sándor Petőfi, abolished censorship in Pest and formulated a series of demands. Seizing the moment, Kossuth prodded the Diet to rush through a body of laws. The April Laws enacted important internal reforms, such as the generalizing of taxes, the abolition of villein status and the transfer of villein holdings to their cultivators, and the reorganizing of the lower "table" of parliament on a representative basis. They also provided for the restoration of the territorial integrity of the lands of the Hungarian crown (subject, in the case of Transylvania, to the agreement of its Diet) and the appointment of a "responsible independent Hungarian Ministry," which was headed by a progressive magnate, Gróf Lajos Batthyány, and included Kossuth, Széchenyi, Deák, and Eötvös. But the new government had enemies: the conservatives resented the land reform, and the centralists (i.e., those who advocated a Vienna-dominated empire) regarded the independent ministry, particularly its three "common" portfolios, as dangerous to the integrity of the monarchy. They found allies among the disaffected nationalities, notably the Serbs and Romanians, and in the Croats, whose ban, Josip Jelačić, refused to recognize the authority of Buda and Pest. Tension between Vienna and Pest mounted steadily, and in September, when the rest of the monarchy had been reduced, Jelačić, on Vienna's orders, invaded Hungary. Batthyány and other ministers resigned, leaving Kossuth in charge. An improvised national army drove Jelačić out of the country, but in December Ferdinand (whose coronation oath bound him to observe the April Laws) was made to abdicate in favour of his young nephew, Francis Joseph. The invasion was now renewed. A panmonarchic constitution abolished the April Laws, in reply to which a rump Diet, inspired by Kossuth, proclaimed the full independence of Hungary and the deposition of the Habsburg dynasty (April 14, 1849). The Hungarian forces, led by a young soldier of genius, Artúr Görgey, held their own until the Austrian court appealed for help to the Russian tsar, who sent an army across the Carpathians. Bitter fighting went on for some weeks more, but the odds were too heavy. On August 12, Kossuth fled the country, transferring his authority to Görgey, who the next day surrendered at Világos to the Russian commander.

Savage reprisals followed, and the country was again subjected to an absolutist and extortionate rule exercised from Vienna through a foreign bureaucracy. This "Bach regime" (for Alexander Bach, Austrian minister of the interior) was maintained until Austria's defeat in Italy in 1859 forced Francis Joseph to begin his retreat from absolutism. The followers of the exiled Kossuth were irreconcilable. but many inside Hungary rallied behind Deák. He held that the April Laws were legally valid and that Hungary's right to complete internal independence was inalienable but that under the Pragmatic Sanction, which he accepted, foreign affairs and defense were subjects "common" to the two halves of the monarchy and that a mechanism could be devised for handling these affairs constitutionally. A Diet convoked in 1861 was dissolved after a few weeks, hecause the gap between the Hungarians' views and those of Francis Joseph and his centralist ministry in Vienna were still too wide to be bridged. Absolutism was reimposed, but the pressure of international and internal economic difficulties gradually drove Francis Joseph to further concessions. In July 1865 he dismissed his centralist ministry; in December a new Diet was convoked and the negotiations reopened. Interrupted by the outbreak of the Seven Weeks' War, they were resumed after Austria's defeat by Prussia in 1866 had further convinced both parties of the necessity of agreement.

The Dual Monarchy, 1867-1918. A new Transylvanian Diet had already approved reunion with Hungary. In February 1867 Francis Joseph, having admitted the validity of the April Laws conditionally on the revision of those dealing with "common" (i.e., overlapping) affairs, Reprisals from Vienna appointed a responsible Hungarian ministry under Gróf Gyula Andrássy. A committee of the Diet then elaborated a law that, while laying down Hungary's full internal independence, provided for common ministries for foreign affairs and defense, each under a joint minister. A third common minister was in charge of the finance for these portfolios. The respective quotas to be paid for these services by each half of the monarchy were reconsidered every 10 years, as were commercial and customs agreements. At first, the two countries formed a customs union. On June 8 Francis Joseph was crowned king of Hungary, and on July 28 he gase his assent to the law.

Treatment of minorities Francis Joseph had stipulated that the settlement should include a revised Hungaro-Croatian agreement and provisions guaranteeing adequate rights for the non-Magyars of Hungary. The Croatian settlement (1868) left Croatia, including Slavonia, part of the Hungarian crown, under a ban appointed on the proposal of the Hungarian prime minister. Croatia was to enjoy full internal autonomy, but certain questions were designated as common to Croatia and Hungary. When these were under discussion, Croatian depetitions attended the central Parliament, in which they could speak in Serbo-Croatian, the sole language of internal official usage in Croatia.

The Nationalities Law (1868) guaranteed that all citizens of Hungary, whatever their nationality, constituted politically "the indivisible, unitary Hungarian nation," and there could be no differentiation between them except in respect of the official usage of languages, and then only insofar as necessitated by practical considerations. The language of the entiral administrative and judicial services, and of the university, was Hungarian, but there were to be adequate provisions for the use of non-Hungarian languages on lower levels. The consolidation was completed by the incorporation of the Military Frontier and of Transylvania, the latter process involving the abolition of the old "Three Nations," except that the Saxon "university"

was allowed to survive as a purely cultural institution. Hungary under dualism. The Compromise (Ausgleich) of 1867 restored territorial integrity to Hungary and gave it more real internal independence than it had enjoyed since 1526; the monarch's powers in internal affairs were strictly limited. In the conduct of foreign affairs or defense, however, Hungary still formed only part of the monarchy, and its interests in these fields had to be coordinated with those of its other components. But Hungary had a large voice in the monarchy's policy in these fields and enjoyed the great advantage that the resources of the great power of which it formed a part stood behind the country. To some, however, the price still seemed too high, and the parliamentary life of Hungary from 1867 to 1918 was dominated by the conflict between the supporters and the opponents of the Compromise, the latter ranging from complete separatists to those who accepted the Compromise in theory but wanted details of it altered.

The supporters of the Compromise, then known as the Deak Party, held office first but soon got into such financial and personal difficulties that complete chaos threatened. It was averted when in 1875 Kálmán Tisza, the leader of the moderate nationalist Left Centre, merged his party with the remnants of the Deakists on a program that amounted to putting his party's main demands into cold storage until the political and financial situation was stabilized. This new Liberal Party then held office for nearly 30 years. During these years the Compromise stood intact, but there was mounting friction with Vienna over the army, which the Hungarians regarded, with some reason, as imbued with a spirit hostile to themselves; over the economic provisions of the Compromise; and over the question of Hungarian participation in control of the · National Bank. An army question in 1889 marked something of a turning point, after which relations between the supporters of the Compromise, behind whom stood the crown, and its nationalist opponents were permanently strained. The tension reached a climax in 1903, when the obstruction of the "national opposition" made parliamentary government practically impossible. The premier, Gróf István Tisza (Kálmán Tisza's son), dissolved Parliament. Elections in January 1905 gave a coalition of "national"

parties a parliamentary majority, but Francis Joseph refused to entrust the government to them on the basis of their program, which included "national" concessions over the army. A period of nonparliamentary government followed until April 1906, when the coalition leaders, under threat of an extension of the suffrage if they proved recalcitrant, gave the king a secret undertaking that, if appointed, they would not press the essentials of their program. On this basis he appointed a coalition government, but under a Liberal, Sándor Wekerle. With their hands thus tied, the coalition made a wretched showing. Tisza reorganized the Liberal Party as the Party of National Work. and in the elections of 1910 this party secured a large majority. After Gróf Károly Khuen-Héderváry (1910-12) and László Lukács (1912-13), Tisza himself again became prime minister, and Francis Joseph ceased to press his demand for effective franchise reform, to which Tisza was inexorably opposed.

Social and economic developments. Hungary underwent much change after 1867. The achievements of the Deákist and Liberal governments included the assimilation of the former outlying areas of Transylvania and the Military Frontier, a reform of the relations between the central government and the counties, and a general reorganization of the administration. The judicial system was modernized. Relations between the state and the churches were, after a long struggle, restated in 1894-95 on terms satisfactory to the liberal philosophy of the day, which brought with them full emancipation for Hungary's large Jewish population. In 1868 Eötvös carried through an admirable elementary education act, and much headway was made in raising the educational and cultural level of the country. After long difficulties the national finances were put in order and the public debt reduced. There was considerable economic progress in many fields. Agriculture remained the mainstay of the economy. The medium and small landowners had been hard hit by the land reform of 1848, but the survivors were helped by the high agricultural prices and the secure Austrian market, Afterward, the general European agricultural depression plunged even the big landowners into difficulties, but these diminished near the end of the century, when prices rose again, while the quality and quantity of production improved. Many branches of industry failed to survive the customs union with Austria, but agriculture prospered, and later, as domestic capital accumulated, a process of industrialization, helped by state legislation, set in and expanded rapidly after 1890. As late as 1910 agriculture was still the most important branch of the economy, and 70 percent of the population still derived its livelihood from the soil, while

about one-sixth did so from industry and mining. Urbanization proceeded apace. The growth of Budapest (as it was called from the early 1870s) was meteoric—its population before World War I topped 800,000—and two other cities had populations of more than 75,000 and a dozen around 50,000. Communications were largely

modernized.

For all this, Hungary was still a relatively poor country. The extremely rapid growth of the population (from 13 million in 1850 to more than 20 million in 1910) had far outstripped that of the means of production. The growth of industry was still too slow to absorb the surplus rural population, and in spite of high emigration acute rural congestion had developed. While 35 percent of the land was held in 4,000 large estates, there were about 2 million small, or dwarf, holdings, and a further 1.7 million persons (wage earners) were totally landless. A large proportion of these rural workers were forced to live in conditions of extreme misery and near starvation. The living standards and conditions of the industrial workers, especially the unskilled, were also very low.

The political structure was not modern. The unreformed franchise excluded the masses from political influence, and even the vocational organization that they were able to achieve was primitive. The industrial and financial development had been largely the work of Jews (who also held a large part in the professions) or of Magyarized Germans. Its own quasi-allien character and its small numbers prevented the Hungarian middle class from developing

Economic progress

The rise of the Liberal Party Magyari-

zation of

classes

the middle

into a positive factor in the political life, which continued to be dominated by a landowning class whose social and political ideas failed to move with the times.

The "nationalities problem" remained intractable. After 1868 Hungarian political philosophy insisted more strongly than ever that the Hungarian state must be Magyar in spirit, in its institutions, and, as far as possible, linguistically. Suggestions to the contrary, or appeals to the Nationalities Law, met with derision or abuse. In spite of the law, the use of minority languages was banished almost entirely from administration and even justice. While the autonomy of the church schools was hardly attacked until the 20th century, most denominations saw to it that all secondary education in their schools, with trivial exceptions, was in Hungarian, which was also overrepresented in the primary schools, as it was in practically all instruction in the state schools founded from 1870 onward.

By the end of the century, the state apparatus was entirely Hungarian in language, as were business and social life above the lowest levels. The proportion of the population with Hungarian as its mother tongue rose from 46.6 percent in 1880 to 51.4 percent in 1900. The Magyarization of the towns had proceeded at an astounding rate. Nearly all middle-class Jews and Germans and many middle-class Slovaks and Ruthenes had Magvarized.

Most of the Magyarization, however, had been in the centre of Hungary and among the middle classes. It had hardly touched the rural populations of the periphery, and the linguistic frontiers had hardly shifted from the line on which they had been stabilized in the 18th century. In these areas, moreover, a hard core of national feeling had survived. This had weakened during the first decades after the Compromise but was reviving again at the beginning of the 20th century, especially among the Romanians, and was being encouraged from across the frontiers of Romania and Serbia and (in the case of the Slovaks) from Bohemia. Hungaro-Croatian relations, too, deteriorated, after a period of quiescence, when the Serbian government began propagating a theory of "Yugoslay" unity designed to detach the Croats from the monarchy.

Many of these developments threatened the very basis of the Compromise, and to this another uncertainty was added. Francis Joseph could be trusted to support and accept the policies of any Hungarian government that on its side maintained the Compromise lovally; but he was an old man, and his heir presumptive, the archduke Francis Ferdinand, was notoriously hostile to the Hungarian regime. In touch with many of its opponents, the archduke was credited with designs of overthrowing the Compromise to the benefit not of its traditional opponents, the Hungarian Independents, but of its enemies in the opposite camps, especially the nationalities.

World War I. The assassination of the archduke on June 28, 1914, removed this danger and plunged Austria-Hungary into World War I. For the first two years of the war, Tisza upheld the internal system and held the country to its international course; and when Francis Joseph died he persuaded the new king, Charles IV, to accept coronation (December 1916), thus binding himself to uphold the integrity and constitution of Hungary. Charles, however, insisted on electoral reform, and Tisza resigned (May 1917). While short-lived minority governments struggled with increasing difficulties, a threefold agitation grew: of Hungarian nationalists, against a war into which, they maintained, Hungary had been drawn in the interest of Germany and Austria; of the political left, growing daily more radical under the stimuli of privation and the Russian Revolution of 1917; and of the nationalities, encouraged by the favour that their kinsfolk were finding with the Triple Entente. The country began to listen to Gróf Mihály Károlyi, leader of a faction of the Independence Party, who proclaimed that a program of independence from Austria, repudiation of the alliance with Germany, and peace with the Entente, combined with social and internal political reform and concessions to the nationalities, would safeguard Hungary against all dangers at once. Hungary's submergence in the long, devastating war included the mobilization of 3.5 million men and exhausted the Hungarian economy. Agricultural output declined by

half during the last years of the war, and the currency lost more than half of its value. In the autumn of 1918 Hungary was on the brink of economic collapse.

REVOLUTION, COUNTERREVOLUTION, AND THE REGENCY, 1918-45

On Oct. 31, 1918, when the defeat of the monarchy was imminent, Charles appointed Károlyi prime minister at the head of an improvised administration based on a leftwing National Council. After the monarchy had signed an armistice on November 3 and Charles had "renounced participation" in public affairs on the 13th, the National Council dissolved Parliament on the 16th and proclaimed Hungary an independent republic, with Károlyi as provisional president. The separation from Austria was popular, but all Károlyi's supposed friends disappointed him. and all his premises proved mistaken. Serb, Czech, and Romanian troops installed themselves in two-thirds of the helpless country, and, in the confusion, orderly social reform was impossible. The government steadily moved leftward, and in March 1919 Károlyi's government was replaced by a soviet republic, controlled by Béla Kun, who had promised Hungary Russian support against the Romanians. The help never arrived, and Kun's doctrinaire Bolshevism, resting on a "Red terror," antagonized almost the entire population. On August 4 Kun and his associates fled Budapest, and two days later Romanian troops entered the city. Shadow counterrevolutionary governments had already formed themselves in Szeged and Vienna and pressed the Allies to entrust them with the new government. The Allies insisted on the formation of a provisional regime including democratic elements that would be required to hold elections on a wide, secret suffrage. The Romanians were, with difficulty, induced to retire across the Tisza River, and a government, under the presidency of Károly Huszár, was formed in November 1919. Elections were held in January 1920. The new Parliament declared null and void all measures enacted by the Károlyi and Kun regimes as well as the legislation embodying the Compromise of 1867. The institution of the monarchy was thus restored, but its permanent reinstatement was predicated on the resolution of the differences between the nation and the dynasty, an issue that divided Hungarians. In the interim Admiral Miklós Horthy, who had organized the counterrevolutionary armed forces, was elected regent as provisional head of state (March 1, 1920). The Huszár government then resigned, and on March 14 a coalition government, composed of the two main parties in the Parliament (the Christian National Union and the Smallholders), took office under Sándor Simonvi-Semadam.

The Regency, 1920-45. The Treaty of Trianon. The Allies had long had their peace terms for Hungary ready but had been unwilling to present them to an earlier regime. It was, thus, the Simonyi-Semadam government that was forced to sign the Treaty of Trianon (June 4, 1920). The Allies not only assumed without question that the country's non-Hungarian populations wished to leave Hungary but also allowed the successor states, especially Czechoslovakia, to annex large areas of ethnic Hungarian population. The final result was to leave Hungary with only 35,893 of the 125,641 square miles that had constituted the lands of the Hungarian crown. Romania, Czechoslovakia, and Yugoslavia took large fragments, while others went to Austria and even Poland and Italy. Of the population of 20,866,447 (1910 census), Hungary was left with 7,615,117. Romania received 5,257,467; Czechoslovakia, 3,517,568; Yugoslavia, 4,131,249; and Austria, 291,618. Of the 10,050,575 persons for whom Hungarian was the mother tongue, no fewer than 3,219,579 were allotted to the successor states: 1,704,851 to Romania, 1,063,020 to Czechoslovakia, 547,735 to Yugoslavia, and 26,183 to Austria. While the homes of some of these-e.g., the Szeklers-had been in the remotest corners of historic Hungary, many were living immediately across the frontiers. In addition, the treaty required Hungary to pay in reparations an unspecified sum, which was to be "the first charge upon all its assets and revenues," and limited its armed forces to 35,000, to be used exclusively for the

maintenance of internal order and frontier defense.

The soviet republic of Béla Kun

709

Both industrial and agrarian workers were embittered by the failure of their revolutionary hopes. Even more dangerous were the armies of the "new poor," not only the homeless refugees but also a large part of the middle classes in general, reduced to penury by the galloping inflation. They formed a radical army, one of the right that ascribed their misery precisely to the revolutions, on which they put the blame for all Hungary's misfortunes. Feelings ran particularly high against the Jews, who had played a disproportionately large part in both revolutions, especially Kun's, but the resentment extended also to the Social Democrats and even to Liberal democracy, "White terrorists" wreaked indiscriminate vengeance on persons whom they associated with the revolutions. Huszár's government itself had turned so sharply on the Social Democrats and the trade unions that the former withdrew their representatives from the government and boycotted the elections, in protest against the widespread arrests and internments (roughly 5,000 people were executed and 70,000 interned or imprisoned). Communists, radical democrats, and Jewish intellectuals emigrated in large numbers.

The government of Pál Teleki, who succeeded Simonvi-Semadam in July 1920, blunted the edge of the agrarian unrest with a modest reform-promised as a first installment-that took 1.7 million acres (7.5 percent of the total area of the country) from the biggest estates for distribution in smallholdings, but it had hardly touched any other social problem when in March 1921 the legitimist question was raised by King Charles's sudden return to Hungary. He was ordered to withdraw by the Allies with the willing compliance of the right-wing radicals, toward whom Horthy was then leaning. The government, several of whose members were legitimists, resigned, and the succession was assumed by the conservative Gróf István Bethlen, who had been waiting behind the scenes. Bethlen devised a formula that, while not legally excluding the king's return (under Entente pressure, Parliament had voted a law dethroning the Habsburgs, but even Hungary's own antilegitimists never took it as morally binding), excluded it in practice. In return for this, the Smallholders Party agreed with the antilegitimists among the Christian nationalists to form a new Party of Unity under Bethlen's leadership. He persuaded Parliament to accept as still legally in force the franchise enacted in 1918, which reduced the number of voters and reintroduced open voting in rural districts. Elections in May 1922 gave this party a large majority.

Meanwhile, a second attempt by the king (in October 1921) to recover his throne again failed, and, soon after, the legitimist question lost its acuteness with Charles's death. In December 1921 Bethlen concluded a secret pact with the Social Democrats, under which the latter promised to abstain from political agitation and to support the government's foreign policy in return for the end of persecution, the release of political prisoners, and the restoration of the sequestrated trade union funds. The peasant leaders were persuaded to accept the indefinite postponement of further land reform. The "White terror" was liquidated quietly but effectively, chiefly by finding government employment for the right-wing radical leaders.

Bethlen's domestic program was made possible by his cautious international policy. Almost all Hungarians were passionately convinced of the injustice of the Treaty of Trianon, the redress of which was the all-dominant motive of Hungary's foreign policy throughout the interwar period and the key to the hostile relations between Hungary and those states that had chiefly profited by it. Bethlen was as revisionist at heart as any of his countrymen, but he was convinced that Hungary could not act effectively in this field until it had acquired friends abroad and had achieved political and economic consolidation at home. This depended on financial reconstruction; to achieve this, he applied for Hungary's admission to the League of Nations, which was granted (not without difficulty) in September 1922. In March 1924, in return for an agreement to carry out loyally the obligations of the treaty, he obtained a League loan, which had almost magical effects. Inflation stopped immediately. The League loan was followed by a flood of private lending, and the expatriated domestic capital returned. With this help, Hungary enjoyed some years of prosperity, during which agriculture revived and industrialization made progress.

Abroad, Bethlen's only other important move was the conclusion in 1927 of a treaty of friendship with Italy. At home his regime, which was conservative but not tyrannical, rested on Hungary's conservative-liberal forces, to the exclusion of extremism from left or right.

Financial crisis: the rise of right radicalism. Bethlen's command of Parliament was complete and unshaken by the disastrous fall in world wheat prices in 1929. In June 1931 he had just held elections that returned his party with its usual large majority when a world financial crisis supervened on the economic one to shatter the foundations of his structure. Foreign creditors called in their money, and Hungary, its trade balance annihilated by the collapse of the wheat market, could not meet their demands and had to apply for help from the League of Nations, which imposed a regime of rigid orthodox deflation. Industrial unemployment soared again, the agricultural population was rendered almost literally penniless, and the government services had to carry through large-scale dismissals and salary reductions in the interests of a balanced budget.

In August Bethlen resigned, His successor, Grof Gyula Károlyi, was unable to cope with the situation. Political agitation mounted, and on Oct. 1, 1932. Horthy appointed as prime minister the leader of the right-wing radicals,

Gvula Gömbös. At home Gömbös found the leading strings of financial forces, international and domestic, as invincible as had his predecessors. Previously a violent anti-Semite, he had to recant his views on this point and was unable to carry through any other points of his fascist program, particularly as Horthy at first refused to allow him to hold elections. Neither was he able to realize his foreign political ideal of an "Axis" composed of Hungary, Italy, and Germany, since his two proposed partners were then at loggerheads over Austria, and Gömbös, one of whose first acts had been to dash to Rome and breathe new life into Hungary's friendship with Italy, found himself drawn into the "Rome Triangle" (Italy, Austria, and Hungary) that was directed precisely against Germany, Finally, Adolf Hitler upset another of his calculations by telling him that, while Germany would help Hungary against Czechoslo-

vakia, it would not do so against Romania or Yugoslavia. Nevertheless, by the time of Gömbös' premature death in October 1936, he had managed to achieve at least some of his goals. Shortly before Gömbös died, Horthy had allowed him to hold elections, which brought into Parliament a strong right-wing radical contingent from which it could never thereafter free itself. Abroad, when Benito Mussolini became subordinate to Hitler, Hungary found itself after all in a sort of Axis camp, membership of which might help it at least to accomplish partial revision of the Treaty of Trianon. On the other hand, if Germany chose to apply economic or political pressure, Hungary would be defenseless but for such shadow help as Italy could offer.

This threat already loomed large, and it became inextricably involved with Hungary's internal politics, by reason of the ideological character of the Nazi regime and in particular its anti-Semitism. Anti-Semitism at that stage was running high in Hungary itself, and those infected by it-not just the right-wing radicals of various brands but other members of the middle classes as well-welcomed Germany's support for their own ideas while making light of its dangers. They even argued, not without reason, that the danger lay in affronting Germany, which could easily crush unarmed little Hungary but would not wish to attack a friend and ideological partner. They further believed Gömbös appointed prime minister

The right-

wing

radicals

question of support for Germany

(most army officers held this view) that, should Hitler's policies lead to war, Germany would emerge the victor; Hungary's salvation thus lay in joining forces with Germany. On the other side a curious shadow front emerged, composed of all elements antagonistic to Nazism-not only Hungary's Jews but also the legitimists, the traditionalist conservative-liberals, and the Social Democrats. Many of these were not convinced that Germany was invincible and held that if war came, only disaster could follow for Hungary if it became too closely involved with Germany. Even they, however, were unwilling to draw the ultimate conclusion that Hungary should abandon all its revisionist claims and join hands with the Little Entente, which, for its part, indicated that it would accept nothing short of total renunciation. It was of the highest importance that by this time Horthy had shed his earlier right-wing radical leanings and sympathized with this shadow front.

To succeed Gömbös, Horthy appointed Kálmán Darányi, more of a conservative than a right-wing radical; the appointment was ill-received in Germany, which grew more hostile the next year, when Darányi's foreign minister, Kálmán Kánya, obtained the tacit consent of the Little Entente for Hungary to rearm, although Hungary was still short of armaments, for which Germany was its only source of supply. On a visit to Berlin, Darányi and Kánya smoothed over the difficulties; but, when Darányi tried to placate the extremists at home, Horthy replaced him (in May 1938) with Béla Imrédy, who introduced a largely token "Jewish Law" but nevertheless pinned his hopes on the West. When the Munich crisis broke in September, Imrédy and Kánya, while presenting Hungary's claims on Czechoslovakia, limited the claims to what they hoped would be acceptable to the Western powers, whose endorsement they made every effort to obtain. Ignored by the West, the Hungarian leaders had to turn to Germany and Italy, which, under the "First Vienna Award" of November 2, gave Hungary the fringe of southern Slovakia inhabited by ethnic Hungarians. Imrédy, disillusioned with the West, dismissed Kánya for the pro-Axis Gróf István Csáky and sought to recover Hitler's favour by introducing a more far-reaching Jewish Law. Imrédy's enemies secured his resignation in February 1939 by unearthing documents purporting to show a Jewish strain in his own ancestry. Pál Teleki, who succeeded him, was a most convinced Westerner, but Hungary's recovery of Carnatho-Ruthenia (March 1939) was, again, sanctioned by Hitler.

War and renewed defeat. When Germany attacked Poland (Sept. 1, 1939), Hungary refused to allow German troops to cross Hungarian territory. In the first months of World War II none of the belligerents wanted the war to extend to southeastern Europe, so Teleki and Horthy were able to keep Hungary at peace. After the Soviet Union had occupied Bessarabia in June 1940, the Hungarian leaders compelled a reluctant Germany (but a willing Italy) to cede to Hungary northern Transylvania under the "Second Vienna Award." But they then allowed German troops to cross Hungarian territory into southern Romania and in

November signed the Tripartite Pact. The next step was more fatal still. In his search for cautious reinsurance, Teleki concluded with the like-minded government of Yugoslavia a treaty unluckily characterized as one of "Eternal Friendship." On March 26, 1941, that Yugoslav government was overthrown by a pro-Western regime. Hitler prepared to invade Yugoslavia and called on Hungary to help him. Hungary refused to join in the attack but again allowed German troops to cross its territory. Great Britain threatened to declare war, and Teleki, blaming himself for the development of a situation that it had been his life's aim to avoid, took his own life on April 2. His successor, László Bárdossy, waited until Croatia had declared its independence (April 10); then, arguing that Yugoslavia had already disintegrated, he occupied the ex-Hungarian areas of Yugoslavia.

Although he was not a fascist, Bárdossy believed that the Axis powers would win the war and that Hungary's salvation lay in placating them; otherwise, he believed, Romania (now pro-Axis) would persuade Hitler to reverse the Second Vienna Award. Accordingly, when Germany attacked the Soviet Union (June 22), Bárdossy sent a

token force to assist in what everyone expected to be a brief operation. The strength of the Soviet resistance upset the calculation, and in January 1942 the Germans forced Hungary to mobilize practically all its available manpower and send it to the Soviet Union, Meanwhile, Britain, by this point allied with the Soviet Union, declared war (December 1941) on Hungary, which in its turn declared war on the United States. Further, Britain recognized the Czechoslovak government-in-exile and withdrew recognition of the First Vienna Award, and the Soviet Union recognized Czechoslovakia's 1937 frontiers.

Many Hungarians by then agreed with Bárdossy that Hungary's only course was to fight on until the Axis won the war-the more so because all Hungarians except those of the extreme left regarded Bolshevism as the embodiment of evil. Horthy, however, while sharing the latter view, still believed in a Western victory and thought it possible for Hungary, while continuing the struggle in the east, to regain the favour of the West. In March 1942 he replaced Bárdossy with Miklós Kállay, who shared these hones. For two years Kállay conducted a remarkable balancing act-protecting Hungary's Jews and allowing the left (except for the communists) almost untrammeled freedom while putting out innumerable feelers to the Western Allies, to which he actually promised to surrender unconditionally when their troops reached Hungary's frontiers. Meanwhile, in January 1943 the Hungarian expeditionary force suffered a crushing defeat at Voronezh in western Russia that cost it much of its manpower and nearly all

But the Western forces did not approach the Danube valley, and, as the Soviet army neared the Carpathians, Hitler decided that he could not leave his vital communications at the mercy of an untrustworthy regime. In March 1944 he offered Horthy the choice between full cooperation under German supervision or undisguised German occupation with the treatment accorded to an enemy country. Horthy chose the former course and appointed a collaborationist government under Döme Sztójav. For a while the Germans did much as they wished-they suppressed parties and organizations of potential opponents and arrested their leaders. With the cooperation of Hungarian authorities, Jews were compelled to wear a yellow star, robbed of their property, and incarcerated in ghettos as in other Nazi-occupied areas. Except for the Jews in the capital and those in the forced-labour camps of the Hungarian army-whose turn would come later-they were deported to the gas chambers of German concentration camps. In spite of the efforts of representatives of some neutral countries-such as Raoul Wallenberg of Sweden, the papal nuncio, and diplomats of Switzerland, Portugal. and even Spain, who saved tens of thousands of livesmore than 550,000 of Hungary's nearly 750,000 Jews, as

defined by racist legislation, perished during the war. In the summer the pressure relaxed; and in August, after Romania's surrender to the Allies, Horthy appointed a new government under the loyal general Géza Lakatos and again extended peace feelers. A "preliminary armistice" was concluded in Moscow, but, when on October 15 Horthy announced this on the radio, he was abducted by the Germans, who forced him to recant and to abdicate. The Germans put Ferenc Szálasi, the leader of the rightwing extremist Arrow Cross movement, in charge. By then, however, Soviet troops were far inside the country. The Germans and their Hungarian allies were driven back slowly, while numerous refugees fled with them. The last armed forces crossed the Austrian frontier in April 1945.

The defeat was sealed in a new peace treaty, signed in Paris on Feb. 10, 1947, which restored the Trianon frontiers, with a rectification in favour of Czechoslovakia and the Soviet Union. It imposed on Hungary a reparations bill of \$300 million and limited its armed forces. The implementation of the treaty's provisions was to be supervised by a Soviet occupation force, a large contingent of which remained in the country.

HUNGARY SINCE 1945

As in 1920, a new regime recognized the defeat of its predecessor. As early as December 1944 a makeshift ProHungary in the war

Soviet

troops in

Hungary

German troops in Hungary visional National Assembly had accepted a government list and program presented to it by communist agents following in the wake of the Soviet armies. Beginning cautiously, the communists announced that the new Hungary was to rest on "all its democratic elements." The government contained only two communists: its other members were representatives of four noncommunist leftwing parties-the Smallholders, the Social Democrats, the National Peasants, and the Progressive Bourgeoisie-and four men associated with the Horthy regime. The program provided for the expropriation of the large estates and the nationalization of the banks and heavy industry; but it promised guarantees of democratic rights and liberties. respect for private property, and encouragement of private

initiative in trade and small industry. The communist regime. Political developments. The full political takeover, however, proceeded systematically, although not according to any timetable, for the communists, misjudging feeling in the country, allowed the first elections (November 1945) to be relatively free. Only the parties of the coalition were allowed to contest them; but the adherents of the proscribed parties voted for the Smallholders, who received an absolute majority. The head of the Soviet mission, however, insisted that the coalition must be maintained; a Smallholder was allowed to be prime minister, but the Ministry of the Interior, with the control of the police, was given to the communists. Pressure and intimidation were then applied to the Smallholders to expel their more courageous members as "fascists": and in the next election (August 1947) the Smallholders polled only 15 percent of the votes cast. The communists had meanwhile forced the Social Democrats to form a "workers' bloc" with them. Although the pressure this time was considerable, the bloc still polled only 45 percent of the votes (other parties were allowed to participate this time); however, the communists then forced the Social Democrats to join them in a single Workers' Party, from

Commu-

nist takeover

which recalcitrants were expelled. In the next election (May 1949) voting was open, and the voters were presented with a single list, on which candidates identified as Smallholders and National Peasants were actually tools of the communists. In August a new constitution was enacted-a copy of that of the Soviet Union. Hungary, a republic since Feb. 1, 1946, now became a "people's republic," and, although its president (Zoltán Tildy) and for a while its prime ministers (Ferenc Nagy, then Lajos Dinnyés) were Smallholders, all real power rested with the Workers' Party, which was controlled by its first secretary, Mátyás Rákosi. Finally, the party's "Muscovite" wing turned on its "national" wing. The leader of this latter group, László Rajk, was executed on questionable charges in October 1949, and his chief adherents were similarly executed or imprisoned. Meanwhile, hundreds were executed or imprisoned as war criminals, many of them for no other offense than loyalty to the Horthy regime. Many thousands more were interned. The State Security Department (AVO) was omnipotent, The judiciary, civil service, and army were purged, and party orthodoxy became the criterion for positions in them. The trade unions were made into mere executants of party orders. After the dissolution of the parties, the chief ideological opposition to the communist regime came from the churches; but their estates were expropriated, making it impossible for them to maintain their schools, and in 1948 the entire educational system was nationalized. The Calvinist and Lutheran churches accepted financial arrangements imposed by the state. The head of the Roman Catholic church, József Cardinal Mindszenty, who refused to follow their example, was arrested in December 1948 and condemned to life imprisonment. The monastic orders were dissolved. Thereafter, the Roman Catholic church accepted financial terms similar to those offered to the other churches, and eventually the bishops, with visible repugnance, took the oath of loyalty to the state.

Economic developments. The communists' economic program, like their political program, could not be realized immediately, because in 1945 Hungary was in a state of economic chaos worse even than that of 1918. This time the country had been a theatre of war. Many cities were in ruins, and communications were wrecked; the retreating Germans had destroyed the bridges between Buda and Pest and had taken with them all they could of the country's portable wealth. The Soviet armies lived off the land. and the Soviet Union took its share of reparations in kind, placing its own values on the objects seized. It also took over former German assets in Hungary, including Jewish property confiscated during the Nazi occupation.

A three-year plan introduced in August 1947 was devoted chiefly to the repair of immediate damage. This was declared completed, ahead of schedule, in December 1949. By then the communists were in full political control, and measures nationalizing banking, most industry, and most internal and all foreign trade had been enacted. Hungary ioined other Soviet-bloc countries in founding the Council for Mutual Economic Assistance (Comecon) in 1949. The land, outside the big estates, was not touched at first, but in 1948 Rákosi announced a policy of collectivization

of agriculture. The three-year plan was succeeded by a five-year plan. the aim of which was to turn Hungary into a predominantly industrial country, with an emphasis on heavy industry. Huge sums were devoted to the construction of foundries and factories, many of them planned with little regard for Hungary's real resources and less still for its needs. In fact, the plan was concerned with the needs of the Soviet Union, for which Hungary was to serve as a workshop. Hungary's newly discovered deposits of uranium went straight out of the country. Industrial production rose steeply, but the standard of living did not; the production of consumer goods was throttled and that of agriculture stagnated.

The revolution of 1956. Rákosi-who in 1952 came to preside over the government as well as the party-was allpowerful until the death of Stalin in 1953, when a period of fluctuation began, In July 1953 Rákosi was deposed from the prime ministership in favour of Imre Nagya "Muscovite" but a Hungarian in his attitudes and not unpopular in the country. Nagy promised an end to the forced development of heavy industry, more consumer goods, no more forcing of peasants into the collectives, the release of political prisoners, and the closing of internment camps. He introduced some of these reforms, but Moscow hesitated to support him. In the spring of 1955 Nagy was dismissed from office and expelled from the party. Rákosi, reinstated, put the country back on its previous course but was dismissed again in July 1956, this time in disgrace. The new Soviet leader, Nikita S. Khrushchev, had sacrificed Rákosi as a gesture to the Yugoslavian leader Josip Broz Tito, whom he wished to placate and whom Rákosi had offended personally. The new leader, Ernő Gerő, Rákosi's deputy, was almost as detested as Rákosi himself. Gerő promptly announced that there would be no concessions on matters of principle to Nagy and his group.

The relaxation of pressure under Nagy (though transitory), Khrushchev's "secret speech" denouncing Stalin's cult of personality delivered at the 20th Congress of the Communist Party of the Soviet Union (February 1956), and the Polish challenge to the Soviet Union in the spring and summer of 1956 emboldened Hungarians. On October 23, students in Budapest staged a great procession, which was to end with the presentation of a petition asking for redress of the nation's grievances. People flocked into the streets to join them. Gerő answered with an unwise and truculent speech, and police fired into the crowds. The shots turned a peaceful demonstration into a revolutionary one. The army joined the revolutionaries, and army depots and munitions factories handed out arms. Outside Budapest local councils sprang up in every centre; the peasants reoccupied their confiscated fields. The communist bureaucracy melted away. Prison doors were opened. The members of the AVO fled if they could. A cheering crowd escorted Cardinal Mindszenty back to the palace. In kaleidoscopic political changes, Nagy resumed power but was driven from one concession to the next, until he found himself at the head of a genuine coalition government composed of Smallholders, Social Democrats, and National Peasants, which, with a "Catholic Association," had reconstituted themselves.

programs

Revolution and change The end

revolution

of the

The Soviet troops had withdrawn, and Nagy was negotiating for the complete evacuation of Hungary. On November I he announced Hungary's withdrawal from the Warsaw Pact and asked the United Nations to recognize Hungary as a neutral state. Soviet officials were uncertain whether to let matters take their course, but Nagy's denunciation of the Warsaw Pact was too threatening, and their tanks, which had halted just across the frontier, began to return, reinforced by other units. On November 4 the tanks entered Budapest. Nagy took refuge in the Yugoslav embassy and Cardinal Mindszenty in the U.S. legation, General Pál Maléter, head of the Hungarian national forces, was imprisoned.

A communist leader, Ferenc Münnich, and János Kádár, a "National Communist" who had been imprisoned under Rákosi and had actually joined the revolutionaries on October 24, formed a new "revolutionary peasantworker government," consisting entirely of communists, with Kádár as prime minister. Kádár promised that when the "counterrevolution" had been suppressed and order restored he would negotiate on the withdrawal of the Soviet garrison (although the denunciation of the Warsaw Pact was retracted): he dissociated himself from the "Rákosi-Gerő clique" and promised internal reforms.

The country was not convinced, and fighting broke out, But the odds were too heavy, and the major hostilities were over within a fortnight. The workers, however, proclaimed a general strike, and it was many weeks before

they were brought to heel.

Meanwhile, Nagy, who had left his place of refuge under safe conduct, had been abducted to Romania. After a secret trial he, Maléter, and a few close associates were executed in 1958. Many lesser figures were seized and transported to the Soviet Union, some never to return: 200,000 refugees escaped to the West. Thus, a substantial proportion of Hungary's educated classes was lost to the country. Material damage was also heavy.

The Kádár regime. In the first uncertain weeks of his regime Kádár made many promises. Workers' councils were to be given a large amount of control in the factories and mines. Compulsory deliveries of farm produce were to be abolished, and no compulsion, direct or indirect, was to be put on the peasants to enter the collectives. The fiveyear plan was to be revised to permit more production of consumer goods. The exchange rate of the ruble and forint was to be adjusted and the uranium contract revised. For a time there was even talk of a coalition government.

The larger hopes were dashed after representatives of the Soviet Union, East Germany, Czechoslovakia, Romania, and Bulgaria conferred with those of Hungary in Budapest in January 1957. A new program was soon issued stating that Hungary was a dictatorship of the proletariat, which in foreign policy relied on the Soviet Union and the Soviet bloc. Further, it was asserted that the Soviet garrison was in Hungary to protect the nation from imperialist aggression. Internal reforms were again promised, however, and foreign trade agreements were to be based on complete equality and mutual advantage.

Subsequently, Kádár was at great pains to give the Soviet Union no cause for uneasiness over Hungary's loyalty. When any international issue arose, he invariably supported Moscow's policy with meticulous orthodoxy, even sending a contingent into Czechoslovakia in 1968. At home he ignored some of his promises and honoured others only superficially. The peasants were so greatly pressured to enter cooperatives that within a few years practically no private farms survived. The workers' councils were dissolved, but trade unions were later granted rights to query decisions by management. Parliament remained a rubber stamp, and a Patriotic People's Front (PPF), on which noncommunists were represented, was a mere façade.

Nevertheless, conditions changed very much for the better. Kádár enunciated the principle that "he who is not against us is with us," which meant ordinary people could go about their business without fear of molestation or even much surveillance and could speak, read, and even write with reasonable freedom. Technical competence replaced party orthodoxy as a criterion for posts of responsibility.

More scope was allowed to private small-scale enterprise in trade and industry, and the New Economic Mechanism (NEM), initiated in 1968, introduced the profit motive into state-directed enterprises. Agricultural cooperatives were allowed to produce industrial goods for their own use or to sell on demand, while the private plots of their members supplied a large proportion of fruits and vegetables for the rest of the population. Contacts with the West were encouraged. A modus vivendi was found with the Vatican and with Protestant churches. The standard of living began to rise substantially. Tourism developed as a significant industry. In addition to a huge influx of foreign visitors to Hungary, an increasing number of Hungarians traveled abroad, especially after the introduction (Jan. 1, 1988) of "global passports," which removed restrictions on travel. Income from tourism increased dramatically, yet the net balance was less in Hungary's favour than would be expected because Hungarians going to the West spent most of their official hard currency quotas on purchases of consumer goods, owing to shortages and skyrocketing prices at home

The two decades of the NEM, which went beyond the liberalization that took place in the Soviet Union itself. were only partially successful. Productivity failed to rise according to expectations. Government regulations persisted in many areas, and the economy remained geared to the Soviet-led Comecon. A burdensome system of subventions aimed at keeping down the prices of basic necessities and services and at promoting the production of statepreferred goods made realistic cost accounting impossible. The price rise of petroleum and other industrial raw materials on the world market also aggravated the situation. The gap grew between the price of energy, sophisticated industrial hardware, and raw materials on the one hand and the price of agricultural products, a main item in Hungary's foreign trade, on the other. (C.A.M./G.Ba./Ed.) Political opposition to reform, including Soviet and Comecon criticism of the NEM, all but brought it to a halt in 1973-78, when administrative interventions by state agencies and party and trade union organizations caused a return to the methods of the centralized command economy under the pretext of protecting the relative earnings of industrial workers compared with those in agriculture or of taxing only "unearned" profits of successful enterprises. Rezső Nyers, the architect of the NEM, was demoted in 1974, only to be brought back to the Polithuro in May 1988, at a time of deepening political and economic crisis. By the end of the 1970s, reformers again prevailed. New measures included cuts in the central bureaucracy, encouragement of small firms and private enterprises, revisions of the price and wage system to reflect more closely conditions on the world market and costs of production, and the creation of a commercial banking system.

Reforms of the late 1980s. Economic reforms. The efforts to introduce market reforms into Hungary's socialist economy extended to the international arena. Already a member of the General Agreement on Tariffs and Trade (GATT), Hungary was admitted to the International Monetary Fund (IMF) in 1982 and received assistance from the World Bank. An agreement with the European Economic Community (now the European Union), the first among members of Comecon, was also concluded. While the Soviet Union remained Hungary's most important trading partner and the source of its energy supply, Hungary had to turn to the West for technological assistance and capital investment in the process of modernizing the economy. Trade relations with the West, in which Austria and West Germany played particularly important roles, were crucial at a time when barely half of Hungary's foreign trade involved members of Comecon. Foreign trade constituted a larger proportion of Hungary's gross national product (GNP) than that of any other Comecon country.

Efforts to adjust Hungary's economy to the world market Economic were handicapped by the adverse effects of the energy crisis of the 1970s and the de facto reversal of the NEM in the same decade. Although agricultural production continued to advance, in part because of favourable international market conditions, the rest of the economy deteriorated. This process was further aggravated by misallocation of

Improvements under Kádár

deteriora-

funds, reluctance to abandon costly projects such as the Danube hydroelectric power plant, participation in joint projects of Comecon, and unwillingness to drastically reduce subsidies to inefficient enterprises and for many basic necessities and services, whose price level was kept artificially low for many years. As a result Hungary's hard currency debt reached \$18 billion by the end of the 1980s, representing the highest per capita indebtedness of any country in eastern Europe. Inflationary pressures began to build up, and real wages and living standards declined.

The appointment of Károly Grósz as prime minister in mid-1987 led to a program of severe belt-tightening; a harsh, hastily prepared income-tax law aimed at cutting consumption; anticipated unemployment in some segments of the economy; and steep rises in consumer prices, transportation costs, and basic services such as gas, electricity, telephone, water, and rents. Minor changes in the party leadership, still controlled by Kádár, and the reshuffling of the government eased acceptance of unpopular measures introduced to stabilize the collapsing economy.

Political changes and reforms. By the late 1980s, growing numbers of Hungarians had concluded that years of misgovernment could not be erased by economic reforms alone. The process of de-Stalinization reinforced the desire to reexamine the political premises of Grósz's program. which seemed to imply that to keep their hard-won personal freedoms Hungarians should pay with economic misery and further social polarization. By the time the Weakening annual inflation rate reached 17 percent, public pressure compelled the party conference in May 1988 not only to replace Kádár with Grósz but also to replace several of Kádár's supporters in the Politburo and Central Committee. Miklôs Németh became the prime minister in November 1988; then in 1989 a quadrumvirate of Imre Pozsgay, Grósz, Németh, and Nyers, chaired by the latter, temporarily took over the direction of a deeply split party. In October the party congress announced its transformation into the Hungarian Socialist Party (MSzP). A splinter group of conservatives retained the old name and continued allegiance to its policies.

of the

Politburo

Meanwhile, informal associations, clubs, and debating circles proliferated and served as points of departure for new political parties. The Democratic Union of Scientific Workers, supported by a substantial portion of academic and clerical employees of scholarly institutions, was the first independent professional association to challenge the communist-controlled National Council of Trade Unions and to establish contact with the Polish Solidarity as well as organized labour in the West. Filmmakers, writers, and journalists rediscovered their right of free speech, publishers printed manuscripts that had been kept locked up for decades, new periodicals appeared, and the press, radio, and television threw over taboos that had prevailed for more than 40 years.

The 950th anniversary of the death of Stephen I was celebrated with medieval pomp in August 1988 in the presence of the primate of Poland, Józef Cardinal Glemp, representing Pope John Paul II. Full diplomatic relations with the Vatican were reestablished in 1990. The state also returned to the Protestant churches some of their former prestigious educational institutions, the Boy Scouts (a conspicuously Christian organization in Hungary) was resuscitated, and the World Jewish Congress held its executive session in Budapest in 1987.

The Kádár regime had tried to avoid offending fraternal communist governments by not raising questions about violations of the rights of Hungarian minorities within their jurisdiction, but, in the late 1980s, Hungarian party and government leaders joined public protests against this repression and the implementation of Romania's policy of reapportionment and relocation of the rural population, which affected a disproportionately large number of ethnic Hungarian settlements. A rift between Hungary and Romania deepened as ethnic disturbances in Transylvania continued even after the fall of the regime of Nicolae Ceaușescu in Romania. Hungary declared all Romanians of Hungarian descent to be dual citizens, in defiance of a 1979 bilateral agreement. This policy, combined with renewed openings toward Austria, establishment of trade relations with South Korea, and the resumption of diplomatic relations with Israel, was taken as a sign of a more independent foreign policy, as were the efforts at strengthening Hungary's ties with western Europe.

In 1989 the long-closed border between Hungary and Austria was opened. Interviews broadcast by Hungarian television with Alexander Dubček and Ota Šik, leaders of the Czechoslovak reform movement, and with the exiled king Michael of Romania, as well as Hungary's refusal to prevent tens of thousands of East German refugees from crossing into Austria on their way to West Germany, led

to formal protests in Prague, Bucharest, and East Berlin. The changes on the domestic scene were no less dramatic. Guidelines for a new constitution did not mention the "leading role of the Party," spelled out by the constitution of 1949. The draft of the new constitution sanctioned a multiparty system that had already been accepted in principle by the party leadership. The new constitution was based on the separation of legislative, executive, and judicial powers and included guarantees of individual and civil rights. Many of these changes were put into effect in October 1989 by a series of amendments to the 1949 constitution; other changes included the creation of the post of state president in place of the Presidential Council and the elimination of the word People's from the name of the country.

Constitutional amendments of 1989

Important new legislation included amendments to the law of assembly, which granted the holding of indoor meetings without special permission, and a new enterprise law, which allowed the private ownership of businesses with up to 500 employees, permitted foreigners to own up to 100 percent of an enterprise, and allowed mixed (i.e., joint state and private) ownership of property. The government consulted with independent organizations and spokesmen of the opposition in the course of preparing the new laws, and the function of the National Assembly underwent a certain change. Theretofore a rubber stamp, the Assembly rejected the government's budget during its autumn 1988 session.

Alternative independent parties and organizations continued to grow. The Independent Smallholders' Party, the Social Democrats, the People's Party, and the Hungarian Independence Party, destroyed or emasculated by the communists in 1949, reemerged. A Christian Democratic Party also began to organize. Few of the new parties chose to support socialist principles. The same held true for the Young Hungarian Workers' Organization, the Federation of Agrarian Youth, the Alliance of Free Democrats (SzDSz), and the Hungarian Democratic Forum (MDF), a right-of-centre party whose membership passed 10,000 by the end of 1988.

Stabilizing democracy and the market economy. In March 1990 Hungary's first free elections led to a landslide victory for the opposition. The MDF, which had become the single strongest party in the parliament, formed a coalition government with the Smallholder and Christian Democratic parties under the premiership of József Antall (until his death in 1993). The MSzP, burdened by the legacy of state socialism, gained less than 10 percent of the votes. The coalition guided Hungary's socioeconomic transformation and attempted to stabilize the economy while implementing privatization and other elements of a market economy. The populist right wing of the MDF was vocal about the "national issue"-the question of the Hungarian minorities in neighbouring countries-and attempted to put it at the centre of the government's platform. After a period in which the discussion of anti-Semitism and discrimination against Gypsies had come to the fore, anti-Semitic rhetoric also appeared, as did an attempt to rehabilitate the reputation of the Horthy regime.

The new political elite, having miscalculated the impact of this policy and propaganda, antagonized a great part of the population. A deep dissatisfaction was expressed in the local elections a few months later that resulted in a devastating defeat for the MDF and a victory for the liberal-left opposition of the SzDSz and MSzP.

Economic transformation was more painful and lasted longer than anybody had thought it would. Unemployment jumped from nonexistence to 14 percent. Inflation increased at an annual rate of 23-35 percent. The living standards of more than one-third of the populace declined to below subsistence level; income disparities increased; and corruption became more widespread and visible. Together with the previously omnipotent police force, street security collapsed in 1990, and the crime rate, especially in Budapest, increased threfold in five years.

In 1994, Hungary's second free elections transformed the country's politics. The MSzP won an absolute ragiotity of the seats in the parliament and formed a government in coalition with the \$2DSz under the premiership of Gyula Horn. Horn pursued many of the policies initiated by Antall, including the privatization of the economy and the pursuit of membership in NATO and the European Union (EU). In March 1995 the government introduced an austerity program designed to trim the budget and instill the financial discipline required by international financial institutions. The reforms precipitated several ministerial resignations, threatened the stability of the governing coalition, and were deeply unpopular.

The economy rebounded over the next several years, and the country attracted the largest amount of direct foreign investment in eastern and central Europe. Moreover, the Hungarian stock market became the region's strongest, resulting in a surge in the government's popularity.

In July 1997, Hungary, along with the Czech Republic and Poland, was invited to join NATO. The public over-whelmingly endorsed membership in November, and the country officially joined NATO in 1999, Meanwhile, the EU rated Hungary the best eastern and central European candidate for membership based on its commitment to democracy, its economic competitiveness, and its advancement in adjusting its laws to EU standards.

Hungarian politics slowly evolved into a bipolar system pitting the left against the centre-right. The centre-right Federation of Young Democrats (Fidesz)-Hungarian Civic Party, which promised improvements in the welfare system to ease the hardships caused by Horn's austerity program, won a surprising victory in May 1998. Fidesz formed a government by entering a coalition with the Hungarian Democratic Forum and the populist, right-wing Independent Smallholders' Party. Prime Minister Viktor Orban immediately launched a radical reform of state administration. He sought to enhance the power of the office of the prime minister, fired the boards that oversaw the social security funds and central social security payments, created a government newspaper, and purged many figures in the state-controlled media. As the country entered the 21st century, the economic boom continued, but the political situation deterioriated, particularly because of acrimonious relations between Orban and the opposition, which regarded the prime minister's leadership style as arrogant. In 2002, after a bitter election campaign, Orban's government was defeated by the Hungarian Socialist Party, led by economist Peter Medgyessy, who formed a twoparty coalition. Medgyessy continued to pursue economic integration with western Europe and maintained cordial relations with the United States. In 2004 Hungary realized one of its primary foreign policy goals by gaining admission to the EU.

For later developments in the history of Hungary, see the BRITANNICA BOOK OF THE YEAR.

Hungary under communism is described in Ernny C. Helmer REICH (ed), Hungary (1957, reissued 1973), MRLGé MONIÑA, A Short History of the Hungarian Communist Party (1978); Bit As Shot, History of the Hungarian Communist Party (1978); Bit Lia, Start, Form Hungarian (1971); and Bennett Koverig, Communism in Hungary-From Kun to Kddar (1978).

The period from the twolution of 1955 to the present is addressed in PAUL E. ZINNER, Revolution in Humany (1962, reissued 1972); CHARLES GATI, Humgary and the Soviet Bloc (1986); WAN T. BEREND (T. VAN BEREND), The Humgarian Economic Reforms, 1933–1938 (1990; originally published in Humgarian, 1988), and Central and Eastern Europe, 1944–1993 (1996), with major sections concerning Humgary and PETER A. TOMA and IVAN VOLGYES, Politics in Humgary (1977). Further references may be found in STEVEN BELA VARDY, Modern Humgarian Humgarian (1994). Democratic Changes in Humgary, trans. from Humgarian (1996).

(C.A.M./G.Ba./I.T.B.)

The Hydrosphere

ater is the most abundant substance at the surface of the Earth. About 1.4 billion cubic kilometres (326 million cubic miles) of water in liquid and frozen form make up the oceans, lakes, streams, glaciers, and groundwaters found there. It is this enormous volume of water, in its various manifestations, that forms the discontinuous layer, enclosing much of the terrestrial surface, known as the hydrosphere.

Central to any discussion of the hydrosphere is the concept of the hydrologic cycle. This cycle consists of a group of reservoirs containing water, the processes by which water is transferred from one reservoir to another (or transformed from one state to another), and the rates of transfer associated with such processes. These transfer paths penetrate the entire hydrosphere, extending upward to about 15 kilometres (nine miles) in the Earth's atmosphere and downward to depths on the order of five kilometres in its crust.

This article examines the processes of the hydrologic cycle and discusses the way in which the various reservoirs of the hydrosphere are related through the hydrologic cycle. It also describes the biogeochemical properties of the waters of the Earth at some length and considers the distribution of global water resources and their utilization and pollution by human society. Details concerning the major water environments that make up the hydrosphere are provided in the articles OCEANS, LAKES, RIVERS, and ICE AND ICE FORMATIONS. See also CLIMATE AND WEATHER for specific information about the impact of climatic factors on the hydrologic cycle. The principal concerns and methods of hydrology and its various allied disciplines are summarized in EARTH SCIENCES, THE. For coverage of other related topics in the Macropædia and Micropædia. see the Propædia, sections 221, 222, 223, 351, and 10/33, and the Index.

The article is divided into the following sections:

Distribution and quantity of the Earth's waters 715 Biogeochemical properties of the hydrosphere 715

Rainwater River and ocean waters Lake waters Groundwaters

DISTRIBUTION AND QUANTITY OF THE EARTH'S WATERS

Ocean waters and waters trapped in the pore spaces of sediments make up most of the present-day hydrosphere (see Table 1). The total mass of water in the oceans equals about 50 percent of the mass of sedimentary rocks now in existence and about 5 percent of the mass of the Earth's crust as a whole. Deep and shallow groundwaters constitute a small percentage of the total water locked in the pores of sedimentary rocks-on the order of 3 to 15 percent. The amount of water in the atmosphere at any one time is trivial, equivalent to 0.013 × 106 cubic kilometres of liquid water, or about 0.001 percent of the total at the Earth's surface. This water, however, plays an important role in the water cycle.

At present, ice locks up a little more than 1 percent of the Earth's water and may have accounted for as much as 3 percent or more during the height of the glaciations of the Pleistocene epoch (from 1,600,000 to 10,000 years ago). Although water storage in rivers, lakes, and the atmosphere is small, the rate of water circulation through the rain-river-ocean-atmosphere system is relatively rapid. The amount of water discharged each year into the oceans from the land is approximately equal to the total mass of water stored at any instant in rivers and lakes.

Soil moisture accounts for only 0.005 percent of the water at the Earth's surface. It is this small amount of water, however, that exerts the most direct influence on evaporation from soils. The biosphere, though primarily H₂O in composition, contains very little of the total water at the terrestrial surface, only about 0.00004 percent. Yet, the biosphere plays a major role in the transport of water vapour back into the atmosphere by the process of transpiration

As will be seen in the next section, the Earth's waters are not pure H₂O but contain dissolved and particulate materials. Thus, the masses of water at the Earth's surface are major receptacles of inorganic and organic substances, and water movement plays a dominant role in the transportation of these substances about the planet's surface.

Table 1: Water Masses at the Earth's Surface

reservoir	volume (in millions of cubic kilometres)	percent of total
Oceans	1,370	97.25
Ice caps and glaciers	29	2.05
Deep groundwater* (750-4,000 metres)	5.3	0.38
Shallow groundwater (< 750 metres)	4.2	0.30
Lakes	0.125	0.01
Soil moisture	0.065	0.005
Atmospheret	0.013	0.001
Rivers	0.0017	0.0001
Biosphere	0.0006	0.00004
Total	1,408.7	100

Environment (1987). Prentice Hall, Inc.

BIOGEOCHEMICAL PROPERTIES OF THE HYDROSPHERE

Rainwater. About 110,300 cubic kilometres of rain fall on land each year. The total water in the atmosphere is 0.013 × 106 cubic kilometres, and this water, owing to precipitation and evaporation, turns over every 9.6 days. Rainwater is not pure but rather contains dissolved gases and salts, fine-ground particulate material, organic substances, and even bacteria. The sources of the materials in rainwater are the oceans, soils, fertilizers, air pollution, and fossil-fuel combustion.

Figure 1 shows some typical maps of the chloride and sodium content of rain over the continental United States. The concentration contours in Figure 1 are subparallel to the coastlines. It also has been observed that rains over oceanic islands and near coasts have ratios of major dissolved constituents very close to those found in seawaConstitnents of rainwater

ter. The discovery of the high salt content of rain near coastlines was somewhat surprising because sea salts are not volatile, and it might be expected that the process of evaporation of water from the sea surface would "filter" out the salts. It has been demonstrated, however, that a large percentage of the salts in rain is derived from the bursting of small bubbles at the sea surface due to the impact of rain droplets or the breaking of waves, which results in the injection of sea aerosol into the atmosphere. This sea aerosol evaporates, with resultant precipitation of the salts as tiny particles that are subsequently carried high into the atmosphere by turbulent winds. These particles may then be transported over continents to fall in rain or as dry deposition.

Assuming equilibrium with the atmospheric carbon dioxide partial pressure (PcO2) of 10-3.5 atmosphere, the approximate mean composition of rainwater is in parts per million (ppm): sodium (Na+), 1.98; potassium (K+), 0.30; magnesium (Mg2+), 0.27; calcium (Ca2+), 0.09; chloride (CI-), 3.79; sulfate (SO2-), 0.58; and bicarbonate (HCO3-), 0.12. In addition to these ions, rainwater contains small amounts of dissolved silica-about 0.30 ppm. The average pH value of rainwater is 5.7. (The term pH is defined as the negative logarithm of the hydrogen ion concentration in moles per litre. The pH scale ranges from 0 to 14, with lower numbers indicating increased acidity.) On a global basis, as much as 35 percent of the sodium, 55 percent of the chlorine, 15 percent of the potassium, and 37 percent of the sulfate in river water may be derived from the oceans through sea aerosol generation.

A considerable amount of data has become available for marine aerosols. These aerosols are important because (1) they are vital to any description of the global biogeochemical cycle of an element; (2) they may have an impact on climate; (3) they are a sink, via heterogeneous chemical reactions, for trace atmospheric gases; and (4) they influence precipitation of cloud and rain droplets. For many trace metals the ratio of the atmospheric flux to the riverine flux for coastal and remote oceanic areas may be greater than

Adapted from data from the National Atmospheric Depo

Figure 1: Contours of the average concentrations of dissolved sodium and chloride in precipitation over the United States during 1987.

one, indicating the importance of atmospheric transport. Figure 2 illustrates the enrichment factors (EF) of North Atlantic marine aerosols and suspended matter in North Atlantic waters relative to the crust, where

$$EF_{crust} = \frac{(X/AI)_{air}}{(X/AI)},$$

and (X/Al), and (X/Al), refer, respectively, to the ratio of the concentration of the element X to that of Al, aluminum, in the atmosphere and in average crustal material. The similarity in trend of enrichment factors for marine aerosols and suspended matter indicates qualitatively the importance of the marine aerosol to the composition of marine suspended matter and, consequently, to deep-sea sedimentation.

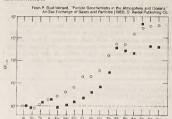

Figure 2: Element enrichment factors (EF) in North Atlantic marine aerosols (squares) compared with factors for suspended matter in North Atlantic ocean waters (circles)

In some instances the ratios of ions in rainwater deviate significantly from those in seawater. Mechanisms proposed for this fractionation are, for example, the escape of chlorine as gaseous hydrogen chloride (HCl) from seasalt aerosol with a consequent enrichment in sodium and bubbling and thermal diffusion. In addition, release of gases like dimethyl sulfide (DMS) from the sea surface and its subsequent reaction in the oceanic atmosphere to sulfate can change rainwater ion ratios with respect to seawater. Soil particles also can influence rainwater composition. Rainfall over the southwestern United States contains relatively high sulfate concentrations because of sulfate-bearing particles that have been blown into the atmosphere from desert soils. Rain near industrial areas commonly contains high contents of sulfate, nitrate, and carbon dioxide (CO2) largely derived from the burning of coal and oil. There are two main processes leading to the conversion of sulfur dioxide (SO2) to sulfuric acid (H2SO4). These are reactions with hydroxyl radicals (OH) and with hydrogen peroxide (H₂O₂) in the atmosphere:

$$SO_2 + OH \rightarrow intermediate species \rightarrow H_2SO_4$$
 (1)

and

$$SO_2 + H_2O_2 = H_2SO_4$$
. (2)

The sulfuric acid then dissociates to hydrogen and sulfate

$$H_3SO_4 = 2H^+ + SO_3^{2-}$$
 (3)

For the nitrogen gases nitric oxide (NO) and nitrogen dioxide (NO2) released from fossil-fuel burning, their atmospheric reactions lead to the production of nitric acid (HNO3) and its dissociation to hydrogen ions (H+) and nitrate (NO3"). These reactions are responsible for the acid rain conditions highly evident in the northeastern United States, southeastern Canada, and western Europe (see below Acid rain). The high sulfate values of the rain in the northeastern United States reflect the acid precipitation conditions of this region.

River and ocean waters. River discharge constitutes the main source for the oceans. Table 2 shows the difference between the composition of seawater and that of river, or

Significance of marine aerosols

Difference in composition stream, water. Seawater has a more uniform composition than river water. It contains, by weight, about 3.5 percent dissolved salts, whereas river water has only 0.012 percent The average density of the world's oceans is roughly 2.75 percent greater than that of typical river water. Of the average 35 parts per thousand salts of seawater, sodium and chlorine make up almost 30 parts, and magnesium and sulfate contribute another four parts. Of the remaining one part of the salinity, calcium and potassium constitute 0.4 part each and carbon, as carbonate and bicarbonate, about 0.15 part. Thus, only eight elements (oxygen, sulfur, chlorine, sodium, magnesium, calcium, potassium, and carbon) make up 99 percent of seawater, though most of the 92 naturally occurring elements have been detected therein. Of importance are the nutrient elements phosphorus, nitrogen, and silicon, along with such essential micronutrient trace elements as iron, cobalt, and copper. These elements strongly regulate the organic production of the world's oceans.

In contrast to ocean water, the average salinity of the world's rivers is low—only about 0.012 percent, or 120 ppm by weight. Of this salt content, carbon as bicarbonate constitutes 58 parts, or 48 percent, and calcium, suffur as sulfate, and silicon as dissolved monomeric silicic acid make up a total of about 39 parts, or 33 percent. The remaining 19 percent consists predominantly of chlorine, sodium, and magnesium in descending importance. It is obvious that the concentrations and relative proportions

of dissolved species in river waters contrast sharply with those of seawater. Thus, even though seawater is derived in part by the chemical differentiation and evaporation of river water, the processes involved affect every element differently, indicating that simple evaporation and concentration are entirely secondary to other processes.

Generally speaking, the composition of river water, and thus that of lakes, is controlled by water-rock interactions. The attack of carbon dioxide-charged rain and soil waters on the individual minerals in continental rocks leads to the production of dissolved constituents for lakes, rivers, and streams. It also gives rise to solid alteration products that make up soils or suspended particles in freshwater aquatic systems. The carbon dioxide content of rain and soil waters is of particular importance in weathering processes. The pH of rainwater equilibrated with the atmospheric carbon dioxide partial pressure of 10-3.5 atmosphere is 5.7. In industrial regions, rainwater pH values may be lower because of the release and subsequent hydrolysis of acid gases-namely, sulfur dioxide and nitrogen oxides (NO,) from the combustion of fossil fuels. After rainwater enters soils, its characteristics change markedly. The usual few parts per million of salts in rainwater increase substantially as the water reacts. The upper part of the soil is a zone of intense biochemical activity. The bacterial population near the surface is large, but it decreases rapidly downward with a steep gradient. One of the major biochemical processes of the bacteria is the oxidation of organic material, which

leads to the release of carbon dioxide. Soil gases obtained above the zone of water saturation may contain 10 to 40 times as much carbon dioxide as the free atmosphere, and in some cases carbon dioxide has been shown to make up 30 percent of the soil gases as opposed to 0.03 percent of the free atmosphere. In addition to the acid effects of carbon dioxide, a highly acidic microenvironment is created by the roots of living plants. Values of pH as low as 2 have been measured immediately adjacent to root hairs. Plants may have several kilometres of root hairs, and so their chemical effects are formidable.

Congruent and incongruent weathering reactions

These acid solutions in the soil environment attack the rock minerals, the bases of the system, producing neutralization products of dissolved constituents and solid particles. Two general types of reaction occur: congruent and incongruent. In the former, a solid dissolves, adding elements to the water in their proportions in the mineral. An example of such a weathering reaction is the solution of calcite (CaCO3) in limestones:

$$CaCO_3 + CO_2(g) + H_2O = Ca^{2+} + 2HCO_3^-$$
. (4)

Here, one of the HCO; ions comes from calcite and the other from CO₂(g) in the reacting water. The amount of carbon dioxide dissolved according to reaction (4) depends on temperature, pressure, original bicarbonate content of the weathering solution, and the partial pressure of the carbon dioxide. The carbon dioxide and the temperature are the most important variables. Increases in one or both of these variables lead to increases in the amount of calcite dissolved. For example, for a carbon dioxide pressure of 10-3.5 atmosphere, the amount of calcium that can be dissolved until saturation is about 10-3.3 mole, or 20 ppm, at 25° C (77° F). For an atmospheric carbon dioxide pressure of 10-2 atmosphere and for a soil atmosphere of nearly pure carbon dioxide, the values are 65 and 300 ppm, respectively. The weathering of calcite leads to the release of calcium and bicarbonate ions into soil waters and groundwaters, and these constituents eventually reach lake and river systems. The insoluble residue of quartz (SiO₂), clay minerals (cation, aluminum, silicon, oxygen, hydrogen phases), and iron oxides (e.g., FeOOH) in the limestone rock make up the deep-red soils that form from limestone weathering. These particles may be carried into streams by runoff and hence to lakes and the oceans and become part of the suspended load of these systems.

An example of an incongruent weathering reaction is that involving aluminosilicates. One such reaction is the aggressive attack of carbon dioxide-charged soil water on the mineral K-spar (KAlSi₃O₈), an important phase found in continental rocks. The reaction is

$$2KAISi_3O_8 + 2CO_2 + 11H_2O =$$

 $AI_2Si_2O_3(OH)_4 + 2K^+ + 2HCO_3^- + 4H_4SiO_4.$ (5

It should be noted that the K-spar changes into a new mineral-kaolinite (a clay mineral) in this case-plus solution, and acid is consumed. The total dissolved material per litre of soil solution released is about 60 ppm for a solution initially equilibrated with a typical soil carbon dioxide content. The water resulting from reaction (5) would contain bicarbonate, potassium, and dissolved silica in the ratios 1:1:2, and the new solid, kaolinite, would be a weathering product. These dissolved constituents and the solid alteration product would eventually reach rivers to be transferred possibly to lakes and ultimately to the sea. It has been demonstrated that the composition of river water is the product of a variety of mineral-water reactions such as (4) and (5). The dissolved load of the world's rivers comes from the following sources: 7 percent from beds of halite (NaCl) and salt disseminated in rocks; 10 percent from gypsum (CaSO4 · 2H2O) and anhydrite (CaSO₄) deposits and sulfate salts disseminated in rocks; 38 percent from limestones and dolomites; and 45 percent from the weathering of one silicate mineral to another. Of the bicarbonate ions in river water, 56 percent stems from the atmosphere, 35 percent from carbonate minerals, and 9 percent from the oxidative weathering of fossil organic matter. Reactions involving silicate minerals account for 30 percent of the riverine bicarbonate ions.

Besides dissolved substances, rivers also transport solids in traction (i.e., bed load) and, most importantly, suspended load. The present global river-borne flux of solids to the oceans is estimated as 155 × 1014 grams per year. Most of this flux comes from Southeast Asian rivers. The composition of this suspended material resembles soils and shales and is dominated by silicon and aluminum. Present elemental fluxes are estimated in 1012 grams per year as silicon, 4,420; aluminum, 1,460; iron, 740; calcium, 330; potassium, 310; magnesium, 210; and sodium 110. The total load of particulate organic carbon of the world's rivers is 180 × 1012 grams per year. The riverine fluxes of trace metals to the oceans are dominated by their occurrence in the particulate phase as opposed to the dissolved phase. The particulate matter in river water is an important source of silicon, aluminum, ion, titanium, rubidium, scandium, vanadium, the lanthanides, and other elements for deep-sea sediments.

Lake waters. Although lake waters constitute only a small percentage of the water in the hydrosphere, they are an important ephemeral storage reservoir for fresh water Aside from their recreational use, lakes constitute a source of water for household, agricultural, and industrial uses. Lake waters are also very susceptible to changes in chemical composition due to these uses and to other factors.

In general, fresh waters at the continental surface evolve from their rock sources by enrichment in calcium and sodium and by depletion in magnesium and potassium. In very soft waters the alkalies may be more abundant than the alkaline earths, and in the more concentrated waters of open river systems Ca > Mg > Na > K. For the anions, in general, HCO3 exceeds SO4, which is greater in concentration than Cl., It is worthwhile at this stage to consider some major mechanisms that control global surface water composition. These mechanisms are atmospheric precipitation, rock reactions, and evaporationprecipitation. They are illustrated in Figure 3, which shows schematically the envelope of world surface water compo-

Mechanisms responsible for controlling surface water composition

Figure 3: Variation in surface water composition as a function of total dissolved salt content and the ratio of dissolved sodium to sodium plus calcium in the waters. Three major mechanisms governing composition are shown in this diagram: evaporation-precipitation, precipitation, and rock-water reaction.

sitions in terms of the variables of total dissolved salts and Na/(Na + Ca) ratio.

The mechanism principally responsible for waters of very low salinity is precipitation. These waters tend to form in tropical regions of low relief and thoroughly leached source rocks. In these regions rainfall is high, and water compositions are usually dominated by salts brought in by precipitation. Such waters constitute one end-member of a series of water compositions for which the other end-member represents water compositions dominated by contributions of dissolved salts from the rocks and soils of their basins. These waters have moderate salinity and are rich in dissolved calcium and bicarbonate. They are, in turn, the end-member of another series that extends from the calcium-rich, medium-salinity fresh waters to the high-salinity, sodium chloride-dominated waters of which seawater is an example. Seawater composition, however, does not evolve directly from the composition of fresh waters and the precipitation of calcium carbonate; other mechanisms that control its composition are involved. Such factors as relief and vegetation also may affect the composition of the world's surface waters, but atmospheric precipitation, water-rock reactions, and evaporation-crystallization processes appear to be the dominant mechanisms governing continental surface water chemistry.

Continental fresh waters evaporate once they have entered closed basins, and their constituent salts precipitate on the basin floors. The composition of these waters may evolve along several different paths, depending on their initial chemical makeup. Table 3 shows a number of brine compositions from North American saline lakes, and Figure 4 illustrates possible evaporation paths that led to these compositions. For example, Surprise Valley Lake, California, is a body of sodium chloride water that may have evolved from what was initially fresh water which precipitated calcite during evaporation, resulting in water with a dissolved-calcium concentration to alkalnity ratio of less than 2. Further evaporation of such water and precipitation of septolite [MgSi,Og/GOH3]] would give rise to water enriched in alkalinity with respect to dissolved magnesium and hence to sodium chloride-bicarbonate-carbonate water such as that of Surprise Valley Lake. The paths shown in Figure 4 are an oversimplification of the actual processes, which are far more diverse and complex in nature, but they do provide a reasonable picture of how fresh waters evolve into saline lake waters in closed basins.

Biological processes strongly affect the composition of lake waters and are responsible to a significant degree for the compositional differences between the upper water layer (the epilimnion) and the lower water layer (the hypolimnion) of lakes. The starting point is photosynthesis, represented by the following reaction:

$$106 CO_2 + 16 NO_3^- + HPO_4^{2-} + 122 H_2 O + 18 H^{+} \xrightarrow[micro-frequence]{radiant energy} \frac{radiant}{micro-frequence}$$

$$C_{106}H_{263}O_{110}N_{16}P + 138O_2.$$
 (6)

The reversal of this reaction is oxidation-respiration leading to the release of the nutrients nitrogen and phosphorus, as well as carbon dioxide. In a stratified lake, carbon, nutrients, and silica are extracted from the epilimnion during photosynthesis. This process leads to reduced concentrations of nitrate, phosphate, and silica in these waters and, during times of maximum daylight organic production, supersaturation of epilimnion waters with respect to dissolved oxygen. The organic matter produced by phytoplankton may be either grazed upon by zooplankton and other organisms or decomposed by bacteria. Some of it, however, sinks into the hypolimnion. There, it is further decomposed, especially by bacteria, resulting in the release of dissolved phosphorus and nitrogen and the consumption of oxygen. Oxygen concentrations therefore are reduced in these lower lake waters, because stratification prevents oxygen exchange with the atmosphere. Furthermore, the inorganic carbonate and siliceous skeletons of the dead organisms sinking into the hypolimnion may dissolve, giving rise to increased concentrations of dissolved silica and inorganic carbon in the deep waters of stratified lakes. This dissolution is a result of undersaturation of the hypolimnion waters with respect to the opaline silica and calcium carbonate that make up the skeletons of the dead and sinking plankton. These natural biological processes have been accelerated in some lakes because of excess nutrient input by human activity, resulting in the eutrophication of lake waters (and marine systems; see below Eutrophication).

Groundwaters. These waters derive their compositions from a variety of processes, including dissolution, hydrolysis, and precipitation reactions; adsorption and ion exchange; oxidation and reduction; gas exchange between groundwater and the atmosphere; and biological processes (see Table 4). The biological processes (see Table 4). The biological processes of greatest importance are microbial metabolism, organic production, and respiration (oxidation). By far the most important overall process for the major constituents of groundwater is that of mineral—water reactions, which were briefly described

Processes affecting groundwater composi-

above in River and ocean waters. Thus, the composition of groundwaters strongly reflects the types of rock minerals that the waters have encountered in their movement through the subsurface. Table 5 shows the waters found in limestones, crystalline rocks, and two types of finegrained rocks. The mineralogy of the Wissahickon schist is dominated by aluminosilicate compositions, whereas the Ecca shale contains significant carbonate and dispersed salts. The latter minerals are more soluble than aluminosilicate minerals, and their dissolution gives rise to the high salinity of Ecca shale waters. The waters of the Wissahickon schist have low salinity partly because of the low chemical reactivity of the silicate minerals in this rock. In contrast, the Miocene limestone waters are dominated by dissolved calcium and bicarbonate, a characteristic reflecting the higher solubility and rate of dissolution of the calcite that makes up this rock. The groundwater from the granite is rich in the Ca2+ and Na+ cations derived from dissolution of the plagioclase feldspar (a sodium, calcium aluminosilicate), which is a major mineral found in this rock type. In general, the most mobile elements in groundwater-i.e., those most easily liberated by the weathering of rock minerals-are calcium, sodium, and magnesium. Silicon and potassium have intermediate mobilities, and aluminum and iron are essentially immobile and locked up in solid phases.

Groundwaters are highly susceptible to contamination because of human activities and the fact that their dissolved constituents are derived to a large extent from the leaching of surface materials. Some of the nitrogen and phosphorus applied to soils as fertilizers and organic pesticides may be leached and leak into groundwater systems, leading to increased concentrations of ammonium and phosphate. Radioactive wastes, industrial chemicals. household materials, and mine refuse are other anthropogenic sources of dissolved substances that have been detected in groundwater systems.

Ice. Ice is nearly a pure solid and, as such, accommodates few foreign ions in its structure. It does contain, however, particulate matter and gases, which are trapped in bubbles within the ice. The change in composition of these materials through time, as recorded in the successive layers of ice, has been used to interpret the history of the Earth's surface environment and the impact of human activities on this environment. The increase in the lead content of continental glacial ice with decreasing age

of the ice, for example, reflects the progressive input of tetraethyl lead into the global environment from gasoline burning. Also, atmospheric carbon dioxide and methane concentrations, which have increased significantly during the past century because of anthropogenic activities, are faithfully recorded in ice bubbles of the thick continental ice sheets. Present-day atmospheric carbon dioxide and methane concentrations are 25 percent and 167 percent, respectively, higher than their concentrations 200 years ago; the latter concentration values were obtained from measurements of the gases in air trapped in ice.

THE HYDROLOGIC CYCLE

General nature of the cycle. The present-day hydrologic cycle at the Earth's surface is illustrated in Figure 5. Some 496 cubic kilometres of water evaporate from the land and ocean surface annually, remaining for about 10 days in the atmosphere before falling as rain or snow. The amount of solar radiation necessary to evaporate this water is half of the total solar radiation received at the Earth's surface. About one-third of the precipitation falling on land runs off to the oceans primarily in rivers. while direct groundwater discharge to the oceans accounts for only about 6 percent of the total discharge. A small amount of precipitation is temporarily stored in the waters of rivers and lakes. The remaining precipitation over land, 0.073 × 106 cubic kilometres per year, returns to the atmosphere by evaporation. Over the oceans, evaporation exceeds precipitation, and the net difference represents transport of water vapour over land, where it precipitates as rain and returns to the oceans as river runoff and direct groundwater discharge.

The various reservoirs in the hydrologic cycle have different water residence times. Residence time is defined as the amount of water in a reservoir divided by either the rate of addition of water to the reservoir or the rate of loss from it. The oceans have a water residence time of 37,000 years; this long residence time reflects the large amount of water in the oceans. In the atmosphere the residence time of water vapour relative to total evaporation is only 10 days. Lakes, rivers, ice, and groundwaters have residence times lying between these two extremes and are highly variable.

Water residence time

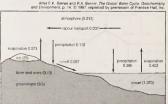

Figure 5: The present-day surface hydrologic cycle. The numbers in parentheses refer to volumes of water in millions of cubic kilometres, and the fluxes adjacent to the arrows are in millions of cubic kilometres of water per year.

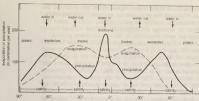

Figure 6: Latitudinal variation in precipitation and evaporation and relationship to major wind belts and oceanic salinity. nzie, and C. Hunt, Chemical Cycles and

There is considerable variation in evaporation and precipitation over the globe. In order to have precipitation, there must be sufficient atmospheric water vapour and enough rising air to carry the vapour to an altitude where it can condense and precipitate. Figure 6 shows the latitudinal variation of precipitation and evaporation and their gross relation to the global wind belts. The trade winds, for example, are initially cool, but they warm up as they blow toward the equator. These winds pick up moisture from the ocean, increasing ocean surface salinity and causing seawater to sink. When the trade winds reach the equator, they rise, and the water vapour in them condenses and forms clouds. Net precipitation is high near the equator and also in the belts of the prevailing westerlies where there is frequent storm activity. Evaporation exceeds precipitation in the subtropics where the air is stable and near the poles where the air is both stable and has a low water vapour content because of the cold. The Greenland and Antarctic ice sheets formed due to the very low evaporation rates at the poles that result in precipitation exceeding evaporation in these local regions. The strong link between wind belts, the water balance, and the salinity of ocean water is apparent in Figure 6.

Processes involved in the cycle. The hydrologic cycle consists of various complicated processes of precipitation, evaporation, interception, transpiration, infiltration, percolation, retention, detention, overland flow, throughflow, and runoff. Figure 7 provides a schematic representation of the details of the hydrologic cycle, illustrating the processes involved. In the following sections, some of these processes are discussed in detail.

Water vapour and precipitation. As noted above, water exists in the atmosphere in gaseous form. Its liquid form, either as water droplets in clouds or as rain, and its solid form, as ice crystals in clouds, snowflakes, or hail, occur only momentarily and locally.

Water vapour performs two major functions: (1) it is important to the radiation balance of the Earth as its presence keeps the planetary surface warmer than would otherwise be the case; and (2) it is the principal phase of the ascending part of the hydrologic cycle.

Primary functions of water vapour

The mass of water vapour in the atmosphere, which represents only 0.001 percent of the hydrosphere, is highest in the tropics and decreases toward the poles. At a mean temperature of the Earth's surface of 15° C, the partial pressure of water vapour at equilibrium with pure water is 0.017 atmosphere. The addition of salts to pure water lowers its vapour pressure. The equilibrium, or saturation, water vapour pressure of a saturated solution of sodium chloride is 22 percent lower than that of pure water. Precipitable water vapour has, on the average, a vapour pressure of 0.0025 atmosphere, which amounts to 15 percent of the saturation vapour pressure. The ratio of observed water vapour pressure to the saturation vapour pressure at the same temperature is the relative humidity of the air. Thus, the mean relative humidity of the atmosphere is only 15 percent, a value that is low in human and biological terms. The relative humidity of the air, however, varies greatly from one geographic region to another and also vertically in the atmosphere. Atmospheric water vapour decreases rapidly with increasing altitude relative to its surface value. The amount of water required to saturate a volume of air depends on the temperature of the air. Air at high temperature can hold more water vapour at saturation than can air at low temperature. Because the temperature of the lower atmosphere (the troposphere) decreases rapidly with increasing altitude to about 15 kilometres, the upper levels of the troposphere contain little water vapour; most of the vapour is found within a few of kilometres of the Earth's surface. The average relative humidity of tropospheric air is about 50 percent. Above 15 kilometres, water vapour is essentially frozen out of

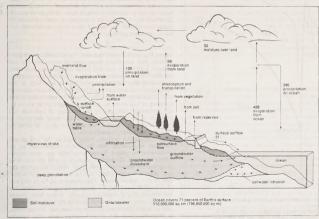

Figure 7: The detailed hydrologic cycle emphasizing processes involved in the transfer of water in the cycle. Numbers on arrows show relative water fluxes

the atmosphere, amounting to less than 0.1 percent of its concentration at the Earth's surface

Aside from temperature, other factors determine the water vapour content of the air and are particularly important in the lower troposphere. These factors include local evaporation and the horizontal atmospheric transportation of moisture, which varies with altitude, latitude, season, and topography. During a period of 10 days (i.e., the residence time of water in the atmosphere), horizontal eddy turbulence may disperse vapour over distances up to 1.000 kilometres.

Interaction between air masses and surface water bodies

When a mass of air at the Earth's surface is exposed to a body of water, it gains water by evaporation or loses water by precipitation, depending on its relative humidity. If the air is undersaturated, with a relative humidity of less than 100 percent, it gains water vapour because the rate of evaporation exceeds the rate of condensation. If the air is supersaturated, with a relative humidity greater than 100 percent, the air mass loses water vapour because the rate of precipitation exceeds that of evaporation. This interaction between air masses and surface water bodies drives the atmosphere toward a state of saturation, which is not achieved for the entire atmosphere because of the variability in weather and because not all air masses are in contact with water bodies. In general, the level of atmospheric water vapour is higher in the summer, since temperatures are higher at this time of year. Also, atmospheric water vapour content is higher near the source of moisture than in distant regions. Over the oceans, the air is almost always near saturation, whereas over the deserts, where the supply of moisture is limited, the air is far below water vapour saturation values. In most cases, atmospheric water vapour content decreases inland over continents, but this decrease is modified by rainfall conditions, by the presence or absence of high mountains, large lakes, extensive forests, and swamps, and by the prevailing wind directions. Horizontal winds and air mass

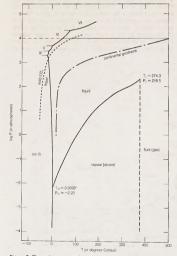

Figure 8: The various states of water as a function of pressure and temperature The continental geotherm (change of temperature with

increasing depth in the Earth's crust) and the pressure temperature boundary for solid CO2-liquid CO2 are shown for comparison.

movements transfer water vapour from the ocean to the land. Although the processes are not completely separable, the horizontal transfer of water vapour seldom causes the vapour to undergo condensation, whereas vertical movements are most important in the condensation process.

Condensation depends strongly on the average temperature of the Earth's surface because the water vapour content of the air is strongly dependent on temperature. This fact is demonstrated in Figure 8, which shows the states of water as a function of the variables of pressure and temperature. The slope of the phase boundary between liquid water and water vapour is positive, implying that with increasing temperature the air at equilibrium will hold increasing amounts of water vapour. Cooling or mixing of this air results in condensation of the vapour and precipitation as water droplets or as ice crystals if the air temperature is below 0° C. When first formed, the wa-ter droplets or ice crystals are very small, on the order of 10-2 to 10-3 centimetre in diameter, and they float freely in the atmosphere. In large quantities, these water droplets and ice crystals produce a cloud. All clouds are formed as a result of cooling below the dew point, the temperature at which condensation begins when air is cooled at constant pressure and constant water vapour content. When the droplets or crystals coalesce to a size of about 10-2 centimetre in diameter, the drops become heavy enough to fall as raindrops or snowflakes. Hailstones measure about 10-1 centimetre in diameter or much larger. Water vapour condensing in the atmosphere contains strongly soluble salts (mostly of oceanic origin), weakly soluble or insoluble solids (dust), and dissolved gases. The dust and sea-salt aerosol particles in the air may act as sites of condensation by serving as nuclei for bringing initially a few water molecules together and inducing condensation from supersaturated air.

Distribution of precipitation. Precipitation falling toward the Earth's surface may suffer several fates. It may be evaporated during its fall or after it reaches the ground surface. If the surface is covered with dense vegetation, much of the precipitation may be held on leaves and plant limbs and stems. This process is termed interception and may result in little water reaching the ground because the water may be directly evaporated from plant surfaces back into the atmosphere. If precipitation reaches the ground in the form of snow, it may remain there for some time. On the other hand, if precipitation falls as rain, it may evaporate, infiltrate the soil, be detained in small catchment areas, or become overland flow-a form of runoff. Overland flow (R_o) may be expressed in terms of intensity units, water depth per unit of time (e.g., centimetres per hour, or inches per hour), as

$$R_{o} = P - I, \tag{7}$$

where P is precipitation rate and I is infiltration rate (rate of entry and downward movement of water into the soil profile). Infiltration rate will equal precipitation rate until the limit of the infiltration rate, or infiltration capacity, is reached. Soil infiltration rates are usually high at the beginning of a rain preceded by a dry spell and decrease as the rainfall continues. This change in rate is due to the clogging of soil pores by particles brought from above by the infiltrating rain and to the swelling of colloidal soil particles as they absorb water. Thus, rapid decreases in infiltration rates during a rain are more likely to occur in clay-rich soils than in sandy soils.

Between rainfall periods, water held in the soil as soil moisture is gradually lost by direct evaporation or by withdrawal by plants. Evaporation into the open atmosphere occurs at the surface of the soil, and the soil dries progressively downward with time. Water vapour in the soil diffuses upward, replenishing the evaporated water, and in turn is evaporated. The pumping of air in and out of the soil by atmospheric pressure changes enhances the movement of soil moisture upward. It has been shown that evaporation of a water droplet in the free atmosphere, and to a first approximation in various soil atmospheres, is proportional to the droplet surface area $4\pi r^2$ (square centimetres), the diffusional flux of water at the droplet surface, and the transfer of heat as the droplet evaporates. Overland

The equation for the rate of shrinkage of a water droplet due to evaporation is

$$\frac{dr}{dt} = -\frac{D\rho_{vo}(Sp-1)}{ro(1+Y)},\tag{8}$$

where dr/dt is the rate of change in the radius of the water droplet (centimetres per second), D is the diffusion coefficient of water vapour in air (cubic centimetres per second), ρ_{vo} is the equilibrium vapour concentration at the droplet surface, Sp is the degree of undersaturation of water vapour in the environment, r is the radius of the droplet (centimetres), ρ_L is the density of liquid water (grams per cubic centimetre), and X is a dimensionless parameter depending on D. ρ_{xo} , temperature, the heat of evaporation of water vapour, the coefficient of thermal conductivity of air, and the spherical coordinate system necessary to define processes occurring to a spherical water droplet. Water droplets shrink-dr/dt < 0, evaporatewhen the water vapour concentration in the environment (atmosphere or soil atmosphere) is less than the saturation water vapour concentration at the droplet surface. They grow-dr/dt > 0, condense—when the converse is true in the free atmosphere. The term dr/dt has negative values for evaporation and positive ones for condensation. Use of this equation shows, as an example, that it would take 23 minutes for a water droplet to shrink (evaporate) in size from 50 to five micrometres in air at 10° C and a water vapour undersaturation of 1 percent.

Besides simple evaporation of water from soils, water is also returned to the atmosphere by transpiration in plants. Plants draw water from soil moisture through their vast network of root hairs and rootlets. This water is carried upward through the plant trunk and branches into the leaves, where it is discharged as water vapour. The term evapotranspiration is used in climatic and hydrologic studies to include the combined water loss from the Earth's surface resulting from evaporation and transpiration. The maximum possible evapotranspiration is termed potential evapotranspiration and is governed by the available heat energy. It is taken as equal to evaporation from a large water surface and is generally much less than actual evapotranspiration. Actual evapotranspiration is never greater than precipitation except on irrigated land because of percolation of water into groundwater bodies

Evapo-

ation

transpir-

and surface runoff. Figure 9 provides a detailed picture of the hydrologic cycle in the soil zone and at depth. The soil-moisture zone gains water by precipitation and infiltration and loses water by evapotranspiration, overland flow, and percolation of water downward due to gravity into the groundwater zone. The contact between the groundwater zone (phreatic zone) and the overlying unsaturated zone (vadose zone) is called the groundwater table. The water balance equation for change of soil-moisture storage in a soil is given as

$$S = P - E - R \tag{9}$$

where S is storage, P is precipitation, E is evaporation, and R is surface runoff plus percolation rate into the groundwater zone; all terms are in units of length per unit of time (e.g., millimetres per day, centimetres per month).

ter A.N. Strahler and A.H. Strahler, Environmenta Geoscience (1973), Hamilton Publishing Co

Figure 9: The cycle of water in the soil zone and at depth Many factors influence water movement in this surface zone and are illustrated here.

In humid, midlatitude climates where a strong contrast between winter and summer temperatures exists, there is an annual cycle of the water content of soils. One such annual cycle is shown in Figure 10 and demonstrates the processes controlling soil moisture. Of special importance is the fact that the soils are saturated in this temperate climate in the spring, and the evaporation rate is low because of the low input of radiant energy from the Sun. By contrast, in the summer, evaporation increases because of increasing solar radiation, and with the growth of plants so does transpiration. Soil moisture is reduced to very low levels at this time of year.

Figure 10: Annual cycle of moisture in soil in Ohio. U.S. showing factors controlling soil moisture content.

Groundwaters and river runoff. This section focuses on term R in equation (9) representing groundwater and river runoff losses from the soil-moisture zone. Water percolates from the soil-moisture zone through the unsaturated (vadose) zone to the water table. Flow through the unsaturated zone is complicated. After a rainfall, water may form nearly a continuous phase in pores in this zone, but with drying the last amount of water is held in wedges at points of contact of solid grains and as thin films on solid surfaces. The flow paths of water become more tortuous, and the water-conducting properties decrease rapidly. Structured soils and fractured rock in the vadose zone may act as conduits for fluids to reach the water table. Because of the complex geometry of water contained in the unsaturated zone, the properties of water are expressed by means of empirical relationships. Darcy's law, derived in 1856 from experimentation by the French engineer Henri Darcy, permits quantification of water flow through porous media. The law states that the rate of flow Q of a fluid through a porous layer of medium (e.g., a sand bed) is directly proportional to the area A of the layer and to the difference Δh between the fluid heads at the inlet and outlet faces of the layer and inversely proportional to the

thickness L of the layer, or, expressed analytically,

$$Q = \frac{KA \Delta h}{I} \,, \tag{10}$$

where K is a constant characteristic of the medium. The term K for a porous rock medium is the volume of fluid of unit viscosity passing through a unit cross section of the rock in unit time under the action of a unit pressure gradient and is called permeability. The permeability of a rock is dependent on the geometric properties of the rock. such as porosity, shape and size distribution of constituent rock grains, and degree of cementation of the rock. Permeabilities of rocks vary greatly. Unconsolidated sands may have permeabilities measured in hundreds of darcys, whereas consolidated sands that will transmit reasonable amounts of fluid have permeabilities of 0.01 to one darcy. A rough idea of the meaning of one darcy of permeability (which equals 9.869×10^{-12} square metre) can be obtained by imagining a cube of sand one foot on a side. If the sand has a permeability of one darcy, approximately one barrel of water per day will pass through the one-foot cube with a one-pound pressure head. The general equation of Darcy can be modified to express flow in both the unsaturated zone and the saturated groundwater zone.

Groundwater is constantly in motion. When a lake

or stream intersects the groundwater table, groundwater communicates directly with these bodies of water. If the groundwater table is higher than the stream or lake level, a pressure head will develop such that the groundwater flows into the water body; conversely, if the groundwater table is lower than the river or lake level, the pressure gradient induces flow into the groundwater. Most groundwater ultimately reaches the channels of surface streams and rivers and flows to the sea. On the average, groundwater contributes to total river runoff about 30 percent of its water on a global basis.

Water runoff from the land surface is that part of precipitation which eventually appears in perennial or intermittent surface streams. Streamflow-generation mechanisms have been studied for several decades, and there is now considerable knowledge regarding rainfall-runoff processes and their controls. This understanding is the result of both careful observations from field experiments and the heuristic simulations of hypothetical realities with rigorous mathematical models. The discharge measured at the downstream end of a channel reach is supplied by channel inflow at the upstream end of the reach and by the lateral inflows that enter the channel from the hillslope along the reach. The lateral inflows may arrive at the stream in one of three forms: (1) groundwater flow, (2) subsurface storm flow, or (3) overland flow.

Groundwater flow provides the base flow component of streams that sustains their flow between storms. The "flashy" response of streamflow to individual precipitation events may be ascribed to either subsurface storm flow or overland flow. Subsurface storm flow can be a dominant streamflow-generation mechanism only when the impeding subsoil horizon laterally diverts infiltrating water downslope. Under intense rainfall events during which the surface soil layer becomes saturated to some depth, water is able to migrate through "preferred pathways" rapidly enough to deliver contributions to the stream during the peak runoff period. The conditions for subsurface storm flow are quite restrictive. The mechanism is most likely to be operative on steep, humid, forested hillslopes with very permeable surface soils.

Overland flow is generated at a point on a hillslope only after surface ponding takes place. Ponding cannot occur until the surface soil layers become saturated. It is now widely recognized that surface saturation can occur because of two quite distinct mechanisms-namely, Horton overland flow and Dunne overland flow.

The former classic mechanism is for a precipitation rate that exceeds the saturated hydraulic conductivity of the surface soil. A moisture content versus depth profile during such a rainfall event will show moisture contents that increase at the surface as a function of time. At some point in time the surface becomes saturated, and an inverted zone of saturation begins to propagate downward into the soil. It is at this time that the infiltration rate drops below the rainfall rate and overland flow is generated. The time is called the ponding time. The necessary conditions for the generation of overland flow by the Horton mechanism are (1) a rainfall rate greater than the saturated hydraulic conductivity of the soil and (2) a rainfall duration longer than the required ponding time for a given initial moisture profile. Horton overland flow is generated from partial areas of the hillslope where surface hydraulic conductivi-

In Dunne overland flow, the precipitation rate is less than the saturated hydraulic conductivity, and the initial water table is shallow or there is a shallow impeding layer. Surface saturation occurs because of a rising water table; ponding and overland flow occur at a time when no further soil-moisture storage is available. The Dunne mechanism is more common to near-channel areas. Dunne overland flow is generated from partial areas of the hillslope where water tables are shallowest. Both Horton and Dunne mechanisms result in variable source areas that expand and contract through wet and dry periods.

The distribution of total global runoff is shown in Figure 11, and the chemical characteristics of this runoff are delineated in Figure 12. It can be seen that total river discharge and the chemistry of the discharge vary from

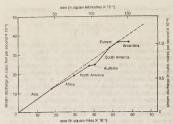

Figure 11: Distribution of total global water discharge to the oceans on a continental basis

continent to continent; some continents are wetter and some drier than the world average, but the deviations are not extreme. The runoff per unit area from Asia and Europe is almost exactly equal to the world average; it is a little lower in Africa and North America; and it is considerably higher in South America. Antarctica is frozen and Australia is arid, and so they contribute little runoff. Also, since their areas are relatively small, they do not affect the global runoff average significantly. The waters draining the continents have quite different chemistries; those from Europe are very rich in calcium and bicarbonates, whereas those from Africa and South America are not. North American and Asian rivers are somewhat intermediate in their concentrations of these dissolved constituents. Such differences in composition reflect a variety of factors, including runoff, temperature, and relief, but certainly the bulk composition of the continental rocks in contact with these waters and their underground sources play a major role (see Figure 3). The surface rocks of Europe are rich in carbonates and those of South America are not; the latter are dominated by sediments rich in silicate minerals.

The chemistry of groundwater and river runoff is being modified by human activities on a global scale. The natural dissolved riverine input of major constituents to the oceans already has been increased by more than 10 percent because of human activities. In the case of sodium, chlorine, and sulfate, the increases are as high as 30 percent. In the United States alone, total water utiliza-

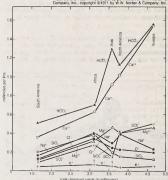

Figure 12: The chemical characteristics of river water draining various continents

Horton overland flow

Dunne overland flow

tion is equivalent to one-third of total runoff, with about 2 percent of the water used coming from underground wells. In the southwestern region of the country, water supplies have been tapped heavily and in some areas have been exhausted with no hope of replacement. This extensive utilization of fresh waters in the United States and throughout the globe make them particularly susceptible to pollution. Leachates from fertilizers, herbicides, and pesticides are found in some freshwater bodies; toxic and inorganic or organic chemicals are present; radioactive elements have been detected; and some surface-water bodies have had their salinities increased dramatically, rendering them useless for human consumption. It is therefore imperative that nations closely monitor the utilization of freshwater systems and promote their conservation.

ORIGIN AND EVOLUTION OF THE HYDROSPHERE

It is not very likely that the total amount of water at the Earth's surface has changed significantly over geologic time. Based on the ages of meteorites, the Earth is thought to be 4.6 billion years old. The oldest rocks known date 3.8 billion years in age, and these rocks, though altered by post-depositional processes, show signs of having been deposited in an environment containing water. There is no direct evidence for water for the period between 4.6 and 3.8 billion years ago. Thus, ideas concerning the early history of the hydrosphere are closely linked to theories about the origin of the Earth.

The Earth is thought to have accreted from a cloud of ionized particles around the Sun. This gaseous matter condensed into small particles that coalesced to form a protoplanet, which in turn grew by the gravitational attraction of more particulates. Some of these particles had compositions similar to that of carbonaceous chondrite meteorites, which may contain up to 20 percent water. Heating of this initially cool, unsorted conglomerate by the decay of radioactive elements and the conversion of kinetic and potential energy to heat resulted in the development of the Earth's liquid iron core and the gross internal zonation of the planet (i.e., differentiation into core, mantle, and crust). It has been concluded that the Earth's core formed over a period of about 500 million years. It is likely that core formation resulted in the escape of an original primitive atmosphere and its replacement by one derived from the loss of volatile substances from

the planetary interior. At an early stage the Earth thus did not have water or water vapour at its surface. Once the planet's surface had cooled sufficiently, water contained in the minerals of the accreted material and released at depth could escape to the surface and, instead of being lost to space, cooled and condensed to form the initial hydrosphere. A large, cool Earth most certainly served as a better trap for water than a small, hot body because the lower the temperature, the less likelihood for water vapour to escape, and the larger the Earth, the stronger its gravitational attraction for water vapour. Whether most of the degassing took place during core formation or shortly thereafter or whether there has been significant degassing of the Earth's interior throughout geologic time remains uncertain. It is likely that the hydrosphere attained its present volume early in the Earth's history, and since that time there have been only small losses and gains. Gains would be from continuous degassing of the Earth; the present degassing rate of juvenile water has been determined as being only 0.3 cubic kilometre per year. Water loss in the upper atmosphere is by photodissociation, the breakup of water vapour molecules into hydrogen and oxygen due to the energy of ultraviolet light. The hydrogen is lost to space and the oxygen remains behind. Only about 4.8 × 10-4 cubic kilo-· metre of water vapour is presently destroyed each year by photodissociation. This low rate can be readily explained: the very cold temperatures of the upper atmosphere result in a cold trap at an altitude of about 15 kilometres, where most of the water vapour condenses and returns to lower altitudes, thereby escaping photodissociation. Since the early formation of the hydrosphere, the amount of water vapour in the atmosphere has been regulated by the temperature of the Earth's surface-hence its radiation

balance. Higher temperatures imply higher concentrations of atmospheric water vapour, while lower temperatures suggest lower atmospheric levels.

The early hydrosphere. The gases released from the Earth during its early history, including water vapour, have been called excess volatiles because their masses cannot be accounted for simply by rock weathering. An estimate of the excess volatiles is given in Table 6. These volatiles are thought to have formed the early atmosphere of the Earth. At an initial crustal temperature of about 600° C. almost all of these compounds, including H2O, would have been in the atmosphere. The sequence of events that occurred as the crust cooled is difficult to reconstruct. Below 100° C all of the water would have condensed, and the acid gases would have reacted with the original igneous crustal minerals to form sediments and an initial hydrosphere that was dominated by a salty ocean. If the reaction rates are assumed to have been slow relative to cooling. an atmosphere of 600° C would have contained, together with other compounds, water vapour, carbon dioxide, and hydrogen chloride (HCl) in a ratio of 20:3:1 and cooled to the critical temperature of water (i.e., 374° C). The water therefore would have condensed into an early hot ocean. At this stage, the hydrogen chloride would have dissolved in the ocean (about one mole per litre), but most of the carbon dioxide would have remained in the atmosphere. with only about 0.5 mole per litre in the ocean water. This early acid ocean would have reacted vigorously with crustal minerals, dissolving out silica and cations and creating a residue composed principally of aluminous clay minerals that would form the sediments of the early ocean basins.

Formation of a hot, acid ocean

This is one of several possible pathways for the early surface of the Earth. Whatever the actual case, after the Earth's surface had cooled to 100°C, it would have taken only a short time for the remaining acid gases to be consumed in reactions involving igneous rock minerals. The presence of cyanobacteria (e.g., blue-green glage) in the fossil record of rocks older than three billion years attests to the fact that the Earth's surface had cooled to temperatures lower than 100°C by this time, and neutralization of the original acid volatiles had taken place. It is possible, however, that, because of increased greenhouse gas concentrations (see below) in the Earty Archean era (about 3.8 to 3.4 billion years ago), the Earth's surface could still have been warmer than today.

If most of the degassing of primary volatile substances from the Earth's interior occurred early, the chloride released by the reaction of hydrochloric acid with rock minerals would be found in the oceans or in evaporite deposits, and the oceans would have a salinity and volume comparable to that of today. This conclusion is based on the assumption that there has been no drastic change in the ratios of volatiles released through geologic time. The overall generalized reaction indicative of the chemistry leading to the formation of the early oceans can be written in the form: primary igneous rock minerals + acid volatiles + H₂O → sedimentary rocks + oceans + atmosphere. It should be noted from this equation that, if all the acid volatiles and H2O were released early in the history of the Earth and in the proportions found today, then the total original sedimentary rock mass-produced would be equal to that of the present, and ocean salinity and volume would be close to those of today as well. If, on the other hand, degassing were linear with time, then the sedimentary rock mass would have accumulated at a linear rate, as would have oceanic vol-

Source of water for the initial hydrosphere Oxygen

ume. The salinity of the oceans, however, would remain nearly the same if the ratios of volatiles degassed did not change with time. The most likely situation is the one presented here-namely, that major degassing occurred early in Earth's history, after which minor amounts of volatiles were released episodically or continuously for the remainder of geologic time. The salt content of the oceans based on the constant proportions of volatiles released would depend primarily on the ratio of sodium chloride locked up in evaporites to that dissolved in the oceans. If all the sodium chloride in evaporites were added to the oceans today, the salinity would be approximately doubled. This value gives a sense of the maximum salinity that the oceans could have attained throughout geologic time.

One component absent from the early Earth's surface was free oxygen; it would not have been a constitutent released from the cooling crust. Early production of oxygen was by production the photodissociation of water in the Earth's atmosphere, a process that was triggered by the absorption of the Sun's

ultraviolet radiation. The reaction is 2H₂O \$\frac{hv}{\to}\$O₂ + 2H₂, in which hy represents the photon of ultraviolet light. The hydrogen produced would escape into space, while the oxygen would react with the early reduced gases by reactions such as 2H₂S + 3O₂ → 2SO₂ + 2H₂O₂ Oxygen production by photodissociation gave the early reduced atmosphere a start toward present-day conditions, but it was not until the appearance of photosynthetic organisms approximately three billion years ago that oxygen could accumulate in the Earth's atmosphere at a rate sufficient to give rise to today's oxygenated environment. The pho-

tosynthetic reaction leading to oxygen production is given

in equation (6)

The transitional hydrosphere. The nature of the rock record from the time of the first sedimentary rocks (approximately 3.8 billion years ago) to about one to two billion years ago suggests that the amount of oxygen in the Earth's atmosphere was significantly lower than it is today and that there were continuous chemical trends in the sedimentary rocks formed and, more subtly, in the composition of the hydrosphere. Figure 13 shows how the chemistry of rocks shifted dramatically during this transitional period. The source rocks of sediments during this time may have been more basaltic than subsequent ones. Sedimentary debris was formed by the alteration of such source rocks in an oxygen-deficient atmosphere and accumulated primarily under anaerobic marine conditions. The chief difference between reactions involving mineralocean equilibria at this time and the present day was the role played by ferrous iron (i.e., reduced state of iron). The concentration of dissolved iron in modern oceans is low because of the insolubility of oxidized iron oxides. During the transition stage and earlier, oxygen-deficient environments were prevalent, and these favoured the formation of minerals containing ferrous iron from the alteration of rocks slightly more rich in basalt than those of today. Indeed, iron carbonate siderite and iron silicate greenalite, in close association with chert and iron sulfide pyrite, are characteristic minerals that occur in iron formations of the middle Precambrian (about 2.4 to 1.5 billion years ago). The chert originally was deposited as amorphous silica; equilibrium between amorphous silica, siderite, and greenalite at 25° C and a total pressure of one atmosphere requires a carbon dioxide pressure of about 10-25 atmosphere, or 10 times the present-day value.

The oceans of this transitional period can be thought of as a solution that resulted from an acid leach of basaltic rocks, and, because the neutralization of the volatile acid gases was not restricted primarily to land areas as it is today, much of this alteration may have occurred by submarine processes. Anaerobic depositional environments with internal carbon dioxide pressures of about 10-25 atmosphere prevailed, and the oxygen-deficient atmosphere itself may have had a carbon dioxide pressure close to 10-2.5 atmosphere. If so, the pH of early ocean water was lower than that of modern seawater and the calcium concentration was higher; moreover, the early ocean water was probably saturated with respect to amorphous silicaroughly 120 ppm.

To simulate what might have occurred, it is helpful to imagine emptying the Pacific basin, throwing in great masses of broken basaltic material, filling it with hydrogen chloride dissolved in water so that the acid becomes neutralized, and then carbonating the solution by bubbling carbon dioxide through it. Oxygen would not be permitted into the system. The hydrochloric acid would leach the rocks, resulting in the release and precipitation of silica and the production of a chloride ocean containing sodium, potassium, calcium, magnesium, aluminum, iron, and reduced sulfur species in the proportions present in the rocks. As complete neutralization was approached. the aluminum could begin to precipitate as hydroxides and then combine with precipitated silica to form cationdeficient aluminosilicates. As the neutralization process reached its end, the aluminosilicates would combine with more silica and with cations to form such minerals as chlorite, and ferrous iron would combine with silica and sulfur to produce greenalite and pyrite. In the final solution, chlorine would be balanced by sodium and calcium in roughly equal proportions, with subordinate amounts of potassium and magnesium; aluminum would be quantitatively removed, and silicon would be at saturation with amorphous silica. If this solution were then carbonated, calcium would be removed as calcium carbonate, and the chlorine balance would be maintained by abstraction of more sodium from the primary rock. The sediments formed in this system would contain chiefly silica, ferrous iron silicates, chloritic minerals, calcium carbonate, calcium-magnesium carbonates, and small amounts of pyrite.

Major change in rock chemistry

> Neutralizing of volatile acid gases

If the hydrogen chloride added were in excess of the carbon dioxide, the resultant oceans would have a high content of calcium chloride (CaCl2), but with a pH still near neutrality. If the carbon dioxide added were in excess of the chlorine, calcium would be precipitated as carbonate until it reached a level roughly that of present-day

ocean waters-namely, a few hundred parts per million. If this newly created ocean were left undisturbed for several hundred million years, its waters would evaporate and be transported onto the continents (in the form of precipitation); streams would transport their loads into it. The sediments produced in this ocean would be uplifted and incorporated into the continents. The influence of the continental debris would gradually be felt and the pH might change somewhat. Iron would be oxidized out of the ferrous silicates to yield iron oxides, but the composition of the water would not vary substantially.

The primary minerals of igneous rocks are all mildly basic compounds. When these minerals react in excess with acids such as hydrogen chloride and carbon dioxide, they produce neutral or mildly alkaline solutions as well as a set of altered aluminosilicate and carbonate reaction products It is improbable that seawater has changed through time from a solution approximately in equilibrium with these

reaction products-i.e., with clay minerals and carbonates. The modern hydrosphere. It is likely that the hydrosphere achieved its modern chemical characteristics about 1.5 to two billion years ago. The chemical and mineralogical compositions and the relative proportions of sedimentary rocks of this age differ little from their counterparts of the Paleozoic era (from 540 to 245 million years ago). Calcium sulfate deposits of late Precambrian age (about 1.5 billion to 540 million years ago) attest to the fact that the acid sulfur gases had been neutralized to sulfate by this time. Chemically precipitated ferric oxides in late Precambrian sedimentary rocks indicate available free oxygen, whatever its percentage. The chemistry and mineralogy of middle and late Precambrian shales are similar to those of Paleozoic shales. The carbon isotopic signature of carbonate rocks has been remarkably constant for more than three billion years, indicating exceptional stability in size and fluxes related to organic carbon. The sulfur isotopic signature of sulfur phases in rocks strongly suggests that the sulfur cycle involving heterotrophic bacterial reduction of sulfate was in operation 2.7 billion years ago. It therefore appears that continuous cycling of sediments similar to those of today has occurred for 1.5 to two billion years and that these sediments have controlled hydrospheric. and particularly oceanic, composition.

It was once thought that the saltiness of the modern oceans simply represents the storage of salts derived from rock weathering and transported to the oceans by fluvial processes. With increasing knowledge of the age of the Earth, however, it was soon realized that, at the present rate of delivery of salts to the ocean or even at much reduced rates, the total salt content and the mass of individual salts in the oceans could be attained in geologically short time intervals compared to the planet's age. The total mass of salt in the oceans can be accounted for at today's rates of stream delivery in about 12 million years. The mass of dissolved silica in ocean water can be doubled in just 20,000 years by the addition of streamderived silica: to double the sodium content would take 70 million years. It then became apparent that the oceans were not merely an accumulator of salts; rather, as water evaporated from the oceans, together with some salt, the salts introduced must be removed in the form of minerals deposited in sediments. Accordingly, the concept of the oceans as a chemical system changed from that of a sim-The oceans, ple accumulator to that of a steady-state system in which rates of inflow of materials equal rates of outflow. The steady-state concept permits influx to vary with time, but the inflow would be matched by nearly simultaneous and equal variation of efflux.

In recent years, this steady-state conceptual view of the oceans has undergone some modification. In particular, it has been found necessary to treat components of ocean water in terms of all their influxes and effluxes and to be more cognizant of the time scale of application of the

steady-state concept. Indeed, the recent increase in the carbon dioxide concentration of the atmosphere due to the burning of fossil fuels may induce a change in the pH and dissolved inorganic carbon concentrations of surface ocean water on a time scale measured in hundreds of years. If fossil-fuel burning were to cease, return to the original state of seawater composition could take thousands of years. Ocean water is not in steady state with respect to carbon on these time scales, but on a longer geologic time scale it certainly could be. Even on this longer time scale, however, oceanic composition has varied because of natural changes in the carbon dioxide level of the atmosphere and because of other factors. Figure 14 shows a model calculation of how the carbon dioxide pressure of the atmosphere and the chemistry of seawater may have varied for the past 100 million years.

From R.A. Berner, A.C. Lasaga, and R.M. Garrelle in (A.D.) "An improved of Model of Atmospheric CO₂ Fluctuations Over the Past 100 Mill. Geophysical Monorgaph 22, 6 1985 by the American Geophysical Union "The Carbonate-Stactle Geochemical Cycle and its Effect on Atmosphoud Covin Past 100 Millson Years," American Journal of Science, viol.

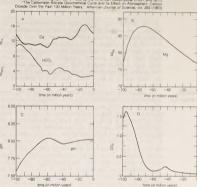

Figure 14: (A,B,C) Results of a model calculation showing possible changes in some parameters of ocean water chemistry and (D) atmospheric carbon dioxide concentration for the past 100 million years. Molar concentration is denoted by M.

It appears that the best description of modern seawater composition is that of a chemical system in a dynamic quasi-steady state. Changes in composition may occur over time, but the system always seems to return to a time-averaged, steady-state composition. In other words, since 1.5 to two billion years ago, evolutionary chemical changes in the hydrosphere have been small when viewed against the magnitude of previous change.

Table 7 shows a tentative mass balance for the modern oceans in terms of sources and sinks of some important elements. It should be noted that rivers supply dissolved constituents to the oceans, whereas high- and low-temperature reactions between seawater and submarine basalts and reactions in sediment pore waters may add or remove constituents from ocean water. Biological processes involved in the formation of the opaline silica skeletons of diatoms and radiolarians and the carbonate skeletons of planktonic foraminiferans and coccolithophorids chiefly remove calcium and silica from seawater. Exchange reactions between river-borne clays entering seawater are particularly significant for sodium and calcium ions. The mass balance of Table 7, highlighting the major processes that govern the steady-state composition of seawater on a long time scale for the elements shown, is reasonable except for sodium and iron. Most of the carbon imbalance represents carbon released to the ocean-atmosphere system during precipitation of carbonate minerals-i.e.

as a steadystate system

In the case of iron, it has been documented that "dissolved" iron carried by rivers is rapidly precipitated as hydroxides in the mixing zone with seawater and that the reduced dissolved iron released from anaerobic sediments also is rapidly precipitated under the oxic conditions (i.e., those with oxygen present) prevailing in the water column. Iron is also precipitated as iron smectites, hydrated iron oxides, and nontronite (iron-rich montmorillonite) in the deep sea. It is thus likely that iron is removed by these processes.

The imbalance in sodium is large; 45 percent of the river input is not accounted for in the mass balance calculations. There are, however, major uncertainties in the estimation of the pore-water flux of sodium ions. An important sink for sodium on a geologic time scale is the formation of evaporites. If the amount of unbalanced sodium is expressed in terms of halite deposition, it would correspond to 1.6 × 1014 grams of sodium chloride per year as compared with a potential total depositional rate of 3.3 × 1014 grams annually. There are no important sodium chloride deposits forming today; thus, one possibility is that sodium is accumulating in the oceans. If so, in 6 × 106 years at an accumulation rate of 63 × 1012 grams of sodium annually, the average salinity of the oceans would increase less than one part per thousand. The chlorine balance for the oceans, however, indicates that it is likely that the major problem in the imbalance for sodium lies in the flux estimates for sediment pore waters and perhaps submarine weathering processes.

Modern seawater chemistry has been characteristic of roughly the past 600 million years of ocean history. Evaporite sediments provide strong evidence that the composition of seawater has not varied a great deal during this interval of geologic time. Nonetheless, it seems likely, as shown in Figure 14, that fluctuations did occur, particularly in the concentrations of calcium, magnesium, and sulfate ions. The isotopic composition of sulfur in seawater, as recorded in evaporites, has varied dramatically during the past one billion years. Although it is difficult to relate these isotopic fluctuations to the calcium and sulfate concentrations of seawater, some scientists believe that the fluctuations do in fact imply changes in the latter. Furthermore, the major features of the sulfur isotopic curve for evaporites versus Phanerozoic time is similar to that of the strontium-87/strontium-86 ratio, and perhaps the strontium/calcium ratio, of sedimentary materials during this time interval. Such covariation is consistent with a model in which fluxes related to alteration of seafloor basalts and continental river runoff vary with time, resulting in variation in seawater composition.

The chemistry of the atmosphere has certainly changed significantly during the past one billion years of Earth history. A modification of this kind implies changes in the chemistry of the hydrosphere as well. Oxygen in the atmosphere rose substantially between two billion years ago and the beginning of the Phanerozoic eon (i.e., 540 million years ago), whereas atmospheric carbon dioxide levels probably decreased. This change led in general to a progressively more oxygenated and less acidic hydrosphere. It is likely that the development of higher land plants during the Devonian period (from 408 to 360 million years ago) resulted in an increase in atmospheric oxygen and a decrease in carbon dioxide. Air trapped within bubbles in Arctic and Antarctic ice shows that the carbon dioxide content of the atmosphere during the climax of the last ice age was about 180 parts per million by volume (ppmv), and atmospheric CO, levels reached approximately 280 ppmv during the last great interglacial of 120,000 years ago, long before modern society initiated its extensive fossil-fuel burning and deforestation activities (see below Buildup of greenhouse gases). These atmospheric changes in themselves can influence the chemistry of the hydrosphere, but they also appear to be coupled with other changes in the rock-ocean-atmosphere-biota system that strongly affect hydrospheric chemistry. For example, though surface waters probably remained oxygenated during the Cretaceous and Devonian periods of Earth history, there is evidence that intermediate and deep ocean waters were more anoxic (oxygen depleted) than today. These "anoxic events" are characterized by dramatic changes in the Earth's oceanatmosphere system, including changes in the rates of the cyclic transfer of elements at the Earth's surface and in atmospheric composition. The probable impact of a bolide (either an asteroid or comet) and increased volcanism at the end of the Cretaceous (about 66.4 million years ago), though still the subject of hot debate, certainly could have caused short-term changes in the chemistry of the Earth's atmosphere-hydrosphere. Scientists speculate that such an event could have had any of several results, including (1) changes in the Earth's radiant-energy balance because of vast amounts of particulate and gaseous input into the atmosphere and subsequent cooling, (2) acid rain stemming from the input into the atmosphere of nitrogen gases generated by the bolide impact, (3) increased trace metal fluxes to the hydrosphere brought on by the destruction of the bolide and increased volcanism, and perhaps (4) increased "anoxia" of the hydrosphere owing to the death of land and marine organisms.

Whatever the case, evidence of change is present in the rock record albeit the composition of the modern hydrosphere has not varied greatly for the past one billion years. Moreover, as will be seen in the following section, humankind is modifying not only the chemistry of local and regional water bodies but also that of the entire global atmosphere-hydrosphere by increasing the rates of input of natural substances and by introducing new synthetic substances to the environment.

IMPACT OF HUMAN ACTIVITIES ON THE HYDROSPHERE

The activities of modern society are having a severe impact on the hydrologic cycle. The dynamic steady state is being disturbed by the discharge of toxic chemicals, radioactive substances, and other industrial wastes and by the seepage of mineral fertilizers, herbicides, and pesticides into surface and subsurface aquatic systems. Inadvertent and deliberate discharge of petroleum, improper sewage

Changes in the chemistry of the atmospherehydrosphere

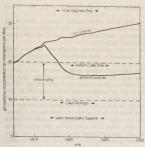

Figure 15: Past and calculated future trends of phosphorus concentrations in the waters of Lake Ontario. It should be noted how the present controls can bring this lake water into a state of mesotrophy (between eutrophy and oligotrophy; thus characterized by a moderate amount of dissolved nutrients). Other Great Lakes water compositions are also shown.

After S.C. Chapra, "Simulation of Recent and Projected Total Phosphorus Trends in Lake Ontano," Journal of Great Lakes Research, vol. 6 (1960)

disposal, and thermal pollution also are seriously affecting the quality of the hydrosphere.

The present discussion focuses on three major problems-eutrophication, acid rain, and the buildup of the so-called greenhouse gases. Each exemplifies human interference in the hydrologic cycle and its far-reaching effects.

Eutrophication. Historically, aquatic systems have been classified as oligotrophic or eutrophic. Oligotrophic waters are poorly fed by the nutrients nitrogen and phosphorus and have low concentrations of these constituents. There is thus low production of organic matter by photosynthesis (equation [6]) in such waters. By contrast, eutrophic waters are well supplied with nutrients and generally have high concentrations of nitrogen and phosphorus and, correspondingly, large concentrations of plankton owing to high biological productivity. The waters of such aquatic systems are usually murky, and lakes and coastal marine systems may be oxygen-depleted at depth. The process of eutrophication is defined as high biological productivity resulting from increased input of nutrients or organic matter into aquatic systems. For lakes, this increased biological productivity usually leads to decreased lake volume because of the accumulation of organic detritus. Natural eutrophication occurs as aquatic systems fill in with organic matter; it is distinct from cultural eutrophication, which is caused by human intervention. The latter is characteristic of aquatic systems that have been artificially enriched by excess nutrients and organic matter from sewage, agriculture, and industry. Naturally eutrophic lakes may produce 75-250 grams of carbon per square metre per year, whereas those lakes experiencing eutrophication because of human activities can support 75-750 grams per square metre per year. Commonly, culturally eutrophic aquatic systems may exhibit extremely low oxygen concentrations in bottom waters. This is particularly true of stratified systems, as, for instance, lakes during summer where concentrations of molecular oxygen may reach levels of less than about one milligram per litre-a threshold for various biological and chemical processes.

Aquatic systems may change from oligotrophic to eutrophic, or the rate of eutrophication of a natural eutrophic system may be accelerated by the addition of nutrients and organic matter due to human activities. The process of cultural eutrophication, however, can be reversed if the excess nutrient and organic matter supply is shut off. This response is demonstrated in Figure 15, which shows how the Great Lakes of the north central United States have responded to government regulations of the early 1970s aimed at reducing phosphorus inputs (principally from detergents) into these lakes.

Not only do freshwater aquatic systems undergo cultural eutrophication, but coastal marine systems also may be affected by this process. On a global scale, the input by rivers of organic matter to the oceans today is twice the input in prehuman times, and the flux of nitrogen, together with that of phosphorus, has more than doubled. This excess loading of carbon, nitrogen, and phosphorus is leading to cultural eutrophication of marine systems. In several polluted eastern U.S. estuaries and in some estuaries of western Europe (e.g., the Scheldt of Belgium and The Netherlands), all of the dissolved silica brought into the estuarine waters by rivers is removed by phytoplankton growth (primarily diatoms) resulting from excess fluxes of nutrients and organic matter. In the North Sea, there is now a deficiency of silica and an excess of nitrogen and phosphorus, which in term has led to a decrease in diatom productivity and an increase in cyanobacteria productivity-a biotic change brought about by cultural eutrophication.

Acid rain. The emission of sulfur dioxide and nitrogen oxides to the atmosphere by human activities-primarily fossil-fuel burning-has led to the acidification of rain and freshwater aquatic systems. Acid rain is a worldwide problem and has been well documented for the eastern United States and the countries of western Europe.

Acid rain is defined as precipitation with a pH of less than 5.7 that results from reactions involving gases other than carbon dioxide. The overall reactions that produce such precipitation are those of equations (1) through (3) and

$$NO_2 + OH \rightarrow HNO_3$$
, (12)

followed by dissociation of the HNO, to H+ + NO,-Figure 16 shows the average pH = $-\log a_H^+$ (a_H^+ is activity of the hydrogen ion) of precipitation over the eastern United States for the period October 1979 through September 1980. The low pH values are a result of equilibration of rainwater with the atmospheric acid gases of carbon, nitrogen, and sulfur. Equilibration only with atmospheric carbon dioxide would give a pH of 5.7. The significantly lower values are a result of reactions with nitrogen- and sulfur-bearing gaseous atmospheric components derived primarily from fossil-fuel burning sources. Nitrate and sulfate concentrations in precipitation over the eastern United States are strongly correlated with pHthe lower the pH of rain, the higher the concentrations

of nitrate and sulfate. Such low pH values and increased with permission, from W.D. Bischoff, V.L. Geochemical Mass Balance for Sulfur- an its: Eastern United States," in O.P. Brick Reposition (1984): Butterworth Publishers

> nitrate and sulfate concentrations also are found in the rains of western Europe and other industrialized regions of the world.

Table 8 provides an illustrative example of events occurring globally-namely, the processes-that remove anthropogenic emissions of sulfur dioxide and nitrogen oxides from the atmosphere of the eastern United States. Wet and dry deposition also removes the hydrogen ion produced in the rain by the oxidation and hydrolysis of these acid gases. This excess hydrogen ion can bring about the acidification of freshwater aquatic systems, particularly those with little buffer capacity (e.g., lakes situated in crystalline rock terrains). Furthermore, the lower pH values of rainwater, and consequently of soil water, can lead to increased mobilization of aluminum. Acidification of freshwater lakes in the eastern United States and increased aluminum concentrations in their waters are thought to be responsible for major changes in the ecosystems of the lakes. In particular, many lakes of this region lack substantial fish populations today, even though they supported large numbers of fish in the early 1900s. Acid rain also may be among the factors responsible for damage to the major forests of the eastern United States and west-

Buildup of greenhouse gases. One problem brought about by human action that is definitely affecting the hydrosphere globally is that of the greenhouse gases (so called because of their heat-trapping "greenhouse" prop-erties) emitted to the atmosphere. Of the greenhouse gases released by anthropogenic activities, carbon dioxide has received much attention. It has been shown from the measurements of carbon dioxide in air bubbles trapped in ice and from the continuous measurement of carbon dioxide concentrations in air samples collected at Mauna Loa, Hawaii, since 1958 that the present atmospheric concentration of nearly 350 ppmv is 25 percent higher than its late-1700s value. Much of this increase is due to carbon dioxide released to the atmosphere from the burning of coal, oil, gas, and wood and from the slash-and-burn activities that accompany deforestation practices (as, for example, those adopted in the Amazon River basin). The component of the hydrosphere most greatly affected by this emission of carbon dioxide is the ocean.

Figure 17A shows the manner in which carbon is cycled in the global environment on a long-term geologic basis. Before human activities had substantially affected the carbon dioxide cycle, there was a net flux of carbon dioxide from the oceans through the atmosphere to the land, where the gas was used in the net production of organic matter and the chemical weathering of minerals in continental rocks. Because of fossil-fuel burning and land-use practices, the net transfer from the ocean to the land has been reversed, and the ocean has now become an important sink of carbon dioxide (Figure 17B). The oceans are currently gaining 2,340 million tons of carbon per year. The net chemical reaction of adding carbon dioxide to the ocean (provided there is no reaction with carbonate solids) is

and a lowering of the pH of surface seawater. Such a pH effect has not been observed but conceivably could occur if carbon dioxide continues to be released to the atmosphere by human activities.

Based on greenhouse climate models and other considerations, it is possible that atmospheric carbon dioxide concentrations may double their late-1700s level by the years 2030-2050 and, along with those of other greenhouse gases (e.g., methane and nitrous oxide), give rise to a global mean surface temperature increase of 1.5° to 5° C. This projected temperature increase would be two to three times greater at the poles than at the equator and greater in the Arctic than in the Antarctic. At present there is no worldwide program to decrease greenhouse gas emissions, except for that affecting chlorofluorocarbon (Freon) releases; thus, it is conceivable that atmospheric carbon dioxide concentrations in the late 21st and early 22nd centuries might reach levels greater than twice their 1700s value. Whatever the case, the effect of the potential rise in surface temperature would be to speed up the hydrologic cycle and probably the rate of chemical weathering of continental rocks. Increases of 4 to 7 percent in the global mean evaporation and precipitation rates might occur for a doubling of the carbon dioxide level and a few degrees rise in global mean temperature. The effect on the water balance would be regional in nature. with some places becoming wetter and others drier. In general, there would be a trend toward greater and longer periods of summer dryness induced by lower soil moisture content and higher evaporation rates in the midlatitudes of the Northern Hemisphere. In the arid western regions of the United States, which depend on irrigation for growing plants, severe water shortages could occur. By contrast, precipitation and runoff might increase, except in summer, at latitudes beyond 60° N because of a greater poleward transport of moisture. In summer, in a zone centred around 60° N, greater dryness might occur due to an earlier end of snowmelt.

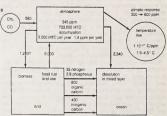

Figure 17: The global carbon cycle (A) past and (B) present. MTC stands for million tons of carbon. Fluxes are in units of million tons of carbon per year.

Impact on lake ecosystems by the melting of ice and snow in the Greenland and Antarctic ice caps and in mountain glaciers, resulting in the transfer of water to the oceans. This process, together with thermal expansion of the oceans because of global warming, could lead to a slow rise in sea level of about 0.7 metre over the next century. If the West Antarctic ice sheet were to disintegrate, a much larger and more rapid rise in sea level of 5-6 metres could occur over the next several hundred years. The melting of all glacial ice would raise the sea level about 56 metres. It is also possible that a global warming could result in a reduction in the areal extent and thickness of sea ice in the Arctic and circum-Antarctic regions. Complete melting of the Arctic sea ice might occur, causing a northward shift in storm tracks and a reduction in Northern Hemispheric precipitation during the spring and fall. Furthermore, a worldwide reduction in sea ice might lead to increased evaporation from the ocean and increased low-altitude cloudiness, which would reflect solar radiation and cause cooling.

The potential changes in the hydrologic cycle induced by a global warming resulting from anthropogenic emissions of greenhouse gases do not seem great. Yet, their consequences could be severe for ecosystems and human populations, especially since the latter are so sensitive to and dependent on such changes. A global rise in sea level of one metre, for example, would almost completely inundate the coastal areas of Bangladesh. Island nations and continental beaches and cities would be endangered. Agricultural lands could be displaced, just as patterns of arid, semiarid, and wet lands might become modified. It is essential that society plan for such potential changes so that, if they do occur, appropriate adjustments can be made to accommodate them.

(F.T.M.)

Ice and Ice Formations

T ce occurs on the Earth's continents and surface waters in a variety of forms. Most notable are the continental glaciers (ice sheets) that cover much of Antarctica and Greenland, Smaller masses of perennial ice called ice caps occupy parts of Arctic Canada and other high-latitude regions, and mountain glaciers occur in more restricted areas, such as mountain valleys and the flatlands below. Other occurrences of ice on land include the different types of ground ice associated with permafrost-that is, permanently frozen soil common to very cold regions. In the oceanic waters of the polar regions, icebergs occur when large masses of ice break off from glaciers or ice shelves and drift away. The freezing of seawater in these regions results in the formation of sheets of sea ice known as pack ice. During the winter months similar ice bodies form on lakes and rivers in many parts of the world. The origins, characteristics, and distribution of all such ice formations are treated in this article, as are the structure and properties of ice in general. For a detailed account of the widespread occurrences of glacial ice during the Earth's. past, see the articles GEOCHRONOLOGY and CLIMATE AND WEATHER. See also GEOMORPHIC PROCESSES and CONTI-NENTAL LANDFORMS for the effects of glaciation.

Structure and properties of ice

STRUCTURE

The water molecule. Ice is the solid state of water, a normally liquid substance that freezes to the solid state at temperatures of 0° C (32° F) or lower and expands to the gaseous state at temperatures of 100° C (212° F) or higher. Water is an extraordinary substance, anomalous in nearly all its physical and chemical properties and easily the most complex of all the familiar substances that are singlechemical compounds. Consisting of two atoms of hydrogen (H) and one atom of oxygen (O), the water molecule has the chemical formula H.O. These three atoms are covalently bonded (i.e., their nuclei are linked by attraction to shared electrons) and form a specific structure, with the oxygen atom located between the two hydrogen atoms. The three atoms do not lie in a straight line, however. Instead, the hydrogen atoms are bent toward each other, forming an angle of about 105°.

The three-dimensional structure of the water molecule can be pictured as a tetrahedron with an oxygen nucleus centre and four legs of high electron probability, as shown in Figure 1. The two legs in which the hydrogen nuclei are present are called bonding orbitals. Opposite the bonding orbitals and directed to the opposite corners of the tetrahedron are two legs of negative electrical charge. Known as the lone-pair orbitals, these are the keys to water's peculiar behaviour, in that they attract the hydrogen nuclei of adjacent water molecules to form what are called hydrogen bonds. These bonds are not especially strong, but, because they orient the water molecules into a specific configuration, they significantly affect the properties of water in its solid, liquid, and gaseous states.

In the liquid state, most water molecules are associated

Hydrogen

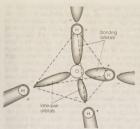

Figure 1: Tetrahedral configuration of a water molecule The oxygen nucleus (O) is covalently bonded to two hydrogen nuclei (H) located within the bonding orbitals. The two lone-pair orbitals form weaker hydrogen bonds with hydrogen nuclei in neighbouring water molecules.

From V.F. Petrenko, Structure of Ordinary Ice I_b, Part 1: Ideal Structure of Ice, October 1993; Cold Regions Research & Engineering Laboratory, U.S. Army Corps of Engineers

in a polymeric structure-that is, chains of molecules connected by weak hydrogen bonds. Under the influence of thermal agitation, there is a constant breaking and reforming of these bonds. In the gaseous state, whether steam or water vapour, water molecules are largely independent of one another, and, apart from collisions, interactions between them are slight. Gaseous water, then, is largely monomeric-i.e., consisting of single moleculesalthough there occasionally occur dimers (a union of two molecules) and even some trimers (a combination of three molecules). In the solid state, at the other extreme, water molecules interact with one another strongly enough to form an ordered crystalline structure, with each oxygen atom collecting the four nearest of its neighbours and arranging them about itself in a rigid lattice. This structure results in a more open assembly, and hence a lower density, than the closely packed assembly of molecules in the liquid phase. For this reason, water is one of the few substances that is actually less dense in solid form than in the liquid state, dropping from 1,000 to 917 kilograms per cubic metre. It is the reason why ice floats rather than sinking, so that, during the winter, it develops as a sheet on the surface of lakes and rivers rather than sinking below the surface and accumulating from the bottom.

As water is warmed from the freezing point of 0° to 4° C (from 32° to 39° F), it contracts and becomes denser. This initial increase in density takes place because at 0° C a portion of the water consists of open-structured molecular arrangements similar to those of ice crystals. As the temperature increases, these structures break down and reduce their volume to that of the more closely packed polymeric structures of the liquid state. With further warming beyond 4° C, the water begins to expand in volume, along with the usual increase in intermolecular vibrations caused by

thermal energy

The ice crystal. At standard atmospheric pressure and at temperatures near 0° C, the ice crystal commonly takes the form of sheets or planes of oxygen atoms joined in a series of open hexagonal rings. The axis parallel to the hexagonal rings is termed the c-axis and coincides with the optical axis of the crystal structure. A view of the ice crystal along this axis is shown in Figure 2A.

When viewed perpendicular to the c-axis, as in Figure 2B, the planes appear slightly dimpled. The planes are stacked in a laminar structure that occasionally deforms by gliding, like a deck of cards. When this gliding deformation occurs, the bonds between the layers break, and the hydrogen atoms involved in those bonds must become attached to different oxygen atoms. In doing so, they migrate within the lattice, more rapidly at higher temperatures. Sometimes they do not reach the usual arrangement of two hydrogen atoms connected by covalent bonds to each oxygen atom, so that some oxygen atoms have only one or as many as three hydrogen bonds. Such oxygen atoms become the sites of electrical charge. The speed of crystal deformation depends on these readjustments, which in turn are sensitive to temperature. Thus the mechanical, thermal, and electrical properties of ice are interrelated

PROPERTIES

Mechanical properties. Like any other crystalline solid. ice subject to stress undergoes elastic deformation, returning to its original shape when the stress ceases. However, if a shear stress or force is applied to a sample of ice for a long time, the sample will first deform elastically and will then continue to deform plastically, with a permanent alteration of shape. This plastic deformation, or creep, is of great importance to the study of glacier flow. It involves two processes: intracrystalline gliding, in which the layers within an ice crystal shear parallel to each other without destroying the continuity of the crystal lattice, and recrystallization, in which crystal boundaries change in size or shape depending on the orientation of the adjacent crystals and the stresses exerted on them. The motion of dislocations-that is, of defects or disorders in the crystal lattice-controls the speed of plastic deformation. Dislocations do not move under elastic deformation.

The strength of ice, which depends on many factors, is difficult to measure. If ice is stressed for a long time, it deforms by plastic flow and has no yield point (at which permanent deformation begins) or ultimate strength. For short-term experiments with conventional testing machines, typical strength values in bars are 38 for crushing, 14 for bending, 9 for tensile, and 7 for shear.

Thermal properties. The heat of fusion (heat absorbed on melting of a solid) of water is 334 kilojoules per kilogram. The specific heat of ice at the freezing point is 2.04 kilojoules per kilogram per degree Celsius. The thermal conductivity at this temperature is 2.24 watts per metre kelvin.

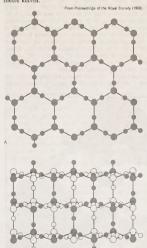

Figure 2: Crystal structure of ice. (A) View along the c-axis, showing the hexagonal formation adopted by the oxygen atoms (represented by large circles); (B) view perpendicular to the c-axis showing the dimpled structure of the layered sheets of

The c-axis

Another property of importance to the study of glaciers is the lowering of the melting point due to hydrostatic pressure: 0.0074° C per bar. Thus for a glacier 300 metres (984 feet) thick, everywhere at the melting temperature, the ice at the base is 0.25° C (0.45° F) colder than at the surface

Optical properties. Pure ice is transparent, but air bubbles render it somewhat opaque. The absorption coefficient, or rate at which incident radiation decreases with depth, is about 0.1 cm-1 for snow and only 0.001 cm-1 or less for clear ice. Ice is weakly birefringent, or doubly refracting, which means that light is transmitted at different speeds in different crystallographic directions. Thin sections of snow or ice therefore can be conveniently studied under polarized light in much the same way that rocks are studied.

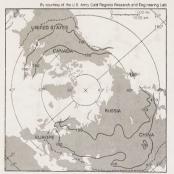

Albedo and radiative properties of ice

Electromagnetic properties. The albedo, or reflectivity (an albedo of 0 means that there is no reflectivity), to solar radiation ranges from 0.5 to 0.9 for snow, 0.3 to 0.65 for firn, and 0.15 to 0.35 for glacier ice. At the thermal infrared wavelengths, snow and ice are almost perfectly "black" (absorbent), and the albedo is less than 0.01. This means that snow and ice can either absorb or radiate long-wavelength radiation with high efficiency. At longer electromagnetic wavelengths (microwave and radio frequencies), dry snow and ice are relatively transparent, although the presence of even small amounts of liquid water greatly modifies this property. Radio echo sounding (radar) techniques are now used routinely to measure the thickness of dry polar glaciers, even where they are kilometres in thickness, but the slightest amount of liquid water distributed through the mass creates great difficulties with the technique. (G.D.A./M.F.M.)

Ice in lakes and rivers

Geographic extent. Much of the world experiences weather well below the freezing point, and in these regions ice forms annually in lakes and rivers. The nature of the ice formations may be as simple as a floating layer that gradually thickens, or it may be extremely complex, particularly when the water is fast-flowing. About half of the surface waters of the Northern Hemisphere freeze annually; the approximate extents of northern ice cover are shown in Figure 3. In warmer climates, waters may freeze only occasionally during periods of unusual cold, and in extremely cold areas of the world, such as Antarctica, lakes may have a permanent ice cover.

The seasonal cycle. In most regions where ice occurs, the formation is seasonal in nature; an initial ice cover forms

Average annual days with ice cover occurrence of annual lake and river free

Figure 3: Distribution of ice cover in the Northern Hemisphere

some time after the average daily air temperature falls below the freezing point; the ice cover thickens through the winter period; and the ice melts and decays as temperatures warm in the spring. During the formation and thickening periods, energy flows out of the ice cover, and, during the decay period, energy flows into the ice cover. This flow of energy consists of two basic modes of energy exchange: (1) the radiation of long-wavelength and short-wavelength electromagnetic energy (i.e., infrared and ultraviolet light) and (2) the transfer of heat energy associated with evaporation and condensation, with convection between the air and the surface, and (to a lesser extent) with precipitation falling on the surface. While radiation transfers are important, the dominant energy exchange in ice formation and decay is the heat transfer associated with evaporation and condensation and with turbulent convection-the latter being termed the sensible transfer. Since these transfers of heat are driven by the difference between air temperature and surface temperature, the extent and duration of ice covers more or less coincide with the extent and duration of average air temperatures below the freezing point (with a lag in the autumn due to the cooling of the water from its summer heating and a lag in the spring due to the melting of ice formed over the winter).

As a general rule, small lakes freeze over earlier than rivers, and ice persists longer on lakes in the spring. Where there are sources of warm water-for example, in underground springs or in the thermal discharges of industrial power plants-this pattern may be disrupted, and water may be free of ice throughout the winter. In addition, in very deep lakes the thermal reserve built up during summer heating may be too large to allow cooling to the freezing point, or the action of wind over large fetches may prevent a stable ice cover from forming.

ICE IN LAKES

Ice formation. Changes in temperature structure. The setting for the development of ice cover in lakes is the annual evolution of the temperature structure of lake water. In most lakes during the summer, a layer of warm water of lower density lies above colder water below. In late summer, as air temperatures fall, this top layer begins to cool. After it has cooled and has reached the same density as the water below, the water column becomes isothermal (i.e., there is a uniform temperature at all depths). With further cooling, the top water becomes even denser and plunges, mixing with the water below, so that the lake continues to be isothermal but at ever colder temperatures. This process continues until the temperature drops to that of the maximum density of water (about 4° C, or 39° F). Further cooling then results in expansion of the space between water molecules, so that the water becomes less dense. This change in density tends to create a new stratified thermal structure, this time with colder, lighter water on top of the warmer, denser water. If there is no mixing of the water by wind or currents, this top layer will cool to the freezing point (0° C, or 32° F). Once it is at the freezing point, further cooling will result in ice formation at the surface. This layer of ice will effectively block the exchange of energy between the cold air above and the warm water below; therefore, cooling will continue at the surface, but, instead of dropping the temperature of the water below, the heat losses will be manifested in the production of ice.

The simple logic outlined above suggests that water at some depth in lakes during the winter will always be at 4° C, the temperature of maximum density, and indeed this is often the case in smaller lakes that are protected from the wind. The more usual scenario, however, is that wind mixing continues as the water column cools below 4° C, thereby overcoming the tendency toward density stratification. Between 4° and 0° C, for example, the density difference might be only 0.13 kilogram per cubic metre (3.5 ounces per cubic yard). Eventually some particular combination of cold air temperature, radiation loss, and low wind allows a first ice cover to form and thicken sufficiently to withstand wind forces that may break it up. As a result, even in fairly deep lakes the water temperature beneath the ice is usually somewhere below 4° C and

Energy transfer during ice formation and decay

Changes in density of cooling quite often closer to 0° °C. The temperature at initial ice formation may vary from year to year depending on how much cooling has occurred before conditions are right for the first initial cover to form and stabilize. In some large lakes, such as Lake Frie in North America, wind effects are so great that a stable ice cover rarely forms over the entire lake, and the water is very near 0° °C throughout the winter.

Nucleation of ice crystals. Before ice can form, water must supercool and ice crystals nucleate. Homogeneous nucleation (without the influence of foreign particles) occurs well below the freezing point, at temperatures that are not observed in water bodies. The temperature of heterogeneous nucleation (nucleation beginning at the surface of foreign particles) depends on the nature of the particles, but it is generally several degrees below the freezing point. Again, supercooling of this magnitude is not observed in most naturally occurring waters, although some researchers argue that a thin surface layer of water may achieve such supercooling under high rates of heat loss. Nucleation beginning on an ice particle, however, can take place upon only slight supercooling, and it is generally believed that ice particles originating from above the water surface are responsible for the initial onset of ice on the surface of a lake. Once ice is present, further formation is governed by the rate at which the crystal can grow. This can be very fast: on a cold, still night, when lake water has been cooled to its freezing point and then slightly supercooled on the surface, it is possible to see ice crystals propagating rapidly across the surface. Typically, this form of initial ice formation is such that the crystal c-axes are vertically oriented-in contrast to the usual horizontal orientation of the c-axis associated with later thickening. Under ideal conditions these first crystals may have dimensions of one metre or more. An ice cover composed of such crystals will appear black and very transparent.

Effects of wind mixing. If the lake surface is exposed to wind, the initial ice crystals at the surface will be mixed by the agitating effects of wind on the water near the surface, and a layer of small crystals will be created. This layer will act to reduce the mixing, and a first ice cover will be formed consisting of many small crystals. Whether it is composed of large or small crystals, the ice cover, until it grows thick enough to withstand the effects of later winds, may form and dissipate and re-form repeatedly. On larger lakes where the wind prevents a stable ice cover from initially forming, large floes may be formed, and the ice cover may ultimately stabilize as these floes freeze together, sometimes forming large ridges and piles of ice. Ice ridges generally have an underwater draft several times their height above water. If they are moved about by the wind, they may scour the bottom in shallower regions. In some cases-particularly before a stable ice cover formswind mixing may be sufficient to entrain ice particles and supercooled water to considerable depths. Water intakes tens of metres deep have been blocked by ice during such events.

Ice growth. Rates of growth. Once an initial layer of ice has formed at the lake surface, further growth proceeds in proportion to the rate at which energy is transferred from the bottom surface of the ice layer to the air above. Because at standard atmospheric pressure the boundary between water and ice is at 0°C, the bottom surface is always at the freezing point. If there is no significant flow of heat to the ice from the water below, as is usually the case, all the heat loss through the ice cover will result in

Figure 4: Heat flow through an ice cover (see text)

ice growth at the bottom. Heat loss through the ice takes place by conduction; designated φ in Figure 4, it is proportional to the thermal conductivity of the ice (k) and to the temperature difference between the bottom and the top surface of the ice $(T_m - T_s)$, and it is inversely proportional to the thickness of the ice (h). Heat loss to the air above (also designated φ) occurs by a variety of processes, including radiation and convection, but it may be characterized approximately by a bulk transfer coefficient (Ha) times the difference between the surface temperature of the ice and the air temperature $(T_{c}-T_{c})$. (In practice, the top surface of an ice layer is not at the air temperature but somewhere between the air temperature and the freezing point. The exact figures are rarely available, but fortunately the top surface temperature, T_0 is not needed for analysis.)

Assuming that the heat flow through the ice equals the heat flow from the surface of the ice to the air above, the following formula for the thickening of ice may be fashioned:

$$h = \left[\frac{2k}{\rho_{i}L}(T_{m} - T_{a})t + \left(\frac{k}{H_{ia}}\right)^{2}\right]^{1/2} - \frac{k}{H_{ia}}.$$
 (1)

In this formula h is the thickness of the ice, T_n is the air temperature, T_m is the freezing point, k is the thermal conductivity of ice (2.24 watts per metre kelvin), ρ_i is the density of ice (916 kilograms per cubic metre). L is the latent heat of fusion (3.34 × 105 joules per kilogram), and t is the time since initial ice formation. The exact value of the bulk transfer coefficient (Hig) depends on the various components of the energy budget, but it usually falls between 10 and 30 watts per square metre kelvin. Higher values are associated with windy conditions and lower values with still air conditions, but, with other information unavailable, a value of 20 watts per square metre kelvin fits data on ice growth quite well. Table 1 presents the results of calculations based on the above formula. The formula is particularly useful in predicting growth when the ice cover is thin. The first growth rate of the ice cover is proportional to the time since formation; as the ice thickens, however, the top surface temperature more closely approaches the air temperature, and growth proceeds proportional to the square root of time.

If there is a snow layer on top of the ice, it will offer a resistance to the flow of heat from the bottom of the ice surface to the air above. In this case, the incremental thickening rate (that is, the incremental thickening [dh] in an incremental time period [dh]) may be predicted by the following formula:

$$\frac{dh}{dt} = \frac{1}{\rho L} \left(\frac{T_m - T_a}{h_d / k_i + h_d / k_z + 1 / H_{ia}} \right), \tag{2}$$

where h_i is now the ice thickness with thermal conductivity k_n and h_i is the snow thickness with thermal conductivity k_i . The thermal conductivity of snow depends on its den-

Snow ice

sity. It is greater at higher densities, ranging from about 0.1 to 0.5 watt per metre kelvin at densities of 200 to 500 kilograms per cubic metre, respectively.

Variations in ice structure. When the weight of a snow cover is sufficient to overcome the buoyancy of the ice supporting it, it is usual for the ice to become submerged and for water to flow through cracks in the ice and saturate the snow, which then freezes. This mode of ice growth is different from that analyzed above, but it is quite common, and the ice so formed is known as snow ice. At typical snow densities, a layer of snow about one-half the thickness of the supporting ice will result in the formation of snow ice lavers.

As the ice thickens, there is a tendency for crystals with a horizontal c-axis orientation to wedge out adjacent crystals with a vertical c-axis orientation and so become larger in diameter with depth. The resulting structure is one of adjacent columns of single crystals and is termed columnar ice. When a very thin section of the ice is cut and examined with light through crossed polaroid sheets, the crystal structure is clearly seen (see Figure 5).

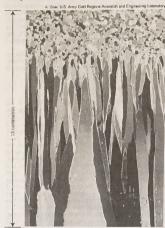

Figure 5: Thin section of lake ice, showing the crystal structure of snow ice above the columnar crystal structure of the thickening ice cover.

Ice decay. Thinning and rotting. In the spring, when average daily air temperatures rise above the freezing point. ice begins to decay. Two processes are active during this period: a dimensional thinning and a deterioration of the ice crystal grains at their boundaries. Thinning of the ice layer is caused by heat transfer and by melting at the top or bottom surface (or both). Deterioration, sometimes called rotting or candling because of the similarity of deteriorating ice crystals to an assembly of closely packed candles, is caused by the absorption of solar radiation. When energy from the Sun warms the ice, melting begins at the grain boundaries because the melting point there is depressed by the presence of impurities that have been concentrated between crystal grains during the freezing process. Rotting may begin at the bottom or at the top, depending on the particular thermal conditions, but eventually the ice rots throughout its thickness. This greatly reduces the strength of the ice, so that rotten ice will support only a fraction of the load that solid, unrotted ice will support. Thinning and deterioration may occur simultaneously or independently of each other, so that sometimes ice thins without internal deterioration, and sometimes it deteriorates internally

with little or no overall thinning. However, both processes usually occur before the ice cover finally breaks up.

Deteriorating ice has a gray, blotchy appearance and looks rotten. Because rotting takes place only by absorption of solar radiation, it progresses only during daylight hours. In addition, the presence of snow or snow ice, which either reflects most solar radiation or absorbs it rapidly in a thin layer, acts to prevent rotting of the ice below until the snow has been completely melted.

Melting of lake ice usually occurs first near the shorelines or near the mouths of streams. At these points of contact with inflowing warm water, the ice melts faster than it does at central lake locations, where most melting is caused by the transfer of heat from the atmosphere. Estimates of the rate at which thinning of the main ice cover occurs are usually based on a temperature index method in which a coefficient is applied to the air temperature above freezing.

Water temperature beneath the ice usually reaches its coldest at the time of freeze-up and then gradually warms throughout the winter. The warming is caused by the absorption of some solar radiation that has penetrated the ice cover, by the release of heat that has been stored in bottom sediments during the previous summer, and by warm water inflows. In deep lakes such warming is slight, while in shallow lakes it may amount to several degrees. After snow on the ice has melted in the spring, more solar radiation penetrates the ice cover, so that significant warming may occur. The mixing of warmed water with deteriorated ice is responsible for the very rapid clearing of lake ice at the end of the melt season. On most lakes, the timing of the final clearing of ice is remarkably uniform from year to year, usually varying by less than a week from the long-term average date of clearing.

Geographic distribution. Freeze-up. The first appearance of lake ice follows by about one month the date at which the long-term average daily air temperature first falls below freezing. Ice appears first in smaller shallow lakes, often forming and melting several times in response to the diurnal variations in air temperature, and finally forms completely as air temperatures remain below the freezing point. Larger lakes freeze over somewhat later because of the longer time required to cool the water. In North America the Canadian-U.S. border roughly coincides with a first freeze-up date of December 1. North of the border freeze-up occurs earlier, as early as October 1 at Great Bear Lake in Canada's Northwest Territories. To the south the year-to-year patterns of freeze-up are ever more erratic until, at latitudes lower than about 45° N, freeze-up may not occur in some years.

In Europe the freeze-up pattern is similar with respect to air temperatures, but the latitudinal pattern shows more variation because much of western Europe is affected by the warming influence of the Gulf Stream. In Central Asia the latitudinal variation is more regular, with first freeze-up occurring about mid-January at 45° N and about October I at 72° N. Exceptions to these patterns occur where there are variations in local climate and elevation.

Clearing. Because of the time required to melt ice that has thickened over the winter, the clearing of lake ice occurs some time after average daily air temperatures rise above freezing. Typically the lag is on the order of one month at latitude 50° N and about six weeks at 70° N. This pattern results in average clearing dates in mid-April at the U.S.-Canadian border and in June and July in the northern reaches of Canada.

ICE IN RIVERS

Formation and growth. *Ice particles*. The formation of ice in rivers is more complex than in lakes, largely because of the effects of water velocity and turbulence. As in lakes, the surface temperature drops in response to cooling by the air above. Unlike lakes, however, the turbulent mixing in rivers causes the entire water depth to cool uniformly even after its temperature has fallen below the temperature of maximum density (4° C, or 39° F). The general pattern is one in which the water temperature that following follows the average daily air temperature but with diurnal variations smaller than the daily excursions of air temperature.

Sources of heat during spring thaw ature. Once the water temperature drops to the freezing point and further cooling occurs, the water temperature will actually fall below freezing-a phenomenon known as supercooling. Typically the maximum supercooling that is observed is only a few hundredths of a degree Celsius. At this point the introduction of ice particles from the air causes further nucleation of ice in the flow. This freezing action releases the latent heat of fusion, so that the temperature of the water returns toward the freezing point. Ice production is then in balance with the rate of cooling occurring at the surface.

The particles of ice in the flow are termed frazil ice. Frazil is almost always the first ice formation in rivers. The particles are typically about 1 millimetre (0.04 inch) or smaller in size and usually in the shape of thin disks. Frazil appears in several types of initial ice formation: thin, sheetlike formations (at very low current velocities); particles that appear to flocculate into larger masses and exhibit a slushlike appearance on the water surface; irregularly shaped "pans" of frazil masses that, while appearing to be shallow, are actually of some depth; and (at high current velocities) a dispersed mixture or slurry of ice particles in the flow.

Frazil ice

The supercooling of river water, while amounting to only a few hundredths of a degree Celsius or even less, provides the context for the particles to stick to one another, since under such conditions ice particles are inherently unstable and actively grow into the supercooled water. When they touch one another or some other surface that is cooled below the freezing point, they adhere by freezing. This behaviour causes serious problems at water intakes, where ice particles may adhere and then build up large accumulations that act to block the intake. In rivers and streams, frazil particles also may adhere to the bottom and successively build up a loose, porous layer known as anchor ice. Conversely, if the water temperature then rises above the freezing point, the particles will become neutral and will not stick to one another, so that the flow will be merely one of solid particles in the flowing water. The slightly above-freezing water may also release the bond between anchor ice and the bottom: it is not unusual for anchor ice to form on the bottom of shallow streams at night, when the cooling is great, only to be released the following day under the warming influence of air temperature and solar radiation.

Alberta Government Photograph

Figure 6: Frazil ice pans on the Athabasca River, Alberta, Can

Accumulating ice cover. As stated above, frazil forms into pans on the surface of rivers (see Figure 6). Eventually these pans may enlarge and freeze together to form larger floes, or they may gather at the leading edge of an ice cover and form a layer of accumulating ice that progresses upstream. The thickness at which such an accumulation collects and progresses upstream depends on the velocity of the flow (V) and is given implicitly in the formula

$$V = \left(1 - \frac{h}{H}\right) \sqrt{2g\left(\frac{\rho - \rho_i}{\rho}\right)h}. \tag{3}$$

in which g is acceleration of gravity, ρ and ρ_i are the densities of water and ice, respectively, h is the thickness of the accumulating ice, and H is the depth of flow just upstream of the ice cover. As a practical matter, floes arriving at the upstream edge will submerge and pass on downstream if the mean velocity exceeds about 60 centimetres (24 inches) per second. At certain thicknesses the ice accumulation may not be able to resist the forces exerted by the water flow and by its own weight acting in the downstream direction, and it will thicken by a shoving process until it attains a thickness sufficient to withstand these forces. During very cold periods, freezing of the top layer will provide additional strength by distributing the forces to the shorelines, so that thinner ice covers actually

may be better able to withstand the forces acting on them. As the ice cover accumulates and progresses upstream, it both adds resistance to the flow and displaces a certain volume of water. These two effects cause the depth of the river to be greater upstream, thus reducing the velocity and enabling further upstream progression to occur where previously the current velocity was too high to allow ice cover formation. This phenomenon is termed staging, by reference to its effect of increasing the water level, or stage." In the process there is a storage of water in the increased depth of the flow upstream, and this somewhat reduces the delivery of water downstream. The breakup of ice in the spring has the opposite effect-that is, the stored water is released and may contribute to a surge of water downstream.

Growth of fixed ice cover. Once the first ice cover has formed and stabilized, further growth is the same as with lake ice: typically columnar crystals grow into the water below, forming a bottom surface that is very smooth. This thickening may be predicted using equation (1), presented above for calculating the thickness of lake ice. An exception to this pattern arises when slightly above-freezing water flows beneath the ice cover. When this occurs, the action of the moving water either causes the undersurface to melt or retards the thickening. Since the rate at which melting occurs is proportional to the velocity times the water temperature, the ice cover over areas of higher velocity may be much thinner than in areas of lower velocity. Unfortunately, areas of thinner ice are often not apparent from above and may be dangerous to those traversing it.

In some rivers the initial formation of fixed ice takes place along the shorelines, with the central regions open to the air. The shore ice then gradually widens from the shoreline, and either the central region forms as described above by accumulation of frazil or the two sides of shore

Ice buildups. In larger, deeper rivers, frazil produced in upstream reaches may be carried downstream and be transported beneath the fixed ice cover, where it may deposit and form large accumulations that are called hanging dams. Such deposits may be of great depth and may actually block large portions of the river's flow. In smaller, shallower streams, similar ice formations may be combinations of shore ice, anchor ice deposits, small hangingdam-like accumulations, and (over slower-flowing areas) sheet ice

Ice in smaller streams shows more variation through the winter, since most of the water comes from groundwater inflows during periods between rain. Groundwater is warm and over time may melt the ice formed during very cold periods. At other times all the water in a small stream freezes; subsequent inflowing water then flows over the surface and freezes, forming large buildups of ice. These are known as icings, Aufeis (German), or naleds (Russian). Icings may become so thick that they completely block culverts and in some cases overflow onto adjacent roads.

Decay and ice jams. In late winter, as air temperatures rise above the freezing point, river ice begins to melt owing to heat transfer from above and to the action of the slightly warm water flowing beneath. As occurs in lake ice, river ice also may deteriorate and rot because of absorption of solar radiation. On the undersurface, the action of the turbulent flowing water causes a melt pattern in the form of a wavy relief, with the waves oriented crosswise to the current direction. Eventually, if the ice cover is

Storage of water upstream

Hanging dams

not subjected to a suddenly increased flow, it may melt in place with little jamming or significant rise in water level. More likely, however, the ice may be moved and form ice jams.

During the spring in very northern areas, and during periods of midwinter thaw in more temperate areas, additional runoff from snowmelt and rain increases the flow in the river. The increased flow raises the water level and may break ice loose from the banks. It also increases the forces exerted on the ice cover. If these forces exceed the strength of the ice, the cover will move and break up and be transported downstream. At some places the quantity of ice will exceed the transport capacity of the river, and an ice jam will form. The jam may then build to thicknesses great enough to raise the water level and cause flooding. Typically, jams form where the slope of the river changes from steeper to milder or where the moving ice meets an intact ice cover-as in a large pool or at the point of outflow into a lake.

Spring breakup jams are usually more destructive than freeze-up jams because of the larger quantities of ice present. Besides causing sudden flooding, the ice itself may collide with structures and cause damage, even to the point of taking out bridges. Sometimes a jam forms, water builds up above it, and the jam breaks loose and moves downstream only to form again. This process may repeat itself several times. In northerly flowing rivers such behaviour is typical, since the upstream ice is freed first and moves toward colder, more stable ice covers.

Ice modification. Mechanical methods. There are a variety of means of modifying ice in rivers. Icebreaking vessels are used to clear paths for other vessels and occasionally to assist in relieving jams on large rivers. Icebreakers are used extensively in northern Europe and to some extent on the Great Lakes and St. Lawrence River of North America. Dusting the ice cover with a dark material such as coal dust or sand can increase the absorption of solar radiation and thus create areas of weakness that aid in an orderly breakup. Dusting has limited effectiveness, however, if a later snowfall covers the dust layer. Trenching of the ice cover with a ditching or similar machine has been practiced to create a weak zone in areas that are historically prone to jamming. Once ice jams have formed, they are sometimes blasted with explosives; however, if there is no current to transport the ice away after blasting, such measures are usually of little effect.

Ice-retention structures such as floating ice booms are used to hold ice in place and prevent it from moving downstream, where it might cause problems. There have been some attempts to control water releases from dammed reservoirs so as to induce breakup in an orderly manner, but these measures are limited to a narrow range of conditions. Air bubbler systems and flow developers (submerged motor-driven propellers) are used to melt small portions of the ice cover by taking advantage of any thermal reserve, relative to the freezing point, that may exist in the water. These are usually more successful in lakes or enclosed areas than in rivers, since the water temperature in rivers is rarely much above the freezing point.

Thermal methods. Wastewater from the cooling of power plants, both fossil-fueled and nuclear, has sometimes been suggested as a source of energy for melting ice downstream of the release points. This method may be advantageous in small areas, but the power requirements for melting extended reaches of ice are immense. Discharges from smaller sources, such as sewage treatment plants, are generally too small to have more than a very localized effect. On the other hand, the water held in reservoirs is often somewhat warmer than freezing, and it can be released in quantities sufficient to result in extended open water downstream-the precise distance depending on how much surface area is required to cool the water back to the freezing point by heat loss to the cold air above.

Geographic distribution. Dates of first freeze-up of rivers follow patterns similar to those of lakes, with a tendency for rivers to freeze over somewhat later than smaller lakes. The many factors that affect the freezing process of rivers make generalizations difficult, however, Slower poollike reaches may freeze over, while more

rapidly flowing reaches may remain open well into the winter. Breakup is even more erratic, particularly in the more temperate zones where midwinter thaws may cause a breakup that is followed by another freeze-up and a later breakup as spring temperatures arrive. As a general rule, rivers break up in response to runoff from snowmelt or rain well before lakes clear of ice-although the first shoreline melting in lakes occurs at about the same times as river breakup In north-flowing rivers, especially in central Russia and western Canada, breakup occurs first in upstream, southerly reaches and then progresses northward with the movement of the spring thaw.

Glaciers and ice sheets

A glacier may be defined as a large mass of perennial ice that originates on land by the recrystallization of snow or other forms of solid precipitation and that shows evidence of past or present flow. The definition is not precise, because exact limits for the terms large, perennial, and flow cannot be set. Except in size, a small snow patch that persists for more than one season is hydrologically indistinguishable from a true glacier. One international group has recommended that all persisting snow and ice masses larger than 0.1 square kilometre (about 0.04 square mile) be counted as glaciers.

GENERAL OBSERVATIONS

Main types of glaciers. Glaciers are classifiable in three main groups: (1) glaciers that extend in continuous sheets, moving outward in all directions, are called ice sheets if they are the size of Antarctica or Greenland and ice caps if they are smaller; (2) glaciers confined within a path that directs the ice movement are called mountain glaciers: and (3) glaciers that spread out on level ground or on the ocean at the foot of glaciated regions are called piedmont glaciers or ice shelves, respectively. Glaciers in the third group are not independent and are treated here in terms of their sources: ice shelves with ice sheets, piedmont glaciers with mountain glaciers. A complex of mountain glaciers burying much of a mountain range is called an ice field.

Distribution of glaciers. A most distinctive aspect of the last ice age, the Pleistocene Epoch (from 1,600,000 to 10,000 years ago), was the recurrent expansion and contraction of the world's ice cover. These glacial fluctuations influenced geological, climatological, and biological environments and affected the evolution and development of early humans. Pleistocene chronology is based primarily on ice-sheet fluctuations. Almost all of Canada, the northern third of the United States, much of Europe, all of Scandinavia, and large parts of northern Siberia were engulfed by ice during the major glacial stages. At times during the Pleistocene Epoch, glacial ice covered 30 percent of the world's land area; at other times the ice cover may have shrunk to less than its present extent. It may not be improper, then, to state that the world is still in an ice age. Because the term glacial generally implies iceage events or Pleistocene time, in this discussion "glacier is used as an adjective whenever reference is to ice of the present day.

Glacier ice today stores about three-fourths of all the fresh water in the world. Glacier ice covers about 11 percent of the world's land area and would cause a world sea-level rise of about 90 metres (300 feet) if all existing ice melted. Glaciers occur in all parts of the world and at almost all latitudes. In Ecuador, Kenya, Uganda, and Irian Jaya (New Guinea), glaciers even occur at or near the Equator, albeit at high altitudes.

Glaciers and climate. The cause of the fluctuation of the world's glacier cover is still not completely understood. Periodic changes in the heat received from the Sun, caused by fluctuations in the Earth's orbit, are known to correlate with major fluctuations of ice sheet advance and retreat on long time scales. Large ice sheets themselves, however, contain several "instability mechanisms" that may have contributed to the larger changes in world climate. One of these mechanisms is due to the very high albedo, or reflectivity of dry snow to solar radiation. No other material of widespread distribution on the Earth even approaches the

Water content of the world's glaciers

Difficulty of ice control

Firn (névé)

albedo of snow. Thus, as an ice sheet expands it causes an ever larger share of the Sun's radiation to be reflected back into space, less is absorbed on the Earth, and the world's climate becomes cooler. Another instability mechanism is implied by the fact that the thicker and more extensive an ice sheet is, the more snowfall it will receive in the form of orographic precipitation (precipitation resulting from the higher altitude of its surface and attendant lower temperature). A third instability mechanism has been suggested by studies of the West Antarctic Ice Sheet. Portions of an ice sheet may periodically surge (move rapidly) outward. perhaps because of the buildup of a thick layer of wet, deformable material under the ice. Although the ultimate causes of ice ages are not known with certainty, scientists agree that the world's ice cover and climate are in a state of delicate, interactive balance.

Only the largest ice masses directly influence global climate, but all ice sheets and glaciers respond to changes in local climate-particularly changes in air temperature or precipitation. The fluctuations of these glaciers in the past can be inferred by features they have left on the landscape By studying these features, researchers can infer earlier climatic fluctuations

FORMATION AND CHARACTERISTICS OF GLACIER ICE

Transformation of snow to ice. Glacier ice is an aggregate of irregularly shaped, interlocking single crystals that range in size from a few millimetres to several tens of centimetres. Many processes are involved in the transformation of snowpacks to glacier ice, and they proceed at a rate that depends on wetness and temperature. Snow crystals in the atmosphere are tiny hexagonal plates, needles, stars, or other intricate shapes. In a deposited snowpack these intricate shapes are usually unstable, and molecules tend to evaporate off the sharp (high curvature) points of crystals and be condensed into hollows in the ice grains. This causes a general rounding of the tiny ice grains so that they fit more closely together. In addition, the wind may break off the points of the intricate crystals and thus pack them more tightly. Thus, the density of the snowpack generally increases with time from an initial low value of 50-250 kilograms per cubic metre (3-15 pounds per cubic foot). The process of evaporation and condensation may continue: touching grains may develop necks of ice that connect them (sintering) and that grow at the expense of other parts of the ice grain, or individual small grains may rotate to fit more tightly together. These processes proceed more rapidly at temperatures near the melting point and more slowly at colder temperatures, but they all result in a net densification of the snowpack. On the other hand, if a strong temperature gradient is present, water molecules may migrate from grain to grain, producing an array of intricate crystal shapes (known as depth hoar) of lowered

density. If liquid water is present, the rate of change is many times more rapid because of the melting of ice from grain extremities with refreezing elsewhere, the compacting force of surface tension, refreezing after pressure melting (regulation), and the freezing of water between grains.

This densification of the snow proceeds more slowly after reaching a density of 500-600 kilograms per cubic metre. and many of the processes mentioned above become less and less effective. Recrystallization under stress caused by the weight of the overlying snow becomes predominant, and grains change in size and shape in order to minimize the stress on them. This change usually means that large or favourably oriented grains grow at the expense of others Stresses due to glacier flow may cause further recrystallization. These processes thus cause an increase in the density of the mass and in the size of the average grain.

When the density of the aggregate reaches about 830 to 840 kilograms per cubic metre, the air spaces between grains are sealed off, and the material becomes impermeable to fluids. With time and the application of stress, the density rises further by the compression of air bubbles (see Figure 7). Only rarely in mountain glaciers does the density exceed 900 kilograms per cubic metre, but at great depths in ice sheets the density may approach that of pure ice (917 kilograms per cubic metre at 0° C and atmospheric pressure).

Snow that has survived one melting season is called firm (or névé); its density usually is greater than 500 kilograms per cubic metre in temperate regions but can be as low as 300 kilograms per cubic metre in polar regions. The permeability change at a density of about 840 kilograms per cubic metre marks the transition from firn to glacier ice. The transformation may take only three or four years and less than 10 metres of burial in the warm and wet environment of Washington state in North America, but high on the plateau of Antarctica the same process takes several thousand years and burial to depths of about 150 metres

Mass balance. Glaciers are nourished mainly by snowfall, and they waste away by melting and runoff or by the breaking off of icebergs (calving). In order for a glacier to remain at a constant size, there must be a balance between income (accumulation) and outgo (ablation). If this mass balance is positive (more gain than loss), the glacier will grow; if it is negative, the glacier will shrink

Accumulation refers to all processes that contribute mass to a glacier. Snowfall is predominant, but additional contributions may be made by hoarfrost (direct condensation of ice from water vapour), rime (freezing of supercooled water droplets on striking a surface), hail, the freezing of rain or meltwater, or avalanching of snow from adjacent slopes. Ablation refers to all processes that remove mass from a glacier. In temperate regions, melting at the surface

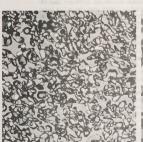

Figure 7: Thin-section photographs illustrating snow-to-ice transformation at depths of (left) metre, (centre) 22 metres, and (right) 100 metres (magnified about 4.6×). At 1 metre and 22 metres the uniformly gray areas between grains of snow represent pore spaces. At 100 metres the snow has become ice and the bubbles become rounded and smaller because of compression of the entrapped gas. Photographs from Camp Century, Greenland, were taken between crossed polaroids to reveal crystal structure

Densification of the snowpack

Accumu-

zones

lation and ablation normally predominates. Melting at the base is usually very slight (1 centimetre [0.4 inch] per year or less). Calving is usually the most important process on large glaciers in polar regions and on some temperate glaciers as well. Evaporation and loss by ice avalanches are important in certain special environments; floating ice may lose mass by melting from below.

by mething from beclose Because the processes of accumulation, ablation, and the transformation of snow to ice proceed so differently, depending on temperature and the presence or absence of liquid water, it is customary to classify glaciers in terms of their thermal condition. A polar glacier is defined as one that is below the freezing temperature throughout its mass for the entire year; a subpolar (or polythermal) glacier is mostly below the freezing temperature throughout its mass, except for surface melting in the summer; and a temperate glacier is at the melting temperature throughout its mass, but surface freezing occurs in winter. A polar or subpolar glacier may be frozen to its bed (coldbased), or it may be at the melting temperature at the bed (vagrandseq).

Another classification distinguishes the surface zones, or facies, on parts of a glacier. In the dry-snow zone no surface melting occurs, even in summer; in the percolation zone some surface melting may occur, but the meltwater refreezes at a shallow depth; in the soaked zone sufficient melting and refreezing take place to raise the whole winter snow layer to the melting temperature, permitting runoff; and in the superimposed-ice zone refrozen meltwater at the base of the snowpack (superimposed ice) forms a continuous layer that is exposed at the surface by the loss of overlying snow. These zones are all parts of the accumulation area, in which the mass balance is always positive. Below the superimposed-ice zone is the ablation zone, in which annual loss exceeds the gain by snowfall. The boundary between the accumulation and ablation zones is called the equilibrium line.

The value of the surface mass balance at any point on a glacier can be measured by means of stakes, snow pits, or cores. These values at points can then be averaged over the whole glacier for a whole year. The result is the net or annual mass balance. A positive value indicates growth, a negative value a decline.

Heat or energy balance. The mass balance and the temperature variations of a glacier are determined in part by the heat energy received from or lost to the external environment—an exchange that takes place almost entirely at the upper surface. Heat is received from short-wavelength solar radiation, from evaluation from clouds or water vapour, turbulent transfer from warm air, conduction upward from warmer lower layers, and the heat released by the condensation of dew or hoarfrost or by the freezing of liquid water. Heat is lost by outgoing long-wavelength radiation, turbulent transfer to colder air, the heat required for the evaporation, sublimation, or melting of ice, and conduction downward to lower layers.

In temperate regions, solar radiation is normally the greatest heat source (although much of the incoming radiation is reflected from a snow surface), and most of the heat loss goes to the melting of ice. It is incorrect to think of snow or ice melt as directly related to air temperature; it is the wind structure, the turbulent eddies near the surface, that determines most of the heat transfer from the atmosphere. In polar regions, heat is gained primarily from incoming solar radiation and lost by outgoing long-wavelength radiation, but heat conduction from lower layers and the turbulent transfer of heat to or from the air also are involved.

Glacier flow. In the accumulation area the mass balance is positive year after year. Here the glacier would become thicker and thicker were it not for the compensating flow of ice away from the area. This flow supplies mass to the ablation zone, compensating for the continual loss of ice there.

Glacier flow is a simple consequence of the weight and creep properties of ice. As stated above (see Structure and properties of ice. Mechanical properties), ice subjected to a shear stress over time will undergo creep, or plastic deformation. The rate of plastic deformation under constant

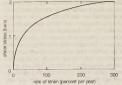

Figure 8: The rate of deformation, or shear strain, of ice at 0° C (32° F).

shear stress is initially high but tapers off to a steady value. If this steady value, the shear-strain rate, is plotted against the stress for many different values of applied stress, a curved graph will result (see Figure 8). The curve illustrates what is known as the flow law or constitutive law of ice: the rate of shear strain is approximately proportional to the cube of the shear stress. Often called the Glen flow law by glaciologists, this constitutive law is the basis for all analyses of the flow of ice sheets and glaciers.

As ice tends to build up in the accumulation area of a glacier, a surface slope toward the ablation zone is developed. This slope and the weight of the ice induce a shear stress throughout the mass. In a case with simple geometry, the shear stress can be given by the following formula:

$$\tau = \rho g h \sin \alpha$$
 (4)

where τ is the shear stress, ρ the ice density, h the ice thickness, and α the surface slope. Each element of ice deforms according to the magnitude of the shear stress, as determined by (4), at a rate determined by the Glen flow law, stated above. By adding up, or integrating, the shear deformation of each element throughout the glacer thickness, a velocity profile can be produced. It can be given numerical expression as:

$$u_1 = k_1 \sin^3 \alpha h^4 \tag{5}$$

where u, is the surface velocity caused by internal deformation and k₁ a constant involving ice properties and geometry. In this simple case, velocity is approximately proportional to the fourth power of the depth (ht). Therefore, if the thickness of a glacier is only slightly altered by changes in the net mass balance, there will be great changes in the rate of flow.

Glaciers that are at the melting temperature at the base may also slide on the bed. Two mechanisms operate to permit sliding over a rough bed. First, small protuberances on the bed cause stress concentrations in the ice, an increased amount of plastic flow, and ice streams around the protuberances. Second, ice on the upstream side of protuberances is subjected to higher pressure, which lowers the melting temperature and causes some of the ice to melt; on the downstream side the converse is true, and meltwater freezes. This process, termed regelation, is controlled by the rate at which heat can be conducted through the bumps. The first process is most efficient with large knobs, and the second process is most efficient with small bumps. Together these two processes produce bed slip. Water-filled cavities may form in the lee of bedrock knobs, further complicating the process. In addition, studies have shown that sliding varies as the basal water pressure or amount changes. Although the process of glacier sliding over bedrock is understood in a general way, none of several detailed theories has been confirmed by field observation. This problem is largely unsolved.

A formula in common use for calculating the sliding speed is:

$$u_2 = \frac{k_2 \sin^2 \alpha}{(p_i - p_a)} \tag{6}$$

where u_2 is the sliding speed at the base, p_i and p_a are the ice pressure and water pressure at the base of the ice, and k_2 is another constant involving a measure of the roughness of the bed. The total flow of a glacier can

Rate of de-

Slidin

thus be given by the sum of equations (5) and (6), u_1 and u_2 . The total sum would be an approximation, because the formulas ignore longitudinal changes in velocity and thickness and other complicating influences, but it has proved to be useful in analyzing situations ranging from

small mountain glaciers to huge ice sheets.

Other studies have suggested that many glaciers and ice sheets do not slide on a rigid bed but "ride" on a deforming layer of water-charged sediment. This phenomenon is difficult to analyze because the sediment layer may thicken or thin, and thus its properties may change, depending on the history of deformation. In fact, the process may lead to an unsteady, almost chaotic, behaviour over time. Some ice streams in West Antarctica seem to have exhibited such unsteady behaviour.

Response of glaciers to climatic change. The relationship of glaciers and ice sheets to fluctuations in climate is sequential. The general climatic or meteorological environment determines the local mass and heat-exchange processes at the glacier surface, and these in turn determine the net mass balance of the glacier. Changes in the net mass balance produce a dynamic response-that is, changes in the rate of ice flow. The dynamic response causes an advance or retreat of the terminus, which may produce lasting evidence of the change in the glacier margin. If the local climate changes toward increased winter snowfall rates, the net mass balance becomes more positive, which is equivalent to an increase in ice thickness. The rate of glacier flow depends on thickness, so that a slight increase in thickness produces a larger increase in ice flow. This local increase in thickness and flow propagates down-glacier, taking some finite amount of time. When the change arrives at the terminus, it causes the margin of the glacier to extend farther downstream. The result is known as a glacier fluctuation-in this case an advance-and it incorporates the sum of all the changes that have taken place up-glacier during the time it took them to propagate to the terminus.

The process, however, cannot be traced backward with assurance. A glacier advance can, perhaps, be related to a period of positive mass balances, but to ascertain the meteorological cause is difficult because either increased snowfall or decreased melting can produce a positive mass

advance

and retreat

The dynamic response of glaciers to changes in mass balance can be calculated several ways. Although the complete, three-dimensional equations for glacier flow are difficult to solve for changes in time, the effect of a small change or perturbation in climate can be analyzed readily. Such an analysis involves the theory of kinematic waves, which are akin to small pulses in one-dimensional flow systems such as floods in rivers or automobiles on a crowded roadway. The length of time it takes the glacier to respond in its full length to a change in the surface mass balance is approximately given as the ratio of ice thickness to (negative) mass balance at the terminus. The time scale for mountain glaciers is typically on the order of 10 to 100 years-although for thick glaciers or those with low ablation rates it can be much longer. Ice sheets normally have time scales several orders of magnitude longer.

Glaciers and sea level. Sea level is currently rising at about 2 millimetres (0.08 inch) per year. Between 0.2 and 0.6 millimetre per year has been attributed to thermal expansion of ocean water, and most of the remainder is thought to be caused by the melting of glaciers and ice sheets on land. There is concern that the rate in sea-level rise may increase markedly in the future owing to global warming. Unfortunately, the state of the mass balance of the ice on the Earth is poorly known, so the exact contributions of the different ice masses to rising sea level is difficult to analyze. The mountain (small) glaciers of the world are thought to be contributing 0.2 to 0.4 millimetre per year to the rise. Yet the Greenland Ice Sheet is thought to be close to balance, the status of the Antarctic Ice Sheet is uncertain, and, although the floating ice shelves and glaciers may be in a state of negative balance, the melting of floating ice should not cause sea level to rise, and the grounded portions of the ice sheets seem to be growing. Thus, the cause of sea-level rise is an enigma.

With global warming, the melting of mountain glaciers Effects will certainly increase, although this process is limited: the of global total volume of small glaciers is equivalent to only about 0.6 metre (2 feet) of sea-level rise. Melting of the marginal areas of the Greenland Ice Sheet will likely occur under global warming conditions, and this will be accompanied by the drawing down of the inland ice and increased calving of icebergs; yet these effects may be counterbalanced to some extent by increased snow precipitation on the inland ice. The Antarctic Ice Sheet, on the other hand, may actually serve as a buffer to rising sea level: increased melting of the marginal areas will probably be exceeded by increased snow accumulation due to the warmer air (which holds more moisture) and decreased sea ice (bringing moisture closer to the ice sheet). Modeling studies that predict sea-level rise up to the time of the doubling of greenhouse gas concentrations (i.e., concentrations of atmospheric carbon dioxide, methane, nitrous oxide, and certain other gases) about the year 2050 suggest a modest rise of about 0.3 metre (1 foot).

THE GREAT ICE SHEETS

Two great ice masses, the Antarctic and Greenland ice sheets, stand out in the world today and may be similar in many respects to the large Pleistocene ice sheets. About 99 percent of the world's glacier ice is in these two ice masses, 91 percent in Antarctica alone.

Antarctic Ice Sheet. Dimensions. The bedrock of the continent of Antarctica is almost completely buried under ice (see Figure 9). Mountain ranges and isolated nunataks (a term derived from Greenland's Inuit language, used for individual mountains surrounded by ice) locally protrude through the ice. Extensive in area are the ice shelves, where the ice sheet extends beyond the land margin and spreads out to sea. The ice sheet, with its associated ice shelves, covers an area of 13.918.000 square kilometres (5,374,000 square miles); exposed rock areas total less than 200,000 square kilometres. The mean thickness of the ice is about 2,100 metres (6,900 feet), and the volume of ice more than 29 million cubic kilometres (7 million cubic miles). The land surface beneath the ice is below sea level in many places, but this surface is depressed because of the weight of the ice. If the ice sheet were melted, uplift of the land surface would eventually leave only a few deep troughs and basins below sea level-even though the sea level itself also would rise about 80 metres from the addition of such a large amount of water. Because of the thick ice cover, Antarctica has by far the highest mean altitude of the continents (2.2 kilometres [1.4 miles]); all other continents have mean altitudes less than 1 kilometre (0.6 mile).

Antarctic Peninsula. Antarctica can be divided into three main parts: the smallest and the mildest in climate is the Antarctic Peninsula, extending from latitude 63° S off the tip of South America to a juncture with the main body of West Antarctica at a latitude of about 74° S. The ice cover of the Antarctic Peninsula is a complex of ice caps, piedmont and mountain glaciers, and small ice shelves.

West Antarctica. The part of the main continent lying south of the Americas, between longitudes 45° W and 165° E, is characterized by irregular bedrock and ice-surface topography and numerous nunataks and deep troughs. Two large ice shelves occur in West Antarctica: the Ronne-Filchner Ice Shelf (often considered to be two separate ice shelves), south of the Weddell Sea, and the Ross Ice Shelf, south of the Ross Sea. Each has an area

exceeding 400,000 square kilometres. East Antarctica. The huge ice mass of East Antarctica, about 10,200,000 square kilometres, is separated from West Antarctica by the Transantarctic Mountains. This major mountain range extends from the eastern margin of the Ross Ice Shelf almost to the Ronne-Filchner Ice Shelf. The bedrock of East Antarctica is approximately at sea level, but the ice surface locally exceeds 4,000 metres above sea level on the highest parts of the polar plateau. Climatic conditions. At the South Pole the snow surface is 2,800 metres in altitude, and the mean annual temperature is about -50° C (-58° F), but at the Russian Vostok Station (78°27' S, 106°52' E), 3,500 metres above sea

warming

The great Antarctic ice shelves

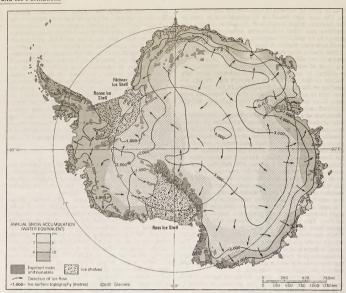

Figure 9: Nunataks, ice shelves, ice flow directions, and snow accumulation in Antarctica.

Adapted from M.B. Governette. "Cranage Systems of Anjarctics. Accumulation." Anjarctic Snow and Ice Studies. Anjarctic Research Sweet vol. 2. American Georgius 1995.1

level, the mean annual temperature is -58° C (-173° F), and in August 1960 (the winter season) the temperature reached a low of -88.3° C (-127° F). The temperatures on the polar plateau of East Antarctica are by far the coldest on Earth; the climate of the Arctic is quite mild by comparison. Along the coast of East or West Antarctica, where the climate is milder, mean annual temperatures range from -20° to -9° C (-4° to 16° F), but temperatures exceed the melting point only for brief periods in summer, and then only slightly. Katabatic (drainage) winds, however, are very strong along the coast; the mean annual wind speed at Commonwealth Bay is 20 metres.

per second (45 miles per hour).

Greenland Ice Sheet. The Greenland Ice Sheet, though subcontinental in size, is huge compared with other glaciers in the world except that of Antarctica. Greenland is mostly covered by this single large ice sheet (1,730,000 square kilometres), while isolated glaciers and small ice caps totaling between 76,000 and 100,000 square kilometres occur around the periphery. The ice sheet is almost 2,400 kilometres long in a north-south direction, and its greatest width is 1,100 kilometres at a latitude of 77° N, near its northern margin. The mean altitude of the ice surface is 2,135 metres. The term Inland Ice, or, in Danish, Indlandsis, is often used for this ice sheets.

The bedrock surface is near sea level over most of the interior of Greenland, but mountains occur around the periphery. Thus, this ice sheet, in contrast to the Antarctic lee Sheet, is confined along most of its margin. The ice surface reaches its greatest altitude on two north-south elongated domes, or ridges. The southern dome reaches almost 3,000 metres at latitudes 63°-65° N; the northern dome reaches about 3,290 metres at about latitude 72° N. The crests of both domes are displaced east of the centre line of Greenland.

The unconfined ice sheet does not reach the sea along

a broad front anywhere in Greenland, so that no large ice shelves occur. The ice margin just reaches the sea, however, in a region of irregular topography in the area of Melville Bay southeast of Thule. Large outlet glaciers, which are restricted tongues of the ice sheet, move through bordering valleys around the periphery of Greenland to calve off into the ocean, producing the numerous icebergs that sometimes penetrate North Atlantic shipping lanes. The best known of these is the Jakobshavn Glacier, which, at its terminus, flows at speeds of 20 to 22 metres per day.

aris climins, along a species of the Ze ineries per day. The climate of the Greenland Ice Sheet, though cold, is not as extreme as that of central Antarctica. The lowest mean annual temperatures, about -31° C (-24° F), occur on the north-central part of the north dome, and temperatures at the crest of the south dome are about -20° C (-4° F).

Mass balance of the ice sheets. Accumulation. The rate of precipitation on the Antarctic Ice Sheet is so low that it may be called a cold desert. Snow accumulation over much of the vast polar plateau is less than five centimetres (two inches) water equivalent per year. Only around the margin of the continent, where cyclonic storms penetrate frequently, does the accumulation rise to values of more than 30 centimetres. The mean for Antarctica is 15 centimetres or less. In Greenland values are higher: less than 15 centimetres in a comparatively small area of north-central Greenland, 30 centimetres along the crests of the domes, and more than 80 centimetres along the southeast and southwest margins; the mean annual snow accumulation is about 37 centimetres of water equivalent. Snow accumulation occurs mainly as direct snowfall when cyclonic storms move inland. At high altitudes on the Greenland Ice Sheet and in central Antarctica, ice crystals form in the cold air during clear periods and slowly settle out as fine "diamond dust." Hoarfrost and rime deposition are generally minor items in the snow-

Annual snowfall accumulation totals. It is almost impossible to measure the precipitation directly in these climates; precipitation gauges are almost useless for the measurement of blowing snow, and the snow is blown about almost constantly in some areas. The thickness and density of snow deposited on the ground equals precipitation plus hoarfrost and rime deposition, less evaporation, less snow blown away, and plus snow blown in from somewhere else. The last two phenomena are thought to cancel each other approximately-except in the coastal areas, where fierce drainage, or katabatic, winds move appreciable quantities of snow out to sea.

The snow surface may be smooth where soft powder snow is deposited with little wind, or very hard packed and rough when high winds occur during or after snowfall. Two features are prominent: snow dunes are depositional features resembling sand dunes in their several shapes: sastrugi are jagged erosional features (often cut into snow dunes) caused by strong prevailing winds that occur after snowfall. Sharp, rugged sastrugi, which can be one to two metres high, make travel by vehicle or on foot difficult. The annual snow layers exposed in the side of a snow pit can usually be distinguished by a low density layer (denth hoar) that forms by the burial of surface hoarfrost or by metamorphism of the snow deposited in the fall at a time when the temperature is changing rapidly.

Almost all of the Antarctic Ice Sheet lies within the drysnow zone. The percolation, soaked, and superimposed ice zones occur only in a very narrow strip in a small area along the coast. In Greenland only the central part of the northern half of the ice sheet, or about 30 percent of the total area, is within the dry-snow zone. Almost half of the area of the Greenland ice sheet is considered to be in the percolation zone. In flat areas near the equilibrium line. especially in west-central Greenland, there are notorious snow swamps, or slush fields, in summer; some of this water runs off, but much of it refreezes. (For an explanation of a glacier's surface zones, see above Formation and characteristics of glacier ice: Mass balance.)

Ablation. The ice sheets lose material by several processes, including surface melting, evaporation, wind erosion (deflation), iceberg calving, and the melting of the bottom surfaces of floating ice shelves by warmer seawater.

In Antarctica, calving of ice shelves and outlet glacier tongues clearly predominates among all the processes of ice loss, but calving is very episodic and cannot be measured accurately. The amount of surface melt and evaporation is small, amounting to about 22 centimetres of ice lost from a five-kilometre ring around half the continent. Wind erosion is difficult to evaluate but probably accounts for only a very small loss in the mass balance. The undersides of ice shelves near their outer margins are subject to melting by the ocean water. The rate of melting decreases inland, and at that point some freezing of seawater onto the base of the ice shelves must occur, but farther inland, near the grounding line, the tidal circulation of warm seawater may produce basal melting.

In Greenland, surface melt is more important, calving is less so, and undershelf melting is virtually nonexistent. Most of the calving is from the termini of a relatively few large, fast-moving outlet glaciers. In Greenland, verticalwalled melt pits in the ice are a well-known feature of the ice surface at the ablation zone. Ranging from a few millimetres to a metre in diameter, these pits are floored with a dark, silty material called cryoconite, once thought to be of cosmic origin but now known to be largely terrestrial dust. The vertical melting of the holes is due to the absorption of solar radiation by the dark silt, possibly augmented by biological activity.

Net mass balance. Because two great ice sheets contain · 99 percent of the world's ice, it is important to know whether this ice is growing or shrinking under present climatic conditions. Although just such a determination was a major objective of the International Geophysical Year (1957-58) and more has been learned each year since, even the sign of the net mass balance has not yet been determined conclusively.

It appears that accumulation on the surface of the Antarctic Ice Sheet is approximately balanced by iceberg calving and basal melting from the ice shelves. Compilations published in 1990-93 suggest the following values, given in gigatons (billions of tons) per year (1 gigaton is equivalent to 1.1 cubic kilometres of water):

the state of the s	
Accumulation	
Accumulation on grounded ice	+ 1.670 ± 330
Accumulation on ice shelves	+ 450 ± 90
Ablation	
Calving of ice shelves and glaciers	$-2,110 \pm 700$
Bottom melting, ice shelves	-540 ± 180
Melting and runoff	- 50 ± 25
Net mass balance	- 580 ±800

The net difference, however, is on the same order as the margin of error in estimating the various quantities. Furthermore, some authors have suggested that the values stated above for calving and ice-shelf melting are too high and that the discharge of ice to the sea, as measured by ice-flow studies, is clearly less than the accumulation. Thus, even the sign of the net balance is not well defined. It appears that the net balance of the grounded portion of the Antarctic Ice Sheet is positive, while that of the floating ice shelves is negative. Studies of fluctuations in the extent of floating ice have been inconclusive.

The net mass balance of the Greenland Ice Sheet also appears to be close to zero, but here, too, the margin of error is too large for definite conclusions. The estimated balance is as follows, again in gigatons per year.

balance of the Greenland Ice Sheet

Accumulation	
Snow accumulation	+ 554 ± 83
Ablation	
Iceberg calving	-311 ± 93
Melting and runoff	-244 ± 73
Net mass balance	0 ± 145

Uncertainties in the quantities given above are due to the difficulty of analyzing the spatial and temporal distributions of accumulation, the relatively few annual measurements of iceberg calving, and a lack of knowledge of the amount of surface meltwater that refreezes in the cold snow and ice at depth. Numerous ice coring, leveling, and flow studies suggest that the Greenland Ice Sheet is increasing in thickness at a rate of up to 0.1 metre per year. One study of changes in thickness between 1978 and 1986, based on satellite measurement, indicates a much higher thickening rate, but this conclusion has not been independently verified. Many of the outlet glaciers and portions of the ice-sheet margin in the southwestern part of Greenland, where many observations have been made, have stopped the retreats that were observed from the 1950s through the 1970s; since the 1980s they have been stable or advancing.

Flow of the ice sheets. In general, the flow of the Antarctic and Greenland ice sheets is not directed radially outward to the sea, Instead, ice from central high points tends to converge into discrete drainage basins and then concentrate into rapidly flowing ice streams. (Such socalled streams are currents of ice that move several times faster than the ice on either side of them.) The ice of much of East Antarctica has a rather simple shape with several subtle high points or domes. Greenland resembles an elongated dome, or ridge, with two summits. West Antarctica is a complex of converging and diverging flow because of the jumble of ridges and troughs in the subglacial bedrock and the convergence of ice streams.

Flow rates in the interior of an ice sheet are very low, being measured in centimetres or metres per year, because the surface slope is minuscule and the ice is very cold. As the ice moves outward, the rate of flow increases to a few tens of metres per year, and this rate of flow increases still further, up to one kilometre per year, as the flow is channeled into outlet glaciers or ice streams. Ice shelves continue the flow and even cause it to increase, because ice spreads out in ever thinner layers. At the edge of the Ross Ice Shelf, ice is moving out about 900 metres per year toward the ocean.

This simple picture of ice flow is made more complicated by the dependence of the flow law of ice on temperature. Because a temperature increase of about 15° C (27° F)

Calving and melting of the Antarctic Ice Sheet

Flow rates

Inspecting

annual

layers

causes a 10-fold increase in the deformation rate of ice, the temperature distribution of an ice sheet partly determines its flow structure. The cold ice of the central part of an ice sheet is carried down into warmer zones. This shift modifies the static temperature distribution, and the shear deformation is concentrated in a thin zone of warmer ice at the base. The forward velocity may be almost uniform throughout the depth to within a few tens or hundreds of metres from the bedrock

Another important effect on ice flow is the heat produced by friction, caused by the sliding of the ice on bedrock or by internal shearing within the basal ice. If a portion of the ice sheet deforms more rapidly than its surroundings, the slight amount of extra heat production raises the temperature of this portion, causing it to deform even more readily. This increased deformation may explain the phenomena of ice streams. Ice streams are very effective in moving ice from large drainage areas of Antarctica and Greenland out to ice shelves or to the sea. It is known that at least one Antarctic ice stream moves rapidly on a laver of water-charged deforming sediment; a nearby ice stream appears to have ceased rapid movement in the past several hundred years, perhaps owing to loss of its sediment layer.

Information from deep cores. Most of the Antarctic Ice Sheet and much of the Greenland Ice Sheet are below freezing throughout. Continuous cores, taken in some cases to the bedrock below, allow the sampling of an ice sheet through its entire history of accumulation. Records obtained from these cores represent exciting new developments in paleoclimatology and paleoenvironmental studies. Because there is no melting, the layered structure of the ice preserves a continuous record of snow accumulation and chemistry, air temperature and chemistry, and fallout from volcanic, terrestrial, marine, cosmic, and manmade sources. Actual samples of ancient atmospheres are trapped in air bubbles within the ice. This record extends back more than 300,000 years.

Near the surface it is possible to pick out annual lavers by visual inspection. In some locations, such as the Greenland Ice core Project/Greenland Ice Sheet Project 2 (GRIP/GISP2) sites at the summit of Greenland, these annual layers can be traced back more than 40,000 years, much like counting tree rings. The result is a remarkably high-resolution record of climatic change. When individual layers are not readily visible, seasonal changes in dust,

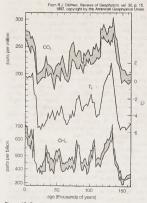

Figure 10: Parallel changes in the concentration of carbon dioxide (CO2) and methane (CH4) and in the temperature of the air over tens of thousands of years. Values are derived from measurements of oxygen and hydrogen isotope levels in air samples from a deep ice core taken at Vostok Station, East Antarctica.

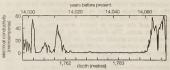

Figure 11: Fluctuations in electrical conductivity in an ice core taken by the Greenland Ice Sheet Project 2 in central Greenland. The changes in conductivity, caused by changes in atmospheric acidity brought about by windblown dust, indicate a rapid climatic transition between a warm period and a cold, glacial period.

From K.C. Taylor et

marine salts, and isotopes can be used to infer annual chronologies. Precise dating of recent layers can be accomplished by locating radioactive fallout from known nuclear detonations or traces of volcanic eruntions of known date. Other techniques must be used to reconstruct a chronology from some very deep cores. One method involves a theoretical analysis of the flow. If the vertical profile of ice flow is known, and if it can be assumed that the rate of accumulation has been approximately constant through time, then an expression for the age of the ice as a function of depth can be developed.

A very useful technique for tracing past temperatures involves the measurement of oxygen isotopes-namely, the ratio of oxygen-18 to oxygen-16. Oxygen-16 is the dominant isotope, making up more than 99 percent of all natural oxygen; oxygen-18 makes up 0.2 percent. However, the exact concentration of oxygen-18 in precipitation, particularly at high latitudes, depends on the temperature. Winter snow has a smaller oxygen-18-oxygen-16 ratio than does summer snow. A similar isotopic method for inferring precipitation temperature is based on measuring the ratio of deuterium (hydrogen-2) to normal hydrogen (hydrogen-1). The relation between these oxygen and hydrogen isotopic ratios, termed the deuterium excess, is useful for inferring conditions at the time of precipitation. The temperature scale derived from isotopic measurements can be calibrated by the observable temperature-depth record near the surface of ice sheets.

Results of ice core measurements are greatly extending the knowledge of past climates. For instance, air samples taken from ice cores show an increase in methane, carbon dioxide, and other "greenhouse gas" concentrations with the rise of industrialization and human population. On a longer time scale, the concentration of carbon dioxide in the atmosphere can be shown to be related to atmospheric temperature (as indicated by oxygen and hydrogen isotopes)-thus confirming the global-warming greenhouse effect, by which heat in the form of long-wave infrared radiation is trapped by atmospheric carbon dioxide and

reflected back to the Earth's surface. Perhaps most exciting are recent ice core results that show surprisingly rapid fluctuations in climate, especially during the last glacial period (160,000 to 10,000 years ago) and probably in the interglacial period that preceded it. Detectable variations in the dustiness of the atmosphere (a function of wind and atmospheric circulation), temperature, precipitation amounts, and other variables show that. during this time period, the climate frequently alternated between full-glacial and nonglacial conditions in less than a decade. Some of these changes seem to have occurred as "flickerings," in which the temperature jumped 5° to 7° C (9° to 13° F), remained in that state for a few years, jumped back, and repeated the process several times before settling into the new state for a long time-perhaps 1,000 years. These findings have profound and unsettling implications for the understanding of the coupled ocean-

atmosphere climate system. MOUNTAIN GLACIERS

In this discussion the term mountain glaciers includes all perennial ice masses other than the Antarctic and Greenland ice sheets. These ice masses are not necessarily assoEvidence of climatic change

tion and

ciated with mountains. Sometimes the term small glaciers is used, but only in a relative sense: a glacier 10,000 square kilometres (4,000 square miles) in surface area would not be called "small" in many parts of the world.

Classification of mountain glaciers. Mountain glaciers are generally confined to a more or less marked path directing their movement. The shape of the channel and the degree to which the glacier fills it determine the type of glacier. Valley glaciers are a classic type; they flow at least in part down a valley and are longer than they are wide. Cirque glaciers, short and wide, are confined to cirques, or amphitheatres, cut in the mountain landscape. Other types include transection glaciers or ice fields, which fill systems of valleys, and glaciers in special situations, such as summit glaciers, hanging glaciers, ice aprons, crater glaciers, and regenerated or reconstituted glaciers. Glaciers that spread out at the foot of mountain ranges are called piedmont glaciers. Outlet glaciers are valley glaciers that originate in ice sheets, ice caps, and ice fields. Because of the complex shapes of mountain landscapes and the resulting variety of situations in which glaciers can develop. it is difficult to draw clear distinctions among the various types of glaciers.

Mountain glaciers also are classified as polar, subpolar, or temperate and their surfaces by the occurrence of drysnow, percolation, saturation, and superimposed-ice zones.

as for ice sheets.

Surface features. The snow surface of the accumulation area of a mountain glacier displays the same snow dune and sastrugi features found on ice sheets, especially in winter, but normally these features are neither as large nor as well developed. Where appreciable melting of the snow occurs, several additional features may be produced. During periods of clear, sunny weather, sun cups (cup-shaped hollows usually between 5 and 50 centimetres [2 and 20 inchesl in depth) may develop. On very high-altitude, lowlatitude snow and firn fields these may grow into spectacular narrow blades of ice, up to several metres high, called nieves penitentes. Rain falling on the snow surface (or very high rates of melt) may cause a network of meltwater runnels (shallow grooves trending downslope) to develop.

Other features are characteristic of the ablation zone. Below icefalls (steep reaches of a valley glacier), several types of curved bands can be seen. The surface of the glacier may rise and fall in a periodic manner, with the spacing between wave crests approximately equal to the amount of ice flow in a year. Called wave ogives (pointed arches), these arcs result from the great stretching of the ice in the rapidly flowing icefall. The ice that moves through the icefall in summer has more of its surface exposed to melting and is greatly reduced in volume compared with the ice moving through in winter. Dirthand ogives also may occur below icefalls; these are caused by seasonal differences in the amount of dust or by snow trapped in the icefall. In plan view, the ogives are invariably distorted into arcs or curves convex downglacier; hence the name ogive.

The ice of the ablation zone normally shows a distinctive layered structure. This can be relict stratification developed by the alternation of dense and light or of clean and dirty snow accumulations from higher on the glacier. This stratification is later subdued by recrystallization accompanying plastic flow. A new layering called foliation is developed by the flow. Foliation is expressed by alternating layers of clear and bubbly or coarse-grained and fine-grained ice. Although the origin of this structure is not fully understood, it is analogous to the process that produces foliated structures in metamorphic rocks.

The ice crystals in strongly deformed, foliated ice invariably have a preferred orientation, relative to the stress directions. In some situations, more often in polar than in temperate ice, the hexagonal axes are aligned perpendicularly to the plane of foliation. This alignment places the crystal glide planes parallel to the planes of (presumed) greatest shearing. In many other locations the hexagonal crystal axes are preferentially aligned in four different directions, none perpendicular to the foliation. This enigmatic pattern has resisted explanation so far.

Crevasses are common to both the accumulation and ablation zones of mountain glaciers, as well as of ice sheets. Transverse crevasses, perpendicular to the flow direction along the centre line of valley glaciers, are caused by extending flow. Splaying crevasses, parallel to the flow in midchannel, are caused by a transverse expansion of the flow. The drag of the valley walls produces marginal crevasses, which intersect the margin at 45°. Transverse and splaying crevasses curve around to become marginal crevasses near the edge of a valley glacier. Splaying and transverse crevasses may occur together, chopping the glacier surface into discrete blocks or towers called seracs Crevasses deepen until the rate of surface stretching is

counterbalanced by the rate of plastic flow tending to close the crevasses at depth. Thus, crevasse depths are a function of the rate of stretching and the temperature of the ice. Crevasses deeper than 50 metres (160 feet) are rare in temperate mountains, but crevasses to 100 metres or more in depth may occur in polar regions. Often the crevasses are concealed by a snow bridge, built by accumulations of

windblown snow.

Mass balance of mountain glaciers. The rate of accumulation and ablation on mountain glaciers depends on latitude, altitude, and distance downwind from sources of abundant moisture, such as the oceans. The glaciers along the coasts of Washington, British Columbia, southeastern Alaska, South Island of New Zealand, Iceland, and southwestern Norway receive prodigious snowfall. Snow accumulation of three to five metres of water equivalent in a single season is not uncommon. With this large income, glaciers can exist at low altitudes in spite of very high melt rates. The rate of snowfall increases with increasing altitude; thus, the gradient of net mass balance with altitude is steep. This gradient also expresses the rate of transfer of mass by glacier flow from high to low altitudes and is called the activity index.

Typical of the temperate, maritime glaciers is South Cascade Glacier, in western Washington (see Figure 12). Its activity index is high, normally about 17 millimetres per metre (0.2 inch per foot); the yearly snow accumulation averages about 3.1 metres of water-equivalent; and the equilibrium line is at the relatively low altitude of 1,900 metres. This glacier contains only ablation and saturation zones; the winter chill is so slight that no superimposed ice is formed.

In the maritime environment of southeastern Alaska are many very large glaciers; Bering and Seward-Malaspina glaciers (piedmont glaciers) cover 5,800 and 5,200 square kilometres in area, respectively. Equilibrium lines are lower than those in Washington state, but the rates of accumulation and ablation and the activity indices are about the same. Because these mountains are high, and some glaciers extend over a great range of altitude, all surface zones except the dry-snow zone are represented.

In more continental (inland) environments, the rate of snowfall is much less, and the summer climate is generally warmer. Thus, glaciers can exist only at high altitudes. High winds may concentrate the meagre snowfall in deep, protected basins, however, allowing glaciers to form even in areas of low precipitation and high melt rates. Glaciers formed almost entirely of drift snow occur at high altitudes in Colorado and in the polar Ural Mountains and are often referred to as Ural-type glaciers. Superimposed ice and soaked zones are found in the accumulation area; in higher areas the percolation zone is found, and in some local extreme areas the dry-snow zone occurs. Because of the decrease in melt rates, continental glaciers in high latitudes occur at lower altitudes and have lower accumulation totals and activity indices. McCall Glacier, in the northwestern part of the Brooks Range in Alaska, has the lowest activity index (two millimetres per metre) measured in western North America. Glaciers in intermediate climates have intermediate equilibrium-line altitudes, accumulation or ablation totals, and activity indices.

Flow of mountain glaciers. Ice flow in valley glaciers has been studied extensively. The first measurements date from the mid-18th century, and the first theoretical analyses date from the middle of the 19th century. These glaciers generally flow at rates of 0.1 to 2 metres per day, faster at the surface than at depth, faster in midchannel than along the margins, and usually fastest at or just below

Ogives and ice stratification

Figure 12: South Cascade Glacier, Washington state, U.S.; a typical small valley glacier By courtesy of the U.S. Geological Survey, photograph, Austin Post

the equilibrium line. Cold, polar glaciers flow relatively slowly, because the constitutive law of ice is sensitive to temperature and because they generally are frozen to their beds. In some high-latitude areas, such as the Svalbard archipelago north of Norway, polythermal glaciers are common; these consist of subfreezing ice overlying temperate ice, and, because they are warm-based, they actively slide on their beds.

The fastest glaciers

The fastest glaciers (other than those in the act of surging) are thick, temperate glaciers in which high subglacial water pressures produce high rates of sliding. Normal temperate glaciers ending on land generally have subglacial water pressures in the range of 50 to 80 percent of the ice pressure, but glaciers that end in the sea may have subglacial water pressures almost equal to the ice pressurethat is, they almost float. The lower reach of Columbia Glacier in southern Alaska, for instance, flows between 5 and 25 metres per day, almost entirely by sliding. Such a high sliding rate occurs because the glacier, by terminating in the ocean, must have a subglacial water pressure high enough to drive water out of the glacier against the pressure of the ocean water.

Glacier hydrology. A temperate glacier is essentially a reservoir that gains precipitation in both liquid and solid form, stores a large share of this precipitation, and then releases it with little loss at a later date. The hydrologic characteristics of this reservoir, however, are complex, because its physical attributes change during a year.

In late spring the glacier is covered by a thick snowpack at the melting temperature. Meltwater and liquid precipitation must travel through the snowpack by slow percolation until reaching well-defined meltwater channels in the solid ice below. In summer the snowpack becomes thinner, and drainage paths within the snow are more defined, so that meltwater and liquid precipitation are transmitted through the glacier rapidly. In winter, snow accumulates, and the surface layer freezes, stopping the movement of meltwater and precipitation at the surface. The rest of the ice reservoir may continue to drain, but in the process the conduits within and under the ice tend to close.

The runoff from a typical Northern Hemisphere temperate glacier reaches a peak in late July or early August. Solar radiation, the chief source of heat to promote melt, reaches a peak in June. The delay in the peak melt rates is primarily because of the changing albedo (surface reflectivity) during the summer; initially the snow is very reflective and covers the whole glacier, but as the summer wears on the snow becomes wet (less reflective), and in addition more and more ice of much lower albedo is exposed. Thus, even though the incoming radiation decreases during midsummer, the proportion of it that is absorbed to cause melt is greatly increased. Other heatexchange processes, such as turbulent transfer from warm air, also become more important during midsummer and late summer.

This albedo variation produces a runoff "buffering effect" against unusually wet or dry years. An unusually heavy winter snowpack causes high-albedo snow to persist longer over the glacier in summer; thus, less meltwater is produced. Conversely, an unusually light winter snowfall causes older firn and ice of lower albedo to be exposed earlier in the summer, producing increased melt and runoff. Thus, glaciers naturally regulate the runoff, seasonally and from year to year. When glacier runoff is combined with nonglacier runoff in roughly equal amounts, the result is very stable and even streamflow. This condition is part of the basis for the extensive hydrologic development that is found in regions such as the Alps, Norway, and western Washington.

Glacier streams are characterized by high sediment concentrations. The sediment ranges from boulders to a distinctive fine-grained material called rock flour, or glacier flour, which is colloidal in size (often less than one micrometre in diameter). The suspended sediment concentration decreases with distance from the glacier, but the rock-flour component may persist for great distances and remain suspended in lakes for many years; it is responsible for the green colour of Alpine lakes. Glacier streams vary in discharge with the time of day, and this variation causes a continual readjustment of the stream channel and the transportation of reworked debris, adding to the sediment load. Rates of glacier erosion (that is, sediment production) are typically on the order of one millimetre per year, averaged over the glacier area, but they are higher in particularly steep terrain or where the bedrock is especially soft.

Glacier floods. Glacier outburst floods, or jökulhlaups, can be spectacular or even catastrophic. These happen when drainage within a glacier is blocked by internal plastic flow and water is stored in or behind the glacier. The water eventually finds a narrow path to trickle out. This movement will cause the path to be enlarged by melting, causing faster flow, more melting, a larger conduit, and so on until all the water is released quite suddenly. The word jökulhlaup is Icelandic in origin, and Iceland has experienced some of the world's most spectacular outburst floods. The 1922 Grimsvötn outburst released about 7.1 cubic kilometres (1.7 cubic miles) of water in a flood that was estimated to have reached almost 57,000 cubic metres (2,000,000 cubic feet) per second. Outburst floods occur in many glacier-covered mountain ranges; some break out regularly each year, some at intervals of two or more

jökulhlaup

Runoff from glacier ice years, and some are completely irregular and impossible to predict.

Glacier surges. Most glaciers follow a regular and nonspectacular pattern of advance and retreat in response to a varying climate. A very different behaviour pattern has been reported for glaciers in certain, but not all, areas, Such glaciers may, after a period of normal flow, or quiescence, lasting 10 to 100 or more years, suddenly begin to flow very rapidly, to up to five metres per hour. This rapid flow, lasting only a year or two, causes a sudden depletion of the upper part of the glacier, accompanied by a swelling and advance of the lower part, although these usually do not reach positions beyond the limits of previous surges. Advances of several kilometres in as many months have been recorded. Even more interesting is the fact that these glaciers periodically repeat cycles of quiescence and activity, irrespective of climate. These unusual glaciers are called surging glaciers.

Although surging glaciers are not rare in some areas (e.g., Alaska Range and St. Elias Mountains), they are totally absent in other areas of similar topography, bedrock, climate, and so forth (e.g., western Chugach Mountains and Coast Mountains). Furthermore, glaciers of all shapes and sizes, from tiny cirque glaciers to major portions of a large ice cap, have been known to surge. The flow instability that results in glacier surges is generally caused by an abrupt decoupling of the glacier from its bed. This decoupling is the result of a breakdown in the normal subglacier water flow system, but the exact mechanisms that cause some glaciers to surge are not fully understood.

Difficulty

of explain-

ing surging

glaciers

Tidewater glaciers. Many glaciers terminate in the ocean with the calving of icebergs. Known as tidewater glaciers, these glaciers are the seaward extensions of ice streams originating in ice fields, ice caps, or ice sheets. Some tidewater glaciers are similar to surging glaciers in that they flow at high speeds—as much as 20 to 25 meters are dispersed by the streams or the stream of the str

The physical mechanisms that control the rate of iceberg calving are not yet well understood. Empirical studies of grounded (not floating) tidewater glaciers in Alaska, Svalbard, and elsewhere suggest that the speed of iceberg calving is roughly proportional to water depth at the terminus. This relation can produce an instability and periodic advance-retreat cycles. For example, a glacier terminating in shallow water at the head of a fjord will have a low calving speed that may be exceeded by the ice flow speed, causing advance of the terminus. At the same time, glacial erosion will cause the deposition of sediment as a moraine shoal at the terminus. With time, the glacier will advance, eroding the shoal on the upstream face and depositing sediment on the downstream face. The shoal, by reducing the depth of the water at the glacier's terminus and thereby inhibiting iceberg calving, will allow the glacier to advance into deep water farther down the fjord. This advance phase is slow-typically 10 to 40 metres per year-and in an Alaskan fjord it may take a period of 1,000 years or more to cover a typical fjord length of 30 to 130 kilometres.

Such a glacier, in an extended position and terminating in shallow water on a moraine shoal, is in an unstable situation. If, for some reason, the terminus retreats slightly, the deeper water upstream of the shoal will cause an increase in iceberg calving; this will result in further retreat into deeper water, which will further increase the calving until the calving speed becomes so high that the normal processes of glacier flow cannot compensate. A rapid, irreversible retreat will result until the glacier reaches shallow water back at the head of the fjord. In contrast to the slow advance phase, the retreat phase may take only a few decades. The fastest glacier retreats observed during historical time (for instance, the opening of Glacier Bay, Alaska), as well as those inferred during the demise of the great Quaternary ice sheets, were caused by this mechanism. Information on the advance and retreat of tidewater glaciers should not be used to infer climatic (MEM) change, however.

Icebergs and pack ice

Ice in the waters of the Earth's polar regions occurs in two forms—namely, pack ice and icebergs. Pack ice forms from seawater and is generally only one to two years old, whereas icebergs are fragments of ice sheets and glaciers that formed on land areas during intervals of thousands of years. Pack ice expands during winter to cover large areas of the occans in both hemispheres. Melting occurs in spring and summer, and the margins of the pack ice retreat. This warmer weather aids calving (separation) of icebergs at the boundaries of ice sheets and glaciers, however, and many icebergs start their transit toward the Equator at this time.

This ice at sea is of substantial importance to humans. Major shipping routes around the world could be shortened by as much as 30 percent if regular navigation through the Arctic Ocean became feasible, for example. The economics of freshwater extraction from icebergs also is instructive. An iceberg 16 kilometres (10 miles) long could be hauled into the Peru (Humboldt) Current, which flows from the south along South America, and ultimately to Los Angeles where it could supply fresh water to that city for three weeks. Factors of wind effect, breakup, grounding, accessible supply, and controlled melting on delivery argue against this venture, however. In the Northern Hemisphere about 10,000 icebergs are produced each year from the West Greenland glaciers and an average of 375 flow south of Newfoundland into the North Atlantic shipping lanes.

Because ice reflects four to five times more sunlight than does the ocean, the change in areal coverage of sea ice between winter and summer is climatically important. There is a change in areal coverage of 20 percent from winter to summer in Arctic pack ice extent, and 80 percent in Antarctic pack ice maximum to minimum coverage. This winter to summer change in area of pack ice coverage is equivalent to twice the area of the United States.

CEBERGS

Formation and distribution. Calving of glaciers and ice sheets. Probably the first mention of icebergs was that of St. Brendan, an Irish monk whose partly fictional writings suggest that he encountered a "floating crystal castle" on the high seas. After calving (breaking off) from the Greenland and Antarctic ice sheets and smaller outlying glaciers, icebergs can move thousands of miles in a few years; those in the Artici can slip down along the eastern North American coast to be caught up in the Gulf Stream and, while melting, be carried in a few weeks to within several hundred kilometres of England and Ireland or by a combination of wind and current to Bermuda, as happened in 1907 and 1926. These and other rare sightings are shown Figure 13.

As previously noted, when snow and freezing rain continue to precipitate over a continent in excess of evaporation, glaciers will form and icebergs will break off their ends and appear in the surrounding ocean. At the point where glaciers or large, extensive ice shelves meet the sea, water pressure beneath the ice shelf or glacier tongue interacts with the outward creeping glacier. The tides, which have ranges up to 6 metres (20 feet) in the Arctic, along with small sea-level changes associated with wind and swells, result in an intermittent increase and decrease in force on the protruding end of the glacier or ice shelf resulting in the birth of a large monolith of drifting ice. There are other ways in which an iceberg is formed. One, which is characteristic of southern Greenland glaciers, consists of a melting or evaporation of the surface portions of the glacier near its terminus at a greater rate than the water erosion on its underside. This results in an underwater shelf, and eventually, through the erosion of water and periodic tidal and other hydraulic forces, this is broken off and an iceberg floats to the surface. Icebergs of varying shapes are produced in this way. A third mechanism by which icebergs are formed is through gradual break-off from a hanging glacier or ice shelf. The type of iceberg mechanism is related to the surrounding topography, the climate, and the rate of flow of associated glaciers.

Importance of ice

Gulf Stream transport

Figure 13: Limits of sea ice and icebergs in the Northern Hemisphere.

Movement of glaciers producing icebergs

The speed of the ice sheet flow, or creep, over Greenland and the Antarctic varies from zero near their centres to as much as 10 kilometres per year in the ice streams that make up glaciers. For the same inclination relative to gravity, ice moves 1/10,000 as fast as water. The average movement in the Antarctic is 360 metres per year, with most of the measurements between extremes of 110 and 1,100 metres per year. These measurements are made near the coast and are much higher than the average flow rate over the entire Greenland or Antarctic ice sheets.

Arctic icebergs. The western shore of Greenland has the fastest-flowing glaciers on the Earth. The one known as the Quarayaq Glacier flows at a velocity between 20 and 24 metres per day, greater than the velocity of most Alpine glaciers. Jakobshavn Glacier at latitude 70° N, approximately, produces 10 percent of all the Greenland icebergs (approximately 1,350 annually) and flows at about 20 metres per day. The icebergs accumulate in a fjord and periodically spill from this fjord in groups accompanied by noise that can be heard for several kilometres. This greatest iceberg-producing glacier measures only 7 kilometres along its front and is 90 metres above sea level. In contrast to the rapidly moving glaciers, the very wide glaciers that move slowly produce only very small icebergs. Some glaciers, such as the Frederikshåb, Greenland, with a 33-kilometre front, have rates of flow equal to the rate of melting, and thus produce no icebergs. The annual yield of icebergs in the Arctic is, at the most, 15,000, with only 5,000 or so of sufficient size to reach the open ocean intact.

The largest glacier in the Northern Hemisphere is the Petterman Glacier, at 81° N 62° W. Although it is only a few metres above seawater, its ice foot extends as far as 40 kilometres out to sea, and it pushes a path through old piled-up sea ice. These long fingers of glacier ice, under severe climatic conditions, break off once every 10 to 20 years. Another glacier of importance is the Jungersen Glacier in northern Greenland. This glacier and the Petterman Glacier produce very large tabular icebergs, known in the Arctic as "ice islands." They are similar in shape and mode of formation to the large tabular icebergs of the Antarctic but are much smaller.

East Greenland icebergs tend to move northward; they are small and few in number. The icebergs that do leave the fjord and the coast area enter the East Greenland Current, and some join the West Greenland icebergs. The icebergs that reach the North Atlantic Ocean from northern Greenland, Siberia, and the Northwest Territories constitute less than 10 percent of the total icebergs produced in the Northern Hemisphere. They do not affect the sea routes and, other than their formation of ice islands, have no importance to humans. Most icebergs originating from western Greenland are of great importance; of an annual production of about 7,500 bergs (Arctic total is 10,000-15,000), the Labrador Current carries 800 to 1,000 into the open ocean.

Sightings in the North Atlantic Of the 10,000 to 15,000 icebergs calved from glaciers annually in the Arctic, only 375 on the average pass Newfoundland, or latitude 48° N, into the North Atlantic Ocean. In some years more than 1,000 are seen, in others fewer than 30. The yearly average diminished over 20 years until 1972, when 1,400 icebergs were sighted south of 48° in the North Atlantic. The distribution of these icebergs in April, May, June, and July is shown in Figure 13.

There are few icebergs in the Arctic Basin proper. The major source area for icebergs in the Barents Sea is Franz Josef Land. Icebergs are not found in the North Pacific except in sounds along the Alaskan-Canadian coast between

latitudes 55° and 60° N.

Aniarctic Icebergs. In the Southern Hemisphere the maximum limit of iceberg drift is 1,600 kilometres farther north than the northern extent of sea ice in the Antarctic (Figure 14). Most icebergs are concentrated south of the Aniarctic current convergence at about 60° S. Some icebergs from the ice shelves of Aniarctica drift north of latitude 42° S in the Allantic Ocean but only to latitude 56° S in the Allantic Ocean but only to latitude 56° S in the South Pacific Ocean. One Antarctic iceberg was sighted only 50 kilometries south of the Cape of Good Hope (Africa) in 1850. The northern limit of ice sighted in the Southern Hemisphere was 26° 30° S.

Size of icebergs. Artic. Artic icebergs vary in size from the size of a large piano, called growlers, to the dimensions of a 10-story building. Icebergs about the size of a small house are called bergy bits. Many icebergs in the Artic are about 45 metres tall and 180 metres long. Icebergs of the Antarctic not only are far more abundant but are of enormous dimensions compared with those in the Artic. Infurly-three percent of the world's mass of

icebergs is found surrounding the Antarctic.

Other than Arctic Basin ice islands, the largest iceberg in the Northern Hemisphere was 11 kilometres long and 5,9 kilometres wide; it was sighted near Baffin Land in 1882. The largest Arctic iceberg sighted south of Newfoundland was encountered by a convoy of ships during World War II at 43° 10° N and 49° 33° W. There were multiple collisions and much confusion before all ships safely limped into port. This ice island was 1,370 metres long, 1100 metres wide, and 18 metres high. These icebergs are similar in size to Antarctic icebergs, but by and large only a few large tabular icebergs are sen in the Arctic as compared with the predominance of the tabular icebergs noted in the Antarctic. The tallest icebergs known were measured at 134 and 158 metres high; the latter was measured and photographed from a helicopter in the latt e1950s.

Antarctic. Antarctic icebergs are characterized by their tremendous size and tabular shape. Lengths up to seven kilometres are not unusual, with ice 45 metres above water. The discovery of the origin of these immense tabular bergs was made in 1841 when the Ross Sea was penetrated and the Ross Ice Shelf was discovered to be afloat. Most Antarctic icebergs are formed from the Antarctic continental ice sheet as it thins toward the coast and exudes into the ocean as a great ice shelf with fronts hundreds of kilometres long. The four major ice shelves are the Ronne-Filchner Shelf in the Weddell Sea, the Ross Ice Shelf in the Ross Sea, the Shackleton Ice Shelf in the Indian Ocean sector, and the Larsen Ice Shelf on the Antarctic Peninsula (also known as Palmer Land and Graham Land). Antarctic icebergs, if they remain locked in the pack ice, will last for many years. One of the largest icebergs sighted was over 140 kilometres in length. This tabular iceberg was first sighted in 1927, and presumably the same iceberg was later seen in 1931, at which time it was 100 kilometres long. The largest known Antarctic iceberg was measured by the icebreaker USS Glacier in 1956; it had a length of 333 kilometres and a width of 100 kilometres.

Age and melting. Greenland icebergs 300 to 450 metres thick represent several centuries of precipitation. This figure is based on the comparison of the thickness of the ice sheet to the known or average annual precipitation of 20 to 60 centimetres (8 to 24 inches) per year in the source area for icebergs. Age of ice in central Greenland, close to bedrock, is estimated at 30,000 to 150,000 years old. The longest core retrieved from the Greenland ice sheet was 1,370 metres long with a bottom date of 100,000 years.

It is probable that the oldest ice melts before reaching the outlet glaciers. From the known amount of precipitation over Greenland, and the assumption that the ice volume and precipitation rate now are approximately the same as they were many centuries ago, it can be estimated that the mean age of icebergs is 5,000 years. Measurements by carbon-14 dating of entrapped air show that icebergs are hundreds to thousands of years old—the oldest actual measurement being 3,000 years. Arctic ice islands and giant Antarctic bergs last as long as 10 years at high latitude. Most western Greenland icebergs melt within two years.

Most western Greenland icebergs melt within two years Once an Arctic iceberg has been calved and moves out to the open sea, it sojourns in Baffin Bay for three months to two years, during which time it undergoes some disintegration through melting and calving of small chunks of ice from its perimeter. This results in a decrease in mass of about 90 percent by the time it reaches the coast of Newfoundland and the Grand Banks in the North Atlantic. When the iceberg enters the region of the Grand Banks. where the warm waters of the Gulf Stream meet the colder waters of the Labrador Current, it has only a few days of life remaining. A large iceberg 120 metres long melted within 36 hours in 27° C (80° F) water. The estimated rate of iceberg melting is based on the observations of a number of individuals from the International Ice Patrol. For mild sea conditions an iceberg deteriorates at a rate of height decrease of two metres per day in 0° to 4° C (32° to 39° F) water, and three metres per day in 4° to 10° C (39° to 50° F) water. Destruction of icebergs in warm water is increased during stormy weather, when mechanical erosion of icebergs is added to the thermal effects of air and water. During the erosion process icebergs usually take on the form of a saddle, because erosion at one pole of the major axis of the iceberg results in that point rising. while the other end of the major axis is being eroded. Subsequently the latter end, owing to loss in weight, arises, and this rocking back and forth continues while constant erosion is occurring along the minor axis leading, usually, to a bipeaked or saddle-shaped structure. Table 2 is an estimate of the time necessary for deterioration and is based on unpublished quantitative measurements in 1960

Wind and current effects. Drift of icebergs. Iceberg movement is influenced by direct wind push on its exposed area to an extent far greater than commonly assumed. Although the bulk of the iceberg is below water, in many situations wind has a dominant influence on the movement. The wind intensity and direction over Baffin Bay in the spring of one year influences the number of icebergs that slip into the North Atlantic that year and the following year. This can be understood by noting that icebergs pouring out of the Arctic north of Newfoundland in spring will run aground or be trapped in the embayments of western Baffin Bay unless wind and current deflect them to the southeast. Of more importance is the effect of wind over western Greenland, however, where intense offshore early summer winds over the ice fjords drive sea ice-entrapped bergs into the West Greenland Current, thus increasing the number of icebergs that, having made the usual counterclockwise circuit, will arrive off Newfoundland the following spring. There is a reasonable correlation between the atmospheric pressure distribution one year and the number of icebergs drifting south of Newfoundland in the following year.

Table 3: Exposed-to-Submerged Proportions, and Wind Factors, for Icebergs

Effect of size and shape

Windage

and drift

The day-to-day movement of an iceberg is controlled by the size and shape of the iceberg, previous and present wind, surface wind current, and general ocean current. The most important factor in assessing wind drift of icebergs is size and shape. Although most icebergs have a specific gravity of 0.9, and thus % of the mass is below the sea surface, it is not true that this means that a 30-metre-high iceberg is 180 metres deep in all cases. This is true only for the rectangular, block, or flat-to-pope cicebergs common to the Antarctic. Table 3 gives the relation between exposed and underwater areas for various shapes of icebergs.

Winged icebergs, those with saillike pinnacles around the central mass, are very much influenced by the winds and move at speeds of 1 knot, or 24 nautical miles per day, under the influence of steady winds of 30 knots. The wind force on an iceberg does not result in movement directly downwind, but, because of the rotation of the Earth (Co-riolis effect), windage on an iceberg is 30° to 50° to the right in the Northern Hemisphere and to the left in the

Southern Hemisphere.

The momentum of icebergs is so great that once in motion they continue for hours after the wind has abated. It is possible for an iceberg to be driven before a 30-knot wind at 1 knot in a direction 30° to the right of the wind, and after the wind stops the iceberg will slow and circle in what is known as an inertial circle, associated with the rotation of the Earth. An iceberg near the Grand Banks will be moving in a direction opposite to that toward which the wind was blowing about eight hours after the wind stops; however, the speed would be low and such anomalous movement would not be observed unless the initial speed and momentum were great. A careful accounting of berg underbody dimensions and the relationship of windcurrent forces and iceberg mass will lead to explanations of anomalous iceberg movements. To emphasize the importance of wind effect and its prediction, one potentially disastrous case will be cited. In 1960 a 60-metre-high, 300metre-long iceberg was driven off the tail of the Grand Banks into the shipping lanes by northwesterly winds averaging 80 kilometres per hour. This iceberg moved 140 kilometres at as much as 3 knots across the Labrador Current and resulted in an emergency move of the North Atlantic shipping lanes to the south.

The drift of icebergs and pack ice is the result of the ocean current and the wind. When the winds are variable or less than 32 kilometres per hour and the current greater than 0.5 knot, the current predominates, but, when steady 30-knot winds blow for more than 12 hours, the wind effect becomes important even in areas where the ocean current is 1 to 2 knots. In addition to windage on the iceberg and the ocean gradient current, the wind-induced surface current has the effect of increasing drift speed by about 10 percent for small icebergs and increasing the angle of drift direction.

Drift of sea ice. Sea ice drift is better understood, but in some respects it is more complicated than iceberg drift. In addition to size, inertia, and exposed-to-underwater dimensions, important additional information on surface roughness, water drag, and internal resistance due to ice-field concentration is needed to describe the motion. The observations of American and Russian scientists drifting on ice islands in the Arctic Basin, Baffin Bay, and Gulf of St. Lawrence, along with Japanese and Russian long-term ice-field observations, are summarized in Table 4. As noted from the table, ice fields consisting of 10 per-

cent ice and 90 percent open water will move at 1 to 8 percent of the surface wind velocity. The angle of drift is from 20° to 40° to the right of the wind in the Northern Hemisphere. The speed will be reduced by a factor of four as the ice becomes packed to 90 percent coverage of the ocean. Smooth ice drifts with less speed than rough ice because the wind has greater effect on a rough surface. Rough or hummocked ice usually is thicker and thus has greater inertia; ice of great inertia takes longer to reach the wind factor speed, but, after the wind stops, the ice continues to move longer than light ice. This phenomenon results in strings of ice floes aligned perpendicular to the wind with small floes packed to windward against larger floes. This wind sorting of ice is a phenomenon of great importance in navigating pack ice, and the strips of open water aligned in a direction approximately perpendicular to the direction of wind explain the successful navigation in ice performed by sailing vessels in the past.

Sediment transport. Both icebergs and pack ice transpour sediment in the form of pebbles, cobbles, boulders, and finer material, and even plant and animal life, thousands of miles from their source area. The distribution of icebergs 10,000 years ago, for example, can be inferred from sediments that are widely disseminated on the ocean floor of the North Pacific Ocean as far south as latitude 48° N and in the South Atlantic Ocean as far north as the latitude of the Cape of Good Hope in the Southern Hemisphere. Ice rafting competes with kelp rafting as an explanation for the occurrence of pebbles and boulders on the seafloor as far south as Baja California and other areas

of the world ocean.

Bottom freezing of ice shelves and reduction of the ice surface results in migration of sediments and organisms upward. Layering of sediment can be seen in sea-ice floes and icebergs from ice shelves. Fossil penguin bones have been found as far north as 30° S, and massive banks of boulders have been noted on the seafloor off South Africa. Thicknesses of as much as 130 centimetres of glacial till have been noted on the ocean floor from discharge by icebergs, apparently during the past one million years.

Icebergs are coloured brown, black, and green by a combination of sediment, plankton deposits under the source area ice shelf, and glacial blue ice.

Iceberg detection and destruction. In the open ocean most ice is seen by radar at ranges depending on fragment size, but smaller icebergs or growlers can be detected only when the sea surface is calm, and then only at ranges of about two kilometres. During slight wind conditions, in particular in heavy seas, the echoes from the waves, known as sea return, may completely mask the echoes of large, potentially very hazardous chunks of ice. In addition, radar return from rain and snow obscures the return from ice in either rain, snow, or fog conditions. Neither radar nor sonar can be relied upon for detection of icebergs and pack ice in choppy seas. The reflectivity of ice and snow to light is great, but reflectivity to radar or short radiowaves is very poor. An iceberg seven metres high cannot be detected with modern equipment if the waves are over one metre high. Various innovations since the inception of radar during World War II have not improved significantly the capabilities of radar to detect icebergs; thus ships are still bound by international agreement to proceed at slow speed in fog.

Sonar is effective in detecting icebergs; however, the range of detection is frequently limited by the water conditions and speed of commercial vessels. The likelihood of insufficient warning for high-speed passenger and cargo ships leaves this mode of detection inadequate. Other sug-

Reliability of radar detection gestions of dropping radio transducers or metal reflectors onto icebergs have the common fault that they are subject to icebergs rolling over and calving, which are frequent occurrences as a dying iceberg melts its way deep into the warmer waters of the shipping lanes.

The problem of iceberg protection, therefore, is one of tracking icebergs as they come down the Labrador Current and reporting the whereabouts of these floating menaces to all North Atlantic shipping as often as twice daily. This sometimes involves 300 ciebergs and requires a team of iceberg experts, oceanographers, aviators, and seamen. During heavy ice conditions two U.S. Coast Guard planes fly six- to eight-hour reconnaissance missions from Argentia, Nfd., Can., over the Grand Banks off Newfoundland and contiguous areas. Positions of icebergs are plotted and are correlated with previous positions of the same icebergs or groups of icebergs. When dangerous icebergs approach the shipping lanes, a ship departs for the scene to stand by near the iceberg and proach ships.

Once an iceberg is spotted in a position of threat to ships, it should be of no harm if destroyed. Destroying a 200 -000-ton block of ice is, however, a task whose difficulties leave it impractical in most situations. The first successful results on breaking up icebergs by explosives were reported in 1929, when a few hundred kilograms of thermite cracked an iceberg into smaller pieces through thermal stress; these then melted more rapidly owing to the greater surface area exposed. Similar thermite experiments on two icebergs in 1959 did not corroborate the original findings, however. Attempts at bombing, torpedoing, shelling, and even ramming have been unsuccessful. With twenty 450kilogram (1,000-pound) bombs acting as direct hits, or as depth charges, it is possible to chip away about 20 percent of a 250,000-ton iceberg. The International Ice Patrol has even tried painting half of an iceberg with lampblack or charcoal to induce thermal stress by heat absorption, but, like other experiments, these attempts were inconclusive.

PACK ICE

Formation and characteristics. On superficial examination, frozen ocean or salt water appears similar to freshwater ice; there are two principal differences, however. First, because the maximum density of seawater occurs below the freezing point, even after freezing the water below the ice will continue to turn over or circulate. As the surface water near the ice becomes colder, it becomes heavier and sinks, resulting in a continuous turnover or vertical circulation of the water beneath the ice. This is a different situation from that which occurs in lakes where, because the maximum density of fresh water is above the freezing point, once ice forms the colder water is lighter than the deeper, somewhat warmer water, and mixing does not occur (see above Ice in lakes and rivers: Ice in lakes). A second characteristic is the fact that, as seawater freezes, minute pools of salty water called brine pockets are entrapped. The final form and the macroscopic physical properties of the ice are very much dependent upon the concentration of the brine pockets within the ice block. Once an ice field has formed, the physical and chemical properties are not locked in a frozen coffin but vary as brine pockets migrate through the ice block in response to gravity and thermal gradients.

Crystallization. In the Northern Hemisphere during September and October, the air temperature lowers sufficiently to form a thin sheet of ice. Freezing temperature for average northern ocean salt water of about 3.5 percent salt composition by weight (usually designated 35 parts per thousand) is -1.8° C (28.8° F). The first signs of freezing are changes in the colour and texture of the sea surface as thin, gray-coloured needles and crystal plates form a * surface-thin sludge. If quiet sea conditions prevail, sheets of crystalline aggregates plate the ocean surface. Initially the ice film is entirely fresh, but, as more ice crystals form, pockets of salt water (brine pockets) become entrapped between lamellae (very fine layers) of tiny ice plates. The amount of brine entrapped depends on the temperature of formation and the age of the ice. The shape of the initial ice crystals varies from square discoids to hexagonal dendritic forms. The average width is 2.54 centimetres (1

inch) and the thickness up to about 0.15 centimetre (0.06 inch). During the surface veneer formation stage each grain is free to grow both laterally and vertically until the sheet consolidates. As the ice sheet thickens, the orientation of these grains will change. Owing to slight breeze and water motion, the thin sheets of ice jostle about and, after but a few hours, form a field of ice paddies.

The appearance is very much similar to a lih, pond completely covered with large gray lih leaves with slightly raised white fringes around their periphery. These disks of ica are known as pancake ice. If the temperature remains below freezing, the pancake ice coalesces as more ice forms, and within a few days the ice cover can be about 8 to 10 centimetres thick with a slightly corrugated surface, unless anow prevails, in which case the entire sea area appears as a smooth white plain. As seawater continues to freeze at the bottom edge and sides of ice floes and fields, snow cover increases and the pressures associated with the stresses and strains caused by water and wind movement result in a hummocking and ridge development in some

places and open water in other places. Growth of the ice sheet. The rate at which the ice forms and thickens depends on the air temperature, ocean turbulent heat flux (mixing conditions), and amount of snow acting as a heat or cold insulator. An empirical formula has been developed and used extensively by Russia and the United States to predict ice appearance and growth rate. The equations are based on the simple concept that ice growth is directly related to the length of time during which the air temperature is below the freezing point for seawater. By adding the number of degrees below the freezing point for each day, a measure of the severity of cold and time of exposure is obtained. This measure is known as the freezing degree days. In north polar regions there are about 8,000 freezing degree days, which is equivalent to four months of -18° C (0° F) air temperature or a mean annual Arctic air temperature of -12° C (10° F;

22° F below freezing).

During ice growth there is surface evaporation and sublimation and bottom ablation when upward heat conduction in the ice is less than ocean upward heat conduction.

The balance between ablation and freezing or accumulation results in an equilibrium thickness of about 3.5 metres (11.6 feet) of ice in the Arctic and probably about the
same in the Antarctic. The lifetime of this North Polar sea
ice is five to eight years, and the lifetime of Antarctic polar
class ice found only in the Bellingshausen and Weddell
seas is about three years. These lifetime values are related
to the rate with which the whole Arctic or Antarctic pack
in certain areas moves toward the Equator.

Sometimes early in the season there is sufficient warming and wind-induced surface motion to completely disintegrate the ice field. Oftentimes after about 10 to 13 centimetres of ice and snow have been formed in a more-or-less uniform manner, a large crack develops, which, through wind and stress, opens into a wide canal commonly known as a lead. This phenomenon is seen frequently in older ice and during the spring breakup. Leads are frequently followed by ships navigating in ice fields, but unfortunately the leads sometimes have a dead end with a very large iceberg blocking the way. With alternating freezing, partial melting, snow, and wind and swell, the ice field develops over a matter of a few weeks to a month into a 15- to 61centimetre-deep ocean cover. At this point the ice field is still navigable by most large vessels; however, if a vessel finds itself in the far north two weeks after the commencement of active surface freezing (e.g., in late October), it is in peril of being locked in for the remainder of the winter.

Salt content. The salt content of seawater as it freezes is always less than that of normal seawater. The amount of salt in the seawater during its first moment in the solid state is dependent upon the rapidity with which the seawater freezes, but in general the salt content is about one-tenth that of seawater. The slower the freezing process, the less the salt content. The most rapid freezing is that which occurs during the first day, and this ice is saltier than underlying ice which forms at the ice-water interface. The salt that remains in the ice is located in tiny pockets of fluid surrounded by normal crystals. These pockets of fluid surrounded by normal crystals. These pockets of

Saltiness of

The freezing process

fluid migrate, mainly by gravity, through the matrix of ice crystals with the result that, after a few weeks to a few months, the surface of the ice becomes lower in salt content than the deeper layers. It had once been thought that the difference in temperature, or thermal gradient, was the principal driving force for brine pocket migration; careful experiments indicate, however, that although the thermal gradients are a factor, it is principally gravity that accounts for the movement of these brine pockets. This migration continues throughout the winter.

In the summer, when the ice temperature rises, there is a rapid increase in the migration of salt out of the ice. The sea ice at the surface loses so much salt that it becomes potable and, in fact, is used by Eskimos as a source of fresh water. Salinity reaches a value of less than 0.01 percent. In summary, when first formed, the surface layer may have a salinity of 2 to 4 percent, but by April the salinity has dropped to between 0.4 and 0.7 percent, while sea ice that has been through at least one melt season has

Arctic pack ice. North Atlantic. The pack ice of the

a salt content below 0.1 percent.

Northern Hemisphere covers an average area of 10,620,-000 square kilometres (see Figure 13), filling the Arctic Ocean basin and adjacent North Atlantic Ocean. The polar ice field consists of 4,700,000 square kilometres of three- to six-metre-thick polar ice that never melts. Infrared imagery from aircraft, however, shows that 10 percent of the polar pack is open water even during winter. Along with Arctic Basin seasonal sea ice, this Arctic pack exudes into the northern Atlantic through two ice streams. The major exit of drifting pack ice from the Arctic Basin is along the eastern side of Greenland, mostly west of Spitsbergen. This ice tongue stretches 2,400 kilometres out of the Arctic Ocean and empties a stream of sea ice at a drift rate of almost 13 kilometres per day. The second icy arm of the north consists of a discharge through the Arctic-Canadian Archipelago and along the eastern American shore. This outpouring of ice is the principal deterrent to easy Northwest Passage ship transit and northern American migration and exploration. During winter, fast ice and local sea ice form along the Siberian coast, Barents and Kara seas, East Greenland, and Labrador coasts down to Newfoundland. The maximum extent of drifting sea ice is approximately latitude 42° N (about the same latitude as that of Boston); however, this represents the limit of floating ice pieces and not the hazardous ice-pack edge, which seldom reaches south of Newfoundland. During the summer the 240-kilometre belt of ice lying along the Labrador coast from Newfoundland northward melts to leave the approaches into Hudson Bay and the Canadian Northwest Territories clear. The motion of the polar ice follows an enormous clockwise eddy with a centre 85° N 170° W.

North Pacific. In the North Pacific Ocean comparatively little pack ice and icebergs are encountered. The Bering Sea is clear of pack ice during the northern summer, but commencing in September pack ice forms in bays and is carried through the Bering Strait. In winter and spring pack ice is found as far south as 40° N. This is drifting ice from northern latitudes and the Sea of Okhotsk. During winter, pack ice forms in the northern

part of the Sea of Japan.

Antarctic pack ice. Approximately twice as much pack ice forms in the oceans surrounding Antarctica as is found in the Arctic. There are, however, only limited regions in the Bellingshausen and Weddell seas where true polar perennial ice similar to the polar ice cap of the Arctic occurs. The maximum area of Antarctic pack ice is 20 million square kilometres, or about 8 percent of the Southern Hemisphere.

Figure 14 indicates the extent of Antarctic pack ice. It forms a fairly constant band of drifting sea ice around the continent, with the farthest northern extent occurring at the end of the austral (southern) winter in October. The greatest extension of pack ice in the South Pacific sector is found in about latitude 62° S, and in the South Atlantic pack ice extends to roughly 52° S. The average northern boundary for icebergs is 56° S in the Pacific sector and 42° S in the South Atlantic. The minimum ice coverage occurs in March, when most of the Antarctic

coast is free of ice, with the exception of the Weddell and Bellingshausen seas. The eastern and western coasts of the Weddell Sea are ice-free, but the Weddell itself is covered by a slowly (clockwise) revolving ice pack that seems to have a two-year cycle. The west coast of the Ross Sea is the most predictably open area during the Antarctic summer, and it is here at the approaches to McMurdo Station that most of the Antarctic expeditions have worked their way to the continent

A substantial portion of the sea ice encountered in November and December on approaching the continent hundreds of kilometres from landfall represents ice that formed near the coast from the previous austral winter. In January and February there usually is clear water adjacent to the coast in all sectors around the continent but this navigable water might be blocked by hundreds of kilometres of pack ice barrier farther out to sea. The Antarctic freeze-up commences with pack ice formation in the southerly parts of the Weddell Sea followed by pack ice appearance in the Bellingshausen and Ross seas. Beginning in March, ice is formed in sheltered bays, and it extends northward as the sea surface temperature drops. From late February to August, snowfall adds more to the ice thickness than is the case in the Arctic. This gives rise to an important difference between Arctic and Antarctic navigation, in that the presence of snow has a cushioning effect and ice breaking is more difficult. By the October maximum, the action of wind, sea, and some melting results in extremely active ice movement. It was in October that Sir Ernest Shackleton's ship Endurance was crushed and sank in the Weddell Sea in 1915.

The movement of the ice sheet around the Antarctic continent is from east to west except in the most northern part of the Weddell Sea, where there is a west to east movement making up the northern arm of the Weddell Sea Gyral. This clockwise Weddell eddy has been well documented by the drifts of entrapped ships. The ice drift in the Bellingshausen Sea is less definite. The ship Antarctic followed a meandering, aimless course when locked in the ice throughout the 1898-99 winter. From the Ross Sea, ice definitely drifts toward the Weddell Sea under the influence of the prevailing easterly winds near the Antarctic coast.

Sea ice forecasting and reconnaissance. Sea ice reconnaissance and forecasts in the Arctic and Antarctic are conducted by a number of nations, but the principal work is done by the U.S. Navy, either through the Fleet Weather Office or the Ice Forecasting Central of the U.S. Naval Oceanographic Office. The Ice Forecasting Central has for many years supported Arctic and Antarctic research and supply missions through ice reconnaissance and careful short- and long-range forecasting. Additional supportive reconnaissance and regional forecasts are provided by the Canadian government and U.S. Coast Guard ships. Support is even received from commercial airplanes, which frequently spot lonely icebergs far from the area of usual

Satellite photographs lack the resolution for day-to-day iceberg reconnaissance; these photographs do show the edge of the sea ice in both polar regions, however. Ice navigation in the Antarctic is similar to navigation for logistic support of military and scientific expeditions in the Arctic. The emphasis is on pack ice distribution and concentration rather than icebergs, which offer little problem to ships once in the ice pack. (T.F.B./Ed.)

Permafrost

Permafrost, or perennially frozen ground, is naturally occurring material that has a temperature colder than 0° C (32° F) continuously for two or more years. This layer of frozen ground is designated exclusively on the basis of temperature. Part or all of its moisture may be unfrozen, depending on the chemical composition of the water or depression of the freezing point by capillary forces. Permafrost with saline soil moisture, for example, may be colder than 0° C for several years but would contain no ice and would not be firmly cemented. Most permafrost, however, is consolidated by ice; permafrost with no water, and

Ice streams into the North Atlantic

Figure 14: Limits of sea ice and icebergs in the Southern Hemisphere.

thus no ice, is termed dry permafrost. The upper surface of permafrost is called the permafrost table. In permafrost areas the surface layer of ground that freezes in the winter (seasonally frozen ground) and thaws in summer is called the active layer. The thickness of the active layer depends mainly on the moisture content, varying from less than a foot in thickness in wet, organic sediments to several feet in well-drained gravels.

The

active

layer

Permafrost forms and exists in a climate where the mean annual air temperature is 0° C (32° F) or colder. Such a climate is generally characterized by long, cold winters with little snow and short, relatively dry, cool summers. Permafrost, therefore, is widespread in the Arctic, sub-Arctic, and Antarctica. It is estimated to underlie 20 percent of the world's land surface.

DISTRIBUTION IN THE NORTHERN HEMISPHERE

Permafrost zones. Permafrost is widespread in the northern part of the Northern Hemisphere, where it occurs in 85 percent of Alaska, 55 percent of Russia and Canada, and probably all of Antarctica. Permafrost is more widespread and extends to greater depths in the north than in the south. It is 1,500 metres (5,000 feet) thick in northern Siberia, 740 metres thick in northern Alaska, and thins progressively toward the south.

Most permafrost can be differentiated into two broad zones; the continuous and the discontinuous, referring to the lateral continuity of permafrost (see Figure 15). In the continuous zone of the far north, permafrost is nearly everywhere present except under the lakes and rivers that do not freeze to the bottom. The discontinuous zone includes numerous permafrost-free areas that increase progressively in size and number from north to south. Near the southern boundary, only rare patches of permafrost have been found to exist.

In addition to its widespread occurrence in the Arctic Alpine and subarctic areas of the Earth, permafrost also exists at lower latitudes in areas of high elevation. This type of perennially frozen ground is called Alpine permafrost. Although data from high plateaus and mountains are scarce, measurements taken below the active surface layer indicate zones where temperatures of 0° C or colder persist for two or more years. The largest area of Alpine permafrost is in western China, where 1,500,000 square kilometres (580,000 square miles) of permafrost are known to exist. In the contiguous United States, Alpine permafrost is limited to about 100,000 square kilometres in the high mountains of the west. Permafrost occurs at elevations as low as 2,500 metres in the northern states and at about 3,500 metres in Arizona.

A unique occurrence of permafrost-one that has no analogue on land-lies under the Arctic Ocean, on the northern continental shelves of North America and Eurasia. This is known as subsea or offshore permafrost.

Study of permafrost. Although the existence of permafrost had been known to the inhabitants of Siberia for centuries, scientists of the Western world did not take seriously the isolated reports of a great thickness of frozen ground existing under northern forest and grasslands until 1836. Then, Alexander Theodor von Middendorff meapermafrost

Figure 15: Distribution of permafrost in the Northern Hemisphere.

idapted from T.L. Pewe, Arctic and Alpine Research, vol. 15 (1963), no. 2, p. 146

sured temperatures to depths of approximately 100 metres of permafrost in the Shargin shaft, an unsuccessful well dug for the governor of the Russian-Alaskan Trading Company, at Yakutsk, and estimated that the permafrost was 215 metres thick. Since the late 19th century, Russian scientists and engineers have actively studied permafrost and applied the results of their learning to the development of Russia's north.

In a similar way, prospectors and explorers were aware of permafrost in the northern regions of North America for many years, but it was not until after World War II that systematic studies of perennially frozen ground were undertaken by scientists and engineers in the United States and Canada. Since exploitation of the great petroleum resources on the northern continental shelves began in earnest in the 1970s, investigations into subsea permafrost have progressed even more rapidly than have studies of permafrost on land.

Alpine permafrost studies had their beginning in the study of rock glaciers in the Alps of Switzerland. Although ice was known to exist in rock glaciers, it was not until after World War II that investigation by geophysical methods clearly demonstrated slow movement of perennial ice—i.e., permafrost. In the 1970s and '80s, detailed geophysical work and temperature and borehole examination of mountain permafrost began in Russia, China, and Scandinavia, especially with regard to construction in high mountain and plateau areas.

ORIGIN AND STABILITY OF PERMAFROST

Air temperature and ground temperature. In areas where the mean annual air temperature becomes colder than 0° C, some of the ground frozen in the winter will not be completely thawed in the summer; therefore, a layer of permafrost will form and continue to grow downward gradually each year from the seasonally frozen ground. The permafrost layer will become thicker each winter, its thickness controlled by the thermal balance between the heat flow from the Earth's interior and that flowing outward into the atmosphere. This balance depends on the mean annual air temperature and the geothermal gradient. The average geothermal gradient is an increase of 1° C (1.8° F) for every 30 to 60 metres of depth. Eventually the thickening permafrost layer reaches an equilibrium depth at which the amount of geothermal heat reaching the permafrost is on the average equal to that lost to the atmosphere. Thousands of years are required to attain a state of equilibrium where permafrost is hundreds of feet thick.

An example of the change of temperature of frozen ground with depth and the upper and lower limit of permafrost is illustrated in Figure 16. The annual fluctuation of air temperature from winter to summer is reflected in a subdued manner in the upper few metres of the ground. This fluctuation diminishes rapidly with depth, being only a few degrees at 7.5 metres, and is barely detectable at 15 metres. The level of zero amplitude, at which fluctuations are hardly detectable, is 9 to 15 metres. If the permafrost is in thermal equilibrium, the temperature at the level of zero amplitude is generally regarded as the minimum temperature of the permafrost. Below this depth the temperature increases steadily under the influence of heat from the Earth's interior. The temperature of permafrost at the depth of minimum annual seasonal change varies from near 0° C at the southern limit of permafrost to -10° C (14° F) in northern Alaska and -13° C (9° F) in northeastern Siberia.

As the climate becomes colder or warmer, but maintaining a mean annual temperature colder than 0° C, the temperature of the permafrost correspondingly rises or declines, resulting in changes in the position of the base of permafrost. The position of the top of permafrost will be lowered by thawing when the climate warms to a mean annual air temperature warmer than 0° C. The rate at which the base or top of permafrost is changed depends not only on the amount of climatic fluctuation but also on the amount of ice in the ground and the composition of the ground, conditions that in part control the geothermal gradient. If the geothermal gradient is known and if the surface temperature remains stable for a long period of time, it is, therefore, possible to predict from a knowledge of the mean annual air temperature the thickness of permafrost in a particular area that is remote from bodies of water.

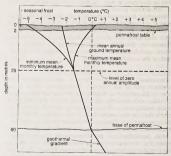

Figure 16: Hypothetical example of a temperature profile and thickness of permafrost in central Alaska.

Geothermal gradient Origin of subsea permafrost

Soil under deep lakes Climatic change. Permafrost is the result of present climate. Many temperature profiles show, however, that permafrost is not in equilibrium with present climate at the sites of measurement. Some areas show, for example, that climatic warming since the last third of the 19th century has caused a warming of the permafrost to a depth of most chan 100 metres (see Figure 17). In such areas much of the permafrost is a product of a colder, former climate.

The distribution and characteristics of subsea permafrost point to a similar origin. At the height of the glacial epoch. especially about 20,000 years ago, most of the continental shelf in the Arctic Ocean was exposed to polar climates for thousands of years. These climates caused cold permafrost to form to depths of more than 700 metres. Subsequently, within the past 10,000 years, the Arctic Ocean rose and advanced over a frozen landscape to produce a degrading relict subsea permafrost. The perennially frozen ground is no longer exposed to a cold atmosphere, and the salt water has caused a reduction in strength and consequent melting of the ice-rich permafrost (which is bonded by freshwater ice). The temperature of subsea permafrost, near -1° C (30° F), is no longer as low as it was in glacial times and is therefore sensitive to warming from geothermal heat and to the encroaching activities of humans.

It is thought that permafrost first occurred in conjunction with the onset of glacial conditions about three million years ago, during the late Pliocene Epoch. In the subarctic at least, most permafrost probably disappeared during interglacial times and reappeared in glacial times. Most existing permafrost in the subarctic probably formed in the cold (glacial) period of the past 100,000 years.

LOCAL THICKNESS

The thickness and areal distribution of permafrost are directly affected by snow and vegetation cover, topography, bodies of water, the interior heat of the Earth, and the temperature of the atmosphere, as mentioned earlier.

Effects of climate. The most conspicuous change in thickness of permafrost is related to climate. At Barrow, Alaska, U.S., the mean annual air temperature is -12° C (10° F), and the thickness is 400 metres. At Fairbanks, Alaska, in the discontinuous zone of permafrost in central Alaska, the mean annual air temperature is -3° C (27° F), and the thickness is about 90 metres. Near the southern border of permafrost, the mean annual air temperature is about 0° or -1° C, and the perennially frozen ground is only a few feet thick.

If the mean annual air temperature is the same in two areas, the permafrost will be thicker where the conductivity of the ground is higher and the geothermal gradient is less. A.H. Lachenbruch of the U.S. Geological Survey reports an interesting example from northern Alaska (see Figure 17). The mean annual air temperatures at Cape Simpson and Prudhoe Bay are similar, but permafrost thickness is 275 metres at Cape Simpson and about 650 metres at Prudhoe Bay because rocks at Prudhoe Bay are more stiliceous and have a higher conductivity and a lower geothermal gradient than rocks at Cape Simpson.

Effects of water bodies. Bodies of water, lakes, rivers, and the sea have a profound effect on the distribution of permafrost. A deep lake that does not freeze to the bottom during the winter will be underlain by a zone of thawed material. If the minimum horizontal dimension of the deep lake is about twice as much as the thickness of permafrost nearby, there probably exists an unfrozen vertical zone extending all the way to the bottom of permafrost. Such thawed areas extending all the way through permafrost are widespread under rivers and sites of recent rivers in the discontinuous zone of permafrost and under major, deep rivers in the far north. Under the wide floodplains of rivers in the subarctic, the permafrost is sporadically distributed both laterally and vertically. Small, shallow lakes that freeze to the bottom each winter are underlain by a zone of thawed material, but the thawed zone does not completely penetrate permafrost except near the southern border of permafrost.

Effects of solar radiation, vegetation, and snow cover. Inasmuch as south-facing hillslopes receive more incoming solar energy per unit area than other slopes, they are

warmer; permafrost is generally absent on these in the discontinuous zone (Figure 18) and is thinner in the continuous zone. The main role of vegetation in permafrost areas is to shield perennially frozen ground from solar energy. Vegetation is an excellent insulating medium and removal or disturbance of it, either by natural processes or by humans, causes thawing of the underlying permafrost. In the continuous zone the permafrost table may merely be lowered by the disturbance of vegetation, but in a discontinuous zone permafrost may be completely destroyed in certain area.

Snow cover also influences heat flow between the ground and the atmosphere and therefore affects the distribution of permafrost. If the net effect of timely snowfalls is to prevent heat from leaving the ground in the cold winter, permafrost becomes warmer. Actually, local differences in vegetation and snowfall in areas of thin and warm permafrost are critical for the formation and existence of the permafrost are critical for the formation and existence of the permafiled frozen ground. Permafrost is not present in areas of the world where great snow thicknesses persist throughout most of the winter.

ICE CONTENT

Types of ground ice. The ice content of permafrost is probably the most important feature of permafrost affecting human life in the north. Ice in the perennially frozen ground exists in various sizes and shapes and has definite distribution characteristics. The forms of ground ice can

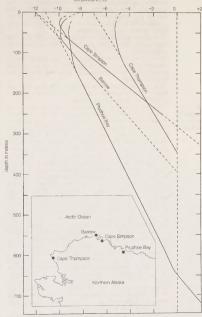

Figure 17: Generalized temperature profiles through permafrost at four sites on the Alaskan Arctic coast. Solid lines represent measured temperatures; dashed lines represent extrapolations.

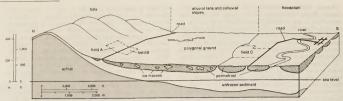

Figure 18: Character and distribution of permafrost in the Fairbanks, Alaska, area

be grouped into five main types: (1) pore ice, (2) segregated, or Taber, ice, (3) foliated, or wedge, ice, (4) pingo ice, and (5) buried ice.

 Pore ice, which fills or partially fills pore spaces in the ground, is formed by pore water freezing in situ with no addition of water. The ground contains no more water in the solid state than it could hold in the liquid state.

2. Segregated, or Taber, ice includes ice films, seams, lenses, pods, or layers generally 0.15 to 13 centimertes (0.06 to 5 inches) thick that grow in the ground by drawing in water as the ground freezes. Small ice segregations are the least spectualize but one of the most extensive types of ground ice, and engineers and geologists interested in ice growth and its effect on engineering structures have studied them considerably. Such observers generally accept the principle of bringing water to a growing ice crystal, but they do not completely agree as to the mechanics of the processes. Pore ice and Taber ice occur both in seasonally frozen ground and in permafrost.

 Foliated ground ice, or wedge ice, is the term for large masses of ice growing in thermal contraction cracks in permafrost.

4. Pingo ice is clear, or relatively clear, and occurs in permafrost more or less horizontally or in lens-shaped masses. Such ice originates from groundwater under hydrostatic pressure.

5. Buried ice in permafrost includes buried sea, lake, and river ice and recrystallized snow, as well as buried blocks

of glacier ice in permafrost climate. World estimates of the amount of ice in permafrost vary from 200,000 to 500,000 cubic kilometres (49,000 to 122,000 cubic miles), or less than 1 percent of the total volume of the Earth. It has been estimated that 10 percent by volume of the upper 3 metres of permafrost on the northern Coastal Plain of Alaska is composed of foliated ground ice (ice wedges). Taber ice is the most extensive type of ground ice, and in places it represents 75 percent of the ground by volume. It is calculated that the pore and Taber ice content in the depth between 0.5 and 3 metres (surface to 0.5 metre is seasonally thawed) is 61 percent by volume, and between 3 and 9 metres it is 41 percent. The total amount of pingo ice is less than 0.1 percent of the permafrost. The total ice content in the permafrost of the Arctic Coastal Plain of Alaska is estimated to be 1,500 cubic kilometres, and below 9 metres most of that is present as pore ice.

Ice wedges. The most conspicuous and controversial type of ground ice in permafors is that formed in large ice wedges or masses with parallel or subparallel foliation structures. Most foliated ice masses occur as wedgeshaped, vertical, or inclined sheets or dikes 2.5 centimetres to 3 metres wide and 0.3 to 9 metres high when viewed in transverse cross section (Figure 19). Some masses seen on the face of frozen cliffs may appear as horizontal bodies a few centimetres to 3 metres in thickness and 0.3 to 14 metres long, but the true shape of these ice wedges can be seen only in three dimensions. Ice wedges are parts of polygonal networks of ice enclosing cells of frozen ground 3 to 30 metres or more in diameter.

Origins. The origin of ground ice was first studied in Siberia, and discussions in print of the origin of large ground-ice masses in perennially frozen ground of North America have gone on since Otto von Kotzebue recorded

ground ice in 1816 at a spot now called Elephant's Point in Eschscholtz Bay of Seward Peninsula. The theory for the origin of ice wedges now generally accepted is the thermal contraction theory that, during the cold winter, polygonal thermal contraction cracks, a centimetre or two wide and a few metres deep, form in the frozen ground: then when, in early spring, water from the melting snow runs down these tension cracks and freezes, a vertical vein of ice is produced that penetrates into permafrost; when the permafrost warms and re-expands during the following summer, horizontal compression produces upturning of the frozen sediment by plastic deformation; then during the next winter, renewed thermal tension reopens the vertical ice-cemented crack, which may be a zone of weakness; another increment of ice is added in the spring when meltwater again enters and freezes. Over the years the vertical wedge-shaped mass of ice is produced (Figure 19).

Active wedges, inactive wedges, and ice-wedge casts. Ice wedges may be classified as active, inactive, and ice-wedge casts. Active ice wedges are those that are actively growing. The wedge may not crack every year, but during many or most years cracking does occur, and an increment of ice is added. Ice wedges require a much more riegorous climate

sions and

to grow than does permafrost. The permafrost table must be chilled to -15° to -20° C (5° to -4° F) for contraction cracks to form. On the average, it is assumed that ice wedges generally grow in a climate where the mean annual air temperature is -6° or -8° C (21° or 18° F) or colder. In regions with a general mean annual temperature only slightly warmer than -6° C, ice wedges occasionally form in restricted cold microclimate areas or during cold periods of a few years' durations.

The area of active ice wedges appears to roughly coincide with the continuous permafrost zone. From north to south across the permafrost area in North America, a decreasing number of wedges crack frequently. The line dividing zones of active and inactive ice wedges is arbitrarily placed at the position where it is thought most wedges do not

frequently crack.

Inactive ice wedges are those that are no longer growing. The wedge does not crack in winter and, therefore, no new ice is added. A gradation between active ice wedges and inactive ice wedges occurs in those wedges that crack rarely. Inactive ice wedges have no ice seam or crack extending from the wedge upward to the surface in the spring. The wedge top may be flat (Figure 19), especially if thawing has lowered the upper surface of the wedge at some time in the past.

Ice wedges in the world are of several ages, but none appear older than the onset of the last major cold period, about 100,000 years ago. Wedges dated by radiocarbon analyses range from 3,000 to 32,000 years in age.

In many places in the now temperate latitudes of the world, in areas of past permaferost, ice wedges have melted, and resulting voids have been filled with sediments collapsing from above and the sides. These ice-wedge casts are important as paleoclimatic indicators and indicate a climate of the past with at least a mean annual air temperature of –6° or –8° C or colder.

SURFACE MANIFESTATIONS OF PERMAFROST

AND SEASONALLY FROZEN GROUND

Many distinctive surface manifestations of permafrost exist in the Arctic and subarctic, including such geomorphic features as polygonal ground, thermokarst phenomena, and pingos. In addition to the above, there are many features caused in large part by frost action that are common in but not restricted to permafrost areas, such as solifluction (soil flowage) and frost-sorted patterned ground.

Areas underlain by permafrost. Polygonal ground. One of the most widespread geomorphic features associated with permafrost is the microrelief pattern on the according to the property of the

The ice-wedge polygons may be low-centred or highcentred. Upturning of strata adjacent to the ice wedge may make a ridge of ground on the surface on each side of the wedge, thus enclosing the polygons. Such polygons are lower in the centre and are called low-centre polygons or raised-edge polygons and may contain a pond in the centre. Low-centre, or raised-edge, polygons indicate that ice wedges are actually growing and that the sediments are being actively upturned. If erosion, deposition, or thawing is more prevalent than the up-pushing of the sediments along the side of the wedge or if the material being pushed up cannot maintain itself in a low ridge, the low ridges will be absent, and there may be either no polygons at the surface or the polygons may be higher in the centre than the troughs over the ice wedges that enclose them. Both highcentre and low-centre tundra polygons are widespread in the polar areas and are good indicators of the presence of foliated ice masses; care must be taken, however, to demonstrate that the pattern is not a relic and an indication of ice-wedge casts.

In many parts of the temperate latitudes of Asia, Europe, and North America, incompletely developed or poorly developed polygonal ground occurs on the same scale as in the Arctic. These large-scale polygons in the nonpermafrost areas are excellent evidence of the former extent of permafrost and ice wedges in the past placial period.

In many areas of the continuous permafrost zone surface, drainage follows the troughs of the polygons (tops of the ice wedges); and at ice wedge junctions, or elsewhere, melting may occur to form small pools. The joining of these small pools by a stream causes the pools to resemble beads on a string, a type of stream form called beaded drainage. Such drainage indicates the presence of perennially frozen, fhor-grained sediments cut by ice wedges.

Thermokarst formations. The thawing of permafrost creates thermokarst topography, an uneven surface that contains mounds, sinkholes, tunnels, caverns, and steep-walled ravines caused by melting of ground ice. The hummocky ground surface resembles karst topography in limestone areas. Thawing may result from artificial or

natural removal of vegetation or from a warming climate. Thawed depressions filled with water (thaw lakes, thermokarst lakes, cave-in lakes) are widespread in permafrost areas, especially in those underlain with perennially frozen silt. They may occur on hillsides or even on hilltops and are good indicators of ice-rich permafrost. Locally, deep thermokarst pits 6 metres deep and 9 metres across may form as ground ice melts. These openings may exist as undetected caverns for many years before the roof collapses. Such collapses in agricultural or construction areas are real dangers. Thermokarst mounds are polygonal or circular hummocks 3 to 15 metres in diameter and 0.3 to 2.5 metres high that are formed as a polygonal network of ice melts and leaves the inner-ice areas as mounds.

Pingos. The most spectacular landforms associated with permafrost are pingos, small ice-cored circular or elliptical hills of frozen sediments or even bedrock, 3 to more than 60 metres high and 15 to 450 metres in diameter. Pingos are widespread in the continuous permafrost zone and are quite conspicuous because they rise above the tundra. They are much less conspicuous in the forested area of the discontinuous permafrost zone. They are generally cracked on top with summit craters formed by melting ice. There are two types of pingos, based on origin. The closed-system type forms in level areas when unfrozen groundwater in a thawed zone becomes confined on all sides by permafrost, freezes, and heaves the frozen overburden to form a mound. This type is larger and occurs mainly in tundra areas of continuous permafrost. The open-system type is generally smaller and forms on slopes when water beneath or within the permafrost penetrates

Figure 20: Raised-edge ice wedge polygons on the seacoast near Barrow, Alaska, in summer. The polygons are from 7 to 15 metres in diameter.

Indication of a cooler past

Ice-wedge polygons lobes

the permafrost under hydrostatic pressure. A hydrolaccolith (water mound) forms and freezes, heaving the overlying frozen and unfrozen ground to produce a mound.

Present pingos are apparently the result of postglacial climate and are less than 4,000-7,000 years old. Pingos were present in now temperate latitudes during the latest glacial epoch and are now represented by low circular ridges enclosing bogs or lowlands.

Near the southern border of permafrost occur palsas, low hills and knobs of perennially frozen peat about 1.5 to 6 metres high, evidently forming with accumulation of peat

and segregation of ice. Features related to seasonal frost. Many microgeomorphic features common to the periglacial environment may or may not be associated with permafrost.

Patterned ground. Intense seasonal frost action, repeated freezing and thawing throughout the year, produces smallscale patterned ground. Repetitive freezing and thawing tends to stir and sort granular sediments, thus forming circles, stone nets, and polygons a few centimetres to 6 metres in diameter. The coarse cobbles and boulders form the outside of the ring and the finer sediments occur in the centre. The features require a rigorous climate with some fine-grained sediments and soil moisture, but they do not necessarily need underlying permafrost. Permafrost, however, forms an impermeable substratum that keeps the soil moisture available for frost action. On gentle slopes the stone nets may be distorted into garlands by downslope movement or, if the slope is steep, into stone stripes about half a metre wide and 30 metres long.

Soil flow. In areas underlain by an impermeable layer (seasonally frozen ground or perennially frozen ground), the active layer is often saturated with moisture and is Solifluction quite mobile. The progressive downslope movement of saturated detrital material under the action of gravity and working in conjunction with frost action is called solifluction. This material moves in a semifluid condition and is manifested by lobelike and sheetlike flows of soil on slopes. The lobes are up to 30 metres wide and have a steep front 0.3 to 1.5 metres high. An outstanding feature of solifluction is the mass transport of material over lowangle slopes. Solifluction deposits are widespread in polar areas and consist of a blanket 0.3 to 1.8 metres thick of unstratified or poorly stratified, unsorted, heterogeneous, till-like detrital material of local origin. In many areas the terrain is characterized by relatively smooth, round hills and slopes with well-defined to poorly defined solifluction lobes or terraces. If the debris is blocky and angular and fine material is absent, the lobes are poorly developed or absent. Areas in which solifluction lobes are well formed

> In many areas the frost-rived debris contains few fine materials and little water and consists of angular fragments of well-jointed, resistant rock. Under such circumstances, solifluction lobes do not often occur, but instead striking sheets or streams of angular rubble form. These are called rock streams or rubble sheets.

PROBLEMS POSED BY PERMAFROST

Permafrost engineering. General issues. Development of the north demands an understanding of and the ability to cope with problems of the environment dictated by permafrost. Although the frozen ground hinders agricultural and mining activities, the most dramatic, widespread, and economically important examples of the influence of permafrost on life in the north involve construction and maintenance of roads, railroads, airfields, bridges, buildings, dams, sewers, and communication lines. Engineering problems are of four fundamental types; (1) those involving thawing of ice-rich permafrost and subsequent subsidence of the surface under unheated structures such as roads and airfields, (2) those involving subsidence under heated structures, (3) those resulting from frost action, generally intensified by poor drainage caused by permafrost, and (4) those involved only with the temperature of permafrost that causes buried sewer, water, and oil lines to freeze.

A thorough study of the frozen ground should be part of the planning of any engineering project in the north. It is generally best to attempt to disturb the permafrost as little as possible in order to maintain a stable foundation for engineering structures, unless the permafrost is thin; then, it may be possible to destroy the permafrost. The method of construction preserving the permafrost has been called the passive method; alternately, the destroying of permafrost is the active method.

Permafrost thawing and frost heaving. Because thawing of permafrost and frost action are involved in almost all engineering problems in polar areas, it is advisable to consider these phenomena generally. The delicate thermal equilibrium of permafrost is disrupted when the vegetation, snow cover, or active layer is compacted. The permafrost table is lowered, the active layer is thickened, and considerable ice is melted. This process lowers the surface and provides (in summer) a wetter active layer with less bearing strength. Such disturbance permits a greater penetration of summer warming. It is common procedure to place a fill, or pad, of gravel under engineering works, Such a fill generally is a good conductor of heat and, if thin, may cause additional thawing of permafrost. The fill must be made thick enough to contain the entire amplitude of seasonal temperature variation-in other words, thick enough to restrict the annual seasonal freezing and thawing to the fill and the compacted active layer. Under these conditions no permafrost will thaw. Such a procedure is quite feasible in the Arctic, but in the warmer subarctic it is impractical because of the enormous amounts of fill needed. Under a heated building, profound thawing may occur more rapidly than under roads and airfields.

Frost action, the freezing and thawing of moisture in the ground, has long been known to seriously disrupt and destroy structures in both polar and temperate latitudes. In the winter the freezing of ground moisture produces upward displacement of the ground (frost heaving), and in the summer excessive moisture in the ground brought in during the freezing operation causes loss of bearing strength. Frost action is best developed in silt-sized and silty clay-sized sediments in areas of rigorous climate and poor drainage. Polar latitudes are ideal for maximum frost action because most lowland areas are covered by finegrained sediments, and the underlying permafrost causes poor drainage.

Development in permafrost areas. Structures on piles. Piles are used to support many, if not most, structures built on ice-rich permafrost. In regions of cold winters. many pile foundations are in ground subject to seasonal freezing and, therefore, possibly subject to the damaging effect of frost heaving, which tends to displace the pile upward and thus to disturb the foundation of the structure. The displacement of piling is not limited to the far north, ings, military installations, pipelines, and other structures have resulted from failure to understand the principles of frost heaving of piling.

A remarkable construction achievement in a permafrost environment is the Trans-Alaska Pipeline System. Completed in 1977, this 1,285-kilometre-long, 122-centimetrediameter pipeline transports crude oil from Prudhoe Bay to an ice-free port at Valdez. The pipeline was originally designed for burial along most of the route. However, because the oil is transported at 70° to 80° C (158° to 176° F), such an installation would have thawed the adjacent permafrost, causing liquefaction, loss of bearing strength, and soil flow. To prevent destruction of the pipeline, about half of the line (615 kilometres) is elevated onto beams held up by vertical support members. The pipeline safely discharges its heat into the air, while frost heaving of the 120,000 vertical support members is prevented by freezing them firmly into the permafrost through the use of special heat-radiating thermal devices

Highways and railroads. Highways in polar areas are relatively few and mainly unpaved. They are subject to subsidence by thawing of permafrost in summer, frost heaving in winter, and loss of bearing strength on finegrained sediments in summer. Constant grading of gravel roads permits maintenance of a relatively smooth highway. Where the road is paved over ice-rich permafrost, Insulation with gravel

pads

lie almost entirely above or beyond the forest limit. though maximum disturbance probably is encountered most widely in the subarctic. Expensive maintenance and sometimes complete destruction of bridges, school build-

> The Trans-Alaska Pipeline System

the roadway becomes rough and is much more costly to maintain than are unpaved roads. Many of the paved roads in polar areas have required resurfacing two or three times in a 10-year period.

Railroads particularly have serious construction problems and require costly upkeep in permafrost areas because of the necessity of maintaining a relatively low gradient and the subsequent location of the roadbed in ice-rich low-lands that are underlain with perennally frozen ground. The Trans-Siberian Railroad, the Alaska Railroad, and some Canadian railroads in the north are locally underlain by permafrost with considerable ground ice. As the large masses of ice melt each summer, constant maintenance is required to level these tracks. In winter, extensive maintenance is also required to combat frost heaving when local displacements of 2,5 to 35 centimetres occur in roadbeds and bridges.

Agriculture. Permafrost affects agricultural developments in many parts of the discontinuous permafrost zone. Its destructive effect on cultivated fields in both Russia and North America results from the thawing of large masses of ice in the permafrost. If care is not exercised in selecting areas to be cleared for cultivation, thawing of the permafrost may necessitate abandonment of fields or their reduction to pasturage. As illustrated in Figure 18, field A, on the southward-facing hillside, is not affected by permafrost; field B, on the alluvial fan, however, is underlain with permafrost containing large masses of ground ice. When field B is cleared, thermokarst topography will form. Field C, on the floodplain, is underlain with permafrost without large ice masses, and so no thermokarst pits and mounds will form when this ground is cleared.

Offshore structures. One of the most active and exciting areas of permafrost engineering is in subsea permafrost. Knowledge of the distribution, type, and water or ice content of subsea permafrost is critical for planning petroleum exploration, locating production structures, burying pipelines, and driving tunnels beneath the seabed. Furthermore, the temperature of the seabed must be known in order to predict potential sites of accumulation of gas hydrates or areas in which groundwater or artesian pressures are likely. In addition, knowledge of the distribution of subsea permafrost permits a thorough interpretation of regional geologic history. (T.L.Pe.)

BIBLIOGRAPHY

General works. SAMUEL C. COLBECK (Ed.), Dynamics of Snow and Ice Masses (1980), includes chapters on valley glaciers; ces sheets, snow packs, icebergs, sea ice, and avalanches, emphasizing the basic physics. P.V. Hosos, Ice Physics (1974), treat all aspects of the physics and chemistry of ice. W. RICHARD PRITIER (ed.), Ice in the Climate System (1993), is a modern review of the past, present, and future interactions between ice and climate.

Ice in lakes and rivers. E.R. POUNDER, The Physics of Ice (1965), teats concisely the structure and physical properties of ice. GEORGE D. ASHTON (ed.), River and Lake Ice Engineering (1986), provides a comprehensive treatment of the general principles for engineering applied to river and lake ice problems. BENARO MICHEL. Winter Regime of Rivers and Lakes (1971), treats freshwater ice. The essay by GEORGE D. ASHTON, "Freshwater Ice Growth and Decay," in the work by Colbeck (cited above), summarizes the general principles of river ice behaviour, including ice accumulation processes and thermal effects. For information regarding the geographic distribution of lake and river ice, the following works are usefult. v.T.R. ALLEN, Freezewy, Break-up, and Ice Thickness in Canada (1977); and, for the former Soviet Union, Iz. GERASIMOV et al. (eds.), ΦIRINIO-GEORPHIC WINTER AND AND ASTENDANCE (1984). (G.D.A.), MISHATSEVA, APMARC CCC (CT (1984).

Glaciers and ice sheets. W.S.B. PATERSON. The Physics of Glaciers, 2nd ed. (1981), is the standard text on glaciers and ice sheets, emphasizing process rather than description. 1r. ANDREWS, Glacial Systems (1975), is a compact, clear introduction to glaciers and their environment. MICHAEL HAMBREY and TORGO ALEAN, Glaciers (1992); and ROBERT P. SHARP, Living Ice (1988), are well-illustrated introductions to glaciers and how

they affect the landscape. NATIONAL RESEARCH COUNCIL (U.S.), AS 10C COMMITTEE ON THE FILELATIONSHIP BETWEEN LAND ICE AND ICE AND SEA LEVEL, Glacier, Le. Shent, State Color, Induced Climatic Change (1983), and created life of department of the Color of

Icebergs and pack ice. The published literature on icebergs is found mainly in U.S. journals and in atlases prepared by the U.S. Coast Guard and U.S. Navy for Arctic and Antarctic military and scientific maritime resupply expeditions. A classic discussion of icebergs and sea ice in the Arctic Ocean is The "Marion" Expedition to Davis Strait and Baffin Bay, vol. 3 by E.H. SMITH, Arctic Ice (1931). Also of interest is the treatment of the oceanography of the north polar basin by FRIDTJOF NANSEN, The Norwegian North Polar Expedition, 1893-1896: Scientific Results, vol. 3 (1902, reprinted 1969), and Farthest North, 2 vol. (1897, reissued 1967). The importance of ice in the water budget of the planet may be studied by consulting JAMES L. DYSON, The World of Ice (1962, reissued 1972), ROBERT C. PRITCHARD (ed.), Sea Ice Processes and Models (1980), a collection of proceedings papers, reports field observations and the development of models in an effort to establish usable flow laws for sea ice. Two reference works are UNITED STATES HY-DROGRAPHIC OFFICE, A Functional Glossary of Ice Terminology (1952); and world meteorological organization, Sea-Ice Nomenclature (1970).

The age of icebergs can be understood by consulting w. DANSOAABD et al., "One Thousand Centures of Climatic Record from Camp Century on Greenland Ice Sheet," Science, 166(3903):377–381 (1969); and F. R. SCHOLANDER et al., "Composition of Gas Bubbles in Greenland Icebergs," The Journal of Glaciology, 3:813–822 (1961). A major reference work on the proposed use of icebergs as a freshwater source is the collected conference papers in A.A. HUSSENY (ed.), Iceberg Utilitation (1978).

Permafrost. A.L. WASHIUEN, Geocryology (1979), is the most thorough book in English on permafrost and periglacial processes. H.M. FRENCH, The Periglacial Environment (1976), clearly summarizes permafrost and periglacial processes, with emphasis on examples from Canada. The greatest source of permafrost information is the proceedings of the vanous international Conference on Permafrost meetings, each volume contains numerous up-to-date papers in English from many difficult of the Conference on Permafrost meetings, each volume contains numerous up-to-date papers in English from many difficult of the Conference of Permafrost,
ARTHUR H. LACHENBRUCH. Mechanics of Thermal Contraction Cracks and Ice-Wedge Polygons in Permafrost (1962), is a classic paper on the quantitative interpretation of the formation of ice-wedge polygons in permafrost. TROY L. PÉWÉ, RICHARD E. CHURCH, and MARVIN J. ANDRESEN, Origin and Paleoclimatic Significance of Large-Scale Patterned Ground in the Donnelly Dome Area, Alaska (1969), discusses the origin of ice-wedge casts and relict permafrost in central Alaska and offers paleoclimatic interpretations. R. DALE GUTHRIE, Frozen Fauna of the Mammoth Steppe (1990), discusses fossil carcasses of Ice Age mammals preserved in permafrost. TROY L. PÉWÉ, Geologic Hazards of the Fairbanks Area, Alaska (1982), a highly illustrated work, contains an up-to-date presentation of the greatest geologic hazard to life in polar areas: problems posed by seasonally and perennially frozen ground. G.H. JOHNSTON (ed.), Permafrost: Engineering Design and Construction (1981), is a comprehensive book on construction problems in permafrost areas, with examples mainly from northern Canada. TROY L. PÉWÉ, "Permafrost," in GEORGE A. KIERSCH et al. (eds.), The Heritage of Engineering Geology: The First Hundred Years (1991), pp. 277–298, provides an up-to-date, well-illustrated treatment of the origin, distribution, and ice content of permafrost and of engineering problems in permafrost regions. (T.L.Pe.)

Iceland

Tecland (Icelandic: Ísland), an island country located in the North Atlantic Ocean, is a land of vivid contrasts. Sparkling glaciers lie across its ruggedly beautiful mountain ranges, while a vast quantity of subterrancan thermal activity makes Iceland one of the most active volcanic regions in the world. Glaciers and cooled lava beds each cover approximately one-tenth of the 39,768 square milles (103,000 square kilometres) of the country. The glaciers are a reminder of Iceland's close proximity to the Arctic Circle, while the volcanoes, reaching deep into the unstable interior of the Earth, are explained by the fact that Iceland is located on the top of the Mid-Atlantic Ridge. It is estimated that since the year 1500 about one-third of the Earth's

total lava flow has poured out of the volcanoes of Iceland. Iceland was founded more than 1,000 years ago during the Viking Age of exploration. The capital, Reykjavik ("Bay of Smokes"), is near the site of the island's first farmstead. The early settlement, made up primarily of Norwegian seafarers and adventurers, fostered further excursions to Greenland and the coasts of North America, or Vinland. In spite of its physical isolation some 500 miles (800 kilometres) from Scotland, its nearest European neighbour, Iceland has remained throughout its history very much a

part of European civilization. It is a Scandinavian country, modern in nearly every respect.

Physical and human geography

THE LANI

Volcanism

Geologically young, Iceland contains about 200 volcanoes of various types. A new volcano erupting on the bottom of the sea between November 1963 and June 1967 created the island of Surtsey, off the southwestern coast. The new island grew to nearly one square mile in area and rose more than 560 feet (170 metres) above sea level, a total of

950 feet from the ocean floor.

Yolcanic activity has been particularly frequent since the 1970s. A major eruption took place in 1973, when a volcano no Heima Island (Heimaey) spilled lava into the town of Vestmannaeyjar, an important fishing centre. Most of the 5,300 residents had to be evacuated, and—although the harbour remained intact—about one-third of the town was destroyed. Continuous eruptions took place in the Krafla area in the northeast in 1975–84. Iccland's best-known volcano, Hekla, erupted four times in the 20th century: in 1947, 1970. 1980, and 1991.

Relief. Iceland is largely a tableland broken up by structural faults. Its average elevation is 1,640 feet above sea level, but one-fourth of the country lies below 650 feet. The highest point is 6,952 feet (2,119 metres), at Hvannadals Peak, the top of Orzefajókull in Vatna Glacier. The glaciers range in size from small ones in mountain receses to enormous glacial caps topping extensive mountain ranges. Vatna Glacier covers an area of about 3,200 square miles (8,288 square kilometres) and is about 3,000 feet [914 metres) deep at its thickest point.

Much of Iceland is underlain by basalt, a dark rock of igneous origin. The oldest rocks were formed about 16 million years ago. The landscape in basaltic areas is one of plateau and fjord, characterized by successive layers of lava visible one above the other on the valley sides. The basalt sheets tend to tilt somewhat toward the centre of the

country. The U shape of the valleys is largely the result of glacial erosion. The depressed zones between the basalt areas have extensive plateaus above which rise single volcanoes, table mountains, or other mountain masses with steep sides.

Iceland has more hot springs and solfataras—volcanic vents that emit hot gases and vapours—than any other country. Alkaline hot springs are found in some 250 areas throughout the country. The largest, Delidartungulver, emits about 48 gallons (180 litres) of boiling water per second. The total power output of the Torfa Glacier area, the largest of the 19 high-temperature solfatara regions, is estimated to equal about 1,000 megawatts. Earthquakes are frequent in Iceland but rarely result in serious damage. Most of the buildings erected since the mid-20th century have been built of reinforced concrete and designed to withstand severe shocks from earthquakes.

Traditionally, Iceland has been divided according to the four points of the compass. The centre of the country is uninhabited. In the southwest several fine natural harbours have directed interest toward the sea, and good fishing grounds lie off the shores of this region. Because of its extensive lava fields and heaths, the southwest has little farmland. The middle west is divided between fishing and farming and has many places of great natural beauty. The western fjords have numerous well-sheltered harbours and good fishing grounds but little lowland suitable for agriculture. The north is divided into several smaller districts, each of which has relatively good farmland. The eastern fjords resemble the western fjords but have, in addition, an inner lowland. The southeast, locked between the glaciers and the sea, has a landscape of rugged splendour. The southern lowland comprises the main farming region. Soil and climatic conditions are favourable, and it is close to the country's largest market, Reykjavík and

Amarstapi, fishing village on Faxa Bay, Snæfell Peninsula, on the west coast of Iceland.

Drainage and soils. Heavy rainfall feeds the numerous rivers and lakes in the glaciated landscape. Many of the lakes are dammed by lava flows or glacial ice. The presence of waterfalls is typical of the geologically young mountain landscape. The rivers are mainly debris-laden streams of glacial origin or clear streams formed by rainfall and springs of underground water. In the regions not drained by glacier rivers, fjords and smaller inlets cut into the rocky coasts. Because glacial erosion has often deepened the inner portions of the fjords, there are many fine natural harbours. Elsewhere the coasts are regular, sandy, and lined extensively with offshore sandbars that form lagoons to the landward side.

Iceland has soils of both mineral and organic composition. The mineral soils are basically a yellow-brown loess, formed by deposits of wind-transported matter. Both types of soil are suitable for agriculture, but, because of the slow rate of biological activity in the northern climate, they re-

quire heavy fertilization.

Climate. The climate of Iceland is maritime subarctic. It is influenced by the location of the country on the broad boundary between two contrasting air currents, one of polar and the other of tropical origin. The climate is affected also by the confluence of two ocean currents, the Gulf Stream, from near the Equator, and the East Greenland Current. The latter sometimes carries Arctic drift ice to Iceland's northern and eastern shores.

Seasonal shifts in temperature and precipitation are largely the result of weather fronts crossing the North Atlantic. Relatively cold weather, particularly in the northern part of the country, results from the movement of a front south of Iceland; mild, rainy weather is brought by the movement of a front northeastward between Iceland and Greenland. Although its northernmost points nearly touch the Arctic Circle, Iceland is much warmer than might be expected.

Mean annual temperatures for Reykjavík (on the west coast), Akureyri (in the north), and Kirkjubaejarklaustur (in the south) are, respectively, 40°, 38°, and 40° F (4°, 3°, and 4° C). For the same locations, the mean January temperatures are 31°, 28°, and 32° F (-0.5° , -2° , and 0° C), and the mean July temperature is 51° F (11° C). Snow falls about 100 days per year in the northwest, about 40 in the southeast. Annual precipitation ranges from 16 inches (410 millimetres) on some high northern plateaus to more than 160 inches on the southern slopes of some ice-capped mountains. In the south it averages about 80 inches. Gales are frequent, especially in winter, and occasionally heavy fogs may occur, but thunderstorms are rare. Reykjavík averages nearly 1,300 hours of bright sunshine a year. Often the aurora borealis appears, especially in fall and early winter.

Plant and animal life. Iceland lies on the border between a tundra vegetation zone of treeless plains and a taiga zone of coniferous forests. Only about one-fourth of the country

is covered by a continuous carpet of vegetation. Bogs and moors are extensive, and sparse grasslands are often overgrazed. The remains of large birch forests are found in many places. A reforestation program instituted by the government in the 1950s has shown considerable success since the mid-1970s.

Foxes were the only land mammals in Iceland at the time of its settlement. Humans brought domestic and farm animals and accidentally introduced rats and mice. Later reindeer were introduced, and many are still found in the northeastern highlands. After 1930 mink that were brought in for the production of furs also became wild in the country. Birdlife in Iceland is varied. Many nesting cliffs are densely inhabited, and the colony of ducks at Lake Mývatn, in the north, is the largest and most varied in Europe. Salmon and trout abound in the lakes, brooks, and rivers. The fishing banks off the Icelandic shores are abundantly endowed with fish, although these resources have been considerably eroded by overexploitation. There are no reptiles or amphibians in Iceland.

Introduc-

animal life

tion of

Settlement patterns. Because agriculture was the chief economic activity, the population of Iceland was evenly distributed throughout the inhabitable parts of the country until the end of the 19th century. With the advent of the fishing industry, commerce, and services at the beginning of the 20th century, the population became increasingly concentrated in towns and villages. By the end of the century, more than 90 percent of the population lived in communities of 200 or more people.

The mainstay of most coastal towns is fishing and fish processing. The greatest population concentration is in Reykjavík and its environs, with about three-fifths of Iceland's total population. Reykjavík is a modern, cosmopolitan urban centre that-in addition to being the seat of government-is the national focus of commerce, industry, higher education, and cultural activity. Akureyri, a fishing and educational centre of about 15,000 inhabitants situated on the Eyia Fjord in the north, is second in importance. Reykjanesbaer is a fishing port on the southwestern peninsula near Keflavík International Airport. The Vestmanna (Westman) Islands, off the southern coast, have some of the most important fishing operations in Iceland. Akranes, located across the bay from Reykjavík, is a service town for its region and has some industry. Isafjördhur is a service town for the western fjord area. Seydhisfjördhur and Neskaupstadhur, on the eastern coast, are important ports for herring and capelin fishing. Höfn, on the southeastern coast, is also an important fishing port. Selfoss is in the southern lowlands, serving the farming region, and is the largest inland rural community in Iceland.

Effects of ocean currents

THE PEOPLE

The population of Iceland is extremely homogeneous. The inhabitants are descendants of settlers that began arriving Norse and Celtic background

in AD 874 and continued in heavy influx for about 60 years thereafter. Historians differ on the exact origin and ethnic composition of the settlers but agree that between 60 and 80 percent of them were from Norway. The rest, from Scotland and Ireland, were largely Celtic. The dominant language in the period of settlement was Old Norse, the language spoken in Norway at the time. Through the centuries it has evolved into modern Icelandic, which is used throughout the country. There are no ethnic distinctions. The early Nordic and Celtic groups have long since merged, and the small number of subsequent immigrants have had no major effect on the population structure. The Lutheran faith has been the dominant religion since the mid-16th century. About nine-tenths of the population belongs to the state-supported Evangelical Lutheran church. There is freedom of religion.

The first comprehensive census in Iceland was taken in 1703, at which time 50,358 people were reported. The 18th century was marked by great economic hardship, and by 1801 the population had declined to 47,240. There began a slow increase in the 19th century, and by 1901 the population had risen to 78,470. Accelerated economic growth during the early decades of the 20th century was paralleled by a rapid growth in population, which in 1950 reached 143,973. During World War II and the early postwar period there was rapid improvement in the standard of living and a new acceleration in the rate of population growth. The annual growth rate reached its peak during the 1950s; it has been declining since 1960, primarily because of a sharply reduced birth rate and continued emigration. For a brief period from the late 1980s to the mid-1990s the birth rate rose again before resuming its downward trend. In the late 1980s the population reached a quarter of a mil-

Between 1870 and 1914 there was large-scale emigration to Canada and the United States because of unfavourable conditions in Iceland; during that period emigrants outnumbered immigrants by the equivalent of about one-fifth of the 1901 population. Since 1901 emigration has continued to exceed immigration, though usually by only a small margin.

THE ECONOMY

Economic

growth

rates

The Icelandic economy is based heavily on fishing and the production of a broad variety of fish products, but it also includes manufacturing and services. Exports account for about two-fifths of the gross national product. Despite Iceland's small population, the economy is modern, and the standard of living is on a par with that of other European

Most of Iceland's production is in private hands. Government ownership has declined since the early 1990s through increased privatization of government-owned enterprises. The state still owns two commercial banks and several other financial institutions and shares ownership of most electricity-generating systems with local governments. The central government receives a major portion of its income from a value-added tax and a progressive income tax, whereas local governments derive most of their revenue from a flat-rate income tax and property levies.

Since World War II the government has aimed for a high rate of economic growth and full employment, and fluctuations in fish prices and catches have been an important influence on the economy. Iceland's real gross domestic product (GDP) increased by an average of about 4 percent per year after the war. After 1987, however, there was a slowdown in economic growth owing to limits imposed on fish catches in response to the depletion of fish stocks that had been overexploited for many years. From the late 1980s to the late 1990s the annual GDP growth rate averaged less than half what it had been. From 1994, however, there was a strong resumption of growth, mainly as a result of an improving fish catch. The inflation rate was high up to the end of the 1980s but thereafter declined. A low rate of inflation did not become a priority until the early 1990s, but Iceland now enjoys as low a rate as the other northern European countries. Unemployment has remained low.

Resources. Iceland's energy resources are vast. Feasible hydroenergy is estimated at nearly six gigawatts and geothermal energy at more than 1.5 million gigawatt hours per year. Only about one-eighth of the hydroelectric power of the country's rivers has been tapped. Geothermal energy heats all of Reykjavík and several other communities; it provides steam for industrial energy and is used in commercial vegetable farming in greenhouses.

Fishing. A steady improvement in Iceland's fishing technology has increased catches despite the gradual erosion of what once were enormously rich fish populations off the country's coasts. During the late 1980s and early 1990s the concern over declining fish stocks led the government to strengthen already strict catch quotas to further husband eroded fish stocks-particularly cod, the most important species. The strict quota regime paid off with a sharp increase in the cod stock in the late 1990s. Those catch quotas for domestic waters led to increased fishing in foreign waters, particularly in the Barents Sea and off the coast of Newfoundland.

Cod and capelin make up about two-thirds of the total catch, and such whitefish (demersal) species as cod and haddock are exported fresh, frozen, salted, or dried. The capelin and herring catches usually are reduced to oil and meal but also are salted. In the mid-1990s Iceland's total fish catch was between about 1.5 million and 2 million tons, of which about one-third was whitefish species and two-thirds were capelin and herring. Such fishing-related industries as boatyards, repair docks, and net factories are also important.

Agriculture. As is the case throughout the Nordic countries, less than 5 percent of Iceland's population is engaged in agriculture, and this number continues to decline. The raising of livestock-mostly sheep-and dairy farming are the main occupations. About one-fifth of the land is arable. most of it used for grazing. Greenhouses are common, especially in the southern part of the country. Iceland is virtually self-sufficient in fresh foods and dairy items, but it imports most other foodstuffs.

Industry. The main manufacturing enterprise for export is aluminum production, which uses domestic hydroelectricity to smelt aluminum from imported alumina. Other manufactured goods for export include ferrosilicon, an alloying agent for steel production; diatomite, an industrial filtration agent produced from diatomaceous earth with geothermal steam; fish-processing equipment; fishing gear; and prosthetic devices. There are also small industries that produce computer software, cement, fertilizer, food, clothing, and books.

Finance. Iceland has three commercial banks with branches throughout the country and a number of savings banks. Other financial institutions include investment credit funds, private pension funds, insurance companies, and securities firms. The financial sector was gradually deregulated in the 1980s. Interest rates were left to market forces, an important stock and bond market developed, and monetary policy-previously quite inflationary-became comparable to that of other industrialized countries. The reform of the financial market played an important part in bringing inflation under control. Capital movements to and from other countries were almost completely liberalized by the mid-1990s. The exchange rate of the country's currency, the króna, is linked to the U.S. dollar, the Japanese yen, and the euro, the currency of the Euro-

Transportation and tourism. The historic isolation of Iceland, caused by the rough seas of the North Atlantic and the country's small market and industry, was broken when steam vessels began to visit Icelandic shores late in the 19th century. The first telegraph cable to Iceland was laid in 1906, and the Iceland Steamship Company (Eimskip) was founded in 1914. Before the 20th century roads were practically unknown, the horse being the means of transportation throughout the island. Iceland has no railroads. Domestic transportation is provided by truck, car, plane, or coastal boats. Most of Iceland's main rural roads are paved, as are most streets in towns and villages. The majority of minor country roads, however, are still gravel. During the summer driving is possible on the extensive sandy plains in the uninhabited interior, permitting expeditions between the glaciers. The Hringvegur ("Ring Road")

Dairy farming Icelandair and tourism

stretches for about 875 miles (1,400 kilometres), forming a circle around the island. The merchant marine fleet transports most of Iceland's imports and exports. Icelandair (Flugleidir), a major international carrier, as well as local air service carriers are important internally in compensating for the limited road system. Keflavík International Airport, the country's primary gateway, is located about 30 miles (48 kilometres) west of Reykjavík. Icelandair has helped make the tourist trade increasingly important to the national economy. Foreign tourists number more than 200,000 a year, and the tourist industry is an important earner of foreign exchange.

Foreign trade. More than three-fifths of Iceland's exports go to the European Union (EU), which also is responsible for more than half of Iceland's imports. About one-eighth of exports go to the United States and about one-tenth to Japan. Iceland has been a member of the European Free Trade Association (EFTA) since 1970. It has stopped short of applying for membership to the EU because of its concern that the EU would control its fishing resources.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Iceland is a parliamentary democracy with a directly elected president as head of state. The powers of the president are similar to those of other heads of state in western European democracies. Real power rests with the 63-member parliament, the Althing (Althingi). One of the oldest legislative assemblies in the world, the Althing is a unicameral legislature in which members serve four-year terms unless parliament is dissolved. The executive branch is headed by a cabinet that must maintain majority support in parliament-or at least avoid censure-otherwise it must resign. The judiciary consists of a supreme court and a system of lower courts, most of which hear both civil and criminal cases. Cases are heard and decided by appointed judges; there is no jury system. Citizens are guaranteed the civil rights customary in Western democracies.

Local government in Iceland is chiefly responsible for primary education, municipal services, and the administration of social programs. The country is divided into 124 municipalities. Since the 1970s their number has decreased by nearly half as a result of consolidation. Each municipality administers local matters through an elected council.

The president, Althing, and local councils are elected every four years, but not necessarily all at once. All citizens 18 years of age and older may vote. Since the late 1970s the Independence Party, centre to conservative in political outlook, has commanded about one-third of the popular vote. The Progressive Party, which has captured the second largest proportion of the vote during this period, draws its strength from rural areas. Among the other main political parties are the Social Democratic Party, the People's Alliance, and the Women's Alliance.

Foreign relations. Iceland joined the United Nations in 1946, a year after its founding, and is a charter member of the North Atlantic Treaty Organization (NATO). In the post-World War II period it has based its foreign policy on peaceful international cooperation and participated in joint Western defense efforts. It does not maintain armed forces. The United States, having assumed responsibility for Iceland's defense, maintains a naval air station at Keflavík International Airport under NATO auspices, Iceland's entry into distant fishing waters has caused friction with other nations over fishing rights. Fishing in the Barents Sea is a source of contention with Norway and Russia, as is herring fishing in the open ocean between Norway and Iceland. Moreover, Canada has objected to Iceland's shrimp fishing off the coast of Newfoundland.

Health and welfare. Iceland, with compulsory health insurance that finances most medical services, has a high standard of public health and one of the highest life expectancies in the world. Hospital inpatient services are provided entirely without charge, other medical services at low cost. Dental care is partially subsidized for children up to age 16 and for retirees with low incomes. Heart disease and cancer together account for about one-half of all deaths. Welfare services include unemployment insurance, old-age and disability pensions, family and childbearing allowances, and sickness benefits. The medical and welfare systems are financed through taxation by central and local government.

Education. Almost all schools from the primary level through the university are free. Education is compulsory through age 16, and secondary and higher education is widely available. Students can enroll in four-year academic colleges at the age of 15 or 16. Graduation from one of these colleges entitles the student to admission to the University of Iceland, founded in 1911, in Reykjavík, A second university was established at Akureyri in 1987. There are also a number of technical, vocational, and specialized schools

CULTURAL LIFE

Icelanders are proof that a rich cultural life can be developed despite a small population. The country's literary heritage stems from writers of the 12th to 14th centuries who vividly recorded the sagas of Iceland's first 250 years. Other traditional arts include weaving, silver crafting, and wood carving. Poetry was the great literary form of expression in the 19th century, whereas the novel and drama were the prime forms of literature in the 20th century.

The Reykjavík area, which supports several professional theatres, a symphony orchestra, an opera, and a number of art galleries, bookstores, cinemas, and museums, has a cultural environment that compares favourably with those of cities several times its size. It also holds biennial international art fectivals

The arts. Art in Iceland was long connected with religion, first the Roman Catholic church and later the Lutheran church. The first professional secular painters appeared in Iceland in the 19th century. Gradually increasing in number, these painters, such as Jóhannes Kjarval, highlighted the character and beauty of their country. Painting continues to thrive in Iceland, where artists have fused foreign influences with local heritage. The old traditions in silver working have been retained, the most characteristic of which is the use of silver thread for ornamentation.

Literary

activity

Literature is also alive and well in Iceland. The literary tradition of the saga has been revived, and Iceland was often the setting of 20th-century fiction. Several Icelandic writers have received international acclaim, such as Halldór Laxness, who received the Nobel Prize for Literature in 1955. Other native writers have written for the theatre, and their work has grown more international in theme and setting. Music also enjoyed a tremendous upsurge after World War II. The programs of the Iceland Symphony are drawn from a classical repertoire and the work of modern Icelandic composers, and one or more operas or musicals are performed every year at the National Theatre and the Icelandic Opera. Popular music by Icelandic performers, such as Björk, has gained international commercial success and critical acclaim.

National folk traditions in applied art have achieved a new popularity. Old designs and forms have been revived, some modified to please modern tastes. Wool, knitted or woven, is the most commonly used material. Many people in the country participate in this industry, creating highquality goods.

Sports. Glima, a form of wrestling that originated with the Vikings, is still practiced in Iceland. Swimming in naturally heated pools, pony trekking, and various ball games also are popular. Team handball became the national sport in the 1980s, with Iceland's national team ranked among the top teams in the world.

Cultural institutions. The National Library of Iceland (founded in 1818) and the University Library (1940) merged in 1994. The National Archives were founded in 1882. The National Museum of Iceland, dating from 1863, has collections representing native Icelandic culture beginning in the Viking Age. Many old houses and ruins throughout the country are preserved under its auspices. The National Gallery of Iceland was founded in 1884, and the great majority of its works are by modern Icelandic

artists. The Natural History Museum was founded in 1889. The National Theatre began operation in 1950. It performs Icelandic as well as foreign classical and modern plays, operas, ballets, and musicals. The Reykjavík Theatre is the other full-time professional repertory theatre. Sev-

Comprehensive health insurance eral theatre groups present numerous plays and musicals, both in Reykjavík and the countryside.

Book publishing also is an active Icelandic tradition. More than 1,000 book titles are published every year. There are three daily newspapers in the country and numerous magazines and journals. The Icelandic Literary Society, founded in 1816, specializes in the publication of historical and classical works. (Va.K./B.M.)

BOOK OF THE YEAR.

History

Sources

EARLY HISTORY

Settlement (c. 870-c. 930). Iceland apparently has no prehistory. According to stories written down some 250 years after the event, the country was discovered and settled by Norse people in the Viking Age. The oldest source. Islendingabók (The Book of the Icelanders), written in about 1130, sets the period of settlement at about AD 870-930. The other main source, Landnámabók (The Book of Settlements), of 12th-century origin but known only in later versions, states explicitly that the first permanent settlers, Ingólfr Arnarson and his wife, Hallveig Fródadóttir, came to Iceland to settle in the year 874. They came from Norway and chose as their homestead a site that Ingolfr named Reykjavík. The Book of Settlements then enumerates more than 400 settlers who sailed with their families, servants, and slaves to Iceland to stake claims to land there. Most of the settlers came from Norway, but some came from other Nordic countries and from the Norse Viking Age settlements in the British Isles.

Some scholars have found it difficult to believe that such a large and habitable country remained unpopulated until the 9th century. On the whole, however, archaeological finds support the documentary evidence and place Iceland among Norse Viking Age settlements of the late 9th or early 10th century. The Icelandic language testifies to the same origin: Icelandic is a Nordic language and is most closely related to the dialects of western Norway.

Although the island was not populated until the Viking Age, Iceland probably had been known to people long before that time. The 4th-century-BC Greek explorer Pytheas of Massalia (Marseille) described a northern country that he called Thule, located six days' sailing distance north of Britain. In the 8th century, Irish hermits who had begun to sail to Iceland in search of solitude also called the island Thule, It is unknown, however, if Pytheas and the hermits were describing the same island. According to the early Icelandic sources, some Irish monks were living in Iceland when the Nordic settlers arrived, but these monks soon left because they were unwilling to share the country with

Commonwealth (c. 930-1264). At the time of Iceland's settlement, Norse people worshiped gods whom they called æsir (singular áss), and this religion has left behind an extensive mythology in Icelandic literature. Thor seems to have been the most popular of the pagan gods in Iceland, although Odin is thought to have been the highest in rank. It appears that heathen worship was organized around a distinct class of priest-chieftains, called godar (singular godi), of which there were about 40. In the absence of royal power in Iceland, the godar were to form the ruling class in the country

By the end of the settlement period, a general Icelandic assembly, called Althing, had been established and was held at midsummer on a site that came to be called Thingvellir. ·This assembly consisted of a law council (lögrétta), in which the godar made and amended the laws, and a system of courts of justice, in which householders, nominated by the godar, acted on the panels of judges. At the local level, three godar usually held a joint assembly in late spring, at which a local court operated, again with judges nominated by the godar. All farmers were legally obliged to belong to a chieftaincy (godord) but theoretically were free to change their allegiance from one godi to another; the godar were allotted a corresponding right to expel a follower. Some scholars have seen in this arrangement a resemblance to the franchise in modern societies. On the other hand, there was no central authority to ensure that the farmers would be able to exercise their right in a democratic way. No one was vested with executive power over the country as a whole. In any case, no trace of democratic practice reached farther down the social scale than to the heads of farming households; women and workers (either free or enslaved) had no role in the political system.

Christianization. By the end of the 10th century the Norwegians were forced by their king, Olaf I Tryggvason, to accept Christianity. The king also sent missionaries to Iceland, who according to 12th-century sources were highly successful in converting the Icelanders. In 999 or 1000 the Althing made a peaceful decision that all Icelanders should become Christians. In spite of this decision, the godar retained their political role, and many of them probably built their own churches. Some were ordained, and as a group they seem to have closely controlled the organization of the new religion. Two bishoprics were established, one at Skálholt in 1056 and the other at Hólar in 1106. Literate Christian culture also transformed lay life, Codification of the law was begun in 1117-18. A little later the Icelanders began to write their sagas, which were to reach their pinnacle of literary achievement in the next century. Economic life. Historians believe that early Icelandic society was a prosperous one. The country proved to be well suited for sheep and cattle, and both were raised for meat and milk. The sheep also vielded wool, and homespun cloth became the chief export. There was some agriculture, but grain was always imported. Timber was also imported: the only indigenous wood was dwarf birch. However abundant driftwood may have been, it could not satisfy the needs of the whole population. The Icelanders built large turf-clad houses on bulky timber frames, and some of the churches were built entirely of timber.

In spite of the seeming abundance, the end was coming for an independent Icelandic commonwealth. In Norway, royal power gained strength in the early 13th century, and the king set himself the aim of uniting all Norwegian Viking Age settlements under his reign. By that time, a score of powerful godar, belonging to some five families, held almost all the chieftaincies in Iceland. The mid-13th century is characterized by a bloody struggle for power among these chieftains. Finally, in 1262-64 all Icelandic chieftains and representatives of the farmers were persuaded to swear allegiance to the king of Norway, partly in the hope that he would bring peace to the country.

ICELAND UNDER FOREIGN RULE Late Middle Ages (1264-c. 1550). To a large extent, Iceland was ruled separately from Norway. It had its own law code, and the Althing continued to be held at Thingvellir, though mainly as a court of justice. Most of the royal officials who succeeded the chieftains were Icelanders. In 1380 the Norwegian monarchy entered into a union with the Danish crown, but that change did not affect Iceland's status within the realm as a personal skattland ("tax land") of the crown.

Economic growth and decline. A fundamental change in Iceland's economy took place in the early 14th century when Norwegian merchants began to import dried fish from Iceland to Bergen, Nor. English merchants in Bergen became acquainted with Icelandic fish supplies, and shortly after 1400 they themselves began sailing to Iceland and either catching fish or buying it from local fishermen. The Danish crown repeatedly tried to stop English trade in Iceland but lacked the naval power with which to defend its remote possession. One of the royal governors was killed by the English when he tried to stop their trade, an event that led indirectly to clashes between Denmark and England (1468-73). In the early 16th century, English interest in Iceland declined, partly because rich fishing grounds had been discovered off the North American coast of Newfoundland. Instead, Germans became the chief foreigners to fish and trade in Iceland.

In spite of the rise of a profitable export industry, it is generally believed that Iceland's economy deteriorated in the late Middle Ages. The birchwood that had covered great parts of the country was gradually depleted, in part

End of the commonwealth

Importance of fishing

The godar

Danish

monopoly of trade

because it was excellent for making charcoal. The destruction of the woodland, together with heavy grazing, led to extensive soil erosion. The climate also became more severe, and grain growing was given up altogether. At the same time, more and more of the land was acquired by ecclesiastical institutions and wealthy individuals, to

whom the farmers had to pay rent. The Reformation. The Lutheran Reformation, which was instituted in Denmark in the 1530s, met greater resistance in Iceland than anywhere else in the realm. In 1541 the bishop of Skálholt was captured by the governor, and Lutheranism was introduced in his diocese, which covered three-quarters of the country. In the northern diocese of Hólar, Bishop Jón Arason was to hold out against Lutheranism for a decade longer. In 1550 he was finally captured and beheaded, without benefit of law or clergy, and all resistance to the Reformation ended. Jón Arason's death is traditionally taken to mark the end of the Middle

Ages in Iceland.

Growth of Danish royal power (c. 1550-c. 1830). After the Reformation the royal treasury confiscated all lands that had belonged to the Icelandic monasteries. Also during the 16th century the German traders were ousted. In 1602 all foreign trade in Iceland was monopolized by a royal decree and handed over to Danish merchants, who paid a rent on it to the crown. This arrangement lasted intact until 1787, when the monopoly was abolished. Only subjects of the Danish crown, however, were permitted to carry on foreign trade, a restriction that remained in force until 1855.

On the constitutional level, also, the Danish crown increased its hold on Iceland, at least in formal terms. In 1661 Frederick III introduced an absolute monarchy in Denmark and Norway, and in the following year his absolutism was acknowledged in Iceland. This event was not of any great immediate significance in Iceland; local officials, most of whom were Icelanders, continued to make important political decisions. Danish officials in Copenhagen rarely had enough knowledge of or interest in Icelandic affairs to enforce their will if the Icelandic officials in Iceland were unanimous on a different policy.

Nevertheless, the bureaucratic state, which formed the backbone of absolutism, was gradually introduced into Iceland. An essential part of that development was the emergence of a town nucleus in Reykjavík, the first one in this hitherto entirely rural country. In the 1750s a tiny village grew up in Reykjavík as a result of a semiofficial attempt to start a wool-processing factory there. Within half a century the two ancient bishoprics were united, with the bishop residing in Reykjavík. The Althing was abolished in 1800, and an appeals court was set up in Reykjavík to succeed it. A few years later the Danish governor also settled in the town, which by then had about

300 inhabitants. Only since the 18th century has there been sufficient information available to allow for a reliable survey of Iceland's economy. The first census, for example, was held in 1703, revealing that the population was just over 50,000. The main occupation of most of the inhabitants was farming, but an important auxiliary occupation, undertaken mostly by rural labourers on the southern and western coasts in late winter and spring, was fishing. With few exceptions, labourers were obliged to stay in the domestic service of a farmer, and the establishment of permanent households in fishing stations was severely restricted. Thus, the landowners, with most of the native officials in their number, succeeded in monopolizing fishing, and they prevented it from becoming an independent industry.

The 18th century, a time of prosperity elsewhere in the Danish realm, was a period of decline and increasing poverty in Iceland. In the 1780s the country was plagued by famine-caused by a volcanic eruption and subsequent years of cold weather-which killed one-fifth of the population. In spite of these hardships, it appears that few Icelanders were critical of the status of the country within the Danish realm. In 1809 a Danish adventurer, Jørgen Jørgensen, seized power in Iceland for two months. When he was removed and Danish power was restored, he received no support from the Icelandic population. Five

years later, when Norway was united politically with Sweden, no Icelander expressed a wish to follow suit.

MODERN ICELAND

Struggle for independence (c. 1830-1904). In the 1830s the Danish crown eased its absolutism by setting up four consultative diets in the realm. Iceland was allotted two representatives in one of them, the assembly of the Danish Isles meeting at Roskilde, Den. This arrangement was never popular in Iceland, and the adherents to emerging nationalist and liberal sentiments wanted the Icelandic Althing to be restored on its ancient site as a consultative assembly for the nation, In 1840 Christian VIII decided to grant them their wish, and five years later a restored Althing, vested with consultative power, met for the first time, not at Thingvellir, however, as originally intended, but in Revkjavík. Franchise to the assembly was almost entirely restricted to officials and (male) farmers.

In 1848, only three years after the first convention of the Althing, Frederick VII renounced his absolute power, and a constitutional assembly was summoned to prepare a representative democracy in Denmark. This led inevitably to the question of what was to become of Iceland in the new form of government. By this time, Iceland had a relatively undisputed political leader, Jón Sigurdhsson, a philologist living in Copenhagen, Sigurdhsson argued that the king could only give his absolute rule over Iceland back to the Icelanders themselves, since they were the ones who had surrendered it to him in 1662. This claim was met with a royal pledge that the constitutional status of Iceland would not be decided until the Icelanders had discussed the matter at a special assembly in Iceland. This assembly met in 1851, but no agreement could be reached between the Icelandic representatives and the Danish government. The assembly was dissolved in disappointment. A stalemate of more than 20 years ensued, but the Althing decided to use the occasion of the millennium of Iceland's settlement (1874) to accept the status that Danish authorities were by then willing to grant. Thus, in 1874 the king presented Iceland with a constitution whereby the Althing was vested with legislative power in internal affairs. As before, however, the cabinet minister responsible for Iceland was the minister of justice in the Danish government.

For an additional three decades the Icelanders fought to get executive power transferred to Iceland, In 1901 the path was opened when rule by parliamentary majority was introduced in Denmark and the Liberal Party always more positive than the Conservatives toward the Icelanders-came into power. In 1904 Iceland got home rule, and the first Icelandic minister opened his office in Reykjavík. At the same time, rule by parliamentary majority was introduced.

The high level of political activity in 19th-century Iceland stands in sharp contrast with its economic stagnation. The considerable growth of Iceland's population put increasing strain on the badly eroded rural areas, and for many people the only visible solution was emigration to North America. Some 15,000 Icelanders emigrated between 1870 and 1914, most of them to Canada. Virtually the only successful technical innovation during that period was the introduction of decked fishing vessels, which made it possible to catch fish farther offshore than could be done on open boats. Still, at the beginning of the 20th century, more than half of the annual catch was still taken in open boats.

Home rule and sovereignty (1904-44). The period of home rule (1904-18) was one of rapid progress. Motors were installed in many of the open fishing boats, and a number of steam-driven trawlers were acquired. The country was connected by telephone cable with Europe. School attendance was made compulsory for children in towns and villages, and a number of schools were built. The University of Iceland was established in Reykjavík, which by 1918 had a population of 15,000. All restrictions on the freedom to move to the fishing villages were either abolished or quietly forgotten. There was a radical transformation in the occupational structure of the country, which, in turn, led to the advent of a labour movement, In 1916 a national organization of trade unions was esConstitution of

Economic conditions tablished. By then, unions were already widely accepted by employers as negotiating bodies, but their formal status was not legalized until 1938. In the political arena, democracy was extended to new groups in the society. Women and propertyless men were given the franchies, subject to certain qualifications, in 1915. Four years earlier, a law had been passed that gave women the right to attend schools of higher education, enter into the professions, and occupy any public office in the country.

The struggle continued for greater autonomy until the dispute with Denmark was solved by an agreement. On Dec. 1, 1918, Iceland became a separate state under the Danish crown, with only foreign affairs remaining under Danish control. Either party, however, had the right to call for a review of the treaty, and if necotiations about its re-

newal proved fruitless at the end of 25 years (i.e., 1943) it

The union

would be terminated.
The struggle for independence that had shaped Icelandic politics for almost a century now subsided, and in the 1920s a new system of political parties based on class divisions emerged. Class antagonism grew more severe during the Great Depression of the 1930s; the depression was prolonged in Iceland when the outbreak of the Spanish Civil War in 1936 closed the important Spanish market for Icelandic fish. The problem of high unemployment persisted until after the outbreak of World War II.

The German occupation of Denmark in April 1940 effectively dissolved the union between Iceland and Denmark. A month later, British forces occupied Iceland. In 1941 the United States took over the defense of Iceland and stationed a force of 60,000 in the country. The foreign forces brought employment, prosperity, and high inflation to the population, which then numbered about 120,000.

The war made it impossible for lecland and Denmark to renegotiate their treaty. In spite of great resentment in Denmark, the leclanders decided to terminate the treaty, break all constitutional ties with Denmark, and establish a republic. On June 17, 1944, now celebrated as National Day, the leclandic republic was founded at Thingvellir, with Sveinn Biornson as its first president.

The Icelandic republic. Since the prosperous years of World War II, Iceland has developed into a modern well-fare state with growing production and consumption. A rapid restoration of the trawler fleet after the war prevented the return of prewar unemployment. Fish freezing became a highly technical industry and the mainstay of lecland's exports. The economy became characterized by the exposition, full employment, high inflation, and much unprofitable investment. It became normal to work overtime and for women to enter the labour market.

The tendency toward overexpansion—which seemed to have been checked in the 1990s—was caused in part by weak political leadership. Generally Iceland has been ruled by coalition governments, and these coalitions have tended to blend parties of the political left and right. This bluring of ideologies has probably been caused by another dividing line in Icelandic postware politics: that between integrationism, generally espoused by the Independence and Social Democratic parties, and isolationism, identified with the Progressives and People's Alliance. This contrast has come to a head over three recurrent issues: defense, European integration, and extension of fishing limits.

From the time that Iceland joined the North Atlantic Treaty Organization (NATO) in 1949, the Independence Party has firmly supported NATO while the People's Alliance has been an ardent opponent. The Social Democratic Party and the Progressives also have supported NATO membership, though with some reluctance over the presence of American forces. Since the 1980s the issue of defense has yielded the foreground to Iceland's relations with Europe. Iceland entered the European Free Trade Association (EFTA) in 1970, in the period of an Independence and Social Democratic coalition, against the votes of the People's Alliance. Since then the Social Democratic Party alone has sought full Icelandic membership in the EU and thus appears to be the most integrationst party.

After World War II Iceland extended its exclusive fishing zone from 3 nautical miles (5.6 kilometres) in 1950 to 200 nautical miles (370 kilometres) in 1975. This action

provoked strong protests, and the British navy was repeatedly sent to Icelandic fishing grounds to protect British trawlers. The confrontation, commonly known as the "Cod Wars," ended in 1976 when Britain recognized the 200-nautical-mile limit. Nevertheless, while all the political parties supported Iceland's claims, only the more isolationist parties were willing to risk Iceland's relations with its NATO partners. Eventually, as the fish stocks around Iceland began to be depleted, Icelandic fishing firms started deep-sea fishing on remote grounds. This led to disputes with other fishing nations—particularly with Norway and Russia over fishing in the Barents Sea.

The status of women has formed still another dimension of Icelandic politics. A woman, Vigdis Finnbogadottir, served as president of the republic for four terms (1980–96), enjoying great popularity, and a Women's Alliance has been represented in the partiament since 1983. However, the Icelandic president typically is not influential in politics, and the Women's Alliance has yet to participate in forming a government. Furthermore, women still earn less income than men, suggesting that they have not yet obtained full equality. (Gu.K.)

Ideology

n ideology is a form of social or political philosophy in which practical elements are as prominent as theoretical ones; it is a system of ideas that aspires both to explain the world and to change it.

This article describes the nature, history, and significance of ideologies in terms of the philosophical, political, and international contexts in which they have arisen. For discussions of particular categories of ideology, see the Macropædia article SOCIO-ECONOMIC DOCTRINES AND REFORM MOVEMENTS, MODERN. Specific ideologies are described in the Micropædia under such headings as COM-MUNISM and FASCISM.

The article is divided into the following sections:

Origins and characteristics of ideology 768 The philosophical context 768 Ideology and religion Ideology in early political philosophy Hegel and Marx The sociology of knowledge The political context 770 Ideology, rationalism, and romanticism Ideology and terror Ideology and pragmatism The context of international relations 771 Ideology in the World Wars Ideology of the Cold War

Bibliography 772

ORIGINS AND CHARACTERISTICS OF IDEOLOGY

The word first made its appearance in French as idéologie at the time of the French Revolution, when it was introduced by a philosopher, A.-L.-C. Destutt de Tracy, as a short name for what he called his "science of ideas, which he claimed to have adapted from the epistemology of the philosophers John Locke and Étienne Bonnot de Condillac, for whom all human knowledge was knowledge of ideas. The fact is, however, that he owed rather more to the English philosopher Francis Bacon, whom he revered no less than did the earlier French philosophers of the Enlightenment. It was Bacon who had proclaimed that the destiny of science was not only to enlarge man's knowledge but also to "improve the life of men on earth," and it was this same union of the programmatic with the intellectual that distinguished Destutt de Tracy's idéologie from those theories, systems, or philosophies that were essentially explanatory. The science of ideas was a science with a mission; it aimed at serving men, even saving them. by ridding their minds of prejudice and preparing them for the sovereignty of reason.

Destutt de Tracy and his fellow idéologues devised a system of national education that they believed would transform France into a rational and scientific society. Their teaching combined a fervent belief in individual liberty with an elaborate program of state planning, and for a short time under the Directory (1795-99) it became the official doctrine of the French Republic. Napoleon at first supported Destutt de Tracy and his friends, but he soon turned against them, and in December 1812 he even went so far as to attribute blame for France's military defeats to the influence of the idéologues, of whom he spoke with scorn.

Thus ideology has been from its inception a word with a marked emotive content, though Destutt de Tracy presumably had intended it to be a dry, technical term. Such was his own passionate attachment to the science of ideas, and such was the high moral worth and purpose he assigned to it, that the word idéologie was bound to possess for him a strongly laudatory character. And equally, when Napoleon linked the name of idéologie with what he had come to regard as the most detestable elements in Revolutionary thought, he invested the same word with all of his feelings of disapprobation and mistrust. Ideology was, from this time on, to play this double role of a term both laudatory and abusive not only in French but also in German, English, Italian, and all the other languages of the world into which it was either translated or transliterated.

Some historians of philosophy have called the 19th century the age of ideology, not because the word itself was then so widely used, but because so much of the thought of the time can be distinguished from that prevailing in the previous centuries by features that would now be called ideological. Even so, there is a limit to the extent to which one can speak today of an agreed use of the word. The subject of ideology is a controversial one, and it is arguable that at least some part of this controversy derives from disagreement as to the definition of the word ideology. One can, however, discern both a strict and a loose way of using it. In the loose sense of the word, ideology may mean any kind of action-oriented theory or any attempt to approach politics in the light of a system of ideas. Ideology in the stricter sense stays fairly close to Destutt de Tracy's original conception and may be identified by five characteristics: (1) it contains an explanatory theory of a more or less comprehensive kind about human experience and the external world; (2) it sets out a program, in generalized and abstract terms, of social and political organization; (3) it conceives the realization of this program as entailing a struggle; (4) it seeks not merely to persuade but to recruit loyal adherents, demanding what is sometimes called commitment; (5) it addresses a wide public but may tend to confer some special role of leadership on intellectuals. In this article the noun ideology is used only in its strict sense; the adjective ideological is used to refer to ideology as broadly defined.

On the basis of the five features above, then, one can recognize as ideologies systems as diverse as Destutt de Tracy's own science of ideas, the Positivism of the French philosopher Auguste Comte, Communism and several other types of Socialism, Fascism, Nazism, and certain kinds of nationalism. That all these "-isms" belong to the 19th or 20th century may suggest that ideologies are no older than the word itself-that they belong essentially to a period in which secular belief has increasingly replaced traditional religious faith.

THE PHILOSOPHICAL CONTEXT

Ideology and religion. Ideologies, in fact, are sometimes spoken of as if they belonged to the same logical category as religions. Both are assuredly in a certain sense "total" systems, concerned at the same time with questions of truth and questions of conduct; but the differences between ideologies and religions are perhaps more important than the similarities. A religious theory of reality is constructed in terms of a divine order and is seldom, like that of the ideologist, centred on this world alone. A religion may present a vision of a just society, but it cannot easily have a practical political program. The emphasis of religion is on faith and worship; its appeal is to inwardness and its aim the redemption or purification of the human spirit. An ideology speaks to the group, the nation, or the class. Some religions acknowledge their debt to revelation, whereas ideology always believes, however mistakenly, that it lives by reason alone. Both, it may be said, demand commitment, but it may be doubted whether commitment has ever been a marked feature of those religions into which a believer is inducted in infancy.

Even so, it is in certain religious movements that the first ideological elements in the modern world can be seen. The city of Florence, which in so many fields witnessed Ideology and strictly defined

Science of ideas

Savonarola as an ideologist

Ideology

in 17th-

century

England

the birth of modernity, produced perhaps the first "ideological" Christian. The attempt of Girolamo Savonarola to construct a puritan utopia was marked by several of the qualities by which one recognizes a modern ideology. Savonarola treated the vision of a Christian community as a model that men should actually seek to realize in the here and now. His method was to dominate the state through an appeal to the populace, and then to use the powers of the state to control both the economy and the private lives of the citizens. The enterprise was given a militant spirit; it was presented by Savonarola as being at one and the same time an outward struggle against papal corruption, the commercial ethos, and Renaissance Humanism, and an inward struggle against worldly ambitions and carnal desires.

Savonarola had numerous followers in his attempt to give Christianity an ideological dimension: he inspired Calvin's Geneva and the Puritan communities of the New World. Indeed, in both the Reformation and the Counter-Reformation, when Christianity was invested with a new militancy and a new intolerance, when a new emphasis was placed on creeds and conversion, religion itself moved

that much nearer to ideology

Ideology in early political philosophy. The Italian political philosopher Niccolò Machiavelli was one of Savonarola's sharpest critics, but he was also, like him, a precursor of modern ideologists. Historians who speak of him only as an immoralist overlook the extent to which Machiavelli was a man with an ideal—a republican ideal. Rousseau recognized this when he spoke of *The Prince* as a "handbook for republicans." Machiavelli's dream was to see revived in modern Italy a republic as glorious as that of ancient Rome, and he suggested that it could be achieved only by means of a revolution that had the strength of will to liquidate its enemies. Machiavelli was the first to link ideology with terror, but he was too much of a political scientist to enact the role of the ideologue.

Seventeenth-century England occupies an important place in the history of ideology. Although there were then no fully fledged ideologies in the strict sense of the term, political theory, like politics itself, began to acquire certain ideological characteristics. The swift movement of revolutionary forces throughout the 17th century created a demand for theories to explain and justify the radical action that was often taken. Locke's Two Treatises of Government is an outstanding example of literature written to justify the rights of man against absolutism. This growth of abstract theory in the 17th century, this increasing tendency to construct systems and discuss politics in terms of principles, marks the emergence of the ideological style. In political conversation generally it was accompanied by a growing use of concepts such as right and liberty-ideals in terms of which actual policies were judged.

Hegel and Marx. Although the word ideology in the sense derived from Destutt de Tracy's understanding has passed into modern usage, it is important to notice the particular sense that ideology is given in Hegelian and Marxist philosophy, where it is used in a pejorative way. Ideology there becomes a word for what these philosophers also call "false consciousness." G.W.F. Hegel argued that people were instruments of history; they enacted roles that were assigned to them by forces they did not understand; the meaning of history was hidden from them. Only the philosopher could expect to understand things as they were. This Hegelian enterprise of interpreting reality and reconciling the world to itself was condemned by certain critics as an attempt to provide an ideology of the status quo, in that if individuals were indeed mere ciphers whose actions were determined by external forces, then there was little point in trying to change or improve political and · other circumstances. This is a criticism Karl Marx took up, and it is the argument he developed in The German Ideology and other earlier writings. Ideology in this sense is a set of beliefs with which people deceive themselves; it is theory that expresses what they are led to think, as opposed to that which is true; it is false consciousness.

Marx, however, was not consistent in his use of the word ideology, for he did not always use the term pejoratively, and some of his references to it clearly imply the possibil-

ity of an ideology being true. Twentieth-century Marxists, who have frequently discarded the pejorative sense of ideology altogether, have been content to speak of Marxism as being itself an ideology. In certain Communist countries "ideological institutes" have been established, and party philosophers are commonly spoken of as party ideologists. Marxism is an excellent example, a paradigm, of an ideology.

The sociology of knowledge. The use of the word ideology in the pejorative sense of false consciousness is found not only in the writings of Marx himself but in those of other exponents of what has come to be known as the sociology of knowledge, including the German sociologists Max Weber and Karl Mannheim, and numerous lesser figures. Few such writers are wholly consistent in their use of the term, but what is characteristic of their approach is their method of regarding idea systems as the outcome or expression of certain interests. In calling such idea systems ideologies, they are treating them as things whose true nature is concealed; they consider the task of sociological research to be the unveiling of what Mannheim called the "life conditions which produce ideologies."

From this perspective, the economic science of Adam Smith, for example, is not to be understood as an independent intellectual construction or to be judged in terms of its truth, consistency, or clarity, rather, it is to be seen as the expression of bourpeois interests, as part of the

ideology of capitalism.

The sociology of knowledge in its more recent formulations has sought support in Freudian psychology (notably) in borrowing from Freud the concepts of the unconscious and of rationalization), in order to suggest that ideologies are the unconscious rationalizations of class interests. This refinement has enabled sociologists of knowledge to rid their theory of the disagreeable and unscientific element of bald accusation; they no longer have to brand Adam Smith as a deliberate champion of the bourgeois ethos but can see him now as simply the unconscious spokesman of capitalism. At the same time, these sociologists of knowledge have argued that Freudian psychology is itself no less a form of ideology than is Adam Smith's economics, for Freud's method of psychoanalysis is essentially a technique for adjusting rebellious minds to the demands and

constraints of bourgeois society.

Critics of the sociology of knowledge have argued that if all philosophy is ideology, then the sociology of knowledge must itself be an ideology like any other idea system and equally devoid of independent validity; that if all seeming truth is veiled rationalization of interest, then the sociology of knowledge cannot be true. It has been suggested that although Weber and Mannheim inspired most of the work that has been done by sociologists of knowledge their own writings may perhaps be exempted from this criticism, if only on the ground that neither of them put forward a consistent or unambiguous theory of ideology. Both used the word ideology in different ways at different times. Weber was in part concerned to reverse Marx's theory that all idea systems are products of economic structures, by demonstrating conversely that some economic structures are the product of idea systems (that Protestantism, for example, generated capitalism and not capitalism Protestantism). Mannheim, on the other hand, tried to restore in a more elaborate form Marx's suggestion that ideologies are the product of the social structure. But Mannheim's analysis may have been obscured by his proposal that the word ideology should be reserved for idea systems that are more or less conservative, and the word utopia for idea systems of a more revolutionary or millenarian nature. Mannheim did not, however, remain faithful to this stipulative definition, even in his book entitled Ideology and Utopia.

On the other hand, Mannheim was well aware of the implication of the doctrine that all idea systems have a class basis and a class bias. As a way out of the dilemma heenvisaged the possibility of a classless class of intellectuals, a "socially unattached intelligentia," as he put it, capable of thinking independently by virtue of its independence from any class interest or affiliation. Such a detached group might hope to acquire knowledge that was not ideology.

Freudian support

THE POLITICAL CONTEXT

Ideology, rationalism, and romanticism. If some theorists emphasize the kinship between ideology and various forms of religious enthusiasm, others stress the connection between ideology and what they call rationalism, or the attempt to understand politics in terms of abstract ideas rather than of lived experience. Like Napoleon, who held that ideology is par excellence the work of intellectuals, some theorists are suspicious of those who think they know about politics because they have read many books; they believe that politics can be learned only by an apprenticeship to politics itself.

Such people are not unsympathetic to political theories, such as Locke's, but they argue that their value resides in the facts that are derived from experience. Michael Oakeshott in England has described Locke's theory of political liberty as an "abridgment" of the Englishman's traditional understanding of liberty, and has suggested that once such a conception is uprooted from the tradition that has given it meaning it becomes a rationalistic doctrine or metaphysical abstraction, like those liberties contained in the Declaration of the Rights of Man, which were so much talked about after the French Revolution but rarely actually enjoyed, in France or elsewhere.

Whereas Oakeshott has seen ideology as a form of rationalism, Edward Shils, a U.S. political scientist, has seen it more as a product of, among other things, romanticism with an extremist character. His argument is that romanticism has fed into and swelled the seas of ideological politics by its cult of the ideal and by its scorn for the actual, especially its scorn for what is mediated by calculation and compromise. Since civil politics demands both compromise and contrivance and calls for a prudent self-restraint and responsible caution, he suggests that civil politics is bound to be repugnant to romanticism. Hence Shils concludes that the romantic spirit is naturally driven

toward ideological politics. Existential

critique of

ideology

Ideology and terror. The "total" character of ideology, its extremism and violence, have been analyzed by other critics, among whom the French philosopher-writer Albert Camus and the Austrian-born British philosopher Sir Karl Popper merit particular attention. Beginning as an Existentialist who subscribed to the view that "the universe is absurd," Camus passed to a personal affirmation of justice and human decency as compelling values to be realized in conduct. An Algerian by birth, Camus also appealed to what he believed to be the "Mediterranean" tradition of moderation and human warmth and joy in living as opposed to the "northern" Germanic tradition of fanatical, puritan devotion to metaphysical abstractions. In his book The Rebel (L'Homme révolté), he argued that the true rebel is not the man who conforms to the orthodoxy of some revolutionary ideology, but a man who could say "no" to injustice. He suggested that the true rebel would prefer the politics of reform, such as that of modern trade-union socialism, to the totalitarian politics of Marxism or similar movements. The systematic violence of ideology-the crimes de logique that were committed in its name-appeared to Camus to be wholly unjustifiable. Hating cruelty, he believed that the rise of ideology in the modern world had added enormously to human suffering. Though he was willing to admit that the ultimate aim of most ideologies was to diminish human suffering, he argued that good ends did not authorize the use of evil means.

A somewhat similar plea for what he called "piecemeal social engineering" was put forward by Popper, who argued that ideology rests on a logical mistake: namely the notion that history can be transformed into science. In The Logic of Scientific Discovery (Logik der Forschung), Popper suggested that the true method of science was not one of observation, hypothesis, and confirmation but one of conjecture and experiment, in which the concept

of falsification played a crucial role. By this concept he meant that in science there is a continuing process of trial and error; conjectures are put to the test of experiment. and those that are not falsified are provisionally accepted; thus there is no definitive knowledge but only provisional knowledge that is constantly being corrected. Popper saw in the enterprise of ideology an attempt to find certainty in history and to produce predictions on the model of what were supposed to be scientific predictions. Ideologists, he argued, because they have a false notion of what science is can produce only prophecies, which are quite distinct from scientific predictions and which have no scientific validity whatever. Though Popper was well disposed toward the idea of a "scientific" approach to politics and ethics, he suggested that a full awareness of the importance of trial and error in science would prompt one to look for similar forms of "negative judgment" elsewhere.

By no means are all ideologists explicit champions of violence, but it is characteristic of ideology both to exalt action and to regard action in terms of a military analogy. Some observers have pointed out that one has only to consider the prose style of the founders of most ideologies to be struck by the military and warlike language that they habitually use, including words like struggle, resist, march. victory, and overcome; the literature of ideology is replete with martial expressions. In such a view, commitment to an ideology becomes a form of enlistment so that to become the adherent of an ideology is to become

a combatant or partisan

In the years that followed World War II, a number of ideological writers went beyond the mere use of military language and made frank avowals of their desire for violence-not that it was a new thing to praise violence. The French political philosopher Georges Sorel, for example, had done so before World War I in his book Reflections on Violence. Sorel was usually regarded as being more a Fascist than a Socialist. He also used the word violence in his own special way; by violence Sorel meant passion, not the throwing of bombs and the burning of buildings,

Violence found eloquent champions in several black militant writers of the 1960s, notably the Martinican theorist Frantz Fanon. Moreover, several of the French philosopher Jean-Paul Sartre's dramatic writings turn on the theme that "dirty hands" are necessary in politics and that a man with so-called bourgeois inhibitions about bloodshed cannot usefully serve a revolutionary cause. Sartre's attachment to the ideal of revolution tended to increase as he grew older, and in some of his later writings he suggested that violence might even be a good thing in itself.

In considering Sartre's views on the subject of ideology it must be noted that Sartre sometimes used the word ideology in a sense peculiarly his own. In an early section of his Search for a Method (Critique de la raison dialectique), Sartre drew a distinction between philosophies and ideologies in which he reserved the term philosophy for those major systems of thought, such as the Rationalism of Descartes or the Idealism of Hegel, which dominate men's minds at a certain moment in history. He defined an ideology as a minor system of ideas, living on the margin of the genuine philosophy and exploiting the domain of the greater system. What Sartre proposed in this work was a revitalization and modernization of the "major philosophy" of Marxism through the integration of elements drawn from the "ideology," or minor system, of Existentialism. What emerged from the book was a theory in which the Existentialist elements are more conspicuous than the Marxist.

Ideology and pragmatism. A distinction is often drawn between the ideological and the pragmatic approach to politics, the latter being understood as the approach that treats particular issues and problems purely on their merits and does not attempt to apply doctrinal, preconceived remedies. Theorists have debated whether or not politics has become less ideological and whether a pragmatic approach can be shown to be better than an ideological one.

On the first question, there seemed to be good reason for thinking that after the death of Stalin and the repudiation of Stalinism by the Communist Party, the Soviet Union, at least, was becoming more interested in the "pragmatic"

Sartrian ideology concerns of national security and the balance of power and less interested in the ideological aim of fostering universal Communism. This in turn seemed to many to have resulted-in both the United States and the Soviet Unionin a shift toward a pragmatic policy of coexistence and a peaceful division of spheres of influence. There were indications in many countries that the old antagonisms between capitalist and socialist ideologies were giving way to a search for techniques for making a mixed economy work more effectively for the good of all.

But while many observers believed that there was much evidence of a decline of ideology in the latter 1950s, others believed that there were equally manifest signs in the following decade of a revival of ideology, if not within the major political parties, then at least among the public generally. Throughout the world various left-wing movements emerged to challenge the whole ethos on which pragmatic politics was based. Not all these ideologies were coherent, and none possessed the elaborate intellectual structure of the 19th-century ideologies; but together they served to demonstrate that the end of ideology was not yet at hand.

As suggested earlier, certain controversies about ideology have to some extent been rooted in the ambiguity of the word itself, and this is perhaps especially relevant to the confrontation between ideology and pragmatism, since the word pragmatism raises problems no less intractable than those involved in connection with the word ideology. In the senses outlined at the beginning of this article, ideology is manifestly not the only alternative to pragmatism in politics, and to reject ideology would not necessarily be to adopt pragmatism. Ordinary language does not yet yield as many words as political science needs to clarify the question, and it becomes necessary to introduce such expressions as belief system, or to name the relevant distinctions, to further the analysis.

Almost any approach to politics constitutes a belief system of one kind or another. Some such belief systems are more structured, more ordered, and generally systematic than others. Though an ideology is a type of belief system. not all belief systems are ideologies. One man's belief system may consist of a congeries of ill-assorted prejudices and inarticulate assumptions. Another's may be the result of deep reflection and careful study. It is sometimes felt to be convenient to speak of a belief system of this latter type as a philosophy or, better, to distinguish it from philosophy in the technical or academic sense, as a Weltanschauung (literally, a "view of the world").

The confrontation between ideology and pragmatism may be more instructive if it is translated into a distinction between the ideological and the pragmatic, taking these two adjectives as extremes on a sliding scale. From this perspective, it becomes possible to speak of differences of degree, to speak of an approach to politics as being more or less ideological, more or less pragmatic. At the same time it becomes possible to speak of a belief system such as liberalism as lending itself to a variety of forms, tending at the one extreme toward the ideological, and at the other toward the pragmatic.

THE CONTEXT OF INTERNATIONAL RELATIONS

It has been said that ideology has transformed international relationships in the 20th century-in appearance at least. Earlier centuries experienced dynastic wars, national, civil, and imperial wars, and diplomacy designed to further national security or national expansion or to promote mutual advantages and general peace. Such factors, indeed, appeared to govern international relations until recent times. by ideology International relations today are seemingly dominated more often than not by the exigencies of "-isms": wars are fought, alliances are made, and treaties are signed because of ideological considerations. The balance of power in the contemporary world is a balance weighted by ideological commitment. "The Communist bloc" confronts "the Free peoples," and in the "Third World" emergent nations cultivate a nationalist, anticolonialist ideology in their search for identity and their efforts to achieve modernity.

But this is not to assert that ideological wars, or ideological diplomacy, are entirely new. What has become the most conspicuous element in contemporary international relations-so conspicuous that other elements are often entirely ignored-was present, to a lesser degree, in earlier international relations. It is necessary here to distinguish between the actual events of history and the interpretations that are put on history, for some events lend themselves more readily than others to an ideological interpretation. The ideological perspective has become increasingly significant as the general public has come to play a role in considering questions of war and peace. When questions of defense and diplomacy were settled by kings and their ministers and wars were fought by professional soldiers and sailors, the public was not expected to have any opinion about international relations, and in such a situation there was little place for ideology.

Ideology in the World Wars. In the course of World War I, however, a new element appeared to have been introduced. The war was seen by those who experienced it as being in its early stages a national war of the traditional kind, and as such it was not at first expected to assume any profoundly disturbing form. Each combatant people viewed itself as fighting for king and country in a just war. But by 1916 the Allies were being urged to think of their endeavour as a war "to make the world safe for democracy," and the Germans, on their side, were correspondingly encouraged to visualize the war as a struggle of "culture" against "barbarism." On both sides, the casualties were far more terrible than anyone had foreseen, and the need to sustain the will to war by an appeal to ideology was plainly felt by all the nations involved. Whether such "war aims" were really the main objectives of the governments concerned is another question; what is important is that, as the need was increasingly felt for a justification of war, the justification took an ideological form. Whether or not World War I changed its real nature between 1914 and 1918, the prevailing conception of it underwent significant alteration. This became more marked after the Russian Revolution of 1917, when the Bolsheviks submitted to harsh German peace terms for reasons that were not only practical but ideological—namely, the preservation and promotion of Communism. Pres. Woodrow Wilson took the United States into the war on the Allied side with an alternative ideological vision-that of ensuring permanent peace through the League of Nations and of establishing democratic governments in all the conquered countries.

The rise of Communism clearly marked a corresponding increase in the role of ideology in international relations. Fascism helped to speed the process. The Spanish Civil War of the 1930s was an almost clear-cut confrontation between the ideologies of left and right (not entirely clear-cut because of the ambiguous relationship between Communism and anarchism).

The precise extent of ideological commitment in World War II is a matter of some controversy. At one level, the 1939 war is seen as a continuation of the war of 1914. Two of the leading protagonists-Great Britain and the United States-agreed more in their anti-ideological stance and their hostility to Nazism than in promoting an alternative ideology. Pres. Franklin D. Roosevelt, suspicious of British and French imperialism and eager to cultivate a progressive ideological outlook, was critical of Prime Minister Winston Churchill's politics, hostile toward Charles de Gaulle's, but surprisingly tolerant of Joseph Stalin's. The revival of Wilson's idealistic war aims in the Atlantic Charter provided a basis for a kind of general ideological union of the Allies. But such formulations proved to be of small significance compared to the profound ideological commitment of the Soviet Union to Communism, and that of the United States to an international position more ideologically anti-Communist than pro anything

Ideology of the Cold War. What came to be called the Cold War in the 1950s must be understood, to a large extent, as an ideological confrontation, and, whereas Communism is manifestly an ideology, the "non-Communism," or even the "anti-Communism," of the West is negatively ideological. To oppose one ideology is not necessarily to subscribe to another, although there is a strong body of opinion in the West that feels that the free world needs a coherent ideology if it is to resist successfully an opposing ideology.

Ideology and the will to

fight

"Anti-" and "non-"

Dominance of contemporary international

relations

Pragma-

tism

The connection between international wars and ideology can be better expressed in terms of a difference of degree rather than of kind; some wars are more ideological than others, although there is no clear boundary between an ideological and nonideological war. An analogy with the religious wars of the past is evident, and there is indeed some historical continuity between the two types of war. The Christian Crusades against the Turks and the wars between Catholics and Protestants in early modern Europe have much in common with the ideological conflicts of the contemporary period. Religious wars are often communal wars, as witness those between Hindus and Muslims in India; but an "ideological" element of a kind can be discovered in many religious wars, even those narrated in the Old Testament, in which the people of Israel are described as fighting for the cause of righteousness-fighting, in other words, for a universal abstraction as distinct from a local and practical aim. In the past this "ideological" element has in the main been subsidiary; what is characteristic of the modern period is that the ideological element has become increasingly dominant, first in the religious wars (and the related diplomacy) that followed the Reformation and then in the political wars and diplomacy of recent times.

A useful introduction is M. SELIGER, Ideology BIBLIOGRAPHY. and Politics (1976), which works from a broad definition of the concept of ideology. JOHN PLAMENATZ, Ideology (1970), is a clear and uncomplicated study by a distinguished Oxford philosopher. JEAN BAECHLER, Qu'est-ce que l'idéologie? (1976), is characteristically French in its approach and affords an equally lucid introduction to both the sociological and the historical aspects of the problem. Other books written at a fairly popular level include PATRICK CORBETT, Ideologies (1966); ROY C. MACRIDIS, Contemporary Political Ideologies: Movements and Regimes, 5th ed. (1992); and LEON P. BARADAT, Political Ideologies: Their Origins and Impact, 5th ed. (1993).

Few of the works of the original French idéologues are available in modern editions and even fewer in English translations. However, RICHARD H. COX (ed.), Ideology, Politics, and Political Theory (1969), contains short translated excerpts from Destutt de Tracy and his contemporaries as well as from more recent works. A.L.C. DESTUTT DE TRACY, A Treatise on Political Economy, trans. from French, rev. by THOMAS JEFFERSON (1817, reprinted 1973), is his major work in the field; and the expository study by FRANÇOIS JOSEPH PICAVET, Les Idéologues (1891, reprinted 1975), remains a classic. The life of Destutt de Tracy and his role in the origins of ideology are traced in EM-MET KENNEDY, A Philosophe in the Age of Revolution: Destutt de Tracy and the Origins of "Ideology" (1978).

GEORGE LICHTHEIM, The Concept of Ideology (1967), contains a short but well-informed and sympathetic analysis of ideology as it figures in Hegelian and Marxist thought. LOUIS ALTHUSSER, Politics and History: Montesquieu, Rousseau, Hegel, and Marx, trans. from French (1972, reissued as both Politics and History: Montesquieu, Rousseau, and Marx and Montesquieu, Rousseau. Marx: Politics and History, 1982), traces the relationship between Hegelian and Marxist thought. G.W.F. HEGEL, Lectures on the Philosophy of History (1857, reissued 1956; originally published in German, 3rd ed., 1848), shows relevant elements in his philosophy. Valuable commentaries are provided by ALEXANDRE KOJEVE, Introduction to the Reading of Hegel (1969, reissued 1980; originally published in French, 1947); CHARLES TAYLOR, Hegel (1975); and JEAN HYPPOLITE, Studies on Marx and Hegel (1969, reissued 1973; originally published on Marx and riege (1905, ISSNEY 1773, VIRGINALLY PROVINCIAL IN FRIEDRICH ENGELS, The German Ideology, rev. ed., 2 vol. in 1 (1976; originally published in German, 1932), is the fundamental text. Recent treatments of ideology in the Marxist tradition include ALVIN W. GOULDNER, The Dialectic of Ideology and Technology (1976, reissued 1982); JORGE LARRAIN, The Concept of Ideology (1979, reprinted 1992), and Marxism and Ideology of nacional (197); custimes 1972, sin a Markism and nacology (1983, reprinted 1991); cust Sunner, Reading Ideologies: An Investigation into the Markist Theory of Ideology and Law (1979); and 109 succassives, The Read World of Ideology and Jaw (1979); and 109 succassives, The Read World of Ideology and Political Analysis (1981).

The Concept of Ideology and Political Analysis (1981).

Writers who have attempted to formulate a neo-Marxist theory of ideology, drawing in part on Hegelian philosophy, include HERBERT MARCUSE, One Dimensional Man (1964, reissued 1991); JÜRGEN HABERMAS, Toward a Rational Society (1971); and KARL MANNHEIM, Ideology and Utopia, new ed. (1991; originally published in German, 1929). Also worthy of attention are LOUIS ALTHUSSER, Essays on Ideology (1984); and RAYMOND BOUDON, The Analysis of Ideology (1989; originally published in French, 1986).

Interpretations of ideology that are directly opposed to Marxist theory include JAMES R. FLYNN, Humanism and Ideology (1973); LEWIS S. FEUER, Ideology and the Ideologists (1975): (1973); LEWIS S. FEUER, Ideology and the Ideology (1971); MARTIN SELIGER, The Marxist Conception of Ideology (1970); and D.J. MANNING (ed.), The Form of Ideology (1980). IEAN-PAUL SARTRE, Critique of Dialectical Reason (1976; originally published in French, 1960), constructs a theory of ideology as "marginal system of ideas" that is consciously designed as an

alternative to Marxist theory.

Historical studies that take a relatively extensive view of the impact of ideology as a revolutionary force in the modern world are JAMES H. BILLINGTON, Fire in the Minds of Men (1980); MELVIN J. LASKY, Utopia and Revolution (1976); and IEANNE HERSCH, Idéologies et réalité (1956). HANS KOHN, Po-litical Ideologies of the Twentieth Century, 3rd ed. rev. (1966); ISAAC KRAMNICK and FREDERICK M. WATKINS, The Age of Ideology. Political Thought, 1750 to the Present, 2nd ed. (1979); and TRYGVE R. THOLFSEN, Ideology and Revolution in Modern Europe: An Essay on the Role of Ideas in History (1984), treat ideology as the dominant characteristic of modern political thinking. More polemical commentaries on the development of ideology include ALBERT CAMUS, The Rebel (1953, reissued 1991; originally published in French, 1951; ISAN FRANÇOIS REVEL, Pourquoi des philosophes? (1957, reissued 1976); and KARL POPPER, The Poverty of Historicism (1957, reissued 1986). A systematic critique of the whole notion of ideological politics may be found in MICHAEL OAKESHOTT, On Human Conduct (1975, reissued 1991), On History and Other Essays (1983), and Rationalism in Politics, new and expanded ed. (1991).

RAYMOND ARON, The Opium of the Intellectuals (1957. reprinted 1985; originally published in French, 1955), points to a decline in ideological politics in the West; as does DANIEL BELL, The End of Ideology, rev. ed. (1962, reissued 1988). Less confident views are advanced in DAVID E. APTER (ed.), Ideology and Discontent (1964); and SIDNEY HOOK, Pragmatism and the Tragic Sense of Life (1975). An excellent compilation of the contrasting positions in the "End of Ideology" debate is CHAIM I. WAXMAN (ed.), The End of Ideology Debate (1968). FRANCIS FUKUYAMA, The End of History and the Last Man (1992), asserts that all ideological alternatives to liberal democracy have

been discredited.

Sociological aspects of ideology are explored in DONALD G. Macrae, Ideology and Society (1961); NORMAN BIRNBAUM, The Sociological Study of Ideology (1940-1960) (1962); ERIC CARL-TON, Ideology and Social Order (1977); FRANÇOIS BOURRICAUD, Le Bricolage idéologique (1980); and GRAHAM C. KINLOCH, Ideology and Contemporary Sociological Theory (1981).

The relationship between ideology and political domination is examined in QUINTIN HOARE and GEOFFREY NOWELL SMITH (eds. and trans.), Selections from the Prison Notebooks of Antonio Gramsci (1971, reissued 1987). ARNE NAESS, Democracy, Ideology, and Objectivity (1956), written from the perspective of political philosophy, was the first of a series of works that investigate the relationship between ideology and liberty. Others worthy of mention are Z.A. JORDAN, Philosophy and Ideology (1963); JUDITH N. SHKLAR (ed.), Political Theory and Ideology ogy (1966); DANTE GERMINO, Beyond Ideology (1967, reprinted 1976); and MAURICE CRANSTON and PETER MAIR (eds.), Ideology and Politics (1980). KENNETH MINOGUE, Alien Powers: The Pure Theory of Ideology (1985), uses both a philosophical and a historical approach to provide a far-reaching survey of the subject. Among books that stay close to the main tradition of American political science, the following are notable: ROBERT E. LANE, Political Ideology (1962); WILLIAM E. CONNOLLY, Political Science & Ideology (1967); and ROBERT A. DAHL, After the Revolution?, rev. ed. (1990). ANDREW GYORGY and GEORGE D. BLACKWOOD, Ideologies in World Affairs (1967), analyzes the emergence of ideology as a decisive factor in international relations. Students interested in such modern ideologies as environmentalism and animal rights should consult IAN ADAMS. Political Ideology Today (1993). (M.C./Ed.)

Immunity

mmunity is the ability of humans and other advanced vertebrates to repel disease-causing organisms (pathogens). Immunity from disease is actually conferred by two cooperative mechanisms of the immune system, one called nonspecific, innate immunity and the other specific, acquired immunity. Nonspecific protective mechanisms repel all microorganisms equally, while the specific immune responses are tailored to particular types of invaders. Both systems work together to thwart organisms from entering and proliferating within the body. These immune mechanisms also help eliminate abnormal cells of the body that can develop into cancer.

This article provides a detailed explanation of how nonspecific and specific immunity function and how the immune system evolved. The article also discusses various immune system disorders, including immune deficiencies, allergies, autoimmune disorders, and lymphocyte cancers. For additional information on leukemias, lymphomas, and myelomas, see the article CANCER.

The article is divided into the following sections:

The immune system 773 Nonspecific, innate immunity 773 Barriers against infection Nonspecific responses to infection Specific, acquired immunity The nature of lymphocytes B-cell antigen receptors and antibodies T-cell antigen receptors Life cycle of lymphocytes Activation of lymphocytes Antibody-mediated immune mechanisms Cell-mediated immune mechanisms Immunity against cancer Prophylactic immunization Production of monoclonal antibodies Evolution of the immune system 787

THE IMMUNE SYSTEM

Nonspecific, innate immunity

BARRIERS AGAINST INFECTION

Most microorganisms encountered in daily life are repelled before they cause detectable signs and symptoms of disease. These potential pathogens, which include viruses, bacteria, fungi, protozoans, and worms, are quite diverse, and therefore a nonspecific defense system that diverts all types of this varied microscopic horde equally is quite useful to an organism. The innate immune system provides this kind of nonspecific protection through a number of defense mechanisms, which include physical barriers such as the skin, chemical barriers such as antimicrobial proteins that harm or destroy invaders, and cells that attack foreign cells and body cells harbouring infectious agents. The details of how these mechanisms operate to protect the hody are described in this section.

External barriers. The skin and the mucous membrane linings of the respiratory, gastrointestinal, and genitourinary tracts provide the first line of defense against invasion by microbes or parasites. Human skin has a tough outer layer of cells that produce keratin. This layer of cells, which is constantly renewed from below, serves as a mechanical barrier to infection. In addition, glands in the skin secrete oily substances that include fatty acids, such as oleic acid, that can kill some bacteria; skin glands also secrete lysozyme, an enzyme (also present in tears and saliva) that can break down the outer wall of certain bacteria. Victims of severe burns often fall prey to infections from normally harmless bacteria, illustrating the importance of intact, healthy skin to a healthy immune system.

Like the outer layer of the skin but much softer, the mucous membrane linings of the respiratory, gastrointestinal, and genitourinary tracts provide a mechanical barrier of cells that are constantly being renewed. The lining of the respiratory tract has cells that secrete mucus (phlegm), which traps small particles. Other cells in the wall of the respiratory tract have small hairlike projections called cilia, which steadily beat in a sweeping movement that propels the mucus and any trapped particles up and out of the throat and nose. Also present in the mucus are protective antibodies, which are products of specific immunity. Cells in the lining of the gastrointestinal tract secrete mucus that, in addition to aiding the passage of food, can trap potentially harmful particles or prevent them from attaching to cells that make up the lining of the gut. Protective antibodies are secreted by cells underlying the gastrointestinal lining. Furthermore, the stomach lining secretes hydrochloric acid that is strong enough to kill many microbes.

Chemical barriers. Some microbes penetrate the body's protective barriers and enter the internal tissues. There they encounter a variety of chemical substances that may prevent their growth. These substances include chemicals whose protective effects are incidental to their primary function in the body, chemicals whose principal function is to harm or destroy invaders, and chemicals produced by naturally occurring bacteria.

Some of the chemicals involved in normal body processes are not directly involved in defending the body against disease. Nevertheless, they do help repel invaders. For example, chemicals that inhibit the potentially damaging digestive enzymes released from body cells that have died in the natural course of events also can inhibit similar enzymes produced by bacteria, thereby limiting bacterial growth. Another substance that provides protection against microbes incidentally to its primary cellular role is the blood protein transferrin. The normal function of transferrin is to bind molecules of iron that are absorbed into the bloodstream through the gut and to deliver the iron to cells, which require the mineral to grow. The protective benefit transferrin confers results from the fact that bacteria, like cells, need free iron to grow. As long as it is bound to transferrin, however, iron is unavailable to the invading microbes, and thus their growth is stemmed.

A number of proteins contribute directly to the body's nonspecific defense system by helping to destroy invading microorganisms. One group of such proteins is termed complement because it works with other defense mechanisms of the body, complementing their efforts to eradicate invaders. Many microorganisms can activate complement in ways that do not involve specific immunity. Once activated, complement proteins work together to lyse, or break apart, harmful infectious organisms that do not have protective coats. Other microorganisms can evade these mechanisms but fall prey to scavenger cells, which engulf and destroy infectious agents, and to the mechanisms of the specific immune response. Complement cooperates with both nonspecific and specific defense systems and is described more fully below (see Antibody-mediated immune mechanisms).

Interferons

Another group of proteins that provide protection are the interferons, which inhibit the replication of many-but not all-viruses. Cells that have been infected with a virus produce interferon, which sends a signal to other cells of the body to resist viral growth. When first discovered in 1957, interferon was thought to be a single substance, but since then several types have been discovered, each produced by a different type of cell. Alpha interferon is produced by white blood cells other than lymphocytes, beta interferon by fibroblasts, and gamma interferon by lymphocytes. All interferons inhibit viral replication by interfering with the transcription of viral nucleic acid. Interferons exert additional inhibitory effects by regulating the extent to which lymphocytes and other cells express certain important molecules on their surface membranes and by stimulating the activity of natural killer cells, which are described below.

In the small and large intestines the growth of invading bacteria can be inhibited by naturally gut-dwelling bacteria that do not cause disease. These gut-dwelling microorganisms secrete a variety of proteins that enhance their own survival by inhibiting the growth of the invading bacterial

Cellular defenses. If an infectious agent is not successfully repelled by the chemical and physical barriers described above, it will encounter cells whose function is to eliminate foreign substances that enter the body. These cells are the nonspecific effector cells of the innate immune response. They include scavenger cells-i.e., various cells that attack infectious agents directly-and natural killer cells, which attack cells of the body that harbour infectious organisms. Some of these cells destroy infectious agents by engulfing and destroying them through the process of phagocytosis, while other cells resort to alternative means. As is true of other components of innate immunity, these cells interact with components of acquired immunity to fight infection.

Scavenger cells. All higher animals and many lower ones have scavenger cells-primarily leukocytes (white blood cells)-that destroy infectious agents. Most vertebrates, including all birds and mammals, possess two main kinds of scavenger cells. Their importance was first recognized in 1884 by the Russian biologist Élie Metchnikoff, who named them microphages and macrophages, after Greek words meaning "little eaters" and "big eaters.

Microphages are now called either granulocytes, because of the numerous chemical-containing granules found in their cytoplasm, or polymorphonuclear leukocytes, because of the oddly shaped nucleus these cells contain. Some granules contain digestive enzymes capable of breaking down proteins, while others contain bacteriocidal (bacteria-killing) proteins. There are three classes of granulocytes-neutrophils, eosinophils, and basophilsthat are distinguished according to the shape of the nucleus and the way in which the granules in the cytoplasm are stained by dye. The differences in staining characteristics reflect differences in the chemical makeup of the granules. Neutrophils are the most common type of granulocyte, making up about 60 to 70 percent of all white blood cells. These granulocytes ingest and destroy microorganisms, especially bacteria. Less common are the eosinophils, which are particularly effective at damaging the cells that make up the cuticle (body wall) of larger parasites. Fewer still are the basophils, which release heparin (a substance that inhibits blood coagulation), histamine, and other substances that play a role in some allergic reactions (see below Immune system disorders: Allergies). Very similar in structure and function to basophils are the tissue cells called mast cells, which also contribute to immune responses.

Granulocytes, which have a life span of only a few days, are continuously produced from stem (i.e., precursor) cells in the bone marrow. They enter the bloodstream and circulate for a few hours, after which they leave the circulation and die. Granulocytes are mobile and are attracted to foreign materials by chemical signals, some of which are produced by the invading microorganisms themselves, others by damaged tissues, and still others by the interaction between microbes and proteins in the blood plasma. Some microorganisms produce toxins that poison granulocytes and thus escape phagocytosis; other microbes are indigestible and are not killed when ingested. By themselves, then, granulocytes are of limited effectiveness and require reinforcement by the mechanisms of specific immunity.

The other main type of scavenger cell is the macrophage. the mature form of the monocyte (see Figure 1). Like granulocytes, monocytes are produced by stem cells in the bone marrow and circulate through the blood, though in lesser numbers. But, unlike granulocytes, monocytes undergo differentiation, becoming macrophages that settle in many tissues, especially the lymphoid tissues (e.g., spleen and lymph nodes) and the liver, which serve as filters for trapping microbes and other foreign particles that arrive through the blood or the lymph. Macrophages live longer than granulocytes and, although effective as scavengers, basically provide a different function. Compared with granulocytes, macrophages move relatively sluggishly. They are attracted by different stimuli and usually arrive at sites of invasion later than granulocytes. Macrophages recognize and ingest foreign particles by mechanisms that are basically similar to those of granulocytes, although the digestive process is slower and not as complete. This aspect is of great importance for the role that macrophages play in stimulating specific immune responses-something in which granulocytes play no part (see below Activation of lymphocytes).

Natural killer (NK) cells. Natural killer cells do not attack invading organisms directly but instead destroy the body's own cells that have either become cancerous or been infected with a virus. NK cells were first recognized in 1975, when researchers observed cells in the blood and lymphoid tissues that were neither the scavengers described above nor ordinary lymphocytes but which nevertheless were capable of killing cells. Although similar in outward appearance to lymphocytes, NK cells contain granules that harbour cytotoxic chemicals. NK cells recognize dividing cells by a mechanism that does not depend on specific immunity. They then bind to these dividing cells and insert their granules through the outer membrane and into the cytoplasm. This causes the dividing cells to leak and die. It is not certain whether NK cells belong to a distinct lineage or are a special form of lymphocyte. It is known that they are stimulated by gamma interferon. Their main biological role may be to regulate the growth of stem cells in the bone marrow and elsewhere.

NONSPECIFIC RESPONSES TO INFECTION

The body has a number of nonspecific methods of fighting infection that are called early induced responses. They include the acute-phase response and the inflammation response, which can eliminate infection or hold it in check until specific, acquired immune responses have time to develop. Nonspecific immune responses occur more rapidly than acquired immune responses do, but they do not provide lasting immunity to specific pathogens.

Nonadaptive immune responses rely on a number of chemical signals, collectively called cytokines, to carry out their effects. These cytokines include members of the family of proteins called interleukins, which induce fever and the acute-phase response, and tumour necrosis factoralpha, which initiates the inflammatory response.

Acute-phase response. When the body is invaded by a pathogen, macrophages release the protein signals interMacrophages

Granulocytes

structures of a macrophage.

and eosinophils, which help fight infection.

Inter-

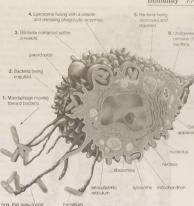

leukins

leukin-1 (IL-1) and interleukin-6 (IL-6) to help fight the infection. One of their effects is to raise the temperature of the body, causing the fever that often accompanies infection. (The interleukins increase body temperature by acting on the temperature-regulating hypothalamus in the brain and by affecting energy mobilization by fat and muscle cells.) Fever is believed to be helpful in eliminating infections because most bacteria grow optimally at temperatures lower than normal body temperature. But fever is only part of the more general innate defense mechanism called the acute-phase response. In addition to raising body temperature, the interleukins stimulate liver cells to secrete increased amounts of several different proteins into the bloodstream. These proteins, collectively called acute-phase proteins, bind to bacteria and, by doing so, activate complement proteins that destroy the pathogen. The acute-phase proteins act similarly to antibodies but are more democratic-that is, they do not distinguish between pathogens as antibodies do but instead attack a wide range of microorganisms equally. Another effect the interleukins have is to increase the number of circulating neutrophils

Inflammatory response. Infection often results in tissue damage, which may trigger an inflammatory response. The signs of inflammation include pain, swelling, redness, and fever, which are induced by chemicals released by macrophages. These substances promote blood flow to the area, increase the permeability of capillaries, and induce coagulation. The increased blood flow is responsible for redness, and the leakiness of the capillaries allows cells and fluids to enter tissues, causing pain and swelling. These effects bring more phagocytic cells to the area to help eliminate the pathogens. The first cells to arrive, usually within an hour, are neutrophils and eosinophils, followed a few hours later by macrophages. Macrophages not only engulf pathogens but also help the healing process by disposing of cellular debris which accumulates from destroyed tissue cells and neutrophils that self-destruct after ingesting microorganisms. If infection persists, components of specific immunity-antibodies and T cells-arrive at the site to fight the infection.

Specific, acquired immunity

It has been known for centuries that persons who have contracted certain diseases and survived generally do not catch those illnesses again. The Greek historian Thucydides recorded that, when the plague was raging in Athens during the 5th century BC, the sick and dying would have received no nursing at all had it not been for the devotion

of those who had already recovered from the disease; it was known that no one ever caught the plague a second time. The same applies, with rare exceptions, to many other diseases, such as smallpox, chicken pox, measles, and mumps. Yet having had measles does not prevent a child from contracting chicken pox, or vice versa. The protection acquired by experiencing one of these infections is specific for that infection; in other words, it is due to specific, acquired immunity, also called adaptive immunity.

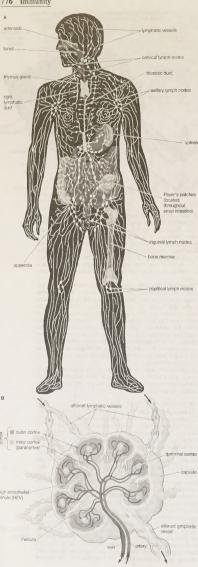

There are other infectious conditions, such as the common cold, influenza, pneumonia, and diarrheal diseases, which can be caught again and again; these seem to contradict the notion of specific immunity. But the reason such illnesses can recur is that many different infectious agents produce similar symptoms (and thus the same disease). For example, more than 100 viruses can cause the cluster of symptoms known as the common cold. Consequently, even though infection with a particular agent does protect against reinfection by that same pathogen, it does not confer protection from other pathogens that have not been encountered.

Acquired immunity is dependent on the specialized white blood cells known as lymphocytes. This section describes the various ways in which lymphocytes operate to confer specific immunity.

THE NATURE OF LYMPHOCYTES

General characteristics. Location in the immune system. Lymphocytes are the cells responsible for the body's ability to distinguish and react to an almost infinite number of different foreign substances, including those of which microbes are composed. Lymphocytes are mainly a dormant population, awaiting the appropriate signals to be stirred to action. The inactive lymphocytes are small, round cells filled largely by a nucleus. Although they have only a small amount of cytoplasm compared with other cells, each lymphocyte has sufficient cytoplasmic organelles (small functional units such as mitochondria, the endoplasmic reticulum, and a Golgi apparatus) to keep the cell alive. Lymphocytes move only sluggishly on their own, but they can travel swiftly around the body when carried along in the blood or lymph. At any one time an adult human has approximately 2 × 1012 lymphocytes, about 1 percent of which are in the bloodstream. The majority are concentrated in various tissues scattered throughout the body, particularly the bone marrow, spleen, thymus, lymph nodes, tonsils, and lining of the intestines, which make up the lymphatic system (see Figure 2). Organs or tissues containing such concentrations of lymphocytes are termed

Lymphoid tissues

lymphoid. The lymphocytes in lymphoid structures are free to move, although they are not lying loose; rather, they are confined within a delicate network of lymph capillaries located in connective tissues that channel the lymphocytes so that they come into contact with other cells, especially macrophages, that line the meshes of the network. This ensures that the lymphocytes interact with each other and with foreign materials trapped by the macrophages in an ordered manner.

T and B cells. Lymphocytes originate from stem cells in the bone marrow; these stem cells divide continuously, releasing immature lymphocytes into the bloodstream. Some of these cells travel to the thymus, where they multiply and differentiate into T lymphocytes, or T cells. The "T" stands for thymus-derived, referring to the fact that these cells mature in the thymus. Once they have left the thymus, T cells enter the bloodstream and circulate to and within the rest of the lymphoid organs, where they can multiply further in response to appropriate stimulation. About half of all lymphocytes are T cells.

Some lymphocytes remain in the bone marrow, where they differentiate and then pass directly to the lymphoid organs. They are termed B lymphocytes, or B cells, and they, like T cells, can mature and multiply further in the lymphoid organs when suitably stimulated. Although it is appropriate to refer to them as B cells in humans and other mammals, because they are bone-marrow derived, the "B" actually stands for the bursa of Fabricius, a lymphoid organ found only in birds, the organisms in which B cells were first discovered.

B and T cells both recognize and help eliminate foreign molecules (antigens), such as those that are part of invading organisms, but they do so in different ways. B cells secrete antibodies, proteins that bind to antigens. Since antibodies circulate through the humours (i.e., body fluids), the protection afforded by B cells is called humoral immunity. T cells, in contrast, do not produce antibodies but instead directly attack invaders. Because this second type of acquired immunity depends on the direct involvement of cells rather than antibodies, it is called cell-mediated immunity. T cells recognize only infectious agents that have entered into cells of the body, whereas B cells and antibodies interact with invaders that remain outside the body's cells. These two types of specific, acquired immunity, however, are not as distinct as might be inferred from this description, since T cells also play a major role in regulating the function of B cells. In many cases an immune response involves both humoral and cell-mediated assaults on the foreign substance. Furthermore, both classes of lymphocytes can activate or enhance a variety of nonspecific immune responses.

Ability to recognize foreign molecules. Receptor mole-Lymphocytes are distinguished from other cells by their capacity to recognize foreign molecules. Recognition is accomplished by means of receptor molecules. A receptor molecule is a special protein whose shape is complementary to a portion of a foreign molecule. This complementarity of shape allows the receptor and the foreign molecule to conform to each other in a fashion roughly analogous to the way a key fits into a lock Receptor molecules are either attached to the surface of

the lymphocyte or secreted into fluids of the body. B and T lymphocytes both have receptor molecules on their cell surfaces, but only B cells manufacture and secrete large numbers of unattached receptor molecules, called antibodies. Antibodies correspond in structure to the receptor molecules on the surface of the B cell.

Any foreign material-usually of a complex nature and often a protein-that binds specifically to a receptor molecule made by lymphocytes is called an antigen. Antigens include molecules found on invading microorganisms, such as viruses, bacteria, protozoans, and fungi, as well as molecules located on the surface of foreign substances, such as pollen, dust, or transplanted tissue. When an antigen binds to a receptor molecule, it may or may not

Figure 2: (A) The human lymphatic system, showing the lymphatic vessels and lymphoid organs. (B) Internal and external structures of a lymph node.

Antigens and immune response evoke an immune response. Antigens that induce such a response are called immunogens. Thus, it can be said that all immunogens are antigens, but not all antigens are immunogens. For example, a simple chemical group that can combine with a lymphocyte receptor (i.e., is an antigen) but does not induce an immune response (i.e., is not an immunogen) is called a hapten. Although haptens cannot evoke an immune response by themselves, they can become immunogenie when joined to a larger, more complex molecule such as a protein, a feature that is useful in the study of immune responses.

Many antigens have a variety of distinct three-dimensional patterns on different areas of their surfaces. Each pattern is called an antigenic determinant, or epitope, and each epitope is capable of reacting with a different lymphocyte receptor. Complex antigens present an "antigenic mosaic" and can evoke responses from a variety of specific lymphocytes. Some antigenic determinants are better than others at effecting an immune response, presumably because a greater number of responsive lymphocytes are present. It is possible for two or more different substances to have an epitope in common. In these cases, immune components induced by one antigen are able to react with all other antigens carrying the same epitope. Such antigens are known as cross-reacting antigens.

T cells and B cells differ in the form of the antigen they recognize, and this affects which antigens they can detect. B cells bind to antigen on invaders that are found in circulation outside the cells of the body, while T cells detect only invaders that have somehow entered the cells of the body. Thus foreign materials that have been ingested by cells of the body or microorganisms such as viruses that penetrate cells and multiply within them are out of reach of antibodies but can be eliminated by T cells.

Diversity of lymphocytes. The specific immune system (in other words, the sum total of all the lymphocytes) can recognize virtually any complex molecule that nature or science has devised. This remarkable ability results from the trillions of different antigen receptors that are produced by the B and T lymphocytes. Each lymphocyte produces its own specific receptor, which is structurally organized so that it responds to a different antigen. After a cell encounters an antigen that it recognizes, it is stimulated to multiply, and the population of lymphocytes bearing that particular receptor increases.

How is it that the body has such an incredible diversity of receptors that are always ready to respond to invading molecules? To understand this, a quick review of genes and proteins will be helpful. Antigen receptor molecules are proteins, which are composed of a few polypeptide chains (i.e., chains of amino acids linked together by chemical bonds known as peptide bonds). The sequence in which the amino acids are assembled to form a particular polypeptide chain is specified by a discrete region of DNA called a gene. But, if every polypeptide region of every antigen receptor were encoded by a different gene, the human genome (all the genetic information encoded in the DNA that is carried on the chromosomes of cells) would need to devote trillions of genes to code just for these immune system proteins. Since the entire human genome contains approximately 30,000 genes, individuals cannot inherit a gene for each particular antigen receptor component. Instead, a mechanism exists that generates an enormous variety of receptors from a limited number of genes.

What is inherited is a pool of gene segments for each type of polypeptide chain. As each lymphocyte matures, these gene segments are pieced together to form one gene for each polypeptide that makes up a specific antigen receptor. This rearrangement of alternative gene segments occurs predominantly, though not entirely, at random, so that an enormous number of combinations can result. Additional diversity is generated from the imprecise recombination of gene segments—a process called junctional diversification—through which the ends of the gene segments can be shortened or lengthened. The genetic rearrangement takes place at the stage when the lymphocytes generated from stem cells first become functional, so that each mature lymphocyte is able to make only one type of receptor. Thus, from a pool of only hundreds of genes, an unlimit-

ed variety of diverse antigen receptors can be created. Still other mechanisms contribute to receptor diversity, Superimposed on the mechanism outlined in simplified terms above is another process, called somatic mutation. Mutation is the spontaneous occurrence of small changes in the DNA during the process of cell division. It is called somatic when it takes place in body cells (Greek soma means "body") rather than in germ-line cells (eggs and sperm). Although somatic mutation can be a chance event in any body cell, it occurs regularly in the DNA that codes for antigen receptors in lymphocytes. Thus, when a lymphocyte is stimulated by an antigen to divide, new variants of its antigen receptor can be present on its descendant cells, and some of these variants may provide an even better fit for the antigen that was responsible for the original stimulation.

B-CELL ANTIGEN RECEPTORS AND ANTIBODIES

The antigen receptors on B lymphocytes are identical to the binding sites of antibodies that these lymphocytes manufacture once stimulated, except that the receptor molecules have an extra tail that penetrates the cell membrane and anchors them to the cell surface. Thus, a description of the structure and properties of antibodies, which are well studied, will suffice for both.

Basic structure. Antibodies belong to the class of preteins called globulins, so named for their globular structure. Collectively, antibodies are known as immunoglobulins (abbreviated Ig). All immunoglobulins have the same basic molecular structure, consisting of four polypeptide chains (see Figure 3). Two of the chains, which are identical in any given immunoglobulin molecule, are heavy (H) chains; the other two are identical light (L) chains. The terms "heavy" and "light" simply mean larger and smaller. Each chain is manufactured separately and is encoded by different genes. The four chains are joined in the final immunoglobulin molecule to form a flexible Y shape, which is the simplest form an antibody can take.

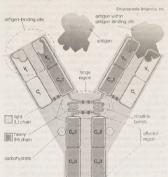

Figure 3: The four-chain structure of an antibody, or immunoglobulin, molecule.

The basic unit is composed of two identical light (L) chains and two identical heavy (H) chains, which are held together by disulfide bonds to form a flexible Y shape. Each chain is composed of a variable (V) region and a constant (C) region.

At the tip of each arm of the Y-shaped molecule is an area called the antigen-binding, or antibody-combining, site, which is formed by a portion of the heavy and light chains. Every immunoglobulin molecule has at least two of these sites, which are identical to one another. The antigen-binding site is what allows the antibody to recognize a specific part of the antigen (the epitope, or antigenic determinant). If the shape of the epitope corresponds to the shape of the antigen-binding site, it can fit into the site—that is, be "rec

Genetic coding of antigen receptors

> Binding of antibody to antigen

The heavy and light chains that make up each arm of the antibody are composed of two regions, called constant (C) and variable (V). These regions are distinguished on the basis of amino acid similarity—that is, constant regions have essentially the same amino acid sequence in all antibody molecules of the same class (IgG, IgM, IgA, IgD, or IgE), but the amino acid sequences of the variable regions differ quite a lot from antibody to antibody. This makes sense, because the variable regions determine the unique shape of the antibody-binding site. The tail of the molecule, which does not bind to antigens, is composed entirely of the constant regions of heavy chains.

The variable and constant regions of both the light and the heavy chains are structurally folded into functional units called domains. Each light chain consists of one variable domain (V_i) and one constant domain (C_i). Each heavy chain has one variable domain (V_{ij}) and three or four constant domains (C_{i1}) , C_{i1} , C_{i2} , C_{i2} , C_{i2} , C_{i3} , C_{i4}). Those domains that make up the "tail" of the basic V-shaped mole cube (in other words, all the H-chain constant domains except (C_{i1}) are responsible for the special biological properties of immunoglobulins—except, of course, for the capacity to bind to a specific antigenic determinant. The tail of the antibody determines the fate of the antigen once it becomes bound to the antibody.

The hinge region of the antibody is a short stretch of amino acids on the heavy chain located between the chain's $C_{\rm H}1$ and $C_{\rm H}2$ regions. It provides the molecule with flexibility, which is very useful in binding antigens. This flexibility can actually improve the efficiency with which an antigen binds to the antibody. It can also help in crosslinking antigens into a large lattice of antigen-antibody complexes, which are easily identified and destroyed by macrophages.

Classes of immunoglobulins. The term "constant region" is a bit misleading in that these segments are not identical in all immunoglobulins. Rather, they are basically similar among broad groups. All immunoglobulins that have the same basic kinds of constant domains in their H chains are said to belong to the same class. There are five main classes—IgG, IgM, IgA, IgD, and IgE—some of which include a number of distinct subclasses. Each class has its own properties and functions determined by the structural variations of the H chains. In addition, there are two basic kinds of L chains, called lambda and kappa chains, either of which can be associated with any of the H

chain classes, thereby increasing still further the enormous diversity of immunoglobulins (see Figure 4).

IgG is the most common class of immunoglobulin. It is present in the largest amounts in blood and tissue fluids. Each IgG molecule consists of the basic four-chain immunoglobulin structure—two identical H chains and two identical L chains (either kappa or lambda)—and thus carries two identical at legen-briding sites. There are four sub-classes of IgG, each with minor differences in its H chains but with distinct biological properties. IgG is the only class of immunoglobulin capable of crossing the placenta; consequently, if provides some degree of immune protection to the developing fetus. These molecules also are secreted into the mother's milk and, once they have been ingested by an infant, can be transported into the blood, where they confer immunical.

IgM is the first class of immunoglobulin made by B cells as they mature, and it is the form most commonly present as the antigen receptor on the B-cell surface. When IgM is secreted from the cells, five of the basic Y-shaped units become joined together to make a large pentamer molecule with 10 antigen-binding sites. This large antibody molecule is particularly effective at attaching to antigenic determinants present on the outer coats of bacteria. When this IgM attachment occurs, it causes microorganisms to agglutinate, or clump together.

IgA is the main class of antibody found in many body secretions, including tears, saliva, respiratory and intestinal secretions, and colostrum (the first milk produced by lactating mothers). Ver little IgA is present in the serum. IgAs is produced by B cells located in the muccus membranes.

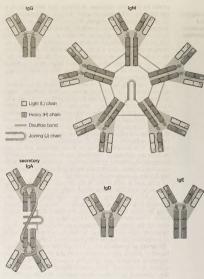

Figure 4: The five main classes of antibodies (immunoglobulins): log, loM, loA, loD, and loE.

of the body. Two molecules of IgA are joined together and associated with a special protein that enables the newly formed IgA molecule to be secreted across epithelial cells that line various ducts and organs. Although IgG is the most common class of immunoglobulin, more IgA is synthesized by the body daily than any other class of antibody. However, IgA is not as stable as IgG, and therefore it is present in lower amounts at any given time.

IgD molecules are present on the surface of most, but not all, B cells early in their development, but little IgD is ever released into the circulation. It is not clear what function IgD performs, though it may play a role in determining

whether antigens activate the B cells.

IgE is made by a small proportion of B cells and is present in the blood in low concentrations. Each molecule of BE consists of one four-chain unit and so has two antigenbinding sites, like the IgG molecule; however, each of its Hoains has an extra constant domain (C₄4), which confers on IgE the special property of binding to the surface of basphils and mast cells. When antigens bind to these attached IgE molecules, the cell is stimulated to release chemicals, such as histamines, that are involved in allergic reactions (see below Immune system disorders: Type I hypersensitivity). IgE antibodies also help to protect against parastite infections.

Normal production of antibody. Most individuals have fairly constant amounts of immunoglobulin in their blood, which represent the balance between continuous breakdown of these proteins and their manufacture. There is about 4 times as much IgG (including its subclasses) as IgA, 10 to 15 times as much as IgM, 300 times as much as IgD, and 30,000 times as much as

Part of the normal production of immunoglobulin undoubtedly represents the response to antigene stimulation that happens continually, but even animals raised in surroundings completely free from microbes and their products make substantial, though lesser, amounts of immunoglobulin. Much of the immunoglobulin therefore must represent the product of all the B cells that are, so to speak, "ticking over" even if not specifically stimulated. It is therefore not surprising that extremely sensitive methods can detect traces of antibodies that react with antigenic determinants to which an animal has never been exposed but for which cells with receptors are present.

All B cells have the potential to use any one of the constant-region classes to make up the immunoglobulin they secrete. As noted above, when first stimulated, most secrete IgM. Some continue to do so, but others later switch to producing IgG, IgA, or IgE. Memory B cells, which are specialized for responding to repeat infections by a given antigen, make IgG or IgA immediately (see below Activation of lymphocytes). What determines the balance among the classes of antibodies is not fully understood. However, it is influenced by the nature and site of deposition of the antigen (for example, parasites tend to elicit IgE), and their production is clearly mediated by factors, called cytokines, which are released locally by T cells.

T-CELL ANTIGEN RECEPTORS

Memory

cells and

long-term

immunity

Structure. T-cell antigen receptors are found only on the cell membrane. For this reason, T-cell receptors were difficult to isolate in the laboratory and were not identified until 1983. T-cell receptors consist of two polypeptide chains. The most common type of receptor is called alphabeta because it is composed of two different chains, one called alpha and the other beta (see Figure 5). A less common type is the gamma-delta receptor, which contains a different set of chains, one gamma and one delta. A typical T cell may have as many as 20,000 receptor molecules on its membrane surface, all of either the alpha-beta or gamma-delta type.

antigen-binding site Alpha (a) V Variable domain C Constant domain disulfide bond cytoplasm

Figure 5: The basic structure of a typical T-cell receptor.

The T-cell receptor molecule is embedded in the membrane of the cell, and a portion of the molecule extends away from the cell surface into the area surrounding the cell. The chains each contain two folded domains, one constant and one variable, an arrangement similar to that of the chains of antibody molecules. And, as is true of antibody structure, the variable domains of the chains form an antigen-binding site. However, the T-cell receptor has only one antigen-binding site, unlike the basic antibody molecule, which has two.

Many structural similarities exist between antibodies and T-cell receptors. Therefore, it is not surprising that the organization of genes that encode the T-cell receptor chains is similar to that of immunoglobulin genes. Similarities also exist between the mechanisms B cells use to generate antibody diversity and those used by T cells to create T-cell diversity. These commonalities suggest that both systems evolved from a more primitive and simpler recognition system (see below Genetic origins of the immune system).

Function. Despite the structural similarities, the receptors on T cells function differently from those on B cells. The functional difference underlies the different roles played by B and T cells in the immune system. B cells secrete antibodies to antigens in blood and other body fluids, but T cells cannot bind to free-floating antigens. Instead they bind to fragments of foreign proteins that are displayed on the surface of body cells. Thus, once a virus succeeds in infecting a cell, it is removed from the reach of circulating antibodies only to become susceptible to the defense system of the T cell.

But how do fragments of a foreign substance come to be displayed on the surface of a body cell? First, as is shown in Figure 6, the substance must enter the cell, which can happen through either phagocytosis or infection. Next, the invader is partially digested by the body cell, and one of its fragments is moved to the surface of the cell, where it becomes bound to a cell-surface protein. This cell-surface protein is the product of one of a group of molecules encoded by the genes of the major histocompatibility complex (MHC). In humans MHC proteins were first discovered on leukocytes (white blood cells) and, therefore, are often referred to as HLA (human leukocyte antigens). There are two major types of MHC molecules: class I molecules, which are present on the surfaces of virtually all cells of the body that contain nuclei-that is, most body cells-and class II molecules, which are restricted to the surfaces of most B cells and some T cells, macrophages, and macrophage-like cells.

Major patibility

Two main types of mature T cells-cytotoxic T cells and helper T cells-are known. Some scientists hypothesize the existence of a third type of mature T cell called regulatory T cells. Some T cells recognize class I MHC molecules on the surface of cells; others bind to class II molecules. Cvtotoxic T cells destroy body cells that pose a threat to the individual-namely, cancer cells and cells containing harmful microorganisms. Helper T cells do not directly kill other cells but instead help activate other white blood cells (lymphocytes and macrophages), primarily by secreting a variety of cytokines that mediate changes in other cells. The function of regulatory T cells is poorly understood. To carry out their roles, helper T cells recognize foreign antigens in association with class II MHC molecules on the surfaces of macrophages or B cells. Cytotoxic T cells and regulatory T cells generally recognize target cells bearing antigens associated with class I molecules. Because they recognize the same class of MHC molecule, cytotoxic and regulatory T cells are often grouped together; however, populations of both types of cells associated with class II molecules have been reported. Cytotoxic T cells can bind to virtually any cell in the body that has been invaded by a pathogen.

T cells have another receptor, or coreceptor, on their surface that binds to the MHC molecule and provides additional strength to the bond between the T cell and the target cell. Helper T cells display a coreceptor called CD4, which binds to class II MHC molecules, and cytotoxic T cells have on their surfaces the coreceptor CD8, which recognizes class I MHC molecules. These accessory receptors add strength to the bond between the T cell and the target cell.

The T-cell receptor is associated with a group of molecules called the CD3 complex, or simply CD3, which is also necessary for T-cell activation. These molecules are agents that help transduce, or convert, the extracellular binding of the antigen and receptor into internal cellular signals; thus, they are called signal transducers. Similar signal transducing molecules are associated with B-cell receptors.

LIFE CYCLE OF LYMPHOCYTES

T cells. When T-cell precursors leave the bone marrow on their way to mature in the thymus, they do not yet express receptors for antigens and thus are indifferent to stimulation by them. Within the thymus the T cells multiply many times as they pass through a meshwork of thymus cells. In the course of multiplication they acquire antigen receptors and differentiate into helper or cytotoxic T cells. As mentioned in the previous section, these cell types, similar in appearance, can be distinguished by their function and by the presence of the special surface proteins, CD4 and CD8. Most T cells that multiply in the thymus also die there. This seems wasteful until it is remembered that the random generation of different antigen receptors yields a large proportion of receptors that

Helper T cells and cytotoxic T cells

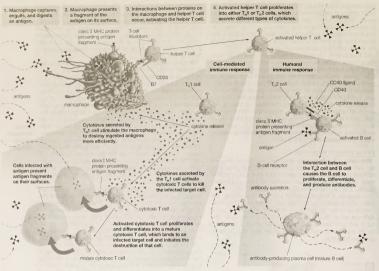

Figure 6. Stimulation of immune response by activated helper T cells. Activated by complex interaction with molecules on the surface of a macrophage or some other antigen-presenting cell, a helper T cell profilerates into two general subtypes, T_n1 and T_n2. These in turn stimulate the complex pathways of the cell-mediated immune response and the humoral immune response, respectively.

recognize self antigens-i.e., molecules present on the body's own constituents-and that mature lymphocytes with such receptors would attack the body's own tissues. Most such self-reactive T cells die before they leave the thymus, so that those T cells that do emerge are the ones capable of recognizing foreign antigens. These travel via the blood to the lymphoid tissues, where, if suitably stimulated, they can again multiply and take part in immune reactions. The generation of T cells in the thymus is an ongoing process in young animals. In humans large numbers of T cells are produced before birth, but production gradually slows down during adulthood and is much diminished in old age, by which time the thymus has become small and partly atrophied. Cell-mediated immunity persists throughout life, however, because some of the T cells that have emerged from the thymus continue to divide and function for a very long time.

B cells. B-cell precursors are continuously generated in the bone marrow throughout life, but, as with T-cell generation, the rate diminishes with age. Unless they are stimulated to mature (as described below), the majority of B cells also die, although those that have matured can survive for a long time in the lymphoid tissues. Consequently, there is a continuous supply of new B cells throughout life. Those with antigen receptors capable of recognizing self antigens tend to be eliminated, though less effectively than are self-reactive T cells. As a result, some self-reactive cells are always present in the B-cell population, along with the majority that recognize foreign antigens. The reason the self-reactive B cells normally do no harm is explained in the following section.

ACTIVATION OF LYMPHOCYTES

In its lifetime a lymphocyte may or may not come into contact with the antigen it is capable of recognizing, but if it does it can be activated to multiply into a large number of identical cells, called a clone. Each member of the clone carries the same antigen receptor and hence has the same antigen specificity as the original lymphocyte. The process, called clonal selection, is one of the fundamental concepts of immunology.

Two types of cells are produced by clonal selection-effector cells and memory cells. Effector cells are the relatively short-lived activated cells that defend the body in an immune response. Effector B cells are called plasma cells and secrete antibodies, and activated T cells include cytotoxic T cells and helper T cells, which carry out cell-mediated responses. The production of effector cells in response to first-time exposure to an antigen is called the primary immune response. Memory cells also are produced at this time, but they do not become active at this point. However, if the organism is reexposed to the same antigen that stimulated their formation, the body mounts a second immune response that is led by these long-lasting memory cells, which then give rise to another population of identical effector and memory cells. This secondary mechanism is known as immunological memory, and it is responsible for the lifetime immunities to diseases such as measles that arise from childhood exposure to the causative pathogen.

T cells. Helper T cells do not directly kill infected cells, as cytotoxic T cells do. Instead they help activate cytotoxic T cells and macrophages to attack infected cells, or they stimulate B cells to secrete antibodies. Helper T cells become activated by interacting with antigen-presenting cells, such as macrophages. Antigen-presenting cells ingest a microbe, partially degrade it, and export fragments of the microbe—i.e., antigens—to the cell surface, where they are presented in association with class II MHC molecules. A receptor on the surface of the helper T cell then binds to the MHC-antigen complex. But this event alone does not

Activation of T cells

activate the helper T cell. Another signal is required, and it is provided in one of two ways: either through stimulation by a cytokine or through a costimulatory reaction between the signaling protein, B7, found on the surface of the antigen-presenting cell, and the receptor protein, CD28, on the surface of the helper T cell. If the first signal and one of the second signals are received, the helper T cell becomes activated to proliferate and to stimulate the appropriate immune cell. If only the first signal is received, the T cell may be rendered anergic—that is, unable to respond to antigen.

A discussion of helper-T-cell activation is complicated by the fact that helper T cells are not a uniform group of cells but rather can be divided into two general subpopulations—T₁₄I and T₁₄Z cells—that have significantly different chemistry and function. These populations can be distinguished by the cytokines they secrete. T₁₄I cells primarily produce the cytokines gamma interferon, tumour necrosis factor-beta, and interleukin-2 (IL-2), while T₁₄Z cells mainly synthesize the interleukins IL-4, IL-5, IL-6, IL-9, IL-10, and IL-13. The main role of the T₁₄I cells is to stimulate cell-mediated responses (those involving cytotoxic T cells and macrophages), while T₁₄Z cells primarily assist in stimulating B cells to make antibodies.

Once the initial steps of activation have occurred, helper T cells synthesize other proteins, such as signaling proteins and the cell-surface receptors to which the signaling pro-

teins bind. These signaling molecules play a critical role not only in activating the particular helper T cell but also in determining the ultimate functional role and final differentiation state of that cell. For example, the helper T cell produces and displays IL-2 receptors on its surface and also secretes IL-2 molecules, which bind to these receptors and stimulate the helper T cell to grow and divide.

The overall result of helper-T-cell activation is an increase in the number of helper T cells that recognize a specific foreign antigen, and several T-cell cytokines are produced. The cytokines have other consequences, one of which is that IL-2 allows cytotoxic or regulatory T cells that recognize the same antigen to become activated and to multiply. Cytotoxic T cells, in turn, can attack and kill other cells that express the foreign antigen in association with class I MHC molecules, which-as explained above-are present on almost all cells. So, for example, cytotoxic T cells can attack target cells that express antigens made by viruses or bacteria growing within them (see below Cell-mediated immune mechanisms). Regulatory T cells may be similar to cytotoxic T cells, but they are detected by their ability to suppress the action of B cells or even of helper T cells (perhaps by killing them). Regulatory T cells thus act to damp down the immune response and can sometimes predominate so as to suppress it completely.

B cells. A B cell becomes activated when its receptor recognizes an antigen and binds to it. In most cases, how-

Figura 7: Clonal selection of a B cell.

Activated by the binding of an antigen to a specific matching receptor on its surface, a B cell profiferates into a clone. Some clonal cells differentiate into plasma cells, which are short-lived cells that secrete ambiody against the antigen. Others from memory coils, which are binager-lived and which, by profiferating rapidly, help to mount an effective defense upon a second exposure to the antigen.

ever, B-cell activation is dependent on a second factor mentioned above-stimulation by an activated helper T cell. Once a helper T cell has been activated by an antigen, it becomes capable of activating a B cell that has already encountered the same antigen. Activation is carried out through a cell-to-cell interaction that occurs between a protein called the CD40 ligand, which appears on the surface of the activated helper T cells, and the CD40 protein on the B-cell surface. The helper T cell also secretes cytokines, which can interact with the B cell and provide additional stimulation. Antigens that induce a response in this manner, which is the typical method of B-cell activation, are called T-dependent antigens.

Most antigens are T-dependent. Some, however, are able to stimulate B cells without the help of T cells. The T-independent antigens are usually large polymers with repeating, identical antigenic determinants. Such polymers often make up the outer coats and long, tail-like flagella of bacteria. Immunologists think that the enormous concentration of identical T-independent antigens creates a strong enough stimulus without requiring additional stimulation

from helper T cells.

Interaction with antigens causes B cells to multiply into clones of immunoglobulin-secreting cells (see Figure 7). Then the B cells are stimulated by various cytokines to develop into the antibody-producing cells called plasma cells. Each plasma cell can secrete several thousand molecules of immunoglobulin every minute and continue to do so for several days. A large amount of that particular antibody is released into the circulation. The initial burst of antibody production gradually decreases as the stimulus is removed (for example, by recovery from infection), but some antibody continues to be present for several months afterward

The process just described takes place among the circulating B lymphocytes. The B cells that are called memory cells, however, encounter antigen in the germinal centres-compartments in the lymphoid tissues where few T cells are present-and are activated in a different way. Memory cells, especially those with the most effective receptors, multiply extensively, but they do not secrete antibody. Instead, they remain in the tissues and the circulation for many months or even years. If, with the help of T cells, memory B cells encounter the activating antigen again, these B cells rapidly respond by dividing to form both activated cells that manufacture and release their specific antibody and another group of memory cells. The first group of memory cells behaves as though it "remembers" the initial contact with the antigen. So, for example, if the antigen is microbial and an individual is reinfected by the microbe, the memory cells trigger a rapid rise in the level of protective antibodies and thus prevent the associated illness from taking hold.

ANTIBODY-MEDIATED IMMUNE MECHANISMS

Protective attachment to antigens. Many pathogenic microorganisms and toxins can be rendered harmless by the simple attachment of antibodies. For example, some harmful bacteria, such as those that cause diphtheria and tetanus, release toxins that poison essential body cells. Antibodies, especially IgG, that combine with such toxins neutralize them. Also susceptible to simple antibody attachment are the many infectious microbes-including all viruses and some bacteria and protozoans-that live within the body cells. These pathogens bear special molecules that they use to attach themselves to the host cells so that they can penetrate and invade them. Antibodies can bind to these molecules to prevent invasion. Antibody attachment also can immobilize bacteria and protozoans that swim by means of whiplike flagella. In these instances antibodies protect simply by combining with the repeating protein units that make up these structures, although they do not kill or dispose of the microbes. The actual destruction of microbes involves phagocytosis by granulocytes and macrophages, and this is greatly facilitated by the participation of the complement system.

Activation of the complement system. "Complement" is a term used to denote a group of more than 30 proteins that act in concert to enhance the actions of other defense mechanisms of the body. Complement proteins are produced by liver cells and, in many tissues, by macrophages, Most of these proteins circulate in the blood and other body fluids in an inactive form. They become activated in sequential fashion; once the first protein in the pathway is turned on, the following complement proteins are called into action, with each protein turning on the next one in

The action of complement is nonspecific-i.e., complement proteins are not recognized by and do not interact with antigen-binding sites. In fact, complement proteins probably evolved before antibodies. Complement functions are similar among many species, and corresponding components from one species can carry out the same functions when introduced into another species. The complement system is ingenious in providing a way for antibodies, whatever their specificity, to produce the same biological

effects when they combine with antigens.

Originally immunologists thought that the complement system was initiated only by antigen-antibody complexes, but later evidence showed that other substances, such as the surface components of a microorganism alone, could trigger complement activation. Thus, there are two complement activation pathways: the first one to be discovered, the classical pathway, which is initiated by antigen-antibody complexes; and the alternative pathway. which is triggered by other means, including invading pathogens or tumour cells. (The term "alternative" is something of a misnomer because this pathway almost certainly evolved before the classical pathway. The terminology reflects the order of discovery, not the evolutionary age, of the pathways.) The classical and alternative pathways are composed of different proteins in the first part of their cascades, but eventually both pathways converge to activate the same complement components, which destroy and eliminate invading pathogens.

A particularly important complement protein is C3b. which carries out several functions. It brings about lysis (bursting) of the target cell by activating subsequent steps in the cascade, leading to the formation of a ringlike structure called the membrane attack complex. This structure inserts itself into the membrane of the invading pathogen and creates a hole through which the cell contents leak out, killing the cell. But perhaps the most important result of C3b production is that great numbers of C3b molecules are deposited on the surface of an invading pathogen in a process called opsonization. This makes the microorganism more attractive to phagocytic cells such as macrophages and neutrophils. The attraction occurs because receptors on the surface of phagocytes recognize and bind to the C3b molecule on the surface of the pathogen, stimulating phagocytosis. The microbe is then killed by digestive enzymes present in the phagocytes. If microbes are not immediately killed and are able to reach the bloodstream or the liver, spleen, or bone marrow, they can become coated with antibody and complement there and be ingested by phagocytes.

Activation of killer cells. Some cells that hear antigenantibody complexes do not attract complement; their antibody molecules are far apart on the cell surface or are of a class that does not readily activate the complement system (for example, IgA, IgD, and IgE). Other cells have outer membranes that are so tough or can be repaired so quickly that the cells are impermeable to activated complement. Still others are so large that phagocytes cannot ingest them. Such cells, however, can be attacked by killer cells present in the blood and lymphoid tissues. Killer cells, which may be either cytotoxic T cells or natural killer cells, have receptors that bind to the tail portion of the IgG antibody molecule (the part that does not bind to antigen). Once bound, killer cells insert a protein called perforin into the target cell, causing it to swell and burst. Killer cells do not harm bacteria, but they play a role in destroying body cells infected by viruses and some para-

Other antibody-mediated mechanisms. The protection conferred by IgA antibodies, which are transported to the surface of mucous-membrane-lined passages, is somewhat different. Complement activation is not involved; there are

Activation phagocytes

T-cell

against

infection

viral

protection

no complement proteins in the lining of the gut or the respiratory tract. Here the available immune defense mechanism is primarily the action of IgA combining with microbes to prevent them from entering the cells of the lining. The bound microbes are then swept out of the body. IgA also appears to direct certain types of cell-mediated killing.

IgE antibodies also invoke unique mechanisms. As stated earlier, most IgE molecules are bound to special receptors on mast cells and basophils. When antigens bind to IgE antibodies on these cells, the interaction does not cause ingestion of the antigens but rather triggers the release of pharmacologically active chemical contents of the cells' granules. The chemicals released cause a sudden increase in permeability of the local blood vessels, the adhesion and activation of platelets (blood cell fragments that trigger clotting), which release their own active agents, the contraction of smooth muscle in the gut or in the respiratory tubes, and the secretion of fluids-all of which tend to dislodge large multicellular parasites such as hookworms. Eosinophil granulocytes and IgE together are particularly effective at destroying parasites such as the flatworms that cause schistosomiasis. The eosinophils plaster themselves to the worms bound to IgE and release chemicals from their granules that break down the parasite's tough, protective skin. Therefore, IgE antibodies-although they can be a nuisance when they react with otherwise harmless antigens, as discussed in immune system disorder: Type I hypersensitivity-appear to have a special protective role against the larger parasites.

Transfer of antibodies from mother to offspring. A newborn mammal has no opportunity to develop protective antibodies on its own, unless, as happens very rarely, it was infected while in the uterus. Yet it is born into an environment similar to its mother's, that contains all the potential microbial invaders to which she is exposed. Although the fetus possesses the components of innate immunity, it has few or none of its mother's lymphocytes. The placenta generally prevents the maternal lymphocytes from crossing into the uterus, where they would recognize the fetal tissues as foreign antigens and cause a reaction similar to the rejection of an incompatible organ transplant.

What is transferred across the placenta in many species is a fair sample of the mother's antibodies. How this happens depends on the structure of the placenta, which varies among species. In humans maternal IgG antibodies-but not those of the other immunoglobulin classes-are transported across the placenta into the fetal bloodstream throughout the second two-thirds of pregnancy. In many rodents a similar transfer occurs, but primarily across the yolk sac.

In horses and cattle, which have more layers of cells in their placentas, no antibodies are transferred during fetal life, and the newborn arrives into the world with no components of specific immunity. There is, however, a second mechanism that makes up for this deficiency. The early milk (colostrum) is very rich in antibodies-mainly IgA but also some IgM and IgG-and during the first few days of life the newborn mammal can absorb these proteins intact from the digestive tract directly into the bloodstream. Drinking colostrum is therefore essential for newborn horses and cattle and required to a somewhat lesser extent by other mammals. The capacity of the digestive tract to absorb intact proteins must not last beyond one or two weeks, since once foods other than milk are ingested the proteins and other antigens in them would also be absorbed intact and could act as immunogens to which the growing animal would become allergic (see Immune system disorders: Allergies), IgA in milk is, however, rather resistant to digestion and can function within the gut even after intact absorption into the bloodstream has ended. Human colostrum is also rich in IgA, with the concentration highest immediately after birth.

After a newborn has received its supply of maternal antibodies, it is as fully protected as its mother. This means, of course, that if the mother has not developed immunity to a particular pathogen, the newborn will likewise be unprotected. For this reason, a physician may recommend that a prospective mother receive immunizations against tetanus and certain other disorders. (The active immunization of pregnant women against certain viral diseases, such as rubella [German measles], must be avoided, however, because the immunizing agent can cross the placenta and produce severe fetal complications.)

As important as the passively transferred maternal antibodies are, their effects are only temporary. The maternal antibodies in the blood become diluted as the animal grows; moreover, they gradually succumb to normal metabolic breakdown. Because the active development of acquired immunity is a slow and gradual process, young mammals actually become more susceptible to infection during their early stages of growth than they are immediately after birth.

Occasionally the transfer of maternal antibodies during fetal life can have harmful consequences. A well-known example of this is erythroblastosis fetalis, or hemolytic disease of the newborn, a disorder in which maternal antibodies destroy the child's red blood cells during late pregnancy and shortly after birth. The most severe form of erythroblastosis fetalis is Rh hemolytic disease, which develops when: (1) The fetus is Rh-positive; that is, its red blood cells carry an antigen known as the Rh factor. (2) The mother is Rh-negative, which is to say her red blood cells lack the Rh factor. (3) The mother's immune system has been previously activated against the Rh antigen; this usually is the result of exposure to fetal cells during the birth of an earlier Rh-positive baby or a transfusion of Rhpositive blood.

Rh hemolytic disease can be prevented by giving the mother injections of anti-Rh antibody shortly after the birth of an Rh-positive child. This antibody destroys any Rh-positive fetal cells in the maternal circulation, thereby preventing the activation of the mother's immune system should she conceive another Rh-positive fetus.

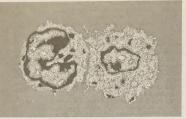

CELL-MEDIATED IMMUNE MECHANISMS

In addition to their importance in cooperating with B cells that secrete specific antibodies, T cells have important, separate roles in protecting against antigens that have escaped or bypassed antibody defenses. Immunologists have long recognized that antibodies do not necessarily protect against viral infections, because many viruses can spread directly from cell to cell and thus avoid encountering antibodies in the bloodstream. It is also known that persons who fail to make antibodies are very susceptible to bacterial infections but are not unduly liable to viral infections. Protection in these cases results from cell-mediated immunity, which destroys and disposes of body cells in which viruses or other intracellular parasites (such as the bacteria that cause tuberculosis and leprosy) are actively growing, thus depriving microorganisms of their place to grow and exposing them to antibodies.

As discussed above in Activation of lymphocytes, cell-mediated immunity has two mechanisms. One involves activated helper T cells, which release cytokines. In particular, the gamma interferon produced by helper T cells greatly increases the ability of macrophages to kill ingested microbes; this can tip the balance against microbes that otherwise resist killing. Gamma interferon also stimulates natural killer cells. The second mechanism of cell-mediated immunity involves cytotoxic T cells. They attach themselves by their receptors to target cells whose surface expresses appropriate antigens (notably ones made by developing viruses) and damage the infected cells enough to

Cytotoxic T cells may kill infected cells in a number of ways. The mechanism of killing used by a given cytotoxic T cell depends mainly on a number of costimulatory signals. In short, cytotoxic T cells can kill their target cells either through the use of pore-forming molecules, such as perforins and various components of cytoplasmic granules, or by triggering a series of events with the target cell that activate a cell death program, a process called apoptosis. In general, the granular cytotoxic T cells tend to kill cells directly by releasing the potent contents of their cytotoxic granules at the site of cell-to-cell contact. This renders the cell membrane of the target cell permeable, which allows the cellular contents to leak out and the cell to die (see Fig-

Role of colostrum

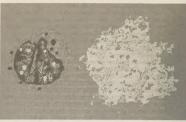

Figure 8: The killing of an infected cell by a cytotoxic T cell (Left) A scanning electron micrograph of a cytotoxic T cell, at left, attaching to a target cell infected by a virus. (Right) The target cell, on the right, is tysed, its internal contents leaking through its perforated outer membrane. @ C. Edelmann/Patit Form

ure 8). The nongranular cytotoxic T cells often kill cells by inducing apoptosis, usually through the activation of a cellsurface protein called Fas. When a protein on the surface of the cytotoxic T cell interacts with the Fas protein on the target cell. Fas is activated and sends a signal to the nucleus of the target cell, thus initiating the cell death process. The target cell essentially commits suicide, thereby destroying the virus within the cell as well.

IMMUNITY AGAINST CANCER

Cancer cells are normal body cells that have been altered in a manner that allows them to divide relentlessly, ignoring normal signals of restraint. As a result, cancer cells form clusters of cells, called tumours, that invade and colonize tissues, eventually undermining organ function and causing death. In the early 20th century the pioneering immunologist Paul Ehrlich pointed out that the enormous multiplication and differentiation of cells during prenatal life must afford many opportunities for aberrant cells to appear and grow but that immune mechanisms eliminate such cells. The idea that such a mechanism continues to function throughout life, weeding out newly arisen cancer cells, became popular in the 1950s and '60s when a number of immunologists postulated immune surveillance, the theory that T-cell-mediated immunity evolved as a specific defense against cancer cells and that T cells constantly patrol the body, searching for abnormal body cells that carry antigens on their surface which are not found on healthy body cells. Although it has its compelling aspects, the immunosurveillance theory remains just a theory, and a controversial one at that,

The role of the immune system in protecting against cancer has not been fully explained, but nevertheless there is no question that in some instances the immune system can distinguish cancer cells from normal cells. The study of tumour immunology has shown unequivocally that cancer cells do carry antigens that are not present on healthy cells. Immunologists distinguish broadly between two types of tumour antigens: tumour-specific antigens, which are found only on cancer cells and not on their normal counterparts, and tumour-associated antigens, which are found on both normal and cancer cells but which are abnormally expressed-e.g., are overproduced-on cancer cells. In both cases these antigens have been shown to evoke an immune response, although not necessarily one strong enough to eliminate the tumour.

Why does a tumour continue to grow if an immune response against it is induced? Through animal experiments, a number of mechanisms have been identified that allow tumours to avoid recognition and destruction by the immune system: (1) The surfaces of cancer cells may lose antigens that are recognizable by the immune system. (2) Cancer cells may lose all class I MHC molecules from their surface, which prevents cytotoxic T cells from recognizing the cells. (3) Some cancer cells produce immunosuppressive chemicals that can inhibit T cells directly or that can

activate regulatory T cells, (4) Some cancer cells shed some of their antigens, and these newly released, free-floating antigens may bind to the receptors on cytotoxic T cells, plugging them up so that the T cells cannot bind to the cancer cells and eliminate them. (5) Certain cancer cells can outmaneuver an immune response by growing so rapidly or becoming such a dense mass that immune cells cannot come in contact with most of them.

Other dysfunctions of the immune system, such as immune suppression and immune deficiency, may contribute to cancer development and growth. Individuals such as transplant patients who have been treated with immunosuppressive drugs for a long period of time are more likely to develop certain types of cancer, as are patients with immunodeficiency diseases. For example, people with AIDS (acquired immunodeficiency syndrome) are more prone to developing cancers associated with viruses, such as Kaposi's sarcoma. The incidence of cancer also increases greatly in old age, when some immune responses decline. But defective immune responses may not be the major factor involved in cancer development in the elderly, since genetic mutations that are linked to cancer also accumulate with age

Much research has been devoted to developing effective immunotherapies against cancer, but the effectiveness of this approach has been marginal. Nevertheless, researchers continue to pursue immunotherapeutic approaches. One avenue of research has focused on finding ways to immunize patients against the specific cancer growing within them. This approach targets tumour-specific antigens found on the cancer cells. Because these antigens are altered forms of normal self antigens, they are "foreign" and could be recognized by the immune system as such, but often they are not. However, investigators are working to develop vaccines that stimulate an immune response to these antigens, hoping that the reaction would be strong enough to eliminate the cancer.

PROPHYLACTIC IMMUNIZATION

Prophylactic immunization refers to the artificial establishment of specific immunity, a technique that has significantly reduced suffering and death from a variety of infectious diseases. There are two types of prophylactic immunization: passive immunization, in which protection is conferred by introducing preformed antibodies or lymphocytes from another individual whose immune system was stimulated by the appropriate antigen, and active immunization, in which protection results from the administration of a vaccine, with dead or harmless living forms of an organism or with an inactivated toxin, that stimulates the immune system to produce lymphocytes and antibodies against that organism or toxin.

Passive immunization. It is sometimes the case that an infectious organism or a poisonous substance can have such a rapid deleterious effect that the victim does not have time to develop an immune response spontaneously. At

such times passive immunization with preformed antibodies can provide life-saving assistance in combating the pathogen or poison. This situation may arise in victims of poisonous snakebites or botulism, as well as in those in whom such infections as diphtheria, tetanus, or gas gangrene have progressed to the point at which bacterial toxins have been absorbed into the bloodstream. It is also the case with bites from a rabid animal, although active immunization is begun at the same time, since the spread of the rabies infection to the central nervous system is relatively slow. Physicians use passive immunization as temporary protection for persons traveling to countries where hepatitis B is prevalent. Passive immunization provides antibodies to persons who suffer from B-cell deficiencies and are therefore unable to make antibodies for themselves (see below Immune system disorders: Immune deficiencies). Also, as discussed earlier, passive immunizations of anti-Rh antibody can prevent erythroblastosis fetalis.

Protective immunoglobulins—primarily of the IgG class—can be prepared from the blood of humans or other species (e.g., horses or rabbits) that have already developed specific immunity against the relevant antigens. These preparations are known as antiserums. (This explains the original term for passive immunization, which is serum therapy). Human IgG is slowly broken down in the recipient's body, the concentration falling by about one-half every three weeks, so that effective amounts of antibody can be present for two or three months. Human antiserum is used whenever it is available, because IgG from other species is far more likely to provoke an immune response that will eliminate the antibody and may lead to serum sickness (see below Immune system disorders: Type III hypersensitivity).

Active immunization. Active immunization aims to ensure that a sufficient supply of antibodies or T and B cells that react against a potential infectious agent or toxin are present in the body before infection occurs or the toxin is encountered. Once it has been primed, the immune system either can prevent the pathogen from establishing itself or can rapidly mobilize the various protective mechanisms described above to abort the infection or toxin in its earliest stages.

The vaccines used to provide active immunization need not contain living microbes. What matters is that they include the antigens important in evoking a protective response and that those antigens be administered in a harmless form sufficient in amount and persistence to produce an immune response similar to the natural infection. Bacterial toxins, such as those that cause tetanus or diphtheria, can be rendered harmless by treatment with formaldehyde without affecting their ability to act as immunogens. These modified toxins, or toxoids, usually are adsorbed onto an inorganic gel before being administered, an approach that increases the likelihood that the toxoid will be retained in a macrophage. Toxoids elicit effective, long-lasting immunity against bacterial toxins. When immunization against several antigenic determinants is desired or the important antigenic component is not known, it may be prudent to use the entire microbe, which has been killed in a manner that does not alter it significantly. Such so-called "killed" vaccines are used to immunize against typhoid, pertussis (whooping cough), plague, and influenza, for example. In other cases, researchers have developed attenuated (i.e., weakened) strains of bacteria or viruses. Attenuated vaccines cause an infection but do not produce the full array of signs and symptoms of the disease, because the infectious agent multiplies to only a limited extent in the body and never reverts to the virulent form. The use of such live microbes provides the most effective prophylaxis of all, since they truly imitate a mild form of the natural infection. Such are the vaccines for yellow fever, poliomyelitis (oral vaccine), measles, rubella, and tuberculosis. Although sufficiently attenuated as far as healthy persons are concerned, live vaccines may cause the full disease in persons who have an immune deficiency

Most vaccines are administered by injection, but a few are given orally. Ultimately mucosal vaccines (those administered to mucosal surfaces such as those lining the gut, nasal

passages, or the urogenital tract) may be the most effective vaccines available because of their unique ability to stimulate IgA responses and because of their ease of administration. Recombinant DNA technology has allowed researchers to use modified bacteria and viruses that are not harmful to humans to immunize individuals against an antigen from a pathogenic microorganism. This approach involves introducing into the DNA of the harmless microorganism a gene from a pathogenic organism that encodes an antigen capable of eliciting a protective immune response but not the full-blown disease. Once inoculated into the host, the microorganism generates the protective antigen of the pathogen and immunizes the host. An effective oral vaccine against cholera was developed based on this approach

Sometimes different strains of a microorganism, each characterized by a different antigenic determinant, give rise to the same disease. In such cases neither natural infection nor prophylactic immunization with any one strain protects against infection by the others. For example, a variety of virus strains cause the common cold, but it is impractical to immunize against each. On the other hand, although there are more than 60 different effains of pneumococci that can cause bacterial pneumonia, some are much more common than others. Consequently a vaccine containing antigens from up to 14 of the most common strains is useful in protecting persons at special risk.

Active immunization is often the most effective and least costly method of protecting against an infectious disease. Vaccination campaigns against many diseases, such as diphtheria, polio, and measles, have been tremendously successful (see Figure 9). In cases in which 95 percent or

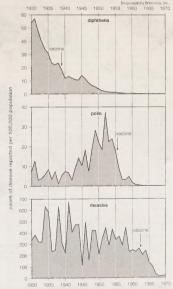

Figure 9: In the United States, mass vaccination programs carried out against diphtheria, pollo, and measles have almost eradicated these diseases from the population. The graphs indicate the years the vaccines were introduced. Data source: U.S. Bureau of the Census, Historical Statistics of the United States: Colonial Times to 1970 (CD-ROM ed., 1997).

more of the population at risk is protected and humans are the only reservoir of infection, active immunization can lead to the worldwide eradication of the infectious agent, as has been achieved in the case of smallpox.

PRODUCTION OF MONOCLONAL ANTIBODIES

It was pointed out above that upon activation by an antigen, a circulating B cell multiplies to form a clone of plasma cells, each secreting the identical immunoglobulin. These immunoglobulins-derived from the descendants of a single B cell-constitute a monoclonal antibody. The complete immune response to a natural infection or an active immunization, however, is polyclonal. In other words, it involves many B-cell clones, each of which recognizes a different antigenic determinant and secretes a different immunoglobulin. Thus the blood serum of an immunized person or animal normally contains a mixture of antibodies. There is, however, a condition in which the blood serum may contain an astonishingly high concentration of a single immunoglobulin. This results from multiple myeloma, a type of cancer in which a single B cell proliferates to form a tumorous clone of antibody-secreting cells that can multiply indefinitely, like all cancer cells. Myelomas have been propagated to produce large quantities of monoclonal antibodies, and the use of myeloma cells to produce specific, desired antibodies has become one of the most important facets of biotechnology.

The artificial production of monoclonal antibodies from cultured myeloma cells was pioneered in 1975 by immunologists Georges Köhler and César Milstein (who received Nobel Prizes in 1984 for their work). The basic process as shown in Figure 10, begins with the selection of myeloma cells that grow well but have lost their ability to secrete immunoglobulin and do not produce a crucial enzyme called HGPRT (hypoxanthineguanine phosphoribosyltransferase). These cells are induced to fuse with a set of plasma cells, taken from the spleen of an inoculated mouse, that is known to secrete a particular antibody. The result is a "hybridoma," or hybrid myeloma, which retains the capacity of its myeloma component to multiply indefinitely but also makes the chosen, identifiable antibody of its plasma-cell component. The fused mixture is placed into a medium known as HAT (hyposanthineguanine phosphoribosyltransferase). The HAT medium kills unfused myeloma cells, which do not produce the HGPRT enzyme, and the naturally short-lived unfused plasma cells also die off. Only the hybridomas live in the HAT medium, and these are grown in bulk to produce the specified antibodies.

Thanks to hybridomas, researchers can obtain monoclonal antibodies that recognize individual antigenic sites on almost any molecule, ranging from drugs and hormones to microbial antigens and cell receptors. The exquisite specificity of monoclonal antibodies and their availability in quantity have made it possible to devise sensitive assays for an enormous range of biologically important substances and to distinguish cells from one another by identifying previously unknown marker molecules on their surfaces. Moreover, if short-lived radioactive atoms are added to these antibodies and they are then administered in tiny quantities to a patient, they become attached

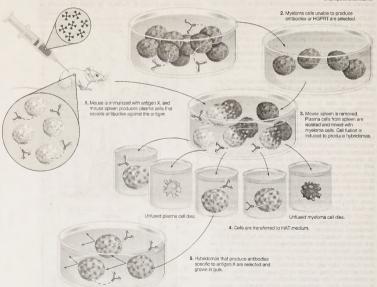

Figure 10: Artificial production of monoclonal antibodies The technique involves fusing certain myeloma cells (cancerous B cells), which can multiply The technique involves using certain hysionia cells (cancerous b cells), which can multiply indefinitely but cannot produce antibodies, with plasma cells (noncancerous B cells), which are short-lived but produce a desired antibody. The resulting hybrid cells, called hybridomas, grow at the rate of myeloma cells but also produce large amounts of the desired antibody. In this way researchers obtain large quantities of antibody molecules that all react against the same

Use of mveloma cells

exclusively to the cancer tissue. By means of instruments that detect the radioactivity, physicians can locate the cancerous sites without surgical intervention. Monoclonal antibodies have also been used experimentally to deliver

cytotoxic drugs or radiation to cancer cells.

Although the preparation of monoclonal antibodies from rat or mouse cells has become routine practice, the construction of human hybridomas has not proved easy. This is partly because most human myeloma cells do not grow well in culture, and those that do so have not produced stable hybridomas. If, however, human B cells isolated from blood are infected by the Epstein-Barr virus (the agent that causes infectious mononucleosis), they can be propagated in culture and continue to secrete immunoglobulin. Very few of them are likely to be making an antibody with a desired specificity, even in a subject who has been immunized; but in some instances immunologists have succeeded in identifying and selecting cells that secrete the wanted immunoglobulin. These can be grown in culture as single clones that secrete a monoclonal antibody. Researchers have used this process to obtain human monoclonal antibodies against the Rh antigen.

A simpler method of constructing human monoclonal antibodies can be accomplished using recombinant DNA techniques. Once a mouse monoclonal antibody has been constructed using the traditional methods just described. DNA encoding the antigen-binding portion of the antibody molecule can be isolated and fused to human DNA that encodes an antibody. Then the hybrid DNA is inserted into a bacterium, which produces half-mouse-halfhuman monoclonal antibodies. The antibodies made by this method are less likely to induce an anti-antibody response when given to humans. Further fine-tuning can be done to change all parts of the antibody that are not directly involved in binding to the specific antigen. This technique has been used to produce a large number of different monoclonal antibodies for use in therapy.

Evolution of the immune system

Virtually all organisms have at least one form of defense that helps repel disease-causing organisms. Advanced vertebrate animals, a group that includes humans, defend themselves against such microorganisms by means of a complex group of defense responses collectively called the immune system. This protective system evolved from simpler defense mechanisms, but the evolutionary twists and turns that led to its development are not entirely clear. To unravel the path that the vertebrate immune system followed in its evolution, investigators have studied the defense responses of various living organisms. They also have examined the genes of immune system proteins for clues to the genetic origins of immunity.

DEVELOPMENT OF IMMUNITY IN MAJOR ANIMAL GROUPS Because the immune system is composed of cells and tissues that do not lend themselves to fossilization, it is impossible to trace the evolution of immunity from the paleontological record. But, because all animals exhibit some general ability to recognize self and to repel foreign substances, it is possible to study the immune capacity of living animals and, based on the relative positions of these animals in the evolutionary tree, to extrapolate a reasonable evolutionary history of the immune system.

Immune capacity among invertebrates. From the lowliest protozoans to the higher marine tunicates, invertebrates have means of distinguishing self components from nonself components. Sponges from one colony will reject tissue grafts from a different colony but will accept grafts from their own. When tissue grafts are made in animals higher up the evolutionary tree-between individual annelid worms or starfish, for example-the foreign tissue is commonly invaded by phagocytic cells (cells that engulf and destroy foreign material) and cells resembling lymphocytes (white blood cells of the immune system), and it is destroyed. Yet tissues grafted from one part of the body to another on the same individual adhere and heal readily and remain healthy. So it seems that something akin to cellular immunity is present at this level of evolution.

Insects engulf and eliminate foreign invaders through the process of phagocytosis ("cellular eating"). They have factors present in their circulatory fluids that can hind to foreign cells and cause clumping, or agglutination, of a number of these cells, an event that facilitates phagocytosis. Insects also seem to acquire immunity to infectious

Immune capacity among vertebrates. The most sophisticated immune systems are those of the vertebrates. Recognizable lymphocytes and immunoglobulins (Ig; also called antibodies) appear only in these organisms. The most primitive living vertebrates-the jawless fishes (hagfish and lampreys)-do not have lymphoid tissues corresponding to a spleen or a thymus, and their immune responses, although demonstrable, are very weak and sluggish. Farther up the evolutionary tree, at the level of the cartilaginous fishes (sharks and rays) and the bony fishes, a thymus and a spleen are present, as are immunoglobulins, although only those immunoglobulins of the IgM class are detectable. Fish lack specialized lymph nodes, but they do have clusters of lymphocytes in the gut that may serve an analogous purpose.

It is not until the level of the terrestrial vertebrates-amphibians, reptiles, birds, and mammals-that a complete immune system with thymus, spleen, bone marrow, and lymph nodes is present and IgM and IgG antibodies are made. Antibodies of the IgA class are found only in birds and mammals, and IgE antibodies are confined to mammals. So it appears that the most primitive devices for producing specific, acquired immunity gradually diversified to meet the new environmental hazards as animals moved out of the sea onto the land.

The evolution of the complement system (a group of proteins involved in immune responses) may have occurred faster than that of the immunoglobulin system. The jawless fishes have complement components corresponding only to the later-acting (i.e., cytolytic, or cell-killing) aspects of complement function, but all higher vertebrates have components similar to the complete complement system of mammals. The fact that the complement system has been so well conserved during evolution implies not only that it has been of great biological value but also that complement and immunoglobulins have interacted throughout the evolution of the immune system in higher vertebrates. (For more information on the complement system, see above Antibody-mediated immune mechanisms).

GENETIC ORIGINS OF THE IMMUNE SYSTEM

Researchers have found many similarities between the structures of proteins involved in antigen recognition and those in cell-to-cell recognition in the immune system. (Antigens are the foreign proteins that antibodies recognize and bind to.) These proteins include the antigen receptors of lymphocytes, the major histocompatibility complex (MHC) proteins, the coreceptors involved in cell-to-cell recognition in immune reactions (such as the receptors named CD4, CD8, and CD28), and the Fc receptor that binds to the stem of the Y-shaped immunoglobulin molecule. A number of proteins not involved in the immune system also share structural features with these proteins. The main feature similarity is a structure called the immunoglobulin domain. Each protein is composed of one or more Ig domains of nearly identical size. The domains are formed into a loop by bonds between sulfur atoms on the amino acids at the ends. Although each domain is different and serves a different function in the molecule as a whole, the number and order of the amino acids forming each domain are far more similar than would be expected if each had arisen independently in the course of evolution. Equally remarkable is the fact that nerve cells, thymus cells, and T lymphocytes in mice and rats carry a surface protein termed Thy-1 (thymus-1 antigen), the function of which is unknown, that also has this same basic structure and a similar arrangement of amino acids. The similarities suggest that the genes for all these molecules originated from some primitive gene involved in the recognition of one cell by another, which is required for orderly development of a complex, multicellular organism, and that during evolution they had acquired different functions. Researchers

Primitive immune systems

Recombi-

nant DNA

techniques

named this group of genes and their protein products the immunoglobulin superfamily. The processes whereby one ancestral gene could have given rise to such a family of genes include gene duplication, crossing over, and mutation, all of which are discussed in detail in GENETICS AND HEREDITY, THE PRINCIPLES OF.

Not surprisingly, molecules that have a similar function in different species (e.g., immunoglobulins or MHC components) show an even closer resemblance. By analyzing the number of differences in the amino acids and their position in the polypeptide chains that make up IgM and IgG molecules in, for example, humans, mice, and rabbits and

by making reasonable assumptions about mutation rates, scientists can estimate roughly how many generations would have had to elapse—and hence how much time—for the present immunoglobulins of these species to have evolved from a common ancestral JgM-like molecule. Such calculations suggest that divergence from the ancestral immunoglobulin took place some 200 million years ago. That was about the same time amphibians are thought to have diverged from the main vertebrate line. So one may conclude that a functional immune system arose even earlier and has continued to provide a defense against foreign agents ever since.

IMMUNE SYSTEM DISORDERS

Disorders of the immune system include immune deficiency diseases, such as AIDS, that arise because of a diminution of some aspect of the immune response. Other types of immune disorders, such as allergies and autoimmune disorders, are caused when the body develops an inappropriate response to a substance—either to a normally harmless foreign substance found in the environment, in the case of allergies, or to a component of the body, in the case of autoimmune diseases. Finally, lymphocytes (white blood cells of the immune system) can become cancerous and give rise to tumours called leukemias, lymphomas, and myelomas. All four types of disorders—immune deficiencies, allergies, autoimmune diseases, and cancers—are discussed in this section.

Immune deficiencies

Immune deficiency disorders result from defects that occur in immune mechanisms. The defects arise in the components of the immune system, such as the white blood cells involved in immune responses (T and B lymphocytes and scavenger cells) and the complement proteins, for a number of reasons. Some deficiencies are hereditary and result from genetic mutations that are passed from parent to child. Others are caused by developmental defects that occur in the womb. In some cases immune deficiencies result from damage inflicted by infectious agents. In others drugs used to treat certain conditions, or even the diseases themselves, can depress the immune system. Poor nutrition also can undermine the immune system.

Immune deficiencies resulting from hereditary and congenital defects are rare, but they can affect all major aspects of the immune system. Luckily many of those conditions can be treated. In the rare hereditary disorder called Xlinked infantile agammaglobulinemia, which affects only males, B lymphocytes are unable to secrete all classes of immunoglobulins. (An immunoglobulin is a type of protein, also called an antibody, that is produced by B cells in response to the presence of a foreign substance called an antigen.) The disease can be treated by periodic injections of large amounts of immunoglobulin G (IgG). The congenital, but not hereditary, T-cell deficiency disease called DiGeorge's syndrome arises from a developmental defect occurring in the fetus that results in the defective development of the thymus. Consequently the infant has either no mature T cells or very few. In the most severe cases-i.e., when no thymus has developed-treatment of DiGeorge's syndrome consists of transplantation of a fetal thymus into the infant. The group of disorders called severe combined immunodeficiency diseases result from a failure of precursor cells to differentiate into T or B cells. Bone marrow transplantation can successfully treat some of those diseases. The immune disorder called chronic granulomatous disease results from an inherited defect that prevents phagocytic cells from producing enzymes needed to break down ingested pathogens. Treatments include administration of a wide spectrum of antibiotics.

Damage to lymphocytes that is inflicted by viruses is common but usually transient. During infectious mononucleosis, for example, the Epstein-Barr virus infects B cells, causing them to express viral antigens. T cells that react against these antigens then attack the B cells, and a tem-

porary deficiency in the production of new antibodies lasts until the overt viral infection has been overcome. Because antibodies already present in the blood are slowly broken down, failure to make new ones is important only if the infection persists for a long time, as it does occasionally. A much more serious viral infection is that caused by the human immunodeficiency virus (HIV), which is responsible for the fatal immune deficiency disease AIDS. HIV selectively infects helper T cells and prevents them from producing cytokines and from functioning in cell-mediated immunity (see Figure 11). Persons with AIDS may be unable to overcome infections by a variety of microbes that are easily disposed of by persons uninfected with HIV. Severe infections by certain parasites, such as trypanosomes, also cause immune deficiency, as do some forms of cancer, but it is uncertain how that comes about. For example, Hodgkin's disease, which attacks the lymphatic system, makes the patient more susceptible to infection.

In countries with advanced medical services, immune deficiency often results from the use of powerful drugs to treat cancers. The drugs work by inhibiting the multiplica-

Genetic immune deficiencies tion of rapidly dividing cells. Although the drugs act selectively on cancer cells, they also can interfere with the generation and multiplication of cells involved in immune responses. Prolonged or intensive treatment with such drugs impairs immune responses to some degree. Although the immune impairment is reversible, the physician must seek a balance between intentional damage to the cancer cells and unintentional damage to the immune system.

Medically induced suppression of the immune system also occurs when powerful drugs, which are designed to interfere with the development of T and B cells, are used to prevent the rejection of organ or bone marrow transplants or to damp down serious autoimmune responses. Although use of such drugs has greatly improved the success of transplants, it also leaves patients highly susceptible to microbial infections. Fortunately, most of those infections can be treated with antibiotics, but the immunosuppressive drugs have to be used with great care and for as short a period as possible.

In countries where the diet, especially that of growing children, is grossly deficient in protein, severe malnutrition ranks as an important cause of immune deficiency. Antibody responses and cell-mediated immunity are seriously impaired, probably because of atrophy of the thymus and the consequent deficiency of helper T cells.

Allergies

Deficien-

by drug

therapy

Types of

sensitivity

reactions

hyper-

cies caused

The immune system recognizes and responds to almost any foreign molecule; it cannot discern between molecules that are characteristic of potentially infective agents and those that are not. In other words, an immune response can be induced by materials that have nothing to do with infection. The mechanisms brought into play, though beneficial for eliminating microbes, are not necessarily beneficial when otherwise innocuous substances are targeted. Furthermore, even initially protective mechanisms can cause secondary disorders when they operate on too great a scale or for a longer period than necessary, thereby damaging tissues remote from the infection. The terms "allergy" and "hypersensitivity" are commonly used to describe inappropriate immune responses that occur when an individual becomes sensitized to harmless substances. Allergic reactions do not as a rule cause symptoms to arise on the first exposure to an antigen. At the initial exposure reactive lymphocytes are generated that go into action only when the individual is reexposed to the antigen.

The manifestations of a particular allergic reaction depend on which of the immune mechanisms predominates in the response. Based on this criterion, immunologists use the Gell-Coombs classification system to recognize four types of hypersensitivity reactions. Types I, II, and III involve antibody-mediated mechanisms and are of rapid onset. The type IV reaction stems from cell-mediated mechanisms and has a delayed onset. It should be noted that the categorization, though useful, is an oversimplification and that many diseases involve a combination of hypersensitivity reactions.

TYPE I HYPERSENSITIVITY

Type I, also known as atopic or anaphylactic, hypersensi-

tivity, involves IgE antibody, mast cells, and basophils. Sensitization, activation, and effector phases. Type I hypersensitivity can be divided into three phases. The first is called the sensitization phase and occurs when the individual is first exposed to antigen. Exposure stimulates the production of IgE antibodies, which bind to mast cells and circulating basophils. The mast cells are found in tissues, often near blood vessels. The second phase is the activation phase, and it occurs when the individual is reexposed to the antigen. Reintroduction of the antigen causes IgE molecules to become cross-linked, which triggers the mast cells and basophils to release the contents of their granules into the surrounding fluids, initiating the third phase, called the effector phase, of the type I reaction. The effector phase includes all the body's complex reactions to the potent chemicals from the granules. The chemicals include histamine, which causes small blood vessels to dilate and smooth muscle in the bronchial tubes of the lungs to constrict; he-

parin, which prevents blood coagulation; enzymes that break down proteins; signaling agents that attract eosinophils and neutrophils; and a chemical that stimulates platelets to adhere to blood vessel walls and to release serotonin, which constricts arteries. In addition the stimulated mast cells make chemicals (prostaglandins and leukotrienes) that have potent local effects; they cause capillary blood vessels to leak, smooth muscles to contract. granulocytes to move more actively, and platelets to be-

Type I allergic reactions. The overall result of the type I reaction is an acute inflammation marked by local seepage of fluid from and dilation of the blood vessels, followed by ingress of granulocytes into the tissues. This inflammatory reaction can be a useful local protective mechanism. If, however, it is triggered by an otherwise innocuous antigen entering the eyes and nose, it results in swelling and redness of the linings of the eyelids and nasal passages, secretion of tears and mucus, and sneezing-the typical symptoms of hay fever. If the antigen penetrates the lungs, not only do the linings of the bronchial tubes become swollen and secrete mucus, but the muscle in their walls contracts and the tubes are narrowed, making breathing particularly difficult. These are the symptoms of acute asthma. If the antigen is injected beneath the skin-for example, by the sting of an insect or in the course of some medical procedure-the local reaction may be extensive. Called a wheal-and-flare reaction, it includes swelling, produced by the release of serum into the tissues (wheal), and redness of the skin, resulting from the dilation of blood vessels (flare). If the injected antigen enters the bloodstream and interacts with basophils in the blood as well as with mast cells deep within the tissues, the release of active agents can cause hives, characterized by severe itching. If the antigen enters through the gut, the consequences can include painful intestinal spasms and vomiting. Local reaction with mast cells increases the permeability of the mucosa of the gut, and in many cases the antigen enters the bloodstream and also produces hives. Regardless of whether the allergen is injected or ingested, if it ends up in the bloodstream, it can induce anaphylaxis, a syndrome that in its most severe form is characterized by a profound and prolonged drop in blood pressure accompanied by difficulty in breathing. Death can occur within minutes unless an injection of epinephrine is administered immediately. This type of severe allergic reaction can occur in response to foods, drugs such as penicillin, and insect venom.

Anaphylaxis

Another feature of type I hypersensitivity reactions is that, once the immediate local reaction to the allergen has taken its course, there may occur an influx of more granulocytes, lymphocytes, and macrophages at the site. If the allergen is still present, a more prolonged form of the same reactionthe so-called late-phase reaction, which lasts a day or two rather than minutes-may supervene. This is a feature of asthmatic attacks in some subjects, in whom repeated episodes also lead to increased sensitivity of the air passages to the constrictive action of histamine. If such persons can escape exposure to the allergen for several weeks, subsequent exposure causes much less severe attacks. A prolonged IgE-induced reaction also causes atopic dermatitis, a skin condition characterized by persistent itching and scaly red patches. These often develop at sites where the skin is bent, such as the elbows and knees. The persistence is due to the influx of mast cells stimulated by the continued presence of the allergen, which is often a harmless substance such as animal hair or dander.

Typical type I allergens. Most people are not unduly susceptible to hay fever or asthma. Those who are-about 10 percent of the population-are sometimes described as atopic (from the term "atopy," meaning "uncommon"). Atopic individuals have an increased tendency to make IgE antibodies. This tendency runs in families, though there is no single gene responsible as there is in some hereditary diseases such as hemophilia. Although many innocuous antigens can stimulate a small amount of IgE antibody in the atopic individual, some antigens are much more likely to do so than others, especially if they are repeatedly absorbed in very small amounts through mucosal surfaces.

Such antigens are often termed allergens. These substances are usually polypeptides that have carbohydrate groups attached to them. They are resistant to drying, but no special characteristic is known that clearly distinguishes allergens from other antigens. Allergens are present in many types of pollen (which accounts for the seasonal incidence of hay fever), in fungal spores, in animal dander and feathers, in plant seeds (especially when finely ground) and berries, and in what is called house dust. The main allergen in house dust has been identified as the excreta of mites that live on skin scales (see Figure 12); other mites (those that live in flour, for example) also excrete potent allergens. This list is far from exhaustive. In addition to those previously named, sensitivities to chocolate, egg whites, oranges, or cow's milk are not uncommon.

Figure 12: Scanning electron micrograph of a dust mite (Dermato phoides) on dust

The amount of allergen needed to trigger an acute type I hypersensitivity reaction in a sensitive person is very small: less than one milligram can produce fatal anaphylaxis if it enters the bloodstream. Medical personnel should inquire about any history of hypersensitivity before administering drugs by injection, and if necessary they should inject a test dose into (rather than through) the skin to ensure that hypersensitivity is absent. In any case, a suitable remedy should be at hand.

Treatment of type I allergic responses. Several drugs are available that mitigate the effects of IgE-induced allergic reactions. Some, such as the anti-inflammatory cromolyn, prevent mast-cell granules from being discharged if administered before reexposure to antigen. For treatment of asthma and severe hay fever, such drugs are best administered by inhalation. The effects of histamine can be blocked by antihistamine agents that compete with histamine for binding sites on the target cells. Antihistamines are used to control mild hay fever and such skin manifestations as hives, but they tend to make people sleepy. Epinephrine counteracts, rather than blocks as antihistamines do, the effects of histamine and it is most effective in treating anaphylaxis. Corticosteroid drugs can help control persistent asthma or dermatitis, probably by diminishing the inflammatory influx of granulocytes, but long-continued administration can produce dangerous side effects and should be avoided.

Sensitivity to allergens often diminishes with time. One explanation is that increasing amounts of IgG antibodies are produced, which preferentially combine with the allergen and so prevent it from reacting with the cell-bound IgE. This is the rationale for desensitization treatment, in which small amounts of the allergen are injected beneath the skin in gradually increasing quantities over a period of several weeks, so as to stimulate IgG antibodies. The method is often successful in diminishing hypersensitivity to a tolerable level or even abolishing it. However, increased IgG production may not be the complete explanation. The capacity to make IgE antibodies depends on the cooperation of helper T cells, and they in turn are regulated by regulatory T cells. There is evidence suggesting that

atopic individuals are deficient in regulatory T cells whose function is specifically to depress the B cells that produce IgE and that desensitization treatment may overcome this deficiency.

TYPE II HYPERSENSITIVITY

Allergic reactions of this type, also known as cytotoxic reactions, occur when cells within the body are destroyed by antibodies, with or without activation of the entire complement system. When antibody binds to an antigen on the surface of a target cell, it can cause damage through a number of mechanisms. When IgM or IgG molecules are involved, they activate the complete complement system, which leads to the formation of a membrane attack complex that destroys the cell (see above Antibody-mediated immune mechanisms). Another mechanism involves IgG molecules, which coat the target cell and attract macrophages and neutrophils to destroy it. Unlike type I reactions, in which antigens interact with cell-bound IgE immunoglobulins, type II reactions involve the interaction of circulating immunoglobulins with cell-bound antigens

Type II reactions only rarely result from the introduction of innocuous antigens. More commonly, they develop because antibodies have formed against body cells that have been infected by microbes (and thus present microbial antigenic determinants) or because antibodies have been produced that attack the body's own cells. This latter process underlies a number of autoimmune diseases, including autoimmune hemolytic anemia, myasthenia gravis, and Goodpasture's syndrome.

Reactions

against

blood

trans-

fusions

Type II reactions also occur after an incompatible blood transfusion, when red blood cells are transfused into a person who has antibodies against proteins on the surface of these foreign cells (either naturally or as a result of previous transfusions). Such transfusions are largely avoidable, but when they do occur the effects vary according to the class of antibodies involved. If these activate the complete complement system, the red cells are rapidly hemolyzed (made to burst), and the hemoglobin in them is released into the bloodstream. In small amounts it is mopped up by a special protein called hemopexin, but in large amounts it is excreted through the kidneys and can damage the kidney tubules. If activation of complement only goes part of the way (to the C3 stage), the red cells are taken up and destroyed by granulocytes and macrophages, mainly in the liver and spleen. The heme pigment from the hemoglobin is converted to the pigment bilirubin, which accumulates in the blood and makes the person appear jaundiced.

Not all type II reactions cause cell death. Instead the antibody may cause physiological changes underlying disease. This occurs when the antigen to which the antibody binds is a cell-surface receptor, which normally interacts with a chemical messenger, such as a hormone. If the antibody binds to the receptor, it prevents the hormone from binding and carrying out its normal cellular function (see below Autoimmune diseases of the thyroid gland).

TYPE III HYPERSENSITIVITY

Type III, or immune-complex, reactions are characterized by tissue damage caused by the activation of complement in response to antigen-antibody (immune) complexes that are deposited in tissues. The classes of antibody involved are the same ones that participate in type II reactions-IgG and IgM-but the mechanism by which tissue damage is brought about is different. The antigen to which the antibody binds is not attached to a cell. Once the antigenantibody complexes form, they are deposited in various tissues of the body, especially the blood vessels, kidneys, lungs, skin, and joints. Deposition of the immune complexes causes an inflammatory response, which leads to the release of tissue-damaging substances, such as enzymes that destroy tissues locally, and interleukin-1, which, among its other effects, induces fever.

Immune complexes underlie many autoimmune diseases, such as systemic lupus erythematosus (an inflammatory disorder of connective tissue), most types of glomerulonephritis (inflammation of the capillaries of the kidney), and rheumatoid arthritis.

Type III hypersensitivity reactions can be provoked by in-

Blocking the effect of histamine

halation of antigens into the lungs. A number of conditions are attributed to this type of antigen exposure, including farmer's lung, caused by fungal spores from moldy hay; pigeon fancier's lung, resulting from proteins from powdery pigeon dung; and humidifier fever, caused by normally harmless protozoans that can grow in air-conditioning units and become dispersed in fine droplets in climate-controlled offices. In each case, the farmer, pigeon fancier, or office worker will be sensitized to the antigen-i.e., will have IgG antibodies to the agent circulating in the blood Inhalation of the antigen will stimulate the reaction and cause chest tightness, fever, and malaise, symptoms that usually pass in a day or two but recur when the individual is reexposed to the antigen. Permanent damage is rare unless individuals are exposed repeatedly. Some occupational diseases of workers who handle cotton, sugarcane, or coffee waste in warm countries have a similar cause, with the sensitizing antigen usually coming from fungi that grow on the waste rather than the waste itself. The effective treatment is, of course, to prevent further exposure.

The type of allergy described in the preceding paragraph was first recognized as serum sickness, a condition that often occurred after animal antiserum had been injected into a patient to destroy diphtheria or tetanus toxins. While still circulating in the blood, the foreign proteins in the antiserum induced antibodies, and some or all of the symptoms described above developed in many subjects. Serum sickness is now rare, but similar symptoms can develop in people sensitive to penicillin or certain other drugs, such as sulfonamides. In such cases the drug combines with the subject's blood proteins, forming a new antigenic determinant to which antibodies react.

Serum

sickness

The consequences of antigen-and-antibody interaction within the bloodstream vary according to whether the complexes formed are large, in which case they are usually trapped and removed by macrophages in the liver, spleen, and bone marrow, or small, in which case they remain in the circulation. Large complexes occur when more than enough antibody is present to bind to all the antigen molecules, so that these form aggregates of many antigen molecules cross-linked together by the multiple binding sites of IgG and IgM antibodies. When the ratio of antibody to antigen is enough to form only small complexes, which can nevertheless activate complement, the complexes tend to settle in the narrow capillary vessels of the synovial tissue (the lining of joint cavities), the kidney, the skin, or, less commonly, the brain or the mesentery of the gut. The activation of complement-which leads to increased permeability of the blood vessels, release of histamine, stickiness of platelets, and attraction of granulocytes and macrophages-becomes more important when the antigen-antibody complexes are deposited in blood vessels than when they are deposited in the tissues outside the capillaries. The symptoms, depending on where the damage occurs, are swollen, painful joints, a raised skin rash, nephritis (kidney damage, causing blood proteins and even red blood cells to leak into the urine), diminished blood flow to the brain, or gut spasms.

The formation of troublesome antigen-antibody complexes in the blood can also result from subacute bacterial endocarditis, a chronic infection of damaged heart valves. The infectious agent is often Streptococcus viridans, normally a harmless inhabitant of the mouth. The bacteria in the heart become covered with a layer of fibrin, which protects them from destruction by granulocytes, while they continue to release antigens into the circulation. These can combine with preformed antibodies to form immune complexes that can cause symptoms resembling those of serum sickness.

TYPE IV HYPERSENSITIVITY

Type IV hypersensitivity is a cell-mediated immune reaction. In other words, it does not involve the participation of antibodies but is due primarily to the interaction of T cells with antigens. Reactions of this kind depend on the presence in the circulation of a sufficient number of T cells able to recognize the antigen. The specific T cells must migrate to the site where the antigen is present. Since this process takes more time than reactions involving antibodies, type IV reactions first were distinguished by their delayed onset and are still frequently referred to as delayed hypersensitivity reactions. Type IV reactions not only develop slowly-reactions appear about 18 to 24 hours after introduction of antigen to the system-but, depending on whether the antigen persists or is removed, they can be prolonged or relatively transient.

The T cells involved in type IV reactions are memory cells derived from prior stimulation by the same antigen. These cells persist for many months or years, so that persons who have become hypersensitive to an antigen tend to remain so. When T cells are restimulated by this antigen presented on the surface of the macrophages (or on other cells that can express class II MHC molecules), the T cells secrete cytokines that recruit and activate lymphocytes and phagocytic cells, which carry out the cell-mediated immune response. Two common examples of delayed hypersensitivity that illustrate the various consequences of type IV reactions are tuberculin-type and contact hypersensitivity.

Tuberculin-type hypersensitivity. The tuberculin test is based on a delayed hypersensitivity reaction. The test is used to determine whether an individual has been infected with the causative agent of tuberculosis. Mycobacterium tuberculosis. (A previously infected individual would harbour reactive T cells in the blood.) In this test, small amounts of protein extracted from the mycobacterium are injected into the skin. If reactive T cells are present-i.e. the test is positive-redness and swelling appear at the injection site the next day, increase through the following day, and then gradually fade away. If a tissue sample from the site of the positive reaction is examined, it will show infiltration by lymphocytes and monocytes, increased fluid between the fibrous structures of the skin, and some cell death. If the reaction is more severe and prolonged, some of the activated macrophages will have fused together to form large cells containing several nuclei. An accumulation of activated macrophages of this sort is termed a granuloma. Immunity to a number of other diseases (for example, leprosy, leishmaniasis, coccidiosis, and brucellosis) also can be gauged by the presence or absence of a delayed reaction to a test injection of the appropriate antigen. In all these cases, the test antigen provokes only a transitory response when the test is positive and, of course, no response at all when the test is negative.

The same cell-mediated mechanisms are elicited by an actual infection with the living microbes, in which case the inflammatory response continues and the ensuing tissue damage and granuloma formation can cause serious damage. Moreover, in an actual infection, the microbes are often present inside the macrophages and are not necessarily localized in the skin. Large granulomas develop when the stimulus persists, especially if undegradable particulate materials are present and several macrophages, all attempting to ingest the same material, have fused their cell membranes to one another. The macrophages continue to secrete enzymes capable of breaking down proteins. and the normal structure of tissues in their neighbourhood becomes distorted. Although granuloma formation may be an effective method the immune system employs to sequester indigestible materials (whether or not of microbial origin) from the rest of the body, the harm inflicted by this immune mechanism may be much more serious than the damage caused by the infectious organisms. This is the case in such diseases as pulmonary tuberculosis and schistosomiasis and in certain fungal infections that become established within the body tissues rather than at their surface.

Contact hypersensitivity and dermatitis. In contact hypersensitivity, inflammation occurs when the sensitizing chemical comes in contact with the skin surface. The chemical interacts with proteins of the body, altering them so that they appear foreign to the immune system. A variety of chemicals can cause this type of reaction. They include various drugs, excretions from certain plants, metals such as chromium, nickel, and mercury, and industrial products such as hair dyes, varnish, cosmetics, and resins. All these diverse substances are similar in that they can diffuse through the skin. One of the best-known examples of a plant that can provoke a contact hypersensitivity reaction

Formation of granulomas

Contact

dermatitis

is poison ivy (Toxicodendron radicans), found throughout North America. It secretes an oil called urushiol, which is also produced by poison oak (T. diversilobum), the poison primrose (Primula obconica), and the lacquer tree (T. vernicifluum). When urushiol comes in contact with the skin, it initiates the contact hypersensitivity reaction.

As sensitizing chemicals diffuse into the skin, they react with some proteins of the body, changing the antigenic properties of the protein. The chemical can interact with proteins located in both the outer horny layer of the skin (dermis) and the underlying tissue (epidermis). Some of the epidermal protein complexes migrate to the draining lymph nodes, where they stimulate T cells responsive to the newly formed antigen to multiply. When the T cells leave the nodes to enter the bloodstream, they can travel back to the site where the chemical entered the body. If some of the sensitizing substance remains there, it can reactivate the T cells, inducing a recurrence of inflammation. The clinical result is contact dermatitis, which can persist for many days or weeks. Treatment is by local application of corticosteroids, which greatly diminish lymphocyte infiltration, and by avoidance of further contact with the sensitizing agent.

Although delayed hypersensitivity can be a nuisance when it produces skin allergies, it is an important part of the immune defense against intracellular parasites, and it may also play a role in the containment of some tumours.

Autoimmune disorders

The mechanism by which the enormous diversity of B and T cells is generated is a random process that inevitably gives rise to some receptors that recognize the body's own constituents as foreign. Lymphocytes bearing such self-reactive receptors, however, are eliminated or rendered impotent by several different mechanisms, so that the immune system does not normally generate significant amounts of antibodies or T cells that are reactive with the body's components (self antigens). Nevertheless, an immune response to self, called autoimmunity, can occur, and some of the ways that self-directed immune responses cause damage have been mentioned above in Allergies.

Understanding and identifying autoimmune disorders is difficult given that all humans have many self-reactive antibodies in the blood but most show no sign of disease Consequently the identification of autoantibodies is not a sufficient diagnostic tool for determining the presence of an autoimmune disorder. There is a difference between an autoimmune response and disease: in the former case the autoantibodies do not cause dysfunction, but in the latter case they do.

BASIC PROCESSES UNDERLYING AUTOIMMUNITY

Immunologists cannot always explain why the mechanisms that normally prevent the development of autoimmunity have failed in a particular autoimmune disorder. They have, however, advanced a number of explanations for such failures.

Alteration of self antigens. Various mechanisms can alter self components so that they seem foreign to the immune system. New antigenic determinants can be attached to self proteins, or the shape of a self antigen can shift-for a variety of reasons-so that previously unresponsive helper T cells are stimulated and can cooperate with preexisting B cells to secrete autoantibodies. Alteration of the shape of a self protein has been shown to occur in experimental animals and is the most probable explanation for the production of the rheumatoid factors that are characteristic of rheumatoid arthritis. Infectious organisms also can alter self antigens, which may explain why viral infection of specialized cells-such as those in the pancreas that secrete insulin or those in the thyroid gland that make thyroid hormones-often precedes the development of autoantibodies against the cells themselves and against their hormonal products.

Release of sequestered self antigens. Intracellular antigens and antigens found on tissues that are not in contact with the circulation normally are segregated effectively from the immune system. Thus, they may be regarded as foreign if they are released into the circulation as a result of tissue destruction caused by trauma or infection. After sudden damage to the heart, for example, antibodies against heart muscle membranes regularly appear in the blood.

Cross-reaction with foreign antigens. This mechanism comes into play when an infectious agent produces antigens so similar to those on normal tissue cells that the antibodies stimulated to react against the foreign antigen also recognize the similar self antigen; hence, the two antigens are said to be cross-reactive. Autoantibodies stimulated by external antigens in this way tend to persist. For example, the streptococci that cause rheumatic fever make antigens that are cross-reactive with those on heart muscle membranes, and the antibodies that react with the bacteria also bind to the heart muscle membrane and cause damage to the heart. Another instance of an autoimmune disorder that arises from cross-reactivity is Chagas' disease. The trypanosomes that cause the disease make antigens that are cross-reactive with antigens on the surface of the specialized nerve cells that regulate the orderly contraction of muscles in the bowel. Antibodies directed against the trypanosomes also interact with these nerve cells and disrupt normal bowel functioning.

Genetic factors. Several autoimmune diseases clearly run in families. Careful studies (for example, those comparing the incidence in identical twins with that in fraternal twins) have shown that the increased incidence of such autoimmune diseases cannot be explained by environmental factors. Rather, it stems from a genetic defect that is passed from one generation to the next. Such disorders include Graves' disease, Hashimoto's disease, autoimmune gastritis (including pernicious anemia), type I (insulin-dependent) diabetes mellitus, and Addison's disease. These diseases are more common in persons who bear particular MHC antigens on their cells. The possession of these antigens does not imply that a person will contract such diseases, only that he or she is more likely to do so. Researchers generally agree that the interaction of many genes is needed before a person develops such autoimmune diseases. For example, type I diabetes is believed to result from at least 14 genes.

Another interesting feature that appears to relate to the inheritance of autoimmune disorders is gender. Most human autoimmune diseases afflict far more women than men. Women are affected more often than men with most of the better-known disorders, including myasthenia gravis, systemic lupus erythematosis, Graves' disease, rheumatoid arthritis, and Hashimoto's disease. The reason for this is not fully understood, but researchers think it probably is related to hormonal effects on immune responses.

EXAMPLES OF AUTOIMMUNE DISORDERS

The spectrum of autoimmune disorders is wide, ranging from those that involve a single organ to others that affect several different organs as a secondary consequence of the presence of immune complexes in the circulation. It is not possible in this article to discuss them all. The following disorders have been chosen to illustrate some of the very different complications that can arise from autoimmunity.

Autoimmune diseases of the thyroid gland, Hashimoto's disease and Graves' disease are two of the most common autoimmune disorders of the thyroid gland, the hormonesecreting organ (located in the throat near the larynx) that plays an important role in the development and maturation of all vertebrates. The thyroid is composed of closed sacs (follicles) lined with specialized thyroid cells. These cells secrete thyroglobulin, a large protein that acts as a storage molecule from which thyroid hormones are made and released into the blood. The rate at which this occurs is regulated by thyroid-stimulating hormone (TSH), which activates the thyroid cells by combining with TSH recentors found on the thyroid cell membrane. Hashimoto's disease involves swelling of the gland (a condition called goiter) and a loss of thyroid hormone production (hypothyroidism). The autoimmune process underlying this disorder is thought to be instigated by helper T cells that react with thyroid antigens, although the mechanism is not

completely understood. Once activated, the self-reactive T

Inherited autoimmune diseases

Hashi. moto's disease Graves' disease

cells stimulate B cells to secrete antibodies against several target antigens, including thyroglobulin.

Graves' disease is a type of overactive thyroid disease (hyperthyroidism) involving excess production and secretion of thyroid hormones. The disease arises with the development of antibodies that are directed against the TSH receptor on the thyroid cells and that can mimic the action of TSH. When bound to the receptor, the antibodies stimulate excessive secretion of thyroid hormones.

In both Hashimoto's disease and Graves' disease, the thyroid gland becomes infiltrated with lymphocytes and is partially destroyed. If the gland is completely destroyed, a condition called myxedema may ensue, involving a swelling of tissues, especially those around the face.

Autoimmune hemolytic anemia. A number of autoimmune disorders are grouped under the rubric autoimmune hemolytic anemia. All result from the formation of autoantibodies against red blood cells, an event that can lead to hemolysis (destruction of red blood cells). The autoantibodies sometimes appear after infection with the bacterium Myconlasma pneumoniae, a rather uncommon cause of pneumonia. In that case the autoantibodies are directed against certain antigens that are present on red cells, and they are probably induced by a similar antigen in the microbes (an example of the cross-reaction of antigens). Autoantibodies directed against a different antigen of red blood cells are often produced in persons who have been taking the antihypertensive medication alpha methyldopa for several months; the reason for autoantibody development in such cases is unknown. Other drugs, such as quinine, sulfonamides, or even penicillin, very occasionally cause hemolytic anemia. In such cases it is thought that the drug acts as a hapten-that is, it becomes bound to a protein on the surface of red blood cells, and the complex becomes immunogenic.

The autoantibodies that form against red blood cells are categorized into two groups on the basis of their physical properties. Autoantibodies that bind optimally to red blood cells at 37° C (98.6° F) are categorized as warm-reacting. Warm-reacting autoantibodies belong primarily to the IgG class and cause about 80 percent of all cases of autoimmune hemolytic anemia. Autoantibodies that attach to red blood cells only when the temperature is below 37° C are called cold-reacting. They belong primarily to the IgM class. Cold-reacting autoantibodies are efficient at activating the complement system and causing the cell to which they are bound to be destroyed. Nevertheless, as long as the body temperature remains at 37° C, cold-reacting autoantibodies dissociate from the cell, and hemolysis is not severe. However, when limbs and skin are exposed to the cold for long periods of time, the temperature of circulating blood can be lowered, allowing cold-reacting autoantibodies to go to work. Infection with M. pneumoniae is met by cold-reacting antibodies.

Pernicious anemia and autoimmune gastritis. anemia stems from a failure to absorb vitamin B,, (cobalamin), which is necessary for the proper maturation of red blood cells. It is characteristically accompanied by a failure to secrete hydrochloric acid in the stomach (achlorhydria) and is in fact a symptom of severe autoimmune gastritis. To be absorbed by the small intestine, dietary vitamin B12 must form a complex with intrinsic factor, a protein secreted by the parietal cells in the stomach lining. Pernicious anemia results when autoantibodies against intrinsic factor bind to it, preventing it from binding to vitamin B, and thus preventing the vitamin from being absorbed into the body. The autoantibodies also destroy the acid-secreting parietal cells, which leads to autoimmune gastritis.

Rheumatoid arthritis. Rheumatoid arthritis is a chronic inflammatory disease that affects connective tissues throughout the body, particularly the synovial membranes that line the peripheral joints. Rheumatoid arthritis is one of the most common autoimmune diseases. Its cause is not known, but a variety of altered immune mechanisms probably contribute to the disorder, especially in more severe

One theory suggests that the inflammatory process of the disease is initiated by autoimmune reactions that involve one or more autoantibodies, referred to collectively as

rheumatoid factor. The autoantibodies react with the tail Rheumaregion of the Y-shaped IgG molecule-in other words, rheumatoid factor is anti-IgG antibodies. Immune complexes form between rheumatoid factor and IgG and apparently are deposited in the synovial membrane of joints. The deposition triggers a type III hypersensitivity reaction, activating complement and attracting granulocytes, which causes inflammation and pain in the joints. The granulocytes release enzymes that break down cartilage and collagen in the joints, and this eventually can destroy the smooth joint surface that is needed for ease of movement. If immune complexes in the blood are not effectively removed by the liver and spleen, they can produce systemic effects similar to those precipitated by serum sickness.

The devastating effects of rheumatoid arthritis also have been seen in patients, especially younger ones, in whom no rheumatoid factor is detected, and thus other mechanisms of initiation of the disorder probably exist.

Systemic lupus erythematosus. Systemic lupus erythematosus (SLE) is a syndrome characterized by organ damage that results from the denosition of immune complexes. The immune complexes form when autoantibodies are made against the nucleic acids and protein constituents of the nucleus of cells. Such autoantibodies, called antinuclear antibodies, do not attack healthy cells, since the nucleus lies within the cell and is not accessible to antibodies. Antigen-antibody complexes form only after the nuclear contents of a cell are released into the bloodstream during the normal course of cell death or as a result of inflammation. The resultant immune complexes are deposited in tissues, causing injury. Certain organs are more commonly involved than others, including the kidneys, joints, skin, heart, and serous membranes around the lungs.

Multiple sclerosis. Multiple sclerosis is an autoimmune disease that results in the gradual destruction of the myelin sheath that surrounds nerve fibres. It is characterized by progressive degeneration of nerve function, interjected with periods of apparent remission. The cerebrospinal fluid of persons with multiple sclerosis contains large numbers of antibodies directed against myelin basic protein and perhaps other brain proteins. Infiltrating lymphocytes and macrophages may exacerbate the destructive response. The reason the immune system launches an attack against myelin is unknown, but several viruses have been suggested as initiators of the response. A genetic tendency toward the disease has been noted; susceptibility to the disorder is indicated by the presence of the major histocompatibility complex (MHC) genes, which produce proteins found on the surface of B cells and some T cells.

Type I (insulin-dependent) diabetes mellitus. Type I diabetes mellitus is the autoimmune form of diabetes and often arises in childhood. It is caused by the destruction of cells of the pancreatic tissue called the islets of Langerhans. Those cells normally produce insulin, the hormone that helps regulate glucose levels in the blood. Individuals with type I diabetes have high blood glucose levels that result from a lack of insulin. Dysfunction of islet cells is caused by the production of cytotoxic T cells or autoantibodies that have formed against them. Although the initiating cause of this autoimmune response is unknown, there is a genetic tendency toward the disease, which also involves class II MHC genes. It can be treated with injections of insulin; however, even when treated, type I diabetes may eventually lead to kidney failure, blindness, or serious circulation difficulties within the extremities.

Other autoimmune disorders. Mechanisms similar to those that produce autoimmune hemolytic anemia can result in the formation of antibodies against granulocytes and platelets, although autoimmune attacks against these blood cells occur less frequently. Antibodies against other types of cells occur in a number of autoimmune diseases, and those self-reactive responses may be primarily responsible for the damage incurred. In myasthenia gravis, a disease characterized by muscle weakness, autoantibodies react against receptors on muscle cells. Normally the receptors bind to acetylcholine, a neurotransmitter released from nerve endings. When acetylcholine binds to an acetylcholine receptor on the surface of muscle cells, it stimulates the muscle to contract. The autoantibodies in

Myasthenia

myasthenia gravis bind to the acetylcholine receptors without activating them. The antibodies prevent muscle contraction either by blocking acetylcholine from binding to its receptor or by destroying the receptors outright. This renders the muscle less responsive to acetylcholine and ultimately weakens muscle contraction.

Cancers of the lymphocytes

Tumours arising from lymphocytes are given various names: they are called leukemias if the cancer cells are present in large numbers in the blood, lymphomas if they are mainly concentrated in lymphoid tissues, and myelomas if they are B-cell tumours that secrete large amounts of immunoglobulin. The following sections describe how cancers of the lymphocytes arise and how immunological techniques are being used to determine the prognosis and treatment of B- and T-cell tumours.

GENETIC CAUSES

Most cancers result from a series of random genetic accidents, or mutations, that occur to genes involved in controlling cell growth. One general group of genes implicated in cancer initiation and growth are called oncogenes. The unaltered, healthy form of an oncogene is called a protooncogene. Proto-oncogenes stimulate cell growth in a controlled manner that involves the interplay of a number of other genes. However, should a proto-oncogene become mutated in some way, it may become hyperactive, leading to uncontrolled cellular proliferation and the exaggeration of some normal cellular activities. A proto-oncogene can become mutated in a number of ways. According to one mechanism, called chromosomal translocation, part of one chromosome is severed from its normal position and reattached (translocated) onto another chromosome. If a proto-oncogene appears on the piece of the chromosome that is moved, it may be separated from the region that normally regulates it. In this manner the proto-oncogene becomes unregulated and turns into an oncogene. Chromosomal translocation of proto-oncogenes is involved in a number of B-cell tumours, including Burkitt's lymphoma and chronic myelogenous leukemia. T-cell leukemia also results from a chromosomal translocation.

MALIGNANT TRANSFORMATION OF LYMPHOCYTES

At any stage in its development, from stem cell to mature form, a lymphocyte may undergo malignant (cancerous) transformation. The transformed cell is no longer constrained by the processes that regulate normal development, and it proliferates to produce a large number of identical cells that make up the tumour. These cells retain the characteristics of the transformed cell's particular developmental stage, and because of this cancers can be distinguished according to the stage at which transformation took place. For example, B cells that become cancerous in the early stages of development give rise to such conditions as chronic myelogenous leukemia and acute lymphocytic leukemia, whereas malignant transformation of late-stage B cells-i.e., plasma cells-can result in multiple myeloma. Regardless of what stage of the cell becomes cancerous, malignant cells outgrow and displace other cells that continue to develop normally.

Both T and B cells have surface antigens that are characteristic of different stages in their life cycle, and antibodies

have been prepared that identify the antigens. Knowledge of the specific type and stage of maturation of the tumour cells helps physicians determine the prognosis and course of treatment for the patient. This information is important because different types of tumours respond to different therapies and also because the chances of effecting a cure vary from type to type. Advances in drug treatments have dramatically improved the outlook for children with acute lymphoblastic leukemia, the most prevalent of the childhood leukemias. Similarly, most cases of Hodgkin's disease, a common type of lymphoma that mainly strikes adults, can be cured by drugs, radiation, or a combination of both. Myelomas primarily arise in older individuals. These tumours grow fairly slowly and are usually diagnosed by virtue of the characteristic immunoglobulin they secrete. However, this immunoglobulin may be produced in such large amounts that it causes secondary damage such as kidney failure.
