The ensuing Peace of Antalcidas, or King's Peace, of 386 specified that Asia, including Cyprus and Clazomenae, were to belong to the king of Persia. (Ionian Clazomenae was included because Athens had interfered there and also because its status-whether it was an island or part of the mainland-was unclear. It was in fact a peninsular site. Cyprus was included because Athens had been helping the rebel king, Evagoras.) The other Greek cities great and small, including the other islands, were to be autonomous, but Athens was allowed to keep Lemnos. Imbros, and Sevros, three long-standing cleruchies. Modern argument centres on the question of whether there were additional clauses, not supplied by the main account (that of Xenophon). For instance, the Athenian navy was perhans ordered to be broken up and the gates on the Piraeus removed, but these may have been consequences, not clauses, of the peace. The same is true of Sparta's position under the peace, which was certainly much strengthened. There is no agreement, however, that Sparta's enhanced position was officially recognized by some such description as "champion" of the peace, Argos' merger with Corinth was cancelled, and, more important (in view of the relative power of the states concerned), Thebes had to relinquish the control of Boeotia that it had been exercizing in an unrecognized but progressively real way since 446.

In Anatolia there was little immediate change-the Spartans had after all pulled out of Anatolia some years before. though an inscription (published in 1976) suggests that the Ionian cities may have clung to a precarious autonomy until 386. One difference after 386 lay in the status of possessions up to then held by various Greek islands on the mainland of Anatolia. These possessions had hitherto been anomalous enclaves of Greek control within basically satrapal Asia, but the King's Peace surely assigned them formally to Persia in general. Anatolia now became the political property of Persia and the satraps for the 50 years until Alexander's arrival. Occasional adventures, such as Greek flirtation with the Revolt of the Satraps in the 360s, do not seriously affect this generalization.

The activities of those 4th-century satraps (and of dynasts without the satrapal title but recognized by Persia) are of great interest, though documented more by inscriptions and archaeology than by written sources. The most energetic of them was the Hecatomnid dynasty of Caria, which took its name from Hecatomnus, the son of Hyssaldomus. Hecatomnus was appointed satrap of the new separate satrapy of Caria, perhaps in the mid-390s, as a counterpoise to Sparta. He ruled his pocket principality under light Persian authority until 377 and made dedications in Greek script at a number of local sites and sanctuaries. The major Hellenizing force, however, was his son Mausolus (Maussollos on the inscriptions), satrap from 377 to 353, who gave his name to the Mausoleum, the tomb he perhaps commissioned for himself. The Mausoleum itself, a creation of Greek artists and sculptors but with some barbarian features, has long been known from surviving sculptural fragments and from Greek and Latin literary descriptions. It was constructed at Halicarnassus, which,

The King's

after a move from inland Mylasa, became the Hecatomnid capital, with palace and harbour built on monarchical lines that surely owed some inspiration to Dionysius of Sicily. The importance of other sites associated with the Hecatomnid dynasty, above all that of Labranda in the hills not far from the family seat of Mylasa, would not have been guessed from the literary sources. Inscriptions placed in aggressive prominence on fine temples and templelike buildings at Labranda (and published in 1972) attest the wealth and the Hellenizing intentions of the rulers (the dedicants include Mausolus' brother and eventual successor Idrieus). They also illustrate the range of the family's diplomatic contacts (for instance with faraway Crete) and their relations with the local communities, both Greek and native Carian. For example, in a text from Labranda, a semi-Greek community called the Plataseis confers tax privileges and citizenship on a man from Cos; the grant is ratified by yet another Hecatomnid brother and satran. Pixodarus. And a remarkable trilingual inscription in Lycian, Greek, and Aramaic (a Semitic script used for convenience in many parts of the Persian empire), found in 1973, proves the family's interests to have spread eastward into Lycia; the text illustrates the cultural, social, and religious heterogeneity of southwestern Anatolia in the period before Alexander's arrival. Hellenization was well under

Helleniza-

tion in

Anatolia

way before he came. The same conclusion is compelled by such dynastic (rather than strictly satrapal) edifices as the Nereid monument from Lycia (early 4th century) or the caryatids (roof-carrying female soutplet statues) from Lycian Limyra, a place ruled by a Hellenizing prince significantly named Pericles

Hellenization at the cultural level and tolerance of the social structures of small local places with no military muscle did not necessarily entail favouring the political interests of the Greek states to the west. In fact, Mausolus, despite a brief and cautious insurrectionary moment in the late 360s when he joined the great Revolt of the Satraps (a movement in which there was also tentative Athenian and Spartan participation), is found actively damaging Athenian interest in the Aegean in the 350s.

In 386, however, the political dividing line between Greek and Persian interests looked relatively clean, although it was usually with the help of Greek mercenaries that over the next decades Persia made its series of attempts on the recovery of Egypt, the immediate task in the sequel to the King's Peace. Unsuccessful there, Persia had better fortune in Cyprus. In Greece, Sparta's supremacy looked as militarily imposing as in 404, though with the abandonment of Asia its moral authority was much weakened.

From 386 BC to Philip II of Macedon. The autonomy guaranteed to the Greek cities by the King's Peace in 386 represented in principle an advance in interstate diplomacy; but then as now the word "autonomy" was elastic, and Sparta by its behaviour soon made clear its intention to interpret it in the way most favourable to itself. That is, it applied the old criterion of "what is best for Sparta." Its first move, in 385, was to break up the polis of Mantinea into its four constituent villages. This move was intended to dismantle the physical polis of Mantinea as well as its democracy; in the particular Mantinean context the return to the villages strengthened the political influence of the wealthy and oligarchic landowners, whose estates adjoined the villages. The "troublesome demagogues," as Xenophon calls them, were expelled. Sparta could perhaps have represented the original 5th- or possibly 6thcentury Mantinean synoecism, whereby the villages had been joined into a polis, as a breach of local autonomy (that is, of the right of the separate villages to exist as political units), but it is doubtful that Sparta even bothered to formulate any such justification. It would have been too hollow a reply to the more obvious interpretation that it was simply exploiting its supremacy to infringe on the autonomy of the Mantinean polis.

Soon after, Sparta responded to an invitation, surely welcome in view of its previous northern and central Greek involvements, to interfere against the rising power of Olynthus in northern Greece. Grown populous and powerful since its synocism in 432 at the instance of Perdicas

II of Macedon, the city had survived the military reorganization of Macedonia by Perdiccas' successor Archelaus (413-399). Now another Macedonian king, Amyntas III. who had succeeded to the Macedonian throne about 393 after a series of short, weak reigns, joined two Greek cities Acanthus and Apollonia, in an appeal to Sparta against Olynthus. The Spartans sent Phoebidas north, but in a momentous development he was asked into Thebes en route by a pro-Spartan faction there. Without reference (naturally) to the authorities at home, Phoebidas installed a garrison on the Cadmea, the Theban acropolis (382). The occupation of the Cadmea was a famous instance of Spartan high-handedness; indeed, it produced such a revulsion of feeling that Sparta lost its leadership of Greece. Had Phoebidas' act been promptly disowned by Sparta. the damage could have been contained. King Agesilaus, however, approached the matter solely from the point of view of Spartan advantage; he once again posed the question of whether this action had been good or bad for Sparta, with the result that Phoebidas was punished with a fine but then reemployed elsewhere, and the garrison in Thebes was retained. Meanwhile (380). Olynthus was reduced

The occupation of the

Agesilaus, however, gave the wrong answer to his own question; the Cadmea episode meant that Sparta would no longer have things its way. When a group of Theban exiles liberated the Cadmea in 379, they were helped by Athens, though at first unofficially. Athens, whose foreign policy in the years 386-380 had been cautious in the extreme, evidently felt it could not risk Spartan reprisals for its help to Thebes without seeking moral and military support from other Greek states. It now made a series of alliances. with Chios, Byzantium, and Methymna on Lesbos, which prefigure the formation of the Second Athenian Confederacy, formally inaugurated in 378. The charter of the new confederacy was issued at the beginning of 377. Athens was right to suspect Spartan anger; an attempted raid on the Piraeus by the Spartan Sphodrias at this time is best seen as a response to the new mood in Athens. The raid failed in its object, whatever exactly that was. Once again Sparta did not pursue the offender.

The aims of the new confederacy are set out on an inscription of cardinal importance, the "charter" document, The enemy singled out is Sparta, while the main ally is Thebes. Hostility toward Sparta, however, though it was certainly the motive shared by Athens and Thebes, does not adequately explain the participation of islanders such as the Rhodians and Chians. In these islands the main fear must have been of encroachment by such Persian satraps as the energetic Mausolus. In this respect the new alliance recalls the early 470s, when alarm felt in eastern Aegean waters about Persia's intentions had led to the formation of the old Delian League. Yet the charter says nothing about Persia or the satraps in so many words; that would have been too provocative given Athens' naval weakness at the time. On the contrary, it is likely that a clause actually spelled out an intention to remain within the structure of the King's Peace. But this is not quite certain because the relevant lines were subsequently erased, probably in a moment of Panhellenist ardour.

Action against Persia may, then, have been once again envisaged, but in other respects the precedent of the Delian League was explicitly avoided. There was to be freedom and autonomy for all as well as an allied chamber, or synedrion, that could put motions directly before the Athenian Assembly. An inscription from 372 shows that this chamber had an allied president. In other words, an improvement was intended on the old synod of the Delian League, which met (presumably) only when Athens called it and had no way of influencing policy in an immediate or effective way; for instance, there is no sign of allied influence in Thucydides' detailed account of the preliminaries to the great Peloponnesian War. The synedrion was to decide on the membership of the confederacy, and it had some financial competence. There was to be joint judicial action; although there would not exactly be a joint court, the synedrion was to participate in treason trials alongside the Athenian Assembly and Council.

The restrictive policies adopted by Athens are interest-

The synedrion

ing as showing awareness of what had been 5th-century grievances. There was to be no tribute, no governors, no garrisons, and no cleruchies. Land outside Attica was not to be cultivated by Athenians, and "unfavourable stelae" (inscribed pillars) were to be taken down. (Perhaps this is a reference to grants of the right to own land in the empire. It does not seem, however, that much or any land had survived in Athenian hands after the end of the empire in 404, and the importance of this clause may be merely symbolic.) Except for the pledge against private cultivation of land outside Attica, every one of these pledges was to be broken sooner or later, mostly sooner. There is even a hint by an orator of a private Athenian estate on the island of Peparethus, and thus one perhaps should make no exceptions at all.

Athens now began to reorganize its public finances and to build ships. A new system of levying taxes by taxation groups, Symmories, was introduced. To make sure there were no cash-flow difficulties, rich individuals were expected to produce money for the state from their own resources and then recoup it from their taxation group. The new Athenian navy defeated Sparta in the battle of Naxos (376), a victory won under the command of the Athenian Chabrias. In western waters another great Athenian commander, Timotheus, won the battle of Alyzia. These successes produced new members for the confederacy (some states had cautiously stood aloof at first). In Boeotia, which Sparta, under King Agesilaus and initially the other king, Cleombrotus I, repeatedly invaded in the years after the liberation, there was a surprising land defeat of some Spartan contingents at the hands of the Theban "Sacred Band," a crack professional force. This, the battle of Tegyra (375), anticipated the more famous Spartan defeat at Leuctra four years later. The very existence of a Sacred Band was militarily significant, indicating that Spartan professionalism was now being copied by others who would soon overtake Sparta.

By 375 these efforts had exhausted all parties, and they were ready to make peace, or rather to accept another King's Peace. (Greeks felt uncomfortable about their involvement in this kind of Persian-inspired diplomacy, in which the various peaces were "sent down"-i.e., imposed—by the Persian king; as a result, the Persian aspect to this and other initiatives tends to be minimized or ignored by some literary sources, notably the "Panhellenist" Xenophon.) This time Athens' improved position was acknowledged in a clause specifically giving it the leadership by sea.

After its expulsion from Thebes, Sparta had steadily lost ground in central Greece. The Thebans energetically centralized Boeotia under their own leadership; for instance, they gained control of Thespiae and-yet again-of the unfortunate Plataea, which must have been resettled at some point, or perhaps just gradually, after the Peloponnesian War. In addition, a new power arose in Thessaly, that of Jason of Pherae, an ally of Thebes and until his assassination in 370 a military despot on the Dionysius model. Sparta was unable to respond to local Thessalian appeals against Jason, proof that Spartan ambition in cen-

tral Greece had finally come to an end. Theban expansionism was bound to drive Athens and Sparta together before long. Despite renewed fighting between Athens and Sparta in the west (374 and 373) and despite Thebes' continued, though increasingly reluctant, contributions to the Athenian navy (373), it was becoming clear that Thebes was the real threat to both Athens and Sparta. In this respect the Second Athenian Confederacy, with its political justification in terms of anti-Spartan sentiment, had already been superseded by events. There were other causes for concern within the confederacy. Tribute by another name had been levied for the western operations of 373, not altogether unreasonably: ships cost money, and Athens did not have great reserves, as it had in the 5th century. Perhaps more disquieting in its implications was the Athenian garrison on Cephallenia, attested by an inscription of 373; there may, however, have been special factors, and it is not known how long the garri-

At a famous peace conference held at Sparta in 371

son remained.

(which, in fact, resulted in another King's Peace), Sparta tried to prevent the Thebans from asserting and formalizing their local pretensions by signing on behalf of the whole of Boeotia. After a breach in the negotiations, signaled by a rhetorical duel between Agesilaus and the Theban Epaminondas, "a man famous for culture and philosophy," as his fellow Boeotian Plutarch described him half a millennium later, the Spartans invaded Boeotia. Twenty days after the peace conference. Sparta was defeated by Thebes on the field of Leuctra, the Theban commander Enaminondas showing more than cultural and philosophical qualities. This was a major and decisive battle in Greek history. Politically, it was to loosen Sparta's hold even on its Peloponnesian dependencies and to end its long subjection of Messenia; it introduced a decade of Theban prominence (which was, however, too inconclusive in its results to deserve its usual name of the "Theban hegemony"). Militarily, the battle was innovative in several ways, not only in the sheer professionalism of the Sacred Band. The left wing of the army was deepened to 50 men, in a further development of the Delium arrangement of 424. This provided a flexible "tail," or reserve force on the left that could be deployed as the course of the battle suggested. The decision about whether, when, and how to deploy it would be the general's, whose influence on the outcome of the battle was thus greater than had been usual hitherto. By placing the best troops on the left, the Thebans aimed to knock out the best Spartan troops, who were positioned opposite them, occupying the right wing in the traditional hoplite manner. Finally, by marching forward obliquely (rather than straightforwardly, as was customary), the Thebans increased the punch administered by this deepened left.

Perhaps the Spartan defeat needs no explanation other than Theban superiority. The Spartans lost about 1,000 men, 400 of them full Spartan citizens. It is disputed, however, whether manpower problems were the most serious factor in the defeat. Aristotle, on the one hand, explicitly made the connection between the defeat at Leuctra and shortage of men. There were not enough ways for talented or physically vigorous outsiders to acquire Spartan citizenship and too many ways by which full citizens could lose their status. Thus full citizens might be degraded in status for alleged cowardice in battle, or they might fall into debt through inability to pay their mess bills (these debts often resulted in the takeover of land by women, whose social and economic position was stronger at Sparta than elsewhere). In addition, the number of full citizens was reduced by unavoidable demographic disasters such as the earthquake of 465. On the other hand, it has been replied that non-Spartans (either degraded Spartans, the so-called "inferiors" like Cinadon, or citizens of the surrounding communities) might be and probably were brigaded alongside full Spartans, at least in the 4th century

After Leuctra there was a second peace of 371, this time at Athens. It is disputed whether Sparta participated, but it is certain that the Thebans were again excluded. It is also certain that the peace included undertakings to accept "the decrees of the Athenian allies"-a possible reference to the Second Athenian Confederacy and in any case a further strengthening of Athens' position.

Sparta's position, by contrast, now began visibly to crumble. In Arcadia, not merely did the Mantineans organize themselves into a polis once more, but Arcadia as a whole became a federal state on the initiative of a Mantinean called Lycomedes. (The capital was to be at Megalopolis, the "Great City," a new foundation made necessary by the ancient rivalry between Tegea and Mantinea.) Both these movements were obviously anti-Spartan, and the Arcadian or federation badly needed military support from some powerful quarter. The Arcadians found it at Thebes, after being rejected by Athens (if Athens had responded positively to this appeal, major Peloponnesian developments of the 360s might never have taken place).

Federal Arcadia was in origin a local growth, but there is no doubt that Theban support was crucial for its subsequent success. Theban promotion of federalism here and in central Greece is a notable political contribution, for which the evidence is largely inscriptional. Federations are decline of Sparta

The effect of Theban expansion

Diony-

sius II

attested in this decade not just in Arcadia but north of the Gulf of Corinth, in Aetolia, an ally of Thebes since 370, and in western Locris. There was also an intriguing Boeotian federal organization of Aegean states in the 350s, complete with synedrion on the Athenian model. All these federations arguably betray the influence of the Thebans, who evidently sought to export the federal principle long familiar in Boeotia itself. On a skeptical view, however, the development was a natural one and merely approximately

simultaneous with the period of maximum Theban power. In 370-69 Epaminondas invaded the Peloponnese (the first of several such invasions) and weakened Sparta irreparably by refounding Messene as a physical and political polis; the "state-of-the-art" fortifications of 4th-century Messene, an artillery-conscious circuit, stretched for nearly four miles over Mount Ithome. They are the best preserved in mainland Greece except perhaps for Aegosthena at the east end of the Gulf of Corinth; in Anatolia only Heraclea on Latmus, in Mausolus' Caria, is comparable. The loss of Messene crippled Sparta economically; in particular, Sparta no longer had a helot population to provide the economic surplus necessary for its military life-style. The combined impact of Leuctra, Megalopolis, and Messene was, however, not immediately obvious; in the "Tearless Battle" of 368, Sparta still managed to win a victory over a force of Arcadians. But Sparta was no longer a leading power.

In the 360s the main focus of Greek history shifted from Sparta to the struggle between Athens and Thebes, Neither power was really strong enough to impose a definitive solution; nor were outside forces available to give either side a decisive margin of superiority in the way that Persia had allowed Sparta to prevail in the Peloponnesian War. The 360s were a period of satrapal revolts in the western half of Artaxerxes' empire, and the subjugation of Egypt continued to elude him. In effect, though there also was some Persian-sponsored inter-Greek diplomacy in this decade, there was even less threat of force behind it than usual (the King's Peace of the 380s and that of the 370s had not been backed up by Persian men or ships). Dionysius I had added his weight on the Spartan side in 386, and his troops were found operating against Thebes as late as the early 360s. After his death, however, Sicily was not a serious factor in mainland Greek politics. Dionysius' son Dionysius II did send help to Sparta, enabling it to recover control over some formerly subject communities in 365, but that was about the limit of his interference. Dionysius II ruled precariously in Syracuse and southern Italy: he recovered Syracuse only to be finally driven to exile in Corinth by the Corinthian Timoleon in the 340s. This mid-century period of Syracusan history is of interest because of Plato's involvement in the politics of the tyranny. Dion, a relative of the older Dionysius by marriage, brought Plato to Syracuse in 367 to tutor Dionysius II in science and philosophy and generally to educate him to become a constitutional king; the visit, however, was

In central and northern Greece, the energetic rule of Jason (which might have given a push to the plans of his Theban allies) had ended abruptly in 370, and his eventual aims remained and remain an enigma. Macedon was the power of the future, but that was far from obvious in the 360s. After the death of Amyntas in 370, Macedon relapsed into a period of short unstable reigns, as in the 390s. Thus neither Thessaly nor Macedon was in a position to tilt the balance of power.

Thessaly and Macedon, however, were valuable prizes. Thessaly was not only enormously fertile but also had good harbours and religious influence in the Delphic amphictyony. Macedon had ship-building timber and great enatural resources (though few outlets to the sea because Greek colonial poleis stood in the way). Sparta could no longer compete for these assets, but Athens and Thebes could. Not long after the peace of 371, Athens restated an old claim to Amphipolis and added a claim to the Chersonese; in 368 it sent its general Iphicrates to Amphipolis. Thebes reacted to the Athenian claims by sending its other great man of the 4th century, Pelopidas, to Thessaly and Macedon. Theban activity in these areas did not add up to much in the end (one incidental result was that the young Philip, son of Amyntas, spent a period in Thebes as a hostage. The relevance, for Philip's subsequent army reforms, of his exposure to the methods of the first military state in Greece has often been noted). It did, however, show the Greek world the scale of Theban ambitions.

By 367, affairs in Thessaly and Arcadia were temporarily stalemated, and a peace conference was held at Susa. inside the Persian empire. Pelopidas asked that Sparta be made to give up Messenia formally and (more importantly, in view of Sparta's relative impotence at this time) that Athens be requested to give up its fleet. When these proposals inevitably failed, Thebes seized the valuable border territory of Oropus, and Athens was after all obliged to accept what was probably a King's Peace (366). There was, however, no question of Athens dismantling its navy; on the contrary, its claims to the Chersonese (reachable only by sea) were recognized in exchange, it seems, for acceptance of Theban leadership of Boeotia, including Oropus.

Athens' pursuit of essentially private Athenian aims, such as control of Amphipolis and the Chersonese, annot have pleased its allies in the confederacy. It was costly, and it was unsuccessful. (Securing the recognition of Athenian claims in theory was not the same thing as making good those claims in practice.) On the other hand, Athens, shortly after the peace of 366, did send help-a force under Timotheus-to a rebel satrap, Ariobarzanes, in the eastern Aegean; this showed a perhaps encouraging willingness to defend Greek interests against Persia, especially since Timotheus ejected a Persian garrison he found installed on Samos. This Persian garrison was a violation of Persia's side of the original King's Peace. It may seem surprising that Athens should act against Persia so soon if the peace of 366 was really a King's Peace, but the risk of reprisals just then was slight. In any case, Timotheus' somewhat contradictory instructions were to keep to the King's Peace while also helping Ariobarzanes. Timotheus' next move, however, the installation of an Athenian cleruchy on Samos, was a capital error. Timotheus' action could be technically justified: Samos was not a member of the Athenian Confederacy, and Persia had violated the King's Peace by installing its garrison; thus the cleruchy could be seen as a military response to Persian provocation in an area not covered by the rules of the charter of 377, Nonetheless, its effect on Greek opinion was damaging, and the Thebans quickly tried to exploit it.

Some naval interest on the part of Thebes can perhaps already be inferred from its designs on Thessaly, with its good harbours. After 365, however, Theban rivalry with Athens became explicit; Thebes planned a fleet of 100 triremes, lured away Athenian allies such as Rhodes and Byzantium, and induced a revolt on Ceos. This scheme was no more successful in the long run than the Thessalian entanglement, except that the Athenian loss of Byzantium seems to have been permanent; this was a serious setback for the Athenian corn supply, given Byzantium's geographically controlling position. Thebes' Aegean synedrion may have been founded at this time; Byzantium was certainly a member of it in the 350s.

In Thessaly, Pelopidas was killed in 364 at Cynoscephalae. Although the immediate outcome of the battle was favourable for Thebes and although Thessaly was reorganized in a way that gave Thebes for the first time an absolute majority of votes on the Delphic Amphictyony, active Theban interference in Thessalv was over

In the meantime the Arcadian federation in the Peloponnese had split in two; the Tegean party appealed for help to the Thebans (who in turn had for allies the Argives and Messenians), and the Mantineans to Athens and Sparta. The great Battle of Mantinea ("Second Mantinea," to distinguish it from the events of 418) was a technical victory for Thebes in the strictly military sense, but (as Xenophon noted) it was actually indecisive: Epaminondas' death permanently crushed Theban hopes of leadership in Greece. The peace after the battle in effect recognized the independence of the Messenians, thus settling at the diplomatic level an issue that in reality had been settled for years. The death of Agesilaus in 360 marked the end Theban schemes Athens

of one era and the beginning of another, the age of Philip and Alexander.

The rise of Macedon. In 359 two new strong rulers came to the throne, Artaxerxes III of Persia and Philip II of Macedon. The last decade of the long reign of Artaxerxes II had been blighted by revolts in the western half of his empire-at first sporadic, then concerted. Already in the late 370s Datames, the governor of Cappadocia, had established his independence. Then, by the middle of the decade. Ariobarzanes of Hellespontine Phrygia went into revolt, assisted by Timotheus of Athens and Agesilaus of Sparta. The last and greatest phase of the revolt was led by Orontes, described by the sources as satrap of Mysia. (Possibly an enclave in the Troy region of Anatolia, "Mysia" could, however, also be an error for "Armenia." If so, the geographic spread of the insurrectionist satraps was still greater.) The other rebelling satraps were Mausolus of Caria (briefly) and Autophradates of Lydia. Some participation by local Greek cities in Anatolia is possible, though perhaps they merely followed the lead of their satrapal overlords; Athens and Sparta seem surreptitiously to have helped. The aims of the revolt are a matter for speculation, but it looked serious for a long moment: a second and successful Cunaxa was a possibility. (One speculation sees the affair in dynastic terms: Orontes, who was well born, presented a greater danger to Artaxerxes than local men like Mausolus, whose ambitions were by definition limited. No one would follow a native Carian in an attempt on the kingship of Persia; it is significant that Mausolus returned to his allegiance so promptly.) At the date of Artaxerxes' death in 359, the revolt was over. the traitors' cause having been ruined by treachery among themselves. Despite setbacks, Artaxerxes II and the empire had weathered the Revolt of the Satraps.

The new king Artaxerxes III promptly ordered the satraps

to dismiss their mercenary armies, thus preempting future trouble of the same sort. This was an early indication of the vigour with which he intended to rule and which was

to regain Egypt for him.

Artaxerxes

In Macedon, Amyntas had eventually been succeeded by Perdiccas, the second of his sons by Eurydice. This happened in 365, after a turbulent five-year interval of two brief reigns, those of Alexander II and Ptolemy, and one intervention by a pretender, Pausanias. Perdiccas himself was killed in 359 in a catastrophic battle against the Illyrians, Macedon's permanent enemies, and his younger brother Philip, the last of Amyntas' sons by Eurydice. succeeded

The achievements of Philip's predecessors have naturally been overshadowed by his own, just as Philip's were to be eclipsed by Alexander's. To some extent the historical injustice is beyond redress, because the literary sources gave no systematic attention to Macedon until it was obvious that the activities of its kings were to be the determining factor in Greek history. That realization came later than 359, when Philip's chances must have looked little better than those of his immediate predecessors; thus there is not even proper information about Philip's early consolidation of power.

Fortunately, Thucydides was specially interested in the north, for personal reasons, and he speaks with admiration of the way Archelaus had pulled Macedon together militarily in the last years of the 5th century. Regarding the culture, there is valuable evidence from Herodotus and from excavations, particularly those conducted in the 1970s and '80s at Macedonian Verghina. The Macedonian kings of the 5th century were sufficiently Hellenized to compete in the Olympic Games (as Herodotus attests) and at the games for Argive Hera (as proved by a dedicated prize tripod found at Verghina). The poets Euripides and Agathon both moved to Macedon at the end of that century, and so evidently did first-rate Greek artists in the course of the next, judging from the paintings discovered in the Verghina tombs. In 1983 investigators discovered, again at Verghina, an inscription in extremely beautiful Greek lettering recording a dedication by Philip's mother, "Eurydice daughter of Sirras," which is further proof of the Hellenism of Macedon in this period.

Cultural Hellenization, however, was compatible with a

Ivory portrait head identified as Philip, c. 350-325 BC, from a tomb at Verghina (enlarged). In the Archaeological Museum. Thessaloniki, Greece

social and military structure that was alien to Greek tradition, resembling instead the feudalism of later societies. (In some respects the contemporary society having most in common with Macedon was Achaemenid Persia.) The 4th century Macedonian kings made grants of land in exchange for military service; this system is hinted at by literary sources and illustrated by inscriptions. Given the size and fertility of the areas controlled by the Macedonian kings, there was huge potential for military achievement, provided Macedon's chronic enemies and invaders could be appeased or crushed.

Philip needed to buy time by means of the first method. appeasement, in order to build the army that would enable him to crush where appeasement failed. (Philip always preferred diplomacy to force, dissimilar in this respect to his son Alexander, whose preferences were the reverse.) Although Philip must have seemed unlucky in coming to the throne at so unpromising a moment in Macedonian history, there were in fact compensations, especially if one looks beyond such real but local enemies as the Illyrians and assumes that from the outset Philip's vision rested on the far horizon. The greatest hoplite power in Greece, namely Sparta, was preoccupied with regaining Messenia, just as Persia was preoccupied with Egypt. Thebes had lost Epaminondas and was soon to overextend itself badly in the Third Sacred War. Athens still had a naval empire of sorts, but this was already showing signs of breakup; in any case, if Philip was to be stopped, it would not be by sea. He could and arguably did time his operations so as to make it impossible for a fleet to get at him (ships could not sail north when the Etesian winds were blowing). On the positive side, the productivity of the silver and gold mines of the Pangaion region would be a huge asset to Philip, and thus it was encouraging that they were currently controlled by a dwarf among imperial powers, Thasos. Although Thasos seems to have been extending its mainland interests remarkably in the 360s, it was not Athens and could be dealt with,

First Philip needed to reorganize his army, which he accomplished by introducing more rigorous training and employing mercenaries. This enabled him to inflict defeats on the Illyrians and other northern enemies. At the same time he made a string of advantageous "marriages," some more official than others and scarcely amounting to more than politically slanted concubinage; one of these was to an Illyrian princess, Audata. In 357, however, all of these were effectively displaced by his marriage to the formidable Olympias, who on or about July 20, 356, gave birth to Alexander. In 358 Philip made a preliminary visit to the strategically and politically crucial area of Thessalv. He was now poised for a "blitzkrieg" against Amphipolis, which he besieged and captured in 357. Then he moved on to conquer Pydna and the mining city of Crenides, renamed Philippi (356). In 356 he formed an alliance with the Olynthians, who had good reason to be alarmed at Philip's dazzlingly rapid progress, which continued with the taking of Potidaea in 356 and the successful siege of Methone (355-354). An inscription shows that the Olynbeginning of Philip's reign

"Social War"

thian alliance was recommended by the Delphic oracle, interesting evidence that the oracle was still politically active. The Olynthian alliance is a reminder that Philip was always happy to operate diplomatically if at all possible; in fact, the Athenians had been kept quiet at the time of Philip's assault on Amphipolis by promises that he would hand it over to them. He never did. The territory of Amphipolis was distributed to Macedonian feoffees.

After the conquest of Methone came some successes in Thrace, which Athens was unable to prevent despite attempts, a little halfhearted and a little late, to strengthen the independent Thracian princes through alliances with itself. Even the great Athenian orator and statesman Demosthenes (384-322) was slow to realize that Athens'

interest required a united, not a divided, Thrace. Athens had difficulties of its own at this time. In 357 the "Social War," the war against its allies, broke out. Already in the 360s in the aftermath of the Samian cleruchy (see above), trouble had occurred on Ceos and elsewhere. In addition, Mausolus of Caria, once more loyal to Persia and its new king Artaxerxes III, and surely remembering Epaminondas' example, incited Rhodes, Chios, and Byzantium to revolt against Athens (though, as stated, Byzantium was probably already detached). Dislike of Athens was as much a factor in the outbreak of war as the intriguing of Mausolus, which Demosthenes (naturally) stressed in his search for an outside scapegoat. (Mausolus' help, however, is a fact and should not be doubted.) To Athens' costly obsession with Amphipolis and the Chersonese should be added its various breaches of the promises made in 377. (For instance, Athens had, despite the charter, installed garrisons and cleruchies and had even levied tribute under the euphemistic name of "contributions.") In fact, it did not even respect its most basic political guarantees: at the end of the 360s, the Athenian commander Chares actually helped an oligarchy to power on Corcyra.

The war went badly for Athens, and it was forced to accept a disadvantageous peace in 355 when the Persian king threatened to intervene on the rebel side. It is disputed how far the inefficiency of the Athenian navy was responsible for the defeat. There are plenty of complaints by contemporary orators to the effect that the trierarchic system was not working properly. Still, there was no absolute shortage of ships, and it has been pointed out that some features denounced by orators, such as the hiring out of trierarchic obligations to third parties, actually tended to promote professionalism, because such hired trierarchs

built up expertise.

In 353 Philip was in undisputed control of a muchenlarged Macedon. He was brought into Greece itself as a result of the Third Sacred War of 355-346. This war originated in a more or less gratuitous Theban attack on Phocis, which in 362 had refused to send a contingent for the Mantinea campaign. The time lag is to be explained in terms of power politics: the Thebans had suffered a reverse on Euboea in 357, when Theban ascendancy was suddenly and humiliatingly replaced by Athenian, and they were looking for a victim. Phocian behaviour offered an excuse. The Thebans, who since 364 had influence over the preponderance of votes in the Delphic Amphictyony, persuaded it to condemn Phocis (autumn 357) to a huge fine for the usual technical offense, "cultivation of sacred land." The hope was that if, or rather when, Phocis was unable to pay, Thebes would be awarded the conduct of the ensuing Sacred War. It all went wrong. The Phocians seized the temple treasure in 356 and recruited a mercenary force of such size and efficiency that the Thebans could not defeat them. The Phocian leaders were Philomelus, followed by Onomarchus, Phayllus, and finally Phalaecus. The actual declaration of the Sacred War was delayed until 355, partly because it was only in that year that the relative impotence of one of Phocis' hitherto most impressive-looking allies, the Athenians, was revealed by the miserable end to the Social War in the Aegean.

After Philomelus' death, Onomarchus formed alliances with the rulers of the Thessalian city of Pherae. Thessaly as a whole had been willing enough to declare war on Phocis in keeping with an enmity of immemorial antiquity already remarked on as long-standing by Herodotus in the context of the Persian Wars. Nonetheless, Thessalian unity on the one hand and Theban ability to influence events in Thessaly on the other were both less than complete. and Onomarchus evidently succeeded in exploiting this fluid situation. Yet another city, Larissa, responded by issuing an invitation that was ultimately to be disastrous to Greek, as well as merely to Thessalian, freedom. It called in Philip.

The immediate consequence, a victory for Onomarchus' Phocians over Philip, his only defeat in the field, was totally unexpected. The Phocians seem to have had a "secret weapon," in the form of nontorsion artillery. In the following year (352) this defeat was, however, completely reversed at the Battle of the Crocus Field. Philip, who had already perhaps been officially recognized as ruler of Thessaly before the Crocus Field, now took over Thessaly in the full sense, acquiring its ports and its revenues. A further asset was the Thessalian cavalry, which was used to augment Macedon's own "companion cavalry" in the

The Battle of the Crocus

great battles of Alexander's early years in Asia. Southern Thessaly was the gateway to Greece proper, as Thermopylae had illustrated in 480 and the Spartans had recognized by their foundation of Heraclea in Trachis. A probe by Philip on Thermopylae itself was, however, firmly repelled by Athens. Philip could afford to wait and perhaps was obliged to do so by Thracian trouble closer to home (end of 352). When he laid siege to a place called Heraeum Teichos, Athens sent a small contingent in September 351. At some date not long before this, perhaps June 351, Demosthenes delivered his "First Philippic," a denouncement of Philip and Macedonian imperialism. He decried the Athenian moves to counter Philip as always being too little and coming too late. He also urged the creation of a task force and larger emergency force. It is not clear how influential Demosthenes' advice was-or how influential, at this stage, it deserved to be: at about the same time, and perhaps actually after the "First Philippic," Demosthenes was found advocating, in the "Speech on the Freedom of the Rhodians," a foolish diversion of resources to the southeastern Aegean against the encroachments of Mausolus' family. The situation there was, in fact, beyond repair.

In summer 349, with Etesian winds about to blow, Philip, despite the alliance of 356, attacked Olynthus, the centre of the Chalcidic Confederation. Olynthus turned to the only and obvious place for help, Athens. This was the occasion of the three "Olynthiac Orations" of Demosthenes. One of Demosthenes' pleas was to make the reserves of the socalled Festival, or Theoric, Fund immediately available for military purposes-in fact, to finance an Olynthian expedition. There is no agreement that his stirring patriotism was correct from the point of view of policy; perhaps the decision to build up Athens' financial resources slowly in preparation for the time when Philip had to be confronted nearer home was right. This unglamorous, though not actually dishonourable, policy is associated with the name of Eubulus, the Athenian leader of the pacifist party, whose caution helped to make possible the prosperous Athens of the time of the statesman and orator Lycurgus.

Olynthus fell in 348, despite the Athenian help that was eventually sent. Many of the inhabitants of the city were sold into slavery. Although Greek warfare always permitted this theoretically, the treatment of Olynthus was, nevertheless, shocking to Greek sentiment. In addition, there was no comfort for Athens from the events on its doorstep; Euboea, which Eubulus and his supporters agreed should always be defended, successfully revolted in 348.

At Athens, it must have seemed that there was no immediate further point in fighting, with Amphipolis and Olynthus gone; Philip, moreover, had been putting out peace feelers for some time. The Sacred War, however, brought Philip back into Greece, when desultory warfare in 347 caused the Boeotians to call him in; in alarm Phocis appealed to Athens and Sparta. The Phocian commander Phalaecus, however, unexpectedly declined to allow the Athenians and Spartans to occupy Thermopylae, and Athens was forced to make peace. This was the notorious

Peace of Philocrates Peace of Philocrates—notorious because of the attempts by various leading Athenian orator-politicians to saddle each other with responsibility for what was in fact an inevitability.

The Phocians surrendered to Philip, who received their Amphictyonic votes. Many individual Phocian troops, branded as temple robbers, had already fled; some of them eventually joined Timoleon in Sicily. The cities of Phocis were physically destroyed and the remaining inhabitants distributed among villages. It is doubful whether Philip ever seriously intended any other solution to the war in its Phocian dimension. Demosthenes was later to allege that Philip at one point had a different plan—namely, to crush Thebes and save the temple robbers in Phocis. This, however, would have been an implausible renunciation of a valuable weapon, the leadership of a Sacred War. Any such threats or promises can have been no more than feints.

Philip was for the moment supreme not merely in Phocis but in Greece, Athens, as its chief concession, had to abandon claims to Amphipolis formally. It also had to enter into an alliance, as well as make peace, with Philip. This raises the interesting question of whether Philip was already thinking of a grand crusade against Persia as early as 346; some of the sources make such a claim, but they may be contaminated by hindsight. He probably was considering such a move. For one thing, the idea of punishing the Persians for their sack of Athens in 480 was not prominent before 346 but was much heard of thereafter. Moreover, Philip had triumphantly ended one religious war and demonstrated his Hellenism and suitability for the leadership of the Greeks. Nothing would be more natural than that he or his propagandists should have hit on the idea of exploiting the still greater moral appeal to the Greeks of an all-out war of revenge for Persian impiety. In fact, the idea of a Macedonian spillage into Anatolia was a very old one indeed, and a natural one. About half a millennium earlier, the Phrygian kingdom of Midas, the predecessor of the Lydian dynasty of Croesus, had emerged as a result of a mass movement of peoples from Macedon. An Asiatic expedition is an idea that Philip could surely have thought of for himself: he did not need Isocrates to urge him, as he did in his pamphlet called the Philippus of 346, to settle the Persian empire with wandering Greeks (or resettle them: some of these wanderers must have been mercenaries rendered unemployed by Artaxerxes' demobilization edict of about 359). Information supplied by Artabazus, a satrap who had fled to the Macedonian court at some time in the late 350s, may have been helpful to Philip. Artabazus could have told Philip-and the very young Alexander perhaps-about the complex Persian system of supplies and travel vouchers for highranking officials, a system revealed to historians only in 1969, with the publication of the Persepolis Fortification Tablets. In addition, Philip seems to have had contacts elsewhere in western Anatolia, for instance with Hermias of Atarneus, a fascinating minor ruler at whose court Aristotle stayed. Whatever Philip's plans may have been, the Persian empire was not yet as debilitated or ripe for takeover as it was to be in the 330s; on the contrary, Persia suppressed revolts in Cyprus and Phoenicia in the mid-340s, and, the greatest success of all, in Egypt in 343.

In Athens after 346 there was a group who seemed to want war against Persia, and this entailed good relations with Philip. However, Demosthenes, who constantly worked against this policy, argued that Philip was untrustworthy, he pointed out that in the second half of the 340s Philip was a persistent peacebreaker, as, for instance, in the Peloponnese and on Euboea. In 344 Demosthenes even persuaded the Athenians to reject a proposed renegotiation of the peace terms offered by Philip in the person of an orator from Byzantium called Python.

Philip had preoccupations closer to Macedon in this period, which themselves make it unlikely that he wanted to upset the arrangements of 346—at least not yet. In 345 he ad to deal with the Illyrians again, which he did at the expense of a bad leg wound. The strains of his intense military life had by now left their effects on his appearance. He must have looked older than his age, scarcely more

than the mid-30s, because he had already lost an eye at Methone. (It is possible that a skull found in Macedonian Verghina bearing traces of a missile wound over the eye may in fact be the actual skull of Philip II of Macedon. This possibility encouraged the forensic reconstruction in 1983 of the entire head, by techniques used for rebuilding the features of unknown crash victims with a view to identification.) Philip's leg wound of 345 did not incapacitate him completely; in 344 he had the energy to reorganize Thessaly into its four old divisions, or "tetrachies," It helps to explain, however, why he was relatively inactive in Macedon until 342, when he made another and final move against Thrace, removing the first local recalcitrant, a ruler named Cersebleptes. From the economic as well as the political point of view, subduing the Thracian rulers was well worth the effort; the gorgeous Thracian Treasure from Rogozen in Bulgaria, discovered in 1986, consists of 165 high-grade silver and gilded vessels; one of them is inscribed "Property of Cersebleptes."

Philip attacked the Greek city of Perinthus in 340. Perinthus was helped by Byzantium and other Greek communities, including Athens, and even by the Persian satraps (which represents the first collision between the two great powers, Macedon and Persia). Despite all Philip's efforts (and artillery), Perinthus held out. In 340 an exasperated Philip declared war on Athens. He also switched his siege engines from Perinthus against Byzantium, but he made no easy headway there either. It is possible that the reason for Philip's abandonment of at least the second of these sieges was not mittary (siege engines were now virtually irresistible when applied to their target over time) but political. Philip's saze was now fixed on Athens, the

greater enemy and the greater prize.

The pretext for Philip's final involvement in Greece was trivial: still another (Fourth) Sacred War, declared this time against the petty city of Amphissa. Philip, its designated leader from the first, entered Greece toward the end of 339. This perilous occasion prompted Demosthenes' famous rallying call to Athens, reported by its author nearly a decade later in the speech "On the Crown." He urged sending an embassy to Thebes at this moment of danger for Greece as well as for Athens. Thebes responded magnificently, and the joint Greek army took up position at Chaeronea in Boeotia. The battle, fought in August 338, settled the political future of Greece until the secondcentury Roman conquest. No accurate account survives of the course of the battle, but it ended in a total victory for Philip. Tradition insists (probably rightly) on the valuable contribution of Alexander on the Macedonian left and suggests (perhaps wrongly) that Philip executed a feigned retreat. The Theban Sacred Band had simply ceased to exist. Athens was treated mildly, its prisoners being allowed to return home without ransom.

Philip's political settlement is illustrated by a speech wrongly attributed to Demosthenes and by an inscription much restored with the help of the speech. The settlement was a masterly construction, the League of Corinth (337). Philip had perhaps waited a little while for the inevitable pro-Macedonian reaction to set in inside the leading Greek cities. Only in Sparta, arrogant but powerless, was there no willingness to adjust. Philip invaded Laconia but did not interfere further than that. Thebes had to receive a garrison. Philip's overall goal was general acquiescence and cooperation in the war against Persia, which was now a certainty. In fact, he wanted an alliance, and without doubt the arrangements of 337 secured one. To this end most of the great federations of Greece were left intact; only Athens' naval confederacy was dissolved (though its cleruchy on Samos was retained) and, less certainly, the

Actolian League suppressed in a punitive measure. Like the King's Peace and the Second Athenian Confederacy, the new league guaranteed freedom and autonomy. Unlike the Athenian organization, however, this new league put the emphasis on property rights. There were specific bans on "confiscation of property, redistribution of land, cancellation of debts, or freeing of slaves with revolutionary intent."

The real novelty of this league was the fact that it had a king at its head and garrisons at crucial places, such as Reorganization of Thessaly

The League of Corinth

Chalcis and Corinth, to maintain the peace. The military requirements made of each state were set out in detail. Philip may have borrowed some of the features of the new arrangement, such as his politic use of titles, from precedents other than the Second Athenian Confederacy. Thus he may have absorbed a lesson about the politic use of titles in his mother's kingdom of Epirus; although it had been ruled by kings, the officials in the confederacy over which they presided were given Greek-sounding titles such as "secretary." Other examples may have been provided by Dionysius I of Syracuse and Leucon of Bosporus, who took different titles for use in different contexts (indeed, this may have suggested to Philip the expedient of avoiding royal titles when dealing with the Greeks: for them he would be "general with full powers"). In fact, the 4th century saw a thorough mixing of political categories, of which Philip's new league is a sophisticated example. A cruder example is present in a curious decree from Labranda, which begins with the words "It seemed good to Mausolus and Artemisia" (his sister and also his wife). Here, one finds combined a regular formula for a Greek city-state with a highly irregular decision-making bodynamely, a Persian satrap and his incestuous wife.

Mixing of political categories, however, was unwelcome at home in Macedon. Perhaps some Macedonian soldiers, who might have preferred Athenian loot to an Athenian alliance, were puzzled about Philip's motives. Thus it may have been for the benefit of such doubters that, after planning his Asiatic war and sending an advance force under Attalus and Parmenio, Philip had himself depicted in a domestic Macedonian context (he would surely not have risked such a thing in Greece) as a "13th Olympian god." (Inscriptional evidence indicates that Philip may have received cult at Philippi, but cult for such founders was well established.) Further speculation about Philip's motive for this action, which is as remarkable in its way as anything he ever did, is unprofitable. For it was at this moment (336) that he was struck down by an assassin, whose own

motives have never been ascertained.

Alexander the Great. Unless Alexander was himself ultimately responsible for his father's assassination (an implausible view, but one already canvassed in antiquity), he cannot have foreseen the moment of his own succession to a father who, though grizzled, was in the prime of life. His reaction to the turn of events was remarkably swift and cool. Two highly placed suspects were killed immediately. Not many actual rivals had to be eliminated, however, because Alexander's succession was not in serious doubt. A son of Philip's brother Perdiccas, Amyntas, was still alive, but there was no reason for Alexander to see him as a threat; in any case, he was probably dead by 335.

Alexander and the Greeks. Alexander began his career of conquest in 335. He started with lightning campaigns against the Triballi and Ilyrians, which took him across the Danube. Thebes was next: the Thebans had risen in the optimistic belief that Alexander had died in Illyria. He reached Thessaly in seven days and was in Boeotia five days later. Then followed the destruction of Thebes. The blame for this act is differently distributed in the two main literary traditions about Alexander, that of Arrian and that of the vulgate. Arrian, a Greek historian and philosopher of the 2nd century AD, relied on the works of two writers nearly contemporary with Alexander, Ptolemy (subsequently king of Egypt) and the historian Aristobulus. Arrian's tradition, which is regarded as the more "official" of the two, shifts the blame away from the Macedonians. The tradition of the vulgate, which is often fuller than that of Arrian, can be used to supplement or correct his. Although the vulgate tends toward the sensational, the greater reliability of Arrian can never be lightly assumed. For instance, on the Theban question, the vulgate more credibly puts the responsibility firmly on the Macedonians. Soon after his accession, Alexander had been voted the leadership of the Persian expedition by the League of Corinth. He set out for Asia in the spring (334). Ancient writers sometimes speak in an implausible way of wars being planned by a father and executed by a son (such as the Macedonian king Perseus' war against Rome, allegedly planned by his father, Philip V). Alexander's invasion of

Asia, however, is surely a clear case where a son does seem automatically to have taken over a great project, one which had been in the cards since the Battle of Cunaxa at the beginning of the century. Philip had created the army, the prosperity, and the human resources that enabled Alexander to embark on his Asian campaign. He left behind his general Antipater as governor of Greece, with 12,000 foot soldiers and 1,500 cavalry, while taking 40,000 foot soldiers (12,000 of them Macedonians) and more than 6,000 cavalry with him to Asia. To what extent Alexander needed to reorganize the army at the outset of the expedition is unclear. It is certain that he made changes during it; for instance, he incorporated Iranian troops to deal with special circumstances in his eastern campaigning and changed the structure of the cavalry so as to reduce the politically dangerous territorial affiliations of the individual brigades (ilai, squadrons of Macedonian cavalry, were replaced by hipparchies). From the first, however, he must have given thought to problems of reconnaissance and supply. Whereas Greek armies expected to live off the land to some extent, Alexander used wagons, despite a tradition that Philip had forced his soldiers to carry their own provisions and equipment. The core of the infantry was the Macedonian phalanx, armed with the long sarissa, or spear; the pick of the cavalry were the Companions, led by Alexander himself on the right wing. Philip's great general Parmenio commanded the Thessalian cavalry on the left. In addition, there were lighter armed troops, such as the scouts, and less-coordinated but highly effective contingents of slingers and other irregulars, usually from the parts of Greece where the concept of polis was imperfectly developed. This army was a formidable machine in the metaphorical sense. There also were literal machines-stone-throwing siege engines that could be assembled on the spot. The Thessalian siege engineers associated with Philip certainly continued into Alexander's reign and enabled him to conquer Anatolia and Phoenicia at comparatively high speed, given the fortified obstacles confronting him.

The Spartan Agesilaus may have hoped merely to construct a belt of rebel satraps, and Philip's ultimate aims are inscrutable. Alexander, however, as soon as he had crossed the Hellespont, cast his spear into Asian soil and openly declared that he laid claim to all Asia (admittedly a geographically fluid concept). At Troy he visited the tombs of the heroes Achilles and Ajax, paying them due religious honour; this was an early and emphatic statement that he saw himself and his expedition in epic, Homeric terms. The conquest of Asia (in the sense of the Persian empire) was more feasible than in 346: Artaxerxes III had died in 338-337, and the king now reigning was the much weaker Darius II (he succeeded in 336, after the brief reign of Arses, whom the trilingual inscription found at Xanthus in 1973 shows to have borne the title Artaxerxes IV)

It was in this region, at the Granicus River, that Alexander was confronted by a Persian army-not the central army of the Persian king but a very sizable force levied by the satraps from Anatolia itself. Alexander attacked in full daylight (the vulgate tradition of a "dawn attack" should probably be rejected); the Persians lined the opposite riverbank-impressively but suicidally. Alexander's victory was achieved in part by his own conspicuous example; he led the right wing with a battle cry to the god of battles. Such "heroic leadership" is, indeed, one of Alexander's main contributions to the history of generalship.

Alexander immediately appointed satraps in the parts of Anatolia thus acquired, thereby giving an early signal that he saw himself as in some sense the successor and continuator of the Achaemenid Persian kings, not merely as an outsider devoted to their overthrow. At the same time, he proclaimed democracy, restored law, and remitted tribute in the Ionian cities. This illustrates how seriously Alexander took the propaganda purpose of the war as revenge for the Persian impieties of 480; it is noticeable that the places he accorded specially favourable treatment in his passage through Anatolia often turn out to be places with a "good" record in the Ionian revolt or the Persian Wars; that is to say, they had been prominent rebels. Alexander felt no scruple about subjecting to direct satrapal rule the tracts

Philip's selfdeification The siege

nassus

of Halicar-

of territory outside the poleis. Whether the Greek cities of Anatolia joined the League of Corinth is an intractable question. Some of the islanders certainly did, as, for instance, Chios, where an inscription recording the terms of Alexander's settlement proclaims bluntly that "the constitution is to be a democracy" and refers to the "decrees of the Greeks." As for Asiatic cities like Priene, there is no certainty, but the probability is that they joined the league.

Priene was a very old city indeed, one of the Ionian "Dodecapolis," but it was physically derelict. It is possible that Alexander in some sense refounded this and other western Anatolian Greek cities, such as Heraclea south of Latmus and Smyrna. (There is, however, an almost equally strong case for associating their physical reconstruction with the Carian Hecatomnids, the family of Mausolus). If Alexander was their founder, this would be the first good evidence of the urbanizing that was a marked feature of his policy for the conquered territories to the south and east. In this respect, however, as in others, credit should be given to Philip for his example: Philippi (the renamed

Crenides) was not his only city foundation.

At Halicarnassus, Alexander met his most serious resistance so far from a defended city, in mid-334; Miletus had not delayed him long (nor was it punished very severelyit had after all been the leader of the Ionian revolt). The siege of Halicarnassus was a far tougher operation. The city had good defenses, both natural and artificial, and had been chosen as the local Persian military headquarters. The fighting was severe, though in the apologetic tradition used by Arrian the severity is minimized. At one moment Alexander was forced to the extremity of having to send a herald to ask for the bodies of some Macedonians who had fallen in front of the walls. After the city was takenthe citadels held out for another year or two-Alexander reappointed the native princess Ada as satrap (his earlier satrapal appointees had been Macedonians). She was the sister of the great Mausolus, and her reinstatement prefigures Alexander's shrewd subsequent policy of allowing local men and women to remain in post (though usually, like Ada herself, under the superintendence of a Macedonian troop commander). A romantic story makes her "adopt" Alexander as her son, a gesture graciously accepted by Alexander. That gesture of conciliation toward the native population was good politics.

After the conquest of Halicarnassus, Alexander moved east, meanwhile sending to Macedon for drafts of reinforcements. The scale of these demands through the whole campaign and their effects on the domestic situation in Macedon are not easy to estimate; the record of the literary sources is too fitful and episodic. According to one view, Alexander's legacy was one of lasting damage; he had exhausted the manpower of Macedon to such a point that the Macedon of Philip V and Perseus inevitably succumbed to the Romans with their almost infinite capacity for replacement. On the other hand, one must allow in the reckoning for a good deal of voluntary emigration by Macedonians to the armies and cities of the successor kingdoms in the Hellenistic period. Thus Alexander was not the only culprit; there were more intangible demographic forces at work,

Alexander's path took him from Carian Halicarnassus to Lycia and Pamphylia. At about the Lycian-Pamphylian horder a strange natural phenomenon occurred that allowed Alexander and those with him to enjoy a freak dry passage along the coastline. This was greeted by his supporters as a portent and a recognition of Alexander's divinity (the sea "doing obeisance" to the great man). It was the first believable suggestion that special religious status could be claimed for Alexander.

In early 333 Alexander moved through Pisidia, where the nearly impregnable mountain city of Termessus, a remarkably well-preserved site 21 miles northwest of the modern Antalya, managed to hold out (even Alexander's early years in Asia were not an uninterrupted success story). Morale and self-esteem had to be satisfied with the taking of Sagalassus and some minor places. Thus it was high time for a piece of propaganda and political theatre. especially since the Aegean he had left behind him was not altogether quiet. A Persian counteroffensive was achieving some notable reconquests (but eventually troop drafts were required by Darius for the campaign that finally took shape at Issus, and the Aegean war shriveled to nothing).

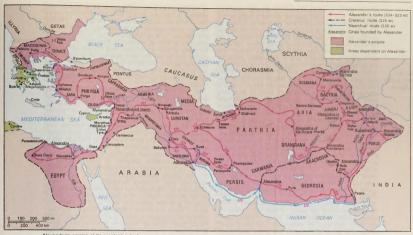

Alexander found his opportunity for propaganda some distance farther north in the Anatolian interior at Gordium, the old capital of the Phrygian kings (themselves, as stated, ultimately of Macedonian origin). There occurred the famous episode of the "cutting of the Gordian knot." The old prophecy was that whoever unloosed the knot or fastening of an ancient chariot would rule Asia. Alexander cut it instead-or perhaps pulled out the pole pin, as one tradition insisted. Either way, he solved the problem by abolishing it.

The visits to Pisidia and Phrygia had been a huge detour, evidently designed to show that Alexander had conquered Anatolia. This statement raises problems of definition: "conquest" was a relative term when there were large tracts of Anatolia, such as Cappadocia, that Alexander had scarcely touched, not to mention the mixed achievement at Pisidia.

A more obvious way of achieving conquest was to defeat the king in open battle. The time had come to face Darius, whose army was already in Cilicia. In fact, Darius got ahead of Alexander, occupying (after a protracted delay) a position to the north of the Macedonians. The numerical advantage at the ensuing Battle of Issus, fought toward the end of 333, was heavily with the Persians, but they were awkwardly squeezed between the sea and the foothills of a mountain range close by. Alexander's Companion cavalry punched a hole in the Persian infantry, making straight for Darius himself, who took flight. The Persian mercenaries Gordian knot

Alexander in battle, detail from the so-called Alexander Sarcophagus, marble, c. 310 BC, from Sidon. In the Archaeological Museums of Istanbul.

Alexander's empire at its greatest extent

were routed by the Macedonian phalanx. After the battle, Darius' wife and mother both fell into Alexander's hands. In an exchange of letters Alexander grandly offered that Darius could have them back-"mother, wife, children, whatever you like"-if he recognized his own claim to be lord of Asia and addressed him as such for the future. Darius, of course, refused the offer.

Alexander did not immediately follow Darius eastward; instead he continued southward in the direction of Phoenicia and eventually Egypt. The Phoenician cities of Byblos and Sidon submitted willingly, but Tyre was a major obstacle. Its walls were not finally breached until summer 332, after various contrivances had been tried, including a huge and elaborate siege mole. The siege of Gaza occupied much of the autumn; when the city at last surrendered, Alexander dishonoured the corpse of Batis, its commander, in the way that Achilles in the Illiad had treated the corpse of Hector. Alexander's imitation of Homeric heroes had its less attractive side.

This was the part of the world in which the Jews might have encountered Alexander. No doubt there was some contact, but virtually all the available evidence is unreliable and romantic or even fabricated to give substance to later Jewish claims to political privileges. Alexander's effect on the Jews was indirect, but no less important for that: he surrounded them with a Greek-speaking world.

Egypt was taken without a struggle, an indication of the dislike the subject population felt toward Persia. (Even though Egypt had been reconquered by Persia hardly more than a decade before, it is possible that there had been yet another revolt since 343.) Alexander's period in Egypt was marked by two major events, the founding of Alexandria and the visit to the oracle of the god Ammon at Siwah in the Western Desert. Although the sources disagree about which event came first, the foundation probably preceded the visit to the oracle.

The new city of Alexandria, the first as well as the most famous and successful of many new Alexandrias, was formed by joining a number of Egyptian villages (April 331). Alexander supervised the religious ceremonies of foundation, including Greek-style athletic and musical games (an indication of his intentions to Hellenize these foundations, at least as far as their cultural life was concerned); he thought that the site was an excellent one and

hoped for its commercial prosperity. It is quite certain. from an inscription, that early Hellenistic Alexandria possessed a civic council; this and other self-governing institutions such as an assembly probably go back to Alexander's time. Not all Alexander's foundations were run on this liberal model, though some were inaugurated with similar symbolic gestures in the direction of Hellenism. One hears of "satraps and generals of the newly founded cities," a phrase that does not imply much self-government. No doubt some of Alexander's "new foundations" were little more than military camps; and one should assume that in all the far eastern Alexandrias the native population was forced to perform menial or agricultural tasks.

The oracle of Ammon at Siwah, to which Alexander now made a pilgrimage, was already well known in the Greek world. Pindar had equated Ammon with Zeus, the oracle had been consulted by Croesus in the 6th century and Lysander in the 5th, and there was a sanctuary to Ammon at Athens in the first half of the 4th. Alexander had a pothos, or yearning, to visit Ammon (the word pothos is often used by the sources to describe his motives and is appropriately suggestive of far horizons, even if it does not reflect a usage of Alexander's own). He wanted to find out more about his own divinity, the implication being that he already had an inkling of it. He was told what he wanted to hear; more than that (some sources offer a great deal more) was probably speculation to fill a gap.

Alexander then crossed Phoenicia again to meet Darius for the second and last time in the open field at Gaugamela (between Nineveh and Arbela) at the beginning of October 331. The tactic was to be the usual one-a leftward charge by Alexander from the right wing toward the centre, while Parmenio held the left wing firm. Parmenio seems, however, to have encountered unusual difficulties and had to summon help from Alexander, who was already in victorious pursuit of Darius. The mechanics of this "summons" are not clear, and the story may be a fabrication intended to discredit Parmenio. Alexander and his troops won the battle, sealing the fate of the Persian empire, but Darius managed to escape. Alexander then moved to Babylon, where in another gesture of conciliation toward the Iranian ruling class he reappointed Mazaeus as satrap, with Macedonians to supervise the garrison and the finances.

This kind of gesture has been much discussed; it can

Alexander in Egypt

Alexander's policy of fusion

be both overinterpreted and unduly minimized. Ideas that Alexander, then or ever, planned to forge a harmony between nations at a mystical level have no solid basis in the evidence. There is nothing odd, however, in supposing that his intentions toward Persians like Mazaeus (or Abulites, confirmed in the Susa satrapy about the same time) were positive. Also, the idea of such "fusion" was not entirely new. Greeks such as Xenophon earlier in the century had by their writings and actions anticipated Alexander's policy of fusion, and the cooperation of Cyrus and Lysander was just the most famous example of mutual understanding between Persian and Greek. Nor is it convincing to interpret Alexander's policy of integrating army and satrapy as a repressive device. Macedonians like Peucestas (appointed satrap of Persia) learned Persian and were rewarded for it; and Hephaestion's position of favour with Alexander is largely to be explained by his support of Alexander's Orientalizing policies. Admittedly, after leaving Iranian territories, Alexander returned to employing Macedonians as, for instance, in the Indus lands; but even there one finds native appointees like the Indian king Porus. Military integration-the use of Iranian horsejavelin men-is first firmly attested soon after the battle of Gaugamela. This is to be explained in purely military terms: the Companion cavalry on their own were not entirely suited to the more disorganized warfare lying ahead against the fierce opponents waiting to the east and north of Iran proper.

After some spectacular campaigning in Persis proper, Alexander occupied the palace of Persepolis, where the strong defensive position known as the "Persian Gates" was taken only after an unsuccessful and costly initial assault. The palace of Persepolis was looted and burned (spring 330). The less creditable tradition of the vulgate maintains that the fire started when a drunken Athenian courtesan called Thais led a revel that got out of hand, and this may well be right. The event, however, could be exploited afterward as a signal to dissident Greeks at home that the "war of revenge" was complete.

To securely establish the propaganda value of the burning of Persepolis would require a more precise chronology for the phases of that Greek dissidence than is ever likely to be achieved. The last fling of 4th-century Sparta was a revolt led by its king Agis III. It was probably still going on in 330 when it culminated in a narrow victory by the Macedonian general Antipater over the Spartans at Megalopolis. If this is right, the burning of Persepolis at about this time makes good propaganda sense. Athens had not participated in the revolt. The quiescence of Athens in the early years of Alexander's campaigning is to be explained partly by the policy of civic retrenchment associated with the name of Lycurgus (a phase of Athenian history that included a remarkable building program, the first since the 5th century) and partly by a well-attested grain shortage in Greece, which may have sapped the will to fight.

The conquest of Bactria and the Indus valley. By the middle of 330 Darius had been killed-not by Alexander but by his own entourage. Alexander now adopted symbolic features of Persian royal dress, but one of Darius' noble followers (and murderers), Bessus, the satrap of Bactria, also proclaimed himself king. The reckoning with Bessus, however, had to be postponed until the middle of 329. Alexander, who had initially followed Darius north. now moved steadily east, through Hyrcania and Areia. where Satibarzanes was confirmed as satrap; Alexander planned an invasion of Bactria and the elimination of Bessus. Satibarzanes, however, revolted almost instantly, and Alexander turned south again to deal with this rebellion. Having done so (though without taking the satrap himself), he maintained direction southward, toward Arachosia and Drangiana, home satrapies of Barsaentes, another of Darius' murderers. Barsaentes, however, fled to India.

At Phrada, capital of Drangiana, occurred the most famous conspiracy of Alexander's expedition, that of Philotas, the son of Parmenio and a commander of the Companion cavalry. There was little solid evidence for the prosecution to go on, but it is clear that Alexander's Orientalizing tendencies and the ever more personal style of Alexander's kingship had begun to irk his Macedonian nobility, accustomed as they were to express themselves freely, as in the outspoken court of Philip's day. Philotas had no doubt spoken very incautiously on some sensitive subjects, such as Alexander's visit to Ammon. The execution of Philotas entailed the execution of his father Parmenio as well, not because there was any serious suggestion that he too had been plotting but as a matter of practical politics; the family group of Parmenio, which can be elucidated by means of prosopography (the investigation of family ties with the help of proper names), had considerable power.

The year 329 saw the final elimination of Satibarzanes and the capture of Bessus in Sogdiana, north of the Oxus River from Bactria. In Sogdiana, Alexander founded the city of Alexandreschate, "Alexandria the Farthest," not far from the site of Cyropolis, a city of Cyrus II the Great, whom Alexander highly admired. This is a reminder that Persian urbanization in Central Asia had not been negligible. (At the interesting Bactrian site of Ai Khanum, which cannot definitely be identified as an Alexandria, there is evidence of Achaemenid irrigation.) Alexandreschate was a prestige foundation, designed, as explicitly stated by Arrian, for both military and commercial success. Alexander had already planted a number of new Alexandrias in central Iran, including Alexandria in Areia (Herat). Alexandria in Arachosia, and almost certainly Qandahār, on the exciting evidence of a metrical inscription found there by a British excavation team in 1978. There was another major foundation called Alexandria in the Caucasus at an important junction of communications in the Hindu Kush. How far Alexander intended these places to be permanent pockets of Hellenism is not clear. That Hellenism could survive in these regions is shown by the case of Ai Khanum, which had many of the features of a Greek polis, including gymnasia and an agora with an oikist (city-founder) cult; there are even inscribed Delphic religious precepts. Nonetheless, many of Alexander's Greek colonists in Bactria tried to return home to the mainland immediately after his death out of pothos, or

yearning for their Greek way of life. Bessus and Satibarzanes were not the last satraps of eastern Iran to offer resistance. It took fully two years (until spring 327) to suppress Spitamenes of Sogdia and other tribal leaders. The period was full of strain, culminating in the disastrous quarrel between Alexander and Cleitus, one of his senior commanders and the newly appointed satrap of Bactria at the end of 328. The guarrel ended in Alexander actually killing Cleitus with his own hands in drunken fury. The issue was a personal one, which, however, merged with a matter of principle: Cleitus had criticized Alexander's leadership (there had admittedly been at least one military reverse due perhaps to inadequate planning), comparing him unfavourably with his father Philip. Before the army moved in the direction of India, there were two more incidents that widened the gap between Alexander's conduct and traditional Macedonian attitudes. First, Alexander attempted to introduce the Persian court ceremonial involving proskynesis, or obeisance. Just what this entailed is disputed; perhaps it amounted to different things in different contexts, ranging from an exchange of kisses to total prostration before the ruler in the way a Muslim says his prayers. What is not in doubt is that for Greeks this meant adoration of a living human being, something they considered impious as well as ridiculous. It was the court historian Callisthenes who voiced the feeling of the Greeks. The proskynesis experiment was not repeated: Alexander did not in the end insist on it. It is difficult, however, not to connect Callisthenes' role in this affair with his downfall not long after, allegedly for encouraging the treason of a group of royal pages. This was the second of the two alarming incidents of the period.

India was the objective in 327, though Alexander did not reach the Indus valley until 326, after passing through Swät Cas from the district of the Kābul River. In 326, at the great Battle of the Hydaspes (Jhelum), he defeated the Indian king Porus in the first major battle in which he faced a force of elephants. How much farther east Alexan-

Conquest of India

Execution

of Philotas

Parmenio

and

der might have gone is a question that has fascinated posterity, but the curiosity and patience of his army was exhausted. At the Hyphasis (Beas) River he was obliged to turn back.

Alexander did not, however, retrace his path but took the route southward through the Indus valley toward the Arabian Sea and the Gulf of Oman. He narrowly avoided eath at the so-called "Malli town," where an arrow seems to have entered his lung. The subsequent march westward in 325 through the desert region of Gedrosia (Balochistan) was a death march; its horrors emerge vividly enough from the literary narratives, but they are certainly understated. Alexander's motive for ordering the march may have been the desire to outdo the mythical queen Semiramis and the legendary Cyrus the Great; but the scale of the catastrophe does suggest that his judgment was by now badly impaired. Meanwhile, Nearchus led the fleet from the mouth of the Indus to that of the Tigris, a voyage recorded by Arrian in his Indica, using the account of Nearchus himself.

The final phase. In Carmania, to the west of Gedrosia, Alexander first staged a week-long drunken revel, in which he himself posed as Dionysus, as a release of tension after the preceding nightmare journey. Then he ordered his satraps and generals to disband their mercenary armies. like Artaxerxes III in 359 and perhaps for the same reason, namely, fear of insurrection. This was a period of punitive action against disobedient or negligent satraps. One official who in this atmosphere preferred to abscond rather than brazen out the inquisition was Harpalus, the royal treasurer, who made his way eventually to Athens. The exact fate of the money he took with him was and still is a celebrated mystery. The fact that Harpalus' activities as treasurer had evidently been quite unsupervised was typical of Alexander's short and impatient way with administrative problems. (It is most unlikely that he planned an ambitious financial restructuring of the empire, giving special responsibilities to men with the right expertise. One finds men like Cleomenes in Egypt or Philoxenus in Anatolia combining territorial with financial responsibilities, but no general conclusions can be drawn.)

At Susa in 324 Alexander staged a splendid mass marriage of Persians and Macedonians. He himself had already married a Bactrian princess, Rhoxane, in 327, but he now took two more wives, a daughter of Darius III called Barsine (or Stateira) and Parysatis, the daughter of Artaxerxes III. This and other demonstrations of "Orientalizing," including the brigading of Iranian units into the army, overcame a final mutiny at Opis near Babylon. After haranguing the troops, threatening them, and finally sulking, Alexander won back their affections; following this meretricious and emotional performance, he chose to heal the rift symbolically by a more organized piece of theatre, a great banquet of reconciliation (thus demonstrating for the last time in Archaic and Classical Greek history the usefulness of the banquet, or symposium, as an instrument of social control).

Other actions or schemes in this final phase were of the same megalomaniae type: a request for his own deification, sent to the Greek cities; a demand that they take back their exiles; a monstrous funeral pyre for his dear friend Hephaestion (never completed); and a plan of circumnavigation and conquest of Arabia. So much is well documented. Lists of other spectacular last plans survive, but they are hardly needed; the achievements of the last 13 years were extravagant enough. Alexander died at Babylon, after an illness brought on by heavy drinking, in the early evening of June 10, 323.

Greek evilization in the 4th century. The 4th century is in many ways the best-documented period of Greek history. There is, admittedly, a greater number of documents from the 3rd century, when inscriptions and papyri abound (there are virtually no documentary papyri before the time of Alexander). The writings of the 3rd-century prose historians, however, are mostly lost. In the 4th century, by contrast, there is an abundance of evidence of all kinds. Inscriptions are much more common than in the 5th century and begin to appear in quantity from states other than Athens. Forensic oratory from the 5th century has scarcely survived at all, but from the 4th century there

are more than 60 speeches attributed to Demosthenes alone. Most of this corpus of oratory is set in an Athenian context, but one speech of Isocrates deals with business affairs on Aegina. Although there is no 4th-century tragedy and no epinician poetry like that of Pindar, the comedies of Aristophanes from the beginning of the century and those of Menander from toward the end have survived. These are illuminating about social life, as are the prose writings of Aristotle's pupil Theophrastus, especially his Characters. The writings of Plato, in their anxiety to define an ideal polis invulnerable to stasis or civil strife, give evidence of the instability of the 4th-century world in which it could be said that in every city there were two cities, that of the rich and that of the poor. Aristotle's Politics examines the theoretical conceptions underlying Greek attitudes toward polis life. This is a precious document, although it can be criticized for insufficient awareness of the monarchical and federal developments of the age.

No such criticism can be leveled at the historiography of the age. It is from Xenophon that one learns of the grand plans of Jason of Pherae, and knowledge about Dionysius I is derived, by less direct routes, from the 4th-century historians of the Greek west Ephorus, Philistus, and (toward the end of the century) Timaeus of Tauromenium. In fact, the process of explaining history in terms of personality already begins with Thucydides, who arguably came to see that a dynamic personality like Alcibiades could by sheer charisma and force of character have an impact on events irrespective of the content of his policies. It was surely this aspect of Thucydides' work that Aristotle had in mind when he defined history as "what Alcibiades did and suffered," Aristotle's nephew Callisthenes began by recording the history of the city-states in a fairly traditional way (which, however, did more justice to the Theban hegemony than had that of Xenophon), but then he joined Alexander's staff in order to write the Deeds of Alexander. Evidently, history was now seen as what Alexander did and suffered. Even earlier than that, however, the central role of Philip's personality had been acknowledged by Theopompus of Chios, who (like Callisthenes) moved in the direction of writing history that revolved around the person of a king; he called his history of Greece Philippica, "The Affairs of Philip." Meanwhile there were local historians of Attica, such as Androtion, who continued to value Athens' past and even ventured to rewrite (not merely to reinterpret) the facts about it. These men, who are known as Atthidographers, were not simply antiquarians escaping from the monarchic present. On the contrary, the greatest of them. Philochorus, was put to death in the 3rd century by a Macedonian king for his excessive partiality toward King Ptolemy II Philadelphus of Egypt. All these authors were, in different ways, coming to terms with monarchy. In addition to works of history there are 4th-century treatises that show how Greeks experienced the new military monarchies. Xenophon's Cyropaedia, or "Education of Cyrus," is a novel about Cyrus the Great, but it is also a tract on kingship and generalship addressed to the class of educated Greek commanders and would-be leaders. (In comparable fashion Isocrates offered advice on kingship to the semi-Hellenized rulers of Cyprus.) The surviving treatise on siege-craft by Aeneas of Stymphalus in Arcadia (known as Aeneas Tacticus) is valuable not only for the evidence it provides about dissensions inside a polis-there is an entire section on "plots"-but also for the awareness both of the ruthless methods of men like Dionysius, who figures prominently, and of the new military technology of the age. (The treatise includes, for example, practical advice on how to defend walls against battering rams.) Aeneas Tacticus' treatise, more than any other surviving prose work of the 4th century, makes the point that this was an age of professionalism. Many technical monographs are known to have been written in this period but have not survived. For instance, Pythius, who worked on the Mausoleum, also wrote a book about another of his projects, the Temple of Athena Polias at Priene. (There were 5th-century precedents for some of this: Polyclitus of Argos had written a famous treatise on proportion in sculpture and Sophocles a monograph about the chorus.) In the sphere of architecture, the 4th century produced

Technical monographs

The state of the sources no Parthenon, but it was the great age of military structures. Most of what survives of the elegant fortifications of the northwestern frontier demes of Attica stems from the 4th century; inscriptions attest refurbishing work on Phyle in particular at about the time of the Battle of Cheronea. Outside Athens there were big projects, such as the temple at Epidaurus and the Mausoleum at Halicarnassus.

Buildings such as the Mausoleum were commissioned by powerful individuals, further proof that the emergence of commanding personalities is a noticeable feature of the 4th century. In some respects it represents a return to Archaic values: a tyrant like Dionysius has much in common with Peisistratus of Athens or Polycrates of Samos, and Philip II of Macedon can be seen as comparable to Pheidon of Argos, a hereditary monarch who transformed his power base into a military autocracy. Revised attitudes toward such individuals are already detectable near the end of the 5th century. It seems that, when Athens founded Amphipolis in 437, its founder Hagnon, father of the oligarch Theramenes, was given some kind of cult in his lifetime. That is the usually neglected implication of a passage of Thucydides, which definitely records the award of cult honours at Amphipolis to the dead Spartan general Brasidas after 422. In the early 4th century another Spartan, Lysander, received cult at Samos, and later in the century Euphron, a tyrant at Sicyon, was buried in the agora "like a founder."

At Athens itself, before the request by Alexander for his

own deification, there could be no question of divine cult for a living man (although it is possible that Alexander had already arranged some kind of hero cult at Athens for Hephaestion). Nonetheless, even at Athens there was a marked trend toward more assertive monuments. This is particularly evident in the commemorative choregic monuments built to celebrate victories in the great Athenian festivals. The most famous of these, the Choregic Monument of Lysicrates, which used to be called the "Lantern of Demosthenes," represents a transitional phase; its inscribed dedication falls between the anonymity (actually more pretended than real) of the corporatist benefactions of Classical Athens and the assertiveness of Hellenistic Greece with its emphasis on individual generosity. On the one hand, the inscription makes clear that what is celebrated is victory by the tribe as a whole; on the other, the great prominence of the man's name stresses individuality, as does the idiosyncratic form of the monument. Clearly, this is an emphatic statement in the first person singular. Consistent with these developments is the marked tendency toward portraiture in art. Persian satraps such as Tissaphernes issued coinage with what were obviously meant to be realistic depictions of the satrap's head. Individual rulers were represented by statues in the round, like that of "Mausolus" from the Mausoleum (which may or may not be an attempt to represent Mausolus himself but which incontrovertibly is a portrait of some powerful individual), or by figures on friezes, as those on the "Alexander Sarcophagus" in the Archaeological Museums of Istanbul, Although the workmanship is evidently Greek, the ethos is uncompromisingly royal. Alexander created a new visual image for himself: unlike the bearded Philip, Alexander is portrayed as clean-shaven, young, and idealized. Lysippus, in particular, is said to have caught Alexander's physical

qualities in his royal sculpture portraits. The Athenian empire had given employment to many artists, architects, and sculptors, both from Athens itself and from the subject states of the empire. When the empire collapsed in 404, many of these had to seek employment elsewhere. Some went to the courts of satraps like Mausolus or of military rulers like Dionysius: both of these had money to spend on art, building, and fortifications. Another wealthy court was that of Macedon. One remaining recourse in Athens, however, was funerary art; the most famous funerary stelae and sculptured monuments found at Kerameikós, the city's prestigious cemetery, date from this period, before such lavish commissions were outlawed by the Athenian ruler Demetrius of Phaleron after Alexander's death. Some of those buried were foreigners; for instance, there was a precinct for the Messenians, one for some immigrants from Heraclea on

the Black Sea, and one for those from Sinope, also in the Black Sea region. (In the Archaeological Museum of Piraeus there is a monument comparable to another one of a Black Sea immigrant, a reminder of Athens' commercial connections with this crucial grain-growing area.) In the Kerameikos there is even a grave of a Persian with a larger-than-life torso of a seated man in Persian dress.

Whatever the political effects of the King's Peace of 386. it was evidently not a barrier to social and commercial exchanges. Inscriptions in the corpus of Demosthenes' speeches frequently mention trade with ports in Phoenicia and Anatolia and occasionally allude casually to piracy, a classic by-product of such trading activity. There is epigraphic evidence for piracy as well: in the 340s Athens honoured Cleomis, tyrant of Methymna on Lesbos, for ransoming a number of Athenians captured by pirates. Lesbos had always enjoyed trading links with the Black Sea region, and in the 4th century more than ever. One should imagine Athenians and metic Athenian traders (i.e., foreigners resident at Athens) going in numbers via Lesbos and the Sea of Marmara to the rich granaries of southern Russia. Some no doubt settled in these regions, though the inscriptional evidence for Athenians abroad in the 4th century (as opposed to evidence for foreigners settling in Athens or Piraeus) is in need of systematic collation.

Immigration and free movement of individuals between one polis and another are typical features of the 4th century. They are best documented for Athens but hardly confined to it, given the attractiveness of the royal and satrapal courts. At Athens itself, the great magnet for immigrants was naturally Piraeus, the city's densely populated, multilingual, multiracial port, Bilingual inscriptions in the Archaeological Museum of Piraeus, in Greek and Aramaic, testify to the presence of Phoenician traders, who also left more strictly epigraphic traces, (Conversely, Greco-Aramaic stelae in the Archaeological Museums in Istanbul may attest Greek or partially Greek settlements in the Persian empire.) An inscription of the period of Alexander, from the Piraeus, records the response of the Athenian Assembly to the request of some merchants from Cyprus for permission to build a sanctuary to Aphrodite (the goddess, born in the sea, allegedly stepped ashore on Cyprus). The inscription mentions, as a precedent for the request, the Temple of Isis founded by the Egyptian community.

Foreign cults of this kind were not by any means brandnew in the late 5th century; if they seem so, it may be because that period is so much better documented than the early part of the century. But they may have increased in number in Greece as a result of the geographically extensive campaigning of the Peloponnesian War and even the period of the Athenian empire. The cult of Adonis is referred to in Plutarch's Life of Nicias. which also mentions the Ammon oracle. Thracian as well as Egyptian cults arrived in Greece in the late 5th century. The cult of the Thracian goddess Bendis at Piraeus features in the first page of Plato's Republic; Bendis was perhaps a female counterpart to the Thracian Hero, Cults were both imported and exported: one of the vessels from Rogozen depicts the Greek myth of Heracles and Auge. labeled as such. This is a reminder that the old Olympian cults remained strong. In fact, some of the best evidence for traditional Greek religion comes from this period; it was the century of the highly informative and basically conservative Attic deme calendars (i.e., lists of festivals, chronologically arranged through the year) and the period when inscriptional information about the great Panhellenic sanctuaries entered its richest phase.

Mercenary service, as well as organized campaigning, must have helped to raise consciousness of such foreign cults as those of Isis or Bendis. Greeks often served in Thrace in the late 5th and the 4th centuries; Xenophon, for example, was there at the beginning of the 4th century and heard the so-called "Ballad of Sitalces" (a 5th-century Thracian ruler who is featured in Thucydides) sung at a banquet in Paphlagonia.

Mercenaries constituted one category of Greeks who strayed away from their cities; they were a potentially disruptive force, whether from the point of view of polisForeign

Portraiture in art

minded Greeks or of autocrats like Artaxerxes III or Alexander the Great. Nobody, however, could dispense with them. The Persian kings used Greek mercenaries in their repeated attempts to recover Egypt in the 4th century-but so did the defending Egyptians. How far inside the Persian empire these Greek mercenaries penetrated is an intriguing question. An inscription first published during World War II appeared to attest a group of Greek mercenaries on an island in the Persian Gulf in the period before Alexander, but it is possible that the text is actually early Hellenistic. Even Spartans like Agesilaus near the end of his life and Thebans like the general Pammenes in the 350s had to hire themselves out to Persian paymasters, whether lovalist or insurrectionist. (It would be better to speak, in this context, not of mercenaries but of "citizenmercenaries" because these Thebans and Spartans did not cease to belong to their home cities.) The military monarchies of Dionysius and Philip were to some extent propped up by mercenary forces, whose loyalty was not subject to political but only to financial blandishments. This leads to the conclusion that the mercenary soldier valued his booty (aposkeue, literally "baggage") more than he valued his commander. One of the early successors of Alexander the Great, the Greek Eumenes of Cardia, was in effect traded by his troops to a rival for gain. Already under Alexander the elite troops known as "Silver Shields." or argyraspides, had taken their name from the conquered Persian treasure of precious metal.

Not all interchange between poleis, or all emigration from the polis into nonpolis areas of settlement, however, was of the haphazard kind caused by mercenary service or the peripatetic life-style of artists and craftsmen. Rather. the poleis themselves promoted much organized activity.

Colonial

connections

First, old ties might be strengthened by renegotiation, or more explicit reaffirmation, of old colonial connections. Inscriptions survive from the 4th century that accord rights of citizenship on a footing of mutuality, for instance, between Miletus and Olbia and between Thera and Cyrene. Some old connections of alliance might be inflated into a pseudo-colonial link. Thus, Hellenistic Plataea, as noted earlier, called itself a "colony" of Athens, which strictly it was not. This claim may well go back to the 4th century, and there is good evidence for other such fabricated claims of kinship in the latter part of this century. An inscription, for example, asserts a colonial connection between Argos and Aspendus in Pamphylia. This is certainly unhistorical but can be explained from the greater prominence enjoyed, in the Hellenistic and Roman periods, by Argos. The reason was that Argos could itself claim a connection with the Macedon of Alexander, and this kind of connection was desirable for obtaining privileges from him or from his successors.

The founding, building, or synoecizing of new cities was another way in which mobility of population was actually encouraged by the poleis themselves. The process is traditionally (and rightly) associated with Alexander the Great himself, but the emphasis is unjust to some innovatory activity in the later 5th and 4th centuries both by individuals (not least Philip) and by cities.

In the late 5th century Olynthus had been synoecized into existence by Perdiccas of Macedon, and the Rhodians had merged the three cities of their island into a new physical and political entity. The same was done in the 360s by the communities of the Dorian island of Cos. Mausolus' new capital of Halicarnassus was the result of a synoecism in which Greeks and native Carians ("Lelegians") were integrated into a new city, which was physically beautified with monumental buildings. Moreover, one can make a case for associating Mausolus with the various refounda-*tions or moving of sites that different kinds of evidence suggest took place at Priene, Erythrae, and Heraclea. Epaminondas' interventions in the Peloponnese led to major urbanization projects at Messene and Megalopolis.

More traditional methods of moving people, such as colonization, were also used; at the beginning of the 4th century Xenophon includes a warm and lyrical description in the Anabasis of a site called Kalpe on the Black Sea, praising its situation, fertility, and relative remoteness from rival and established Greek cities in the vicinity. This

gives substance to the suspicion that what Xenophon was really trying to do was found a colony of Archaic typethe Euboeans of the 8th century would have jumped at a site with Kalpe's advantages of situation. In the 340s Timoleon of Corinth effected a kind of recolonization of Syracuse from the old mother city; he took with him many refugees and brought prosperity back to an island much battered by internal dissension and endless wars with the Carthaginians-against whom he himself scored some notable successes. Athens sent a colony to the west in the time of Alexander and the corn shortage; it was led with symbolic or sentimental appropriateness by a man called Miltiades (the name of the 6th-century founder and dynast ruling in the Chersonese), who went to the Adriatic region. The Adriatic seems to have been a favourite colonizing focus in this period: the scale and even reality of Dionysius' interventions there are controversial, but an inscription gives evidence of a Greek colony on the island of Black Corcyra. The great colonizing surge of the 4th century came, however, in the wake of Alexander; once again, the Ionian Greeks took the lead, just as, on Thucydides' evidence, they had colonized Ionia itself even before the organized phase of colonizing activity in the 8th century.

Also in the 4th century a great number of citizenships were granted to individuals from whom favours were expected or by whom they had already been conferred, or citizenship both. (One standard motive, occasionally made explicit, for the recording of such honours in permanent form was to induce the recipient to continue his generosity.) Most of the evidence is Athenian, but the phenomenon was surely not confined to Athens. Even Persian satraps like Orontes could be enrolled as Athenian citizens, not to mention Macedonians like Menelaus the Pelagonian, a king of the Lyncestians (an independent Macedonian subkingdom until annexed by Philip). This man received citizenship in the 360s because he was reported by the Athenian general Timotheus as helping Athens in its wars in the north. A further and frequent motive for such honours, and one that anticipates the Hellenistic age, is an expression of gratitude for gifts of grain. The Spartocid kings of the Bosporus (southern Russia) were honoured because they had promised to provide Athens with wheat, as their father Leucon had done before them.

This kind of benefaction is called euergetism (the word derives from euergesia, or "doing good deeds"). Now that Athens no longer had the naval power to direct all grain forcibly toward its own harbours, much had to be done by exploiting benefactors. Euergetism of this sort, however, was not entirely new: as early as 444 BC, Egyptian grain in large quantites had been sent by a rebel pharaoh at a time when Athens was certainly not (as it gradually became) a city armed merely with a cultural past and a begging bowl.

No treatment of the main period of Greek civilization should end without emphasizing the continuity both with what went before and with what came after. Continuity is clearest in the sphere of religion, which may be said to have been "embedded" in Greek life. Some of the gods alleged to have been relatively late imports into Greece can in fact be shown to have Mycenaean origins. For instance, one Athenian myth held that Dionysus was a latecomer, having been introduced into Attica from Eleutherae in the 6th century. There is reference to Dionysus (or diwo-no-so-io), however, on Linear B tablets from the 2nd millennium BC. Looking forward, Dionysus' statue was to be depicted in a grand procession staged in Alexandria in the 3rd century BC by King Ptolemy II Philadelphus. (The iconographic significance of the king's espousal of Dionysus becomes clear in light of the good evidence that in some sense Alexander the Great had identified himself with Dionysus in Carmania.) Nor was classical Dionysus confined to royal exploitation: it has been shown that the festivals of the City Dionysia at Athens and the deme festival of the Rural Dionysia were closely woven into the life of the Athenian empire and the Athenian state. Another Athenian, Euripides, represented Dionysus in a less tame and "official" aspect in the Bacchae; this Euripidean

Grants of

Dionysus

Dionysus has more in common with the liberating Dionysus of Carmania or with the socially disruptive Dionysus whose worship the Romans in 186 BC were to regulate in a famous edict. The longevity and multifaceted character of Dionysus symbolizes the tenacity of the Greek civilization, which Alexander had taken to the banks of the Oxus but which in many respects still carried the marks of its (S.H.) Archaic and even prehistoric origins.

Hellenism

POLITICAL DEVELOPMENTS

Alexander's successors. Nothing shows the personality of Alexander the Great more clearly than the way in which people who had seemed pygmies at his side now became leaders of the world he had left behind. Blood still counted: the only male relative, a mentally impaired, illegitimate son of Philip, was proclaimed king as Philip III Arrhidaeus (c. 358-317), together with Rhoxane's son Alexander IV (323-310), born after his father's death in August; both were mere figureheads. For the moment Antipater was confirmed in authority in Macedon and Greece. At Babylon power was shared by two senior officers. Perdiccas (c. 365-321) and Craterus (c. 370-321). By common consent, Alexander's ongoing plans were abandoned. His generals had to be content with the office of governor. Antigonus Monophthalmos ("The One-eyed": c. 382-301), like Antipater, was not in Babylon at the time of Alexander's death in 323. For almost 10 years he had been governing Phrygia and had shown himself a brave soldier and competent administrator. His firmness and tact were popular with the Greek cities. Of the generals in Babylon, it was Ptolemy (c. 367/366-283) who calculated from the first that the empire would not hold together. He secured for himself the governorship of Egypt, where he aspired to set up an independent kingdom. Lysimachus (c. 360-281) was given the less attractive assignment of governing Thrace. Two of the others, noted for their physical and military prowess. Leonnatus and Seleucus, waited on events. The soldiers discounted Eumenes of Cardia, who bore the main responsibility for civil administration, but he knew more about the empire than anyone else.

An uprising by Greek mercenaries who had settled in Bactria but wanted to return to Greece was crushed. Trouble in Greece, led by the Athenians and aimed at liberating the cities from Macedonian garrisons, was tougher to control. Sparta refused to participate, as did the islands, but a coalition of Athens with Argos, Sievon, Elis, and Messenia, supported by Boeotians, Aetolians, and Thessalians, was a formidable challenge to Antipater's authority. For a time Antipater was hard-pressed in Lamia (the war of 323-322 is known as the Lamian War). Leonnatus intervened, nominally in support but in fact ambitious to usurp Antipater's power; he was killed in action, however. In the end Antipater won, Athens capitulated, and Demosthenes (the voice and symbol of anti-Macedonian feeling) committed suicide. Antipater reestablished Macedonian authority autocratically, with no nonsense about a "free" League of Corinth.

The story of the jockeying for power during the next two decades or so is inordinately complex. First Perdiccas. governing in the name of the two kings with the support of Eumenes, was charged with personal ambition and was assassinated. The armies made Antipater regent (Craterus had been killed in battle), and Antigonus, with Antipater's son Cassander (c. 358-297) as second-in-command, was placed in charge of the armies in Asia. Ptolemy was secure in Egypt; Seleucus (c. 358-281), governor of Babylon, and Lysimachus in Thrace continued to watch and wait; and Eumenes, a non-Macedonian with a fortune behind him. could claim to represent the kings against the ambitions of generals and governors.

Then, in 319, Antipater died and was succeeded by a senior commander but maladroit politician named Polyperchon, who tried to win the Greeks of the mainland by a new proclamation of their liberties. The result was that the Athenians used their freedom to execute the pro-Macedonians, including the worthy but compromising Phocion. War flared up. Eumenes, allied with Polyperchon, challenged Antigonus and secured Babylon, but he was betrayed and killed in 316. Seleucus escaped to Egypt, Polyperchon's position was weak, and he was soon ousted by the able, up-and-coming Cassander. In becoming master of Macedon and most of Greece, Cassander rebuilt Thebes and put the Aristotelian Demetrius of Phalerum in charge of Athens, Olympias, Alexander the Great's terrible mother, had eliminated Philip III. Cassander had her put to death, while keeping Rhoxane and Alexander IV under his protection-or guard.

Antigonus was now the dominant figure of the old brigade. Cassander, Ptolemy, and Lysimachus formed a coalition against him. For four years (315-311) they fought indecisively. Antigonus showed himself energetic. resourceful, and imaginative, but he could not strike a decisive blow. The only major change came in the brilliant coup by which Seleucus succeeded in recovering Babylon. In 311 the four leaders agreed to divide the world, leaving Ptolemy with Egypt and Cyprus, Antigonus with Asia, Lysimachus with Thrace, and Cassander with Macedonia and Greece, but only until Alexander IV came of age in 305. Seleucus was left out.

Royal blood, however, was quickly forgotten in the pursuit of power. Cassander murdered Rhoxane and young Alexander in 310, soon after Antigonus had vainly tried to crush Seleucus, Seleucus, however, held on to a damaged Babylon and the eastern provinces, except for India. which he had to yield to the Indian king Chandragupta. Antigonus now had the effective support of his brilliant son Demetrius (336-283), known as Poliorcetes, or Besieger, who ousted the other Demetrius and restored the democracy and eventually the League of Corinth: he was hymned with divine honours and given the Parthenon as his palace. Demetrius, also in 306, crushed Ptolemy in a naval battle and secured Cyprus and the Aegean, though he failed in a famous siege of Rhodes (305-304). Antigonus and Demetrius now proclaimed themselves joint kings in succession to Alexander. Antigonus, however, failed to conquer Egypt, and the other rulers also took the title of king. Cassander, Lysimachus, Seleucus, and Ptolemy formed an alliance against Antigonus and Demetrius, and at Ipsus in 301 the allies, with the help of a force of elephants brought from India by Seleucus, defeated and killed Antigonus. Demetrius escaped, retaining Tyre and Sidon and command of the sea. Lysimachus took large portions of Anatolia; Seleucus assumed control over Mesopotamia and Syria, except for a part in the south occupied de facto by Ptolemy; and Cassander was content with Macedonia and parts of Greece.

Cassander, who was a statesman, had founded two great cities, Cassandreia and Thessalonica, as well as rebuilding Thebes. His death in 297 was a prelude to more disturbances. Demetrius conquered most of Greece and secured Macedonia in 294, but he was ousted in 288 by Lysimachus in alliance with King Pyrrhus of Epirus (319-272). Demetrius now concentrated all his forces on winning Asia and all but succeeded. He fell ill, however, and surrendered to Seleucus, who gave him every opportunity to drink himself to death. The stage was set for a confrontation between Lysimachus and Seleucus.

Ptolemy gained command of the sea by Demetrius' fall. He died in his bed, the only one of Alexander's successors to do so, and was succeeded peacefully by his son Ptolemy II Philadelphus (308-246). However, a son by his first wife, Ptolemy Ceraunus, the Thunderbolt (grandson of Antipater), was stirring the waters round Lysimachus, and the latter soon lost support. Seleucus defeated and killed Lysimachus, and Alexander's empire, except for Egypt, seemed to be his for the asking. Lysimachus' army, however, supported Ceraunus, who assassinated Seleucus in 281. Seleucus' son by a Sogdian noblewoman succeeded him as Antiochus I (324-261). In Greece proper the strongest powers were Antigonus Gonatas (c. 320-239), son of the brilliant Demetrius and himself a man of high character, ability, and culture, and Pyrrhus, king of Epirus. Pyrrhus was about to embark on his ill-starred expedition to Italy, where he soundly defeated the growing power of Rome but at an enormous cost to himself.

At this point, migrating Celts under the command of

Murder of Rhoxane and Alexander

The Lamian War

Bolgius and Brennus caused an added complication, not least by the defeat and death of Ceraunus. Brennus pushed down into Greece but was repulsed by the Aetolians. The dangers posed by the invading Celts led, in 279, to a treaty between Antigonus and Antiochus, who agreed not to interfere in one another's spheres of influence. Each won a decisive victory over the Celtic invaders, who eventually settled in Serbia, Thrace, and Galatia in central Anatolia. Antigonus was able to secure Macedonia. Lysimachus' kingdom was never revived. The three centres of power were Macedonia, Syria, and Egypt.

The mid-3rd century. The power of the rulers was not yet secure. Ptolemy II had already launched an offensive after the death of Seleucus and somehow secured Miletus He made a new drive in 276 to gain Seleucid Syria only to be repulsed. About that same time, however, he renounced his first wife and married his sister Arsinoe, who was actually widow to both Lysimachus and Ceraunus. She was a woman of dynamic authority who inspired Ptolemy's armies to sweep up the coast and secure Phoenicia and much of coastal Anatolia. Her brief years were years of brilliant culture. When she died on July 9, 270, the court poet Callimachus wrote a poem on her deification.

Arsinoe

In the west, Pyrrhus, returning to Epirus full of thwarted ambition, overran Macedon but abandoned it to attack southern Greece. He failed, however, to take Sparta and died in street fighting in Argos, after being struck to the ground by a tile hurled down by a woman watching from the roof. Pyrrhus had fostered the Hellenization of northwestern Greece and built the magnificent theatre at Dodona; he was more than a military adventurer.

Antigonus was influenced by stoic philosophy (see below): he had a high sense of duty and once said that the power of kings was merely a spectacular form of servitude. He also was a friend of the poet Aratus. There was no serious challenge to his power in the north. In the south, Athens, led by the handsome Chremonides, allied with Sparta and other cities against him; the alliance was backed by Egypt and received some support from Epirus. The war was hard-fought for four years (266-262), but the alliance fell apart. The political power of Athens was finally broken, but the city survived as a cultural centre. Antigonus left Sparta to itself and placed dictators (tyrants) of his own choice in other cities.

Antiochus I of Syria died in 261. He was succeeded by his son Antiochus II (287-246), who formed an alliance with Antigonus against Ptolemy II. In the Second Syrian War (259-255), Antiochus recovered most of the coast of Anatolia and Phoenicia, while Antigonus won a naval victory and with it command of the sea; he even was able to put a half-brother into power in Cyrene. The death of Antiochus II in 246, however, brought on a fresh power struggle in Syria, and Ptolemy III Euergetes (c. 284-221), succeeding his father in the following year, was able to march through the distraught realm. Seleucus II Callinicus (c. 265-225) eventually restored stability and recovered some but not all of the lost territory. Yet he was again challenged by civil war and had to abandon Bactria, Parthia, and the eastern provinces (Cappadocia had already been lost before the civil war).

The weakness of the Seleucids brought a new power onto the scene. Pergamum had great resources in silver, agriculture, and stock breeding but had not come to marked prominence. Attalus I Soter (269-197), who ruled from 241 to 197, made Pergamum a great power. He defeated the resurgent Celts of Galatia, took the title of king, for a period held mastery of much of Anatolia, intervened in the west, and all the while made his city a major centre for literature, philosophy, and the arts.

During the middle of the century some remarkable developments in confederation occurred on mainland Greece. Epirus had been a form of confederacy between Molossians, Thesprotians, and Chaonians. Pyrrhus had established an autocratic monarchy, but after his death in the 230s the people reverted to a federal constitution. In Boeotia, a confederacy composed of officials predominantly from Thebes (the largest city in a system that gave all citizens the right to vote in the primary assembly) modified its pattern to grant equality to the constituent cities

regardless of size. In Aetolia, there was a confederacy with a strong primary assembly that met twice a year and a council with proportional representation of the member states based on each state's military contingent; the existence of tribal districts intermediate between the cities and the whole confederacy was an unusual feature. Neighbouring Acarnania also had a federal constitution. The two neighbours were generally hostile, but at one point they actually agreed on limited mutual rights of citizenship.

The best-known of the confederacies was the Achaean League. It had existed earlier, to be revived in 280 by the cities of Dyme, Patrae, Tritaea, and Pherae; it was joined by Aegium, Bura, and Cerynea. "For the first 25 years," wrote the historian Polybius, "the above-mentioned cities shared in a confederacy, appointed a common secretary according to a rota, and two generals. After that they took a fresh decision to appoint a single general and to entrust him with plenary authority. Margus of Cerynea was the first." There were also 10 magistrates called demiourgoi. Then, in 251, the Greek statesman Aratus (271-213), incorruptible, adventurous, persuasive, skilled in diplomacy, passionately attached to freedom and implacably ambitious for his own position, rid his native Sicvon of Aratus its tyrant and brought it into the league. By 245 he was elected general and held the office in alternate years. Aratus heartily loathed tyrants and Macedon alike. A notable guerrilla fighter, he led the league in the work of liberation, freeing Corinth and winning Megara and some cities of the Argolid but not Argos or Athens. Then he clashed with the revolutionary nationalism of Cleomenes III of Sparta (c. 260-219; see below), and, rather than seeing his life's work imperiled by Cleomenes' revolution, he preferred to sell it back to the imperialists of Macedon. Macedon came and conquered. Aratus and the league were allowed to retain a shadow of independence, but no more than that. The league, however, remained intact. Executive power lay with the Council, which seems to have been a large body constituting a kind of representative government. What the Achaean League did, for a limited period over a limited area, was to combine the distinctive character of the city-state with a wider vision. On the coins the local Aphrodite of Corinth and Hera of Argos vield place to the more widely recognized Zeus Homagyrius and Demeter Panachaea, According to Polybius, the whole Peloponnese during the most important phase of the Achaean League could be considered a single polis.

Sparta, always different from the rest of Greece, was a shadow of its former self. There were no more than 700 Spartan citizens, and the land, far from being equally distributed, was in the hands of only a few. Agis IV, coming to power in 244, essayed economic and social reform by abolishing debts and redistributing land. He succeeded in the former but was killed by those whose power he threatened. His widow was married to Cleomenes, son of the other king, Leonidas II. She, however, won him to the need for revolution. In this she was supported by Cleomenes' stoic tutor Sphaerus, who seems to have read a remarkable utopian narrative composed c. 250 by an otherwise obscure author named Iambulus. Cleomenes came to the throne in 235; in 227 he began to break the power of the oligarchy within the aristocracy, abolish the debts owed by poor farmers to rich landlords, and redistribute the land. He also reintroduced the common meals and restored the simplicity of life and the education for character that were traditional in Sparta. Cleomenes III combined a narrow Spartan nationalism with a visionary idealism. The revolution spread; everywhere there was demand for "division of land and cancellation of debts." Cleomenes, however, was stopped by Aratus, an adamant opponent of his reforms, the Macedonians were called in, and at Sellasia, in the summer of 222, the Spartans were beaten and Cleomenes forced into exile, where he died.

The coming of Rome (225-133). In the 3rd century, Rome had been encroaching on the Greek settlements of southern Italy and Sicily. Pyrrhus, as noted above, had been called in by Tarentum in the Tarentines' fear of Rome. Hieron (c. 306-215), a Syracusan supporter of Pyrrhus, seized power in his city; he was made king in 269 and actually reigned for 54 years. For a year or two he

Philip V of

Macedon

continued to oppose Rome, but then he formed an alliance with it, helping it in its wars with Carthage. Farther away yet, Massalia (modern Marseille), an outpost of Greek culture, took care to maintain good relations with Rome; at the same time, it maintained a strong independent navy and a stable oligarchic government. (Massalia is a classic example, often forgotten, of the durability of the Greek city-state in the Hellenistic age; even in 121 BC, when the Roman province of Gallia Narbonensis was established, Massalia was still an equal ally of the Roman Republic.)

In the late 220s new monarchs acceded to the throne in the three great kingdoms of Syria, Egypt, and Macedon, and Polybius chose that point for the formal start of his history. Antiochus III (c. 242-187), called the Great, succeeded his brother Seleucus II in Syria, and from the first he showed a desire for imperialist expansion. His attempt to conquer Egyptian territory in the Palestinian area in the Fourth Syrian War (219-216) was foiled at the battle of Raphia. His campaigns in the east were more successful: he secured Armenia, Parthia and Bactria became his vassals, and he carried out impressive demonstrations near the northwestern frontier of India and across the Persian Gulf. He turned to adventures in Europe but came up against a Rome resurgent after its war with Hannibal; by the peace of Apamea in 188 he was confined to his still considerable Asian domains. In Egypt, Ptolemy IV Philopator (c. 244-205) succeeded to power in 221. He repelled Antiochus III at Raphia with Egyptian soldiers, and his reign was marked by the power of native Egyptians and of Nubian rulers in the south. He died in 205, leaving a five-year-old son. There occurred an uprising, which deposed his minister Agathocles, and disturbances throughout the reign. Philip V of Macedon (238-179) came to the throne in the same year. Although popular with the common people and quite capable on the battlefield, he showed unsound judgment and lacked stability of temperament. Like Antiochus, he had expansionist ambitions, but he supported Hannibal against Rome and was roundly defeated by the Romans at Cynoscephalae in 197.

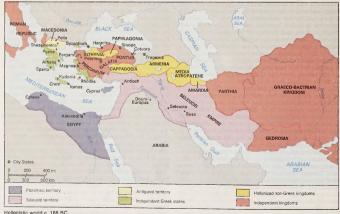

Rome was almost forced into the Greek world. In 229-228 and again in 219 it had been campaigning against pirates in Illyria. Then, from 218 to 201, it was preoccupied with and became drained by the Second Punic War with Hannibal. Even so, Rome kept Philip V at bay and, once Hannibal was eliminated, defeated him in the Second Macedonian War. Rhodes and Pergamum had checked Philip's enterprises in the Aegean but were understandably

nervous about his future intentions. They called in the Romans, who were equally suspicious of Philip. Their victory over him at Cynoscephalae, where the Macedonian phalanx of heavy infantry showed that it was hard to beat if it kept its ranks but vulnerable if it did not, demonstrated Rome's supremacy. Rome, however, annexed no territory; the narrow oligarchy governing Rome had no desire to take on administrative responsibilities that might require extending the circle of those in power. The young commander Titus Quinctius Flamininus (consul in 198) was a philhellene. At the Isthmian Games in 196 he proclaimed the freedom of Greece. A priesthood to him was set up at Chalcis, which still survived in Plutarch's time. and a paean was composed to Titus, Zeus, and Roma, ending "Hail Paean Apollo, hail Titus our Saviour" (or "Liberator"). He checked the ambitions of Nabis of Sparta, who combined the revolutionary program of Cleomenes III with imperialism and cruelty. Yet in 194 all Roman troops were withdrawn from Greece.

The next challenge came from Antiochus, as already indicated. The Romans returned to Greece to fight him. They defeated him in Asia, strengthening Pergamum and Rhodes at his expense but annexing no territory themselves. Then Perseus (c. 212-165), son to Philip V, succeeded to his throne and power in 179. He secured his position by dynastic marriages; he wedded the daughter of Seleucus IV (c. 218-175) and was allied by marriage to Prusias I Cholus of Bithynia. In addition, he used diplomacy to extend his influence. Nevertheless, in 172 Eumenes II of Pergamum (d. 159), who had succeeded his long-lived father in 197 and who was a great builder in his capital, felt threatened by the growth of Macedonian power and appealed to Rome. The result was the so-called Third Macedonian War (172-168), which ended with the defeat of Perseus by Lucius Aemilius Paullus at Pydna. Macedonia was divided into four republics-and yet again the Romans withdrew without annexations. If Rome, as its enemies avowed, was a dragon, it was a reluctant dragon. Meantime, Antiochus IV Epiphanes of Syria (c. 215-

163) had come to power in 175. He had been a hostage in Rome and was a passionate philhellene; he paid lip service to the political traditions of both Athens and Rome. The Romans, however, prevented him from annexing Egypt and Cyprus, which he had invaded in 168.

Antiochus actively pursued a policy of Hellenization as a means to unify his kingdom. This policy, however, led to an uprising in Judaea, though it should be emphasized

Hellenistic world c. 188 BC

Antiochus and Judas Maccabaeus that it was a pro-Syrian party among the Jews that applied to the king for permission to build a gymnasium, with all that this implied. Party conflict among the Jews-i.e., the supporters of Hellenization and the orthodox Jews who fiercely opposed it-was a major factor in the disturbance. Equally, Antiochus' sense of his own divinity, represented by the title Epiphanes (God Manifest), was unacceptable to the orthodox Jews who recognized the absolute claims of the God of Israel. Antiochus forbade the practices of the Jewish faith and placed an altar to Olympian Zeus ("an abomination of desolation") on the altar of the temple. Resistance flared up, first passive, then, under the leadership of Judas Maccabaeus (who made "a league of amity and confederacy" with the Romans), active and military, The details of the conflict as it spread over decades and the reigns of successive rulers of Syria are complex: suffice it to say here that for virtually a century the Jewish people enjoyed a large measure of de facto independence.

By 146 the Romans were impatient with Greek instability, and at the same time they were determined to have done with Carthage. The city was razed and a province established in the fertile farmland of modern Tunisia. A pretender, who had arisen in Macedon, invaded Thessaly; he was defeated, captured, and executed, and Macedonia was annexed as a Roman province. The Greeks clashed with the Romans; patriotic sentiment ran high but to no effect. The Romans treated Corinth as Alexander had treated Thebes-they leveled it. In the rest of Greece the leagues were dissolved, democracies abolished, and power placed with the rich. Intercity peace was established and left to the governor of Macedonia to enforce. The ironic result was that the city-states had, imposed from outside, a degree of autonomy and peace they had previously lacked. Then, in 133, Attalus III of Pergamum (c. 170-133) bequeathed his kingdom to Rome-an odd, though perhaps realistic bequest. It aroused opposition, led by a pretender named Aristonicus, who was driven by a combination of personal ambition, nationalist resentment, and utopian idealism. The movement was backed by a stoic philosopher named Blossius, who had been concerned with the reforms of the Gracchi in Rome. It spread among the oppressed and aimed to establish a utopian "City of the Sun." Roman military power, however, was too strong. Aristonicus was defeated and killed; Pergamene territory became the Roman province of Asia.

For the most part the story of the kingdoms of Egypt and Syria during the 2nd and 1st centuries was one of stormy and deeply divisive feuds. In Egypt brother-and-sister marriage in the royal house was frequently practiced. The rulers were for the most part an undistinguished lot, yet the country remained wealthy, and there was expansion to the south. In Syria civil war and division seemed to be the rule rather than the exception. Antiochus VII Sidetes (c. 159-129), after a victorious campaign in Mesopotamia, Babylonia, and even Media, looked briefly as if he might restore the lost glories. The Parthians, however, rallied, surprising and killing him in the winter of 130-129, and regained all he had recovered. Thereafter the kingdom became weak and divided, and neighbouring states were constantly gnawing at its edges. Far to the east the Greek dynasty that had ruled Bactria since about 256 was coming to an end by the middle of the 1st century. In western India, however, Menander, a hero of Indian legend, was in power; the art of the Gandhara region (present northwestern Pakistan) shows marked Greek influence.

Mithradates (Mithridates) VI Eupator of Pontus (c. 132–63 ac) was still a minor in 120—the year that his father was murdered—when he was named joint ruler with his mother and brother. For some years he was a refugee from his mother's power. Then, in a sudden sally, he secured the throne, imprisoned his mother, killed his brother, and married his sister. Pontus, sprawling along the southern coast of the Black Sea, included Greek colonies and a native population; the largest section of the people, including the rulers, were Iranian. Mithradates was able, cunning, and ambitious. He secured money and men by expanding and ambitions and the nurned to Anatolia, the Aegean islands, and even Greece, where the financial oppression of the Romans made him appear a liberator. The Romans

defeated him time and again, but he showed a subtle resilience until his final defeat by Gnaeus Pompeius Magnus (106-48 ac). In 67 Pompey made his greatest contribution to peaceful trade and development by his systematic destruction of the pirates. He put an end to the danger from Mithradates, who was driven from his kingdom and committed suicide in 63. Pompey in his celebrated settlement of the East annexed Syria as a Roman province, settled Judaea, and planted Roman colonies.

Henceforth the Greek world was dominated by Rome. Julius Caesar and Pompey faced one another at Pharsalus in Thessaly in 48. Mark Antony and Octavian faced Marcus Junius Brutus and Gaius Cassius Longinus at Philippi in Thrace. The brilliant Cleopatra VII (69-30 BC), last of the Greek Ptolemaic dynasty in Egypt, was ambitious to rule the world. In the realism of power politics she had to conquer Rome: the path lay through marriage with whoever held the power there. The surviving portraits show that she was no great beauty. Nonetheless, she charmed Caesar and held Antony in the power of her personality. Yet she backed the wrong man. A third conflict for the mastery of the world in two decades was held in Greece, culminating in the naval battle of Actium off the western coast in 31. The victor was Octavian (63 BC-AD 14), the future Caesar Augustus. The last kingdom of Alexander's successors fell to Rome.

The Greek world under the Roman Empire. Under Augustus, Macedonia, though including Thessaly, was separated from a new province of Achaea with its administrative centre in Corinth; both provinces were assigned to the Roman Senate. Thrace remained a kingdom and was not annexed until AD 46, when it became a province under an imperial procurator. Asia was a province, incorporating the western coast of Anatolia and reaching into the interior. Bithynia-Pontus stretched along the northern coastline. There was a third area of special command in Cilicia, but this did not last; part of it went to Syria, part to a new province, Galatia (25 Bc), and part to small vassal states. The imperial province of Cilicia dates from AD 72. Lycia et Pamphylia became a separate province under Claudius in AD 43; and Cappadocia had been annexed earlier under Tiberius in AD 17. Cyprus constituted a province, at first under the emperor, but later it was transferred to the senate. Crete and Cyrene formed a sin-

gle province. Syria was the most important of the eastern

provinces. Finally there was Egypt, an imperial preserve

and vital for the grain supply and revenue of the empire.

During the next century and a half, four major factors affected the eastern half of the empire. First, a whole series of earthquakes and other calamities devastated the cities of Anatolia. (Strabo, the aforementioned Greek historian and geographer, has an appalling account of the eruptions around Philadelphia, which drove the inhabitants into the open country as refugees.) The Roman emperor Tiberius (ruled AD 14-37) met these disasters with constructive aid, and 12 cities set up a record of his benefactions, calling him "the simultaneous founder of 12 cities." Second, there began to be trouble with the Jews, not just in Judaea but in Alexandria and elsewhere as well. The Roman emperor Caligula's demands for worship led to an embassy to Rome, recorded by the great Hellenized Jewish scholar Philo Judaeus (c. 30 BC-AD 45). The emperor's death resolved the problem, but even the more tolerant Claudius (ruled AD 41-54) had to intervene in Alexandria. The wars of 66-70 and 132-135, revolts against Roman rule in Judea, had the effect of further dispersing the Jewish people around the empire. Third, Nero (ruled 54-68), patron of the arts and philhellene, made a triumphal tour of Greece, dancing, singing, competing, and carrying away the prizes. The four great festivals at Olympia, Delphi, Nemea, and the Isthmus were crowded into one year for his sake. "The Greeks are the only people who understand how to be an audience," he said. He proposed and began a Corinth canal and proclaimed the freedom of the Greeks, which, in effect, meant reduced taxation. Finally, there was the eastern frontier and the power of the Parthians, and subsequently Sāsānian Persia. Armenia was a focal point. The rulers in general walked a tightrope between the great powers with skill. Trajan (ruled 98-117), however, fol-

Cleonatra

"Julia the

Alexander

philosopher" lowed a strong-arm policy. He annexed Armenia, making it a province, did the same to Mesopotamia and to Adiabene, and captured Ctesiphon. On his coins he put the inscription Parthia capta ("Parthia conquered"), followed by rex Parthia datus ("the king given to the Parthians") as he imposed a puppet monarch. He dreamed of being a second Alexander, but he died, and Hadrian (ruled 117–138) gave up the three new provinces, retaining only a

fourth, Arabia. A period of peace was then followed by one of chaos. During the reign of Marcus Aurelius (ruled 161-180), Ctesiphon was again taken; but there also was a disastrous plague spread through the Greek world and even to Italy and Rome. The 19th-century classical historian Barthold Georg Niebuhr said that the ancient world never recovered from the blow. In addition, mainland Greece suffered from an incursion of a people called the Costoboci, who even succeeded in sacking Eleusis in 170-171. The accession of Septimius Severus (ruled 193-211), who came from Africa, brought a remarkable coterie of women from Syria to power in Rome, Julia Domna, "Julia the philosopher," was the emperor's second wife. She established a highly cultured court, inviting to it scholars and writers such as Galen and Philostratus from the Greek east. Her sister Julia Maesa and her nieces Julia Soaemias and Julia Mamaea were responsible for the coming to power first of the fantastic Elagabalus and then of the young Severus

In 224 the Sāsānian dynasty came to power in Persia with an autocratic centralized government upheld by a strong religious commitment. Its rulers aimed to drive the Romans out of Asia; in 256 they ravaged Antioch, and in 260 they captured the emperor Valerian. At Palmyra, an outpost of Greek culture, the remarkable Septimia Zenobia came to power and at one time conquered Syria, Egypt, and much of Anatolia. In 267 the Germanic Heruli actually sacked Athens, Corinth, Argos, and Sparta. But the Romans were resilient. Aurelian recovered the lost ground. He had, however, felt the power of the east, and in 274 he introduced the Unconquered Sun as the supreme god of the Romans. It was clear to the emperor Diocletian that the administrative system had to be changed; he placed two rulers in charge of the east (himself being one of them), and two of the west, with 13 regions and 116 provinces. Nicomedia in Bithynia was chosen as the eastern capital. Constantine (c. 285-337), after winning sole power, went further and moved the capital of the whole empire into the east. He thought first of Troy, as Julius Caesar had before him, but in the end he chose Byzantium with its magnificent site where the Bosporus, the Golden Horn, and the Propontis meet. On May 11, 330, he inaugurated New Rome, or Constantinople, to be the capital of the new Christian empire. It was, in a sense, the triumph of Hellenism and ensured the survival of the Roman dominion in the east for more than 1,000 years.

HELLENISTIC CIVILIZATION

Institutions and administrative developments. The great cities. The greatest of Alexander's foundations became the greatest city of the Hellenistic world, Alexandria-by-Egypt. It was laid out in the typical Hellenistic grid pattern along a narrow strip between Lake Mareotis and the sea. Canopic Way ran the length of the city, finely paved and nearly 100 feet (30 metres) wide, with seven or more main roads parallel to it. Across it was the shorter Transverse Street, with at least 10 parallel major roads. The city was divided into five regions, known as Alpha, Beta (the Palace area), Gamma, Delta (the Jewish quarter), and Epsilon. The great buildings included the palace, Alexander's tomb, the temple of the Muses, the academy and library, the zoological gardens, the temple of Sarapis, the superb gymnasium, stadium, and racecourse, the theatre, and an artificial mound, the shrine of Pan, ascended by a spiral road. There were two harbours. The famous lighthouse lay on an offshore island. A canal to the Nile helped secure the water supply; there also were rainwater cisterns. The city wall was some 10 miles (16 kilometres) long. It was a cosmopolitan city. The so-called Potter's Oracle described the city as "a universal nurse, a city in

which every human race has settled," and Strabo called it "a universal reservoir."

The great Seleucid capital Antioch on the Orontes stood safely some 11 miles from the sea on a major trade route. Originally small, the grid plan with blocks roughly 390 feet by 115 feet was laid out from the first for the expansion over the plain, which eventually took place. A colonnaded street, in Roman times more than 88 feet in width (about one-third carriageway and one-third for each sidewalk), ran the city's length. Aqueducts brought water from the mountains to flow in water conduits along the east-west streets and through terracotta pipes along the cross streets. Like Alexandria, the city was cosmopolitan, and Tacitus speaks of intermarriage between the ethnic groups. When Julia Domna held court, students came from Phoenicia, Palestine, Egypt, Cyprus, Arabia, Cilicia, and Cappadocia, It was a city noted for its luxurious living, as the magnificent mosaics of the Roman period from Antioch itself and the fashionable suburb of Daphne demonstrate. Antioch suffered severely from earthquakes and flooding; thus there was much rebuilding. The population was perhaps 500,000 at its largest.

It seems that Antioch was smaller than Seleuceia on the Tigris, the largest of all the Seleucid foundations, with 600,000 inhabitants according to Strabo. Little, however, is known about it, except that it was on a grid plan and had a stone wall on foundations of baked mudbrick. In 143 nc it became an autonomous Greek city under Parthian control.

Pergamum, a small town before it became the capital of the Attalid dynasty, remains one of the most spectacular of ancient sites. The southern face of the acropolis was brilliantly terraced and carried two agoras, stoas, a gymnasium, palaestras, an odeum, temples, and other buildings. Near the top stood the great altar of Zeus with its mighty frieze (now in Berlin) of the battle of gods and giants, and the throne of Satan. The main street leads through a gate to the upper city. There one finds an imposing sanctuary of Athena, the famous library, and a temple of Trajan, on which excellent restoration work has been done. Below is a vertiginous theatre seating 10,000, with a removable stage building on a terrace leading to the Ionic temple, presumably of Dionysus. Much of the remainder of the upper city was occupied by the palace buildings and storehouses. Less can be discerned of the lower city, except for the sanctuary and hospital of Asclepius, founded about 400

BC but developed in the Hellenistic and Roman periods. The most evocative remains of all the ancient cities are those of Ephesus. It was moved to its longest-lasting site about 290 BC by Lysimachus and built mostly on a grid plan with a wall of more than 5.6 miles. Much of what is visible today dates from the Roman period. By the harbour, today far inland, are the great baths; a broad colonnaded street leads to the theatre, the scene of the silversmiths' riotous protest against the apostle Paul. A cross street passes in front of the theatre, with a huge agora to the south and the imposing Library of Celsus, dedicated in AD 110. From there the slightly eccentric Curetes Street runs eastward. On one side are wealthy houses with mosaics and frescoes, on the other the Baths of Scholasticia and the Temple of Hadrian. Further up the street is the colossal terrace that sustained a Temple of Domitian and leads on to the area of the State agora, the political, administrative, and religious centres, and a magnificent gymnasium. The great Temple of Artemis, a little way off, was one of the Seven Wonders of the World.

The administration of Ptolemaic Egypt. Ptolemaic Egypt represented, in the words of the 20th-century historian Frank William Walbank, "a large-scale experiment in bureaucratic centralism and in mercantilism." Here was a constant need to import material not readily available at home, such as the timber and pitch required for warships and the mercantile fleet and also gold. Demetrius, chief executive of the mint in Alexandria, wrote to Ptolemy Il's finance minister, Apollonius, in 258 ac about the need to import as much gold as possible. The Ptolemies had a closed monetary system, which required all foreign traders on arrival to change their money. Exports included linen, papyrus, faience, and eventually glass (with

Antioch on the Orontes

The Ptolemaic economy a stringent quality control), and, when appropriate, grain. The administrators divided the country into more than 30 regions, or nomes, with smaller divisions into districts and villages. There was military government alongside a complex financial administration responsible for collecting rents and taxes. At the same time, the local finance offices were instructed (a document survives) to encourage the peasants, protect them from disaster, and ensure the sowing of the correct crops. The king, in theory, claimed all the land and let it to peasants on short leases, providing the seed-corn but requiring its equivalent to be returned. The oil-producing crops were state monopolies: so were mines, quarries, salt, nitre, and alum. Other areas of agriculture were controlled by license, taxation, and price-fixing. A surviving letter from a finance minister says, "No one has the right to do what he wants, but all is regulated for the best." Perhaps it was not always as systematic, efficient, and incorrupt as it sounds or as some admirers have proposed. Nor was it all so new. The major change was the imposition of a Macedonian and Greek ruling class, who filled the upper ranks of the civil service. Egyptians held some of the lower posts, but only in the priesthoods could they retain wealth and influence. There was friction at times; for example, a camel driver complained of nonpayment because "I do not know how to behave like a Greek."

Still, there were few slaves outside the cities, and double names attest the gradual acceptance of some Egyptians into the upper echelons of society. The remarkable Cleopatra VII, however, was the first sovereign to learn the native language. When all is said about defects in the administration, Egypt was, and remained, inordinately wealthy, and the Romans were delighted to secure its rev-

enues and its grain.

Military developments. The victories of Philip II and Alexander the Great were made possible by imaginative generalship and inspirational leadership combined with the use of elite troops that were specially trained and equipped. The Macedonian phalanx depended upon a long, heavy spear called a sarissa. The troops were organized in battalions of about 1,500 men forming 15 rows in depth. The 11 rows at the rear held their spears vertically, causing them to tower formidably above them. The four front rows held their spears horizontally so that all projected in front of the phalanx. For protective armour they wore helmets, leather corselets, and metal greaves, and each carried a small round shield. The phalanx was virtually impregnable to a frontal attack but could not easily swerve or reverse. The heavy cavalry of the Companions carried a shorter spear and scimitar and wore metal helmets and breastplates. They advanced in the form of a spearpoint, or triangle, so as to break up the opposing line of battle. On the wings of the phalanx were fairly mobile troops: light cavalry, slingers and archers and javelin men, and light infantry.

The successors recruited large armies of 60,000 or even 100,000 men, including many mercenaries. By about 200 BC troops from Greece, Crete, and the Balkans had decreased in number and many more were recruited from the Syrian territories. The mercenaries were not normally trained for the phalanx but were supplementary to it. The employment of mercenaries increased the number of desertions and the amount of looting; this in turn led to the need for more stringent discipline in the field. At the same time, the armies were relatively free from the hatreds liable to arise between highly politicized national forces. Surrender on easy terms followed by ransom tended to be the order of the day.

Alexander was a great master of siegecraft. He used saps and mines, timbered galleries, catapults and stone throwers, siege towers, scaling ladders, and covers for such operations as filling up ditches or bringing battering rams to bear. These new devices were countered by better walls, towers, ditches, and outworks so that in general the besiegers had to rely on treason, bribery, stratagem, or on starving out the besieged town. Demetrius and Philip V were the only two of the successors who gained much reputation in siege work.

The fleets of the Hellenistic age were smaller in number

of boats than those of the Classical period, but the battleships were larger. Ptolemy II's fleet of 336 was smaller than that of Athens in its war with Sparta. The quinquereme, however, was now the standard battleship, and its crew was about double that of the trireme. Even larger vessels were used, such as a 16-oarer with two banks of oars and eight men to an oar. The Macedonian king Antigonus Gonatas had a flagship of the 18-oar type. One even hears of a 40-oarer. In general, the Macedonian navy dominated the Aegean and the Egyptians the rest of the eastern Mediterranean. There were, however, many fluctuations, and Rhodes was never negligible.

Civic structures. Wherever Hellenization was strong, there tended to be support for the institution of the citystate as well as a measure of syncecism, or gathering of smaller communities in a new polis. The Alexandrias were followed by countless towns, to which were given names such as Antiocheia, Seleucias, Laodicea, Ptolemais, Demetrias, or Cassandreia. Some townships that were not essentially Greek, such as Tyre, Sidon, Byblos, Aradus, and Sardis, were nonetheless treated as cities, except for the towns of Mesopotamia. Non-Greek immigrants into Greek cities might be granted their own administrative system rather than being absorbed into the general citizenship: for example, the Jews in Alexandria had their own

ethnarch and Council of Elders.

Some of the successors were hostile to the Greeks, notably Antipater and Cassander. All were liable to impose conscription and taxation, though occasionally immunity was granted. The kings exercized control through a resident representative (epistates) in the cities, though this was generally handled delicately and diplomatically. Sometimes, however, they preferred to support a puppet dictator. The rights of minting coinage were severely restricted. The apparatus of civic government, however, remained, and, under the Seleucids, decrees were passed by council and assembly in city after city. During the periods of relative freedom in mainland Greece, there was sometimes democracy, and the Ptolemies maintained democracy in Cos. Yet the kings generally, and the Romans after them, encouraged autocratic or oligarchic government. Most cities in mainland Greece and some others, such as Rhodes, Cyzicus, and Byzantium, retained rights of foreign policy, including military action. They also acted to maintain the grain supply, sometimes by the public purchase of grain and its cheap sale or free distribution. The same freedom made possible the remarkable developments in federal government already noted. This in turn led to a great increase in the use of arbitration in the settlement of disputes, which was obligatory within the confederacies or among those cities directly dependent on the monarch and not infrequent outside.

The encouragement by the overlord, whether Greek or Roman, meant changes in the political patterns. These can be seen reflected in Roman times in the works of Plutarch (who, however, idealizes the past to such an extent that one cannot be sure of him as a contemporary witness) or of the Greek rhetorician and philosopher Dion Chrysostom. Plutarch preferred monarchy and was opposed to extending the franchise to all the free population; interestingly, though, he favoured some kind of in the party system, so that there is more than one policy to choose from. The changes meant a more or less settled ruling class in the cities. There was now no room for demagogy because there was no deme which it made any difference to court. Where the politically ambitious had scope was in deputations to the kings or, later, the Roman emperors. Nonetheless, the path of the ruling class was not always strewn with roses. Its members were expected to bear the brunt of public expenditure, which in the harsher times of the later empire could become burdensome. In questions addressed to an oracle, found at Oxyrhynchus and dating from the late 3rd century AD, the inquiries "Am I to become ambassador?" or "Am I to become a senator?" are not very different from the question "Am I to become bankrupt"? They were dictated by fear, not ambition. Similarly, there are some amusing records of council meetings which show nominees eager to wriggle out of an office that might become expensive, while the

Changes political patterns

The armies

Slavery was virtually universal but varied in its incidence. On the whole, though there were numerous exceptions, Greeks did not enslave Greeks; their slaves came predominantly from Anatolia and Syria, Thrace, the Danube basin, and southern Russia. The main sources were war and piracy, fostered by the work of the slave-dealers. The great centres of the trade were Byzantium and Ephesus, but. from the middle of the 2nd century BC to the middle of the 1st, Delos became the dominant market. In the Greek east, slaves were numerous in the cities; it should, however, be noted that they could hold relatively responsible jobs. There were comparatively few slaves in the countryside. Under the early Roman Empire the supply dwindled with the control of piracy and a long period of peace. Liberal legislation by Claudius in the 1st century AD and by Trajan, Hadrian, and Antoninus in the 2nd gave increasing protection and rights to slaves. The price of slaves rose, which implies that often they could be afforded only for skilled work. In the 3rd century, with frontier wars and brigandage resurgent, the prices dropped somewhat, but demand still outstripped supply. The breeding of slaves continued, and the sale of newborn babies was legalized and that of older children, though illegal, was widespread.

Economic developments. Alexander's conquests had four major effects on the economy. In the first instance, it released a large quantity of silver and gold from the treasuries of Persia. The immediate result was a sharp rise in prices, but, as the surplus funds were absorbed into capital, prices began to fall. Second, the integration of quarreling city-states into a single empire removed some of the obstructions to mutual trade. Third, Philip had already adopted the Attic standard for gold, and Alexander adopted it for silver as well. The successors in general followed, though the Ptolemies preferred the Phoenician standard. The complex needs of money-changing were thus greatly reduced. These two standards held good until some time in the 1st century BC, when the Roman challenge to them triumphed. Finally, and most obviously, the extension of empire meant an extension of trade routes; China became open to trade for the first time and East Africa, Arabia, and India became more easily accessible

than before.

The Egyptian trade was mainly by sea, featuring the port of Berenice on the Red Sea, while Alexandria was established as one of the greatest mercantile centres on the Mediterranean. Toward the end of the 2nd century BC an Indian at Alexandria explained to Ptolemy VII the secret of the monsoon, which greatly facilitated the sea passage to India and enhanced the importance of Coptos on the upper Nile. The Egyptians also had an eye to the land routes. This explains their desire to command the Phoenician ports, which were not only the terminus of one land route but also producers of woven stuffs and fine dyes.

The keypoint for Seleucid trade was Seleucia on the Tigris. In one direction, the route led to Antioch on the Orontes with branches to Ephesus and Damascus, In the other, there were three routes to India, two by land and one by sea. Alexander's foundation of Alexandria in Areia was important to the trade. Dura Europus on the Euphrates was a fort protecting the lines of trade: it was retained by the Romans. The caravan cities, such as Petra and Palmyra (formerly Tadmor), flourished on the trade. The advance of Chinese military power from Turkistan in the 2nd century BC fostered the trade with China along the famous Silk Road through central Asia. The Chinese exported silk and other textiles, bamboo, and iron and imported vines and other trees and plants, as well as wine, olives, woolen goods, and artwork (which affected Chinese artistic style). The demand for luxury goods in the prosperous days of the early Roman Empire increased the trade with China, India, and Arabia, and an embassy from Marcus Aurelius actually reached China by way of Annam.

Early in the Hellenistic age, the Greek navigator, geographer, and astronomer Pytheas of Massalia embarked on one of the most remarkable feats of exploration. Evading the Phoenician outposts, he slipped through the Strait of Gibraltar, sailed north along the coasts of the Iberian peninsula and France, crossed over to Cornwall, continned around the north of Britain and on to Helgoland, and then returned. The Phoenicians, however, allowed no other ship to pass Gibraltar and the only tangible result of Pytheas' voyage was an increase in the trade in Cornish tin by overland routes through France.

In general the Romans made transport, whether by land or sea, safer and swifter. The Greek Epictetus could say, "Caesar has procured us a profound peace. There are no wars, no battles, no massive brigandage, no piracy; we may travel at all hours and sail from East to West.' inscription from Hierapolis in Phrygia dating from the imperial period tells how an operator named Flavius Zeuxis passed Cape Tainaron no fewer than 72 times.

The economy of mainland Greece declined during the Hellenistic age, though standards rose briefly about 260 BC. and there were pockets of prosperity, such as the Boeotian city of Tanagra famous for its terra-cotta figurines. The general picture is one of poverty, unemployment, falling wages, depopulation, and emigration. The forests were stripped, the land neglected, and smallholdings swallowed up in large estates, which, however, were underdeveloped. The Athenian silver mines at Laurium were depleted, though they reopened briefly at the end of the 3rd century BC. Demand for fine painted pottery had ceased. Athenian wine was of poor quality. Olive oil, however, continued to command a market, so much so that a law of AD 125 reserved one-third of the production to indigenous use; but, as the historian Moses I. Finley argued, olive oil alone would hardly meet the balance of payments. The centres of Hellenic prosperity had shifted with the movement of Hellenism from Athens, Corinth, Sparta, and Argos to Alexandria, Rhodes, Pergamum, and Antioch.

Within the Mediterranean basin, trade was mostly in essentials or things regarded as such. Metals ranked highest in importance: there was silver from Spain, copper from Cyprus, iron from the Black Sea coast and later China, and tin from Cornwall. Food also was important: grain came from Egypt, North Africa, the Crimea, and perhaps Babylonia. In other areas there was some specialization: Athens was noted for honey as well as olive oil, Byzantium for fish, Jericho for dates, and Damascus for prunes. Textiles were prominent: linen arrived from Egypt, a kind of silk from Tyre and true silk from China, and woolen goods from Miletus. Timber came from the forests of Anatolia and the north, marble for building from Paros and Athens, granite from Egypt: some docks constructed in Delos about 130 BC are of Egyptian granite.

The prosperity of Egypt, "the gift of the Nile." was rooted in agriculture. The land lent itself to the cultivation of wheat, barley and sorghum, flax, vegetables (including lentils, beans, chickpeas, and onions), the date palm, and

papyrus, as well as the raising of animals, such as horses,

donkeys, goats, cattle, poultry, and fish. Strabo gives a vivid picture of the resources of the Seleucid kingdom. He speaks of the rich yields of barley and the varied uses of the products of the palm-for food, drink, sweetening, fuel, and weaving. Mesopotamia is "good pastureland, and rich in vegetation, evergreens and spice." Rice was introduced into Persia from India, and the vine from Greece.

Similarly Strabo identifies the specialties of different regions of Anatolia. He mentions the fruit trees, vines, and olives of Melitene; the stone, timber, and pastures around Mazaca; the orchards of Cappadocia, and its mineral resources in red ochre, crystal, onyx, and mica; the market gardens of Sinope and beyond them olive groves and timber forests; the cattle and cheese of Bithynia; the styrax, producing gum and wood for spears, of the Taurus Mountains; and the superb wools of Laodicea and Colossae.

One figure suffices to indicate the huge economic expansion during the Hellenistic age. The customs revenue of Rhodes in about 170 BC was five times that of Athens in 400, with almost certainly the identical rate of 2 percent. It would be hard to demonstrate more clearly that the Hellenistic world operated in a totally different dimension. Cultural developments. Architecture. It was in the Hellenistic age that the grid plan came into its own, in the Trade in the Mediterranean

Egyptian trade

The Hellenistic theatre at Priene, second half of the 4th century BC C leen Wood Photographs

numerous new foundations, and some of the refoundations such as Priene.

The great buildings of the Classical age had been predominantly religious; those of the Hellenistic age were predominantly secular, though it will not do in the ancient world to make a rigid distinction between the two. The chief characteristic of Hellenistic temple architecture was the predilection for the Corinthian style, which came into its own with the Temple of Olympian Zeus at Athens, begun in 174 BC. Many Hellenistic temples were of immense size: this one is 135 feet by 354 feet on the stylobate. The oracular temple of Apollo at Didyma is 168 feet by 359 feet on the stylobate. Another colossal temple was built at Cyzicus in the 2nd century AD, with columns of more than 6.5 feet in diameter; it displaced the temple of Artemis at Ephesus as one of the Seven Wonders of the World.

Some of the theatres were similarly colossal. Hieron II's 3rd-century modifications of the rock-cut theatre in Syracuse and the theatres at Megalopolis and Ephesus accommodated more than 20,000 people. There were changes of design, initiated at Athens with the emergence of New Comedy, which eliminated the chorus from a significant part in the drama. The result was the introduction of a high shallow stage, removable for revivals of the ancient plays and therefore of wood. Later the proscenium was built in from the first, and eventually it was constructed of stone, as at Oropus in about 200 BC; at Athens the change was deferred until about 150 BC. The Roman-built theatres are distinguishable by the fact that the auditorium is a perfect semicircle. The orchestra was often expanded for gladiatorial and wild animal fights and correspondingly surrounded by a high wall; at Stobi, Tyndaris, and Corinth this was more than 9.8 feet in height. Roman theatres were often built standing free rather than fitted into a hillside: the magnificent theatre at Aspendus is an example. The best-preserved theatre of the Roman Hellenistic world is at Bostra Traiani in present-day Syria.

All stadiums by definition ought to have the course of a given length, though, curiously, they vary by more than 30 feet. The stadium at Athens was built in the shape of a U with one flat end and one rounded; it was reconstructed in Pentelic marble in AD 143 by the millionaire benefactor Herodes Atticus. The great stadiums at Aphrodisias and Nysa in Anatolia and at Laodicea in Syria belong to the Roman period and are rounded at both ends. The one at Aphrodisias seated 30,000 people and is excellently preserved. The gymnasium and palaestra tended in the Hellenistic period to be more formalized in plan and structure.

The palaces of the Greek period have not survived. Remaining houses show increasing elaboration and luxury. Examples from the 3rd century may be seen in Priene, consisting normally of a block of four rooms with a pillared entrance opening on to a courtyard. In some of

the wealthier houses, rooms are found on three sides of the court, and there may be columns opening onto an entrance corridor on the fourth. This structure developed into a peristyle house already found in Olynthus in the 4th century. Delos has a variety of peristyle houses built on irregular plans; generally one finds a great water cistern and often spectacular mosaics. In southern Italy the Greek population developed its own style of house, whose court in Pompeii blended with that of the peristyle structure. These houses presented to the street generally bare walls. The typical house is symmetrical about its long axis. A short hall reaches an atrium, or lofty court with an impluvium, or cistern, at its centre.

The arts. Hellenistic sculpture, often of a very high quality, is notable for its variety. Alexander's pothos, or yearning for something unattained, was a mood that became expressed in the art. Lysippus, Alexander's favourite sculptor, had produced a seminal statue, the "Apoxyomenos" ("The Athlete, Scraping Himself"), a figure standing with one arm extended and the other pulled across his body. The viewer has to move around it because no single viewpoint is satisfactory. Eutychides, a pupil of Lysippus, carried the principle further in his portrayal of "The Fortune of Antioch." Vastly more complex, and showing the search for an original subject, is the brilliant and brutal "The Punishment of Dirce" by Apollonius and Tauriscus of Tralles. "Laocoon," a portrayal of anguish, shows the figure of the priest Laocoon and his two sons in the grip of two snakes. The sculpture, in immobile stone, is bursting with dynamism and energy.

Pergamum was one of the great centres of sculpture. There Attalus I commemorated his victory over the Gauls with a huge monumental group on a circular base. The altar of Zeus at Pergamum bore a frieze 364 feet long portraying the battle of the gods and giants; muscular superhuman figures are rendered in dynamic, agonized conflict.

An aspect of the Hellenistic search for variety was the use of the genre subject, such as a boy with a goose, a drunken old hag, a boy pulling a thorn from his foot. The attractive terra-cotta figurines from Tanagra and Myrina offer a fine selection of scenes from ordinary life, such as a grossly fat nurse with a bulbous nose holding a baby in her lap, a boy wearing a dunce's cap, two women gossiping, or acrobats in all manner of attitudes. The search for variety, paradoxically, also took the form of a return to the Classical style. Examples are the "Venus de Milo," whose face recalls the manner of the 4th-century sculptor Praxiteles, and the "Belvedere Torso," modeled on a 4thcentury sculpture but with a muscular twist that marks it as Hellenistic.

Portraiture was a natural accompaniment of the courts. Rulers were finely portrayed not just in statues but on coins. Some of the finest of these come from the outlying kingdoms of Bactria and India. The portraits do not always

Theatres

scenes

flatter; the monarchs appear podgy or scrawny, brokennosed or hook-nosed. Full statues were rarer. Portraits were not confined to rulers. The statue of Demosthenes in Copenhagen, taut and intense, is copied from a 3rdcentury original by Polyeuctus, sculpted well after the orcord's death. Philosophers were often depicted; although it is possible to distinguish individuals, a type of "philosopher" is imposed on them.

The New Comedy Literature: In literature, just as in the arts, one finds a combination of novelty and commonplace types and themes. In the New Comedy at Athens, of which Menander (c. 342–292 ac) was the leading exponent, the theme is no longer fantasy but real life. The plays are not uproarious, as those of Aristophanes can be, but they are filled with quiet good humour. Besides Menander, there was Herodas (3rd century ac), who in his Mimiambi (Mimes) sketched episodes from life. Theophrastus (c. 370–287 ac) produced a minor masterpiece, Characters, in which he depicted such figures as the Stupid Man, who cannot remember where he lives, or the Tactless Man, who makes a misogynistic speech at a wedding.

Some writers took a deeper interest in psychology. The poet Apollonius of Rhodes (3rd century ne) worde an epic on the Argonauts, in which he closely observed the psychology of Medea at her first experience of love; his sensitive and romantic rendition influenced the Roman poet Virgil in his portrayal of the ill-fated love between Dido and Aeneas. Theocritus (c 300–260 ne), who came from Sicily but lived mostly in Cos and Alexandria, examined in his second idyll the love-hate relationship of a girl to her unfaithful lover. The world of Theocritus is a world of pastoral artifice having little to do with the real hardships of country life, but the details are exquisitely noticed.

Alexandria was noted for its learning. The poet Callimachus (c. 305-240 Bc), who was attached to the city's famous library, wrote poetry of polished craft and allusive scholarship. His great work Aetia ("causes") is a rare miscellany, a long poem made up of short sections. Callimachus, immensely influential, has qualital, has

The major contributions to prose literature fall in the Roman period, though the novel developed earlier in Alexandria. Ingenious and exciting plots are combined with stereotyped characters. Longus' Daphnis and Chloe (date unknown) is perhaps the best of such works of prose fiction. Another important development was the rhetoric of the movement known as the Second Sophistic, which belongs mainly to the 2nd century AD. Its finest practitioner was Dion of Prusa (c. AD 40-112), nicknamed Chrysostom, Herodes Atticus (c. Ap 101-177) and the flowery Polemo (c. AD 88-144) had much influence; more survives from the dull, Athens-loving hypochondriac Aelius Aristides (c. AD 117-187) and the facile Maximus of Tyre (c. AD 125-185). Greater than any of these is the Syrian Lucian (c. AD 120-185), a satirist and brilliant entertainer, who spared neither gods nor humans.

Other writers, worthy enough, must receive passing mention: they are the geographers Strabo (c. 64 Bc-AD 25) and Ptolemy and Pausanias (both 2nd century AD), the historians Diodorus Siculus of Sicily (1st century ac), Arrian (2nd century AD), Appian (2nd century AD) and Dio Cassius (2nd-3rd century AD), the passion of the Control of the Control of Co

Science and medicine. The three great areas of Helenistic scholarship were medicine, astronomy, and mathematics. Alexandria attracted Herophilus (fl. 3rd century Bc) from Chalcedon, who refused to stand in awe of the accepted medical dogmas and was distinguished in systematic anatomy, and the notable physiologist Erasistratus (fl. 3rd century Bc) from Cos, who realized that the heart is the motor for the circulatory system and deduced the existence of capillaries. Philinus (fl. 3rd century Bc) from Cos founded the empirical school, trusting chinical observation founded the empirical school, trusting chinical observation

rather than theory. In the 1st century Bc Asclepiades of Bithynia, who worked in Rome and was a great believer in hygiene, was claimed the founder of the rival methodist school, based on Epicurean atomism. In the 2nd century emerged the towering figure of Galen of Pergamum (c. Ao 129–199), whose authority later was second only to that of Aristotle.

In astronomy the first great advances were due to Aristarchus of Samos in the early 3rd century ac. He was the pioneer of the theory that the Sun is at the centre of the universe. His greatest achievement lay in his method for determining the sizes and distance of the Sun and the Moon, though his observational technique was inadequate for correct results. Later in the century Eratosthenes of Cyrene, a typical polymath, calculated the Earth's circumference by an excellent method, though his good result was due to the mutual canceling out of two errors.

In mathematics the key figures are Euclid (fl. e. 300 Bc), Archimedes (e. 287–212 Bc), and Apollonius (fl. late 3rd century ac). Euclid, whose Elements served as a basic text-book of geometry for 2,000 years, was both a systematizer and original mathematician. Archimedes preferred to concentrate on particular problems, working in the realms of geometry, physics, and mechanics, and he formulated the science of hydrostatics. Apollonius of Perga was the great authority on conics. One other significant mathematician was Hero of Alexandria (fl. 1st century AD), who actually devised a simule steam enaine but treated it as a mere tov.

Philosophy. The philosophers of the period pursued autarkeia: self-sufficiency, or nonattachment. The most extreme position was taken by the cynics, whose founder was Diogenes of Sinope (c. 400-325 BC). Behind his rejection of traditional allegiances lay a profound concern with moral values. What matters to human beings, he taught, was not social status or nationality but individual wellbeing, achieved by a reliance on one's natural endowments. He was followed by the attractive couple Crates (c. 365-285 BC) and Hipparchia. Zeno (335-263 BC), founder of the stoics, began from here. To the stoics nothing is good but virtue, nothing bad but vice; all else is indifferent. The stoics were pantheists. They believed that all is in the hands of God; indeed, God is all. Moreover, all is for the best in the best of all possible worlds, and human beings only have to accept and give praise. Zeno was succeeded by a religious genius named Cleanthes (331-232 BC) and he by the great systematizer Chrysippus (c. 280-207 BC). The 2nd century produced Panaetius (c. 185-109 BC), who smoothed away some of the sharper stoic paradoxes for the Romans, and the 1st brought Poseidonius (c. 135-50 BC), another mediator between east and west.

Epicurus (341–270 ac), an Athenian contemporary of Zeno, stood poles apart in thought from the stoics. In opposition to their moralism he taught that the goal of life is pleasure, a position for which he has been much maligned. In fact, he advocated the simple life as being the most pleasurable and said that it was impossible to live pleasurably without being wise, just, and honest. (J.Fe.)

Ancient Italic peoples

Pre-Roman Italy was inhabited by peoples diverse in origin, language, traditions, stage of development, and territorial extension and was heavily influenced by neighbouring Greece, with its well-defined national characteristics, expansive vigour, and aesthetic and intellectual maturity, Italy attained a unified ethnolinguistic, political, and cultural physiognomy only after the Roman conquest; yet its most ancient peoples remain anchored in the names of the regions of Roman Italy—Latium, Campania, Apulia, Bruttium, Lucania, Samnium, Picenum, Umbria, Etruria, Venetia, and Liguria.

THE ETRUSCANS

The Etruscans formed the most powerful nation in pre-Roman Italy. They created the first great civilization on the peninsula, whose influence on the Romans as well as on 20th-century culture is increasingly recognized. Evidence suggests that it was the Etruscans who taught the Romans the alphabet and numerals, along with many el-

Cynics and stoics

Medicine, astronomy, mathematics ements of architecture, art, religion, and dress. The togawas an Etruscan invention, and the Etruscan-style Doric column (rather than the Greek version) became a mainstay of architecture of both the Renaissance and the later Classical revival. Etruscan influence on the ancient theatre survives in their word for "masked man," phersu, which became persona in Latin and person in English.

General considerations. Nomenclature. The Greeks called the Etruscans Tyrsenoi or Tyrrhenoi, while the Latins referred to them as Tusci or Etrusci, whence the English name for them. In Latin their country was Tuscia or Etruria. According to the Greek historian Dionysius of Halicarnassus (fl. c. 20 BC), the Etruscans called themselves Rasenna, and this statement finds confirmation in the form rasna in Etruscan inscriptions.

"Rasenna"

Geography and natural resources. Ancient Etruria lay in central Italy, bounded on the west by the Tyrrhenian Sea (recognized early by the Greeks as belonging to the Tyrrhenoi), on the north by the Arno River, and on the east and south by the Tiber River. This area corresponds to a large part of modern Tuscany as well as to sections of Latium and Umbria. The chief natural resources of the region, undoubtedly playing a crucial role in Etruscan commerce and urban development, were the rich deposits of metal ores found in both northern and southern Etruria. In the south, in the maritime territory stretching between the first great Etruscan cities, Tarquinii and Caere (modern Cerveteri), the low-lying Tolfa Mountains provided copper, iron, and tin. These minerals also were found inland at Mount Amiata, the highest mountain in Etruria, in the vicinity of the city of Clusium (modern Chiusi). But the most productive area turned out to be in northern Etruria. in the range known as the Catena Metallifera ("Metal-Bearing Chain"), from which copper and especially iron were mined in enormous amounts. The city of Populonia, located on the coast, played a leading role in this industry, as did the adjacent island of Elba, evidently renowned from an early date for the wealth of its deposits.

The forests of Etruria constituted another major natural resource, providing abundant firewood for metallurgical operations as well as timber for the building of ships. The Etruscans were famous, or perhaps infamous, for their maritime activity; they dominated the seas on the western coast of Italy, and their reputation as pirates instilled fear around the Mediterranean. Their prosperity through the centuries, however, seems also to have been founded on a stout agricultural tradition; as late as 205 BC, when Scipio Africanus was outfitting an expedition against Hannibal, the Etruscan cities were able to supply impressive amounts of grain as well as weapons and materials for shipbuilding.

Historical periods. The presence of the Etruscan people in Etruria is attested by their own inscriptions, dated about 700 BC; it is widely believed, however, that the Etruscans were present in Italy before this time and that the prehistoric Iron Age culture called "Villanovan" (9th-8th century BC) is actually an early phase of Etruscan civilization.

Inasmuch as no Etruscan literary works have survived, the chronology of Etruscan history and civilization has been constructed on the basis of evidence, both archaeological and literary, from the better-known civilizations of Greece and Rome as well as from those of Egypt and the Middle East. Contact with Greece began around the time that the first Greek colony in Italy was founded (c. 775-750 BC), when Greeks from the island of Euboea settled at Pithekoussai in the Bay of Naples. Thereafter, numerous Greek and Middle Eastern objects were imported into Etruria, and these items, together with Etruscan artifacts and works of art displaying Greek or Oriental influence, have been used to generate relatively precise dates along with more general ones. In fact, the basic nomenclature for the historical periods in Etruria is borrowed from corresponding periods in Greece; the assigned dates are usually (though perhaps erroneously) conceived of as being slightly later than their Greek counterparts to allow for cultural "time lag." Thus the Etruscan Orientalizing period belongs to the 7th century BC; the Archaic period to the 6th and first half of the 5th century BC; the Classical period to the second half of the 5th and the 4th century BC; and the Hellenistic period to the 3rd to 1st

centuries BC. Etruscan culture became absorbed into Roman civilization during the 1st century BC and thereafter disappeared as a recognizable entity.

Language and writing. Etruscan, the third great language of culture in Italy after Greek and Latin, does not, as noted above, survive in any literary works. An Etruscan religious literature did exist, and evidence suggests that there may have been a body of historical literature and drama as well. (Known, for example, is the name of a playwright, Volnius, of obscure date, who wrote "Tuscan tragedies,") Etruscan had ceased to be spoken in the time of imperial Rome, though it continued to be studied by priests and scholars. The emperor Claudius (d. AD 54) wrote a history of the Etruscans in 20 books, now lost, which was based on sources still preserved in his day. The language continued to be used in a religious context until late antiquity; the final record of such use relates to the invasion of Rome by Alaric, chief of the Visigoths, in AD 410, when Etruscan priests were summoned to conjure lightning against the barbarians.

There are more than 10,000 known Etruscan inscriptions, with new ones being discovered each year These are mainly short funerary or dedicatory inscriptions, found on ash urns and in tombs or on objects dedicated in sanctuaries. Others are found on engraved bronze Etruscan mirrors. where they label mythological figures or give the name of the owner, and on coins, dice, and pottery, Finally, there are graffiti scratched on pottery; though their function is little understood, they seem to include owners' names as

well as numbers, abbreviations, and nonalphabetic signs.

Bucchero ware jug in the shape of a cock, incised with the Etruscan alphabet on both sides, c. 7th-6th century BC, from Viterbo. In the Metropolitan Museum of Art, New York City.

Of the longer inscriptions, the most important is the "Zagreb mummy wrapping," found in Egypt in the 19th century and carried back to Yugoslavia by a traveler (National Museum, Zagreb). It had originally been a book of linen cloth, which at some date was cut up into strips to be wrapped around a mummy. With about 1,300 words, written in black ink on the linen, it is the longest existing Etruscan text; it contains a calendar and instructions for sacrifice, sufficient to give some idea of Etruscan religious literature. From Italy come an important religious text, inscribed on a tile at the site of ancient Capua, and an inscription on a boundary stone at Perugia, noteworthy for its juridical content. The few Etruscan-Latin bilingual inscriptions, all funerary, have little importance with respect to improving knowledge of Etruscan. But inscribed gold plaques found at the site of the ancient sanctuary of Pyrgi, the port city of Caere, provide two texts, one in Etruscan and the other in Phoenician, of significant length (about 40 words) and of analogous content. They are the equivalent of a bilingual inscription and thus offer substantial data for the elucidation of Etruscan by way of

Etruscan inscriptions

a known language-Phoenician. The find is also an important historical document, which records the dedication to the Phoenician goddess Astarte of a "sacred place" in the Etruscan sanctuary of Pyrgi by Thefarie Velianas, king

of Caere, early in the 5th century BC.

The 20th-century notion that there is a "mystery" regarding the Etruscan language is fundamentally erroneous; there exists no problem of decipherment, as is often wrongly asserted. The Etruscan texts are largely legible. The alphabet derives from a Greek alphabet originally learned from the Phoenicians. It was disseminated in Italy by the colonists from the island of Euboea during the 8th century BC and adapted to Etruscan phonetics; the Latin alphabet was ultimately derived from it. (In its turn the Etruscan alphabet was diffused at the end of the Archaic period [c. 500 BC] into northern Italy, becoming the model for the alphabets of the Veneti and of various Alpine populations; this happened concurrently with the formation of the Umbrian and the Oscan alphabets in the peninsula.)

The real problem with the Etruscan texts lies in the difficulty of understanding the meaning of the words and grammatical forms. A fundamental obstacle stems from the fact that no other known language has close enough kinshin to Etruscan to allow a reliable, comprehensive, and conclusive comparison. The apparent isolation of the Etruscan language had already been noted by the ancients; it is confirmed by repeated and vain attempts of modern science to assign it to one of the various linguistic groups or types of the Mediterranean and Eurasian world. However, there are in fact connections with Indo-European languages, particularly with the Italic languages, and also with more or less known non-Indo-European languages of western Asia and the Caucasus, the Aegean, Italy, and the Alpine zone as well as with the relics of the Mediterranean linguistic substrata revealed by place-names. This means that Etruscan is not truly isolated; its roots are intertwined with those of other recognizable linguistic formations within a geographic area extending from western Asia to east-central Europe and the central Mediterranean, and its latest formative developments may have taken place in more direct contact with the pre-Indo-European and Indo-European linguistic environment of Italy. But this also means that Etruscan, as scholars know it, cannot simply be classified as belonging to the Caucasian, the Anatolian, or Indo-European languages such as Greek and Latin, from which it seems to differ in structure.

Methods of interpreting the Etruscan language

Etruscan

alphabet

The traditional methods hitherto employed in interpreting Etruscan are (1) the etymological, which is based upon the comparison of word roots and grammatical elements with those of other languages and which assumes the existence of a linguistic relationship that permits an explication of Etruscan from the outside (this method has produced negative results, given the error in the assumption), (2) the combinatory, a procedure of analysis and interpretation of the Etruscan texts rigorously limited to internal comparative study of the texts themselves and of the grammatical forms of the Etruscan words (this has led to much progress in the knowledge of Etruscan, but its defects lie in the hypothetical character of many of the conclusions due to the absence of external proofs or confirmations), and (3) the bilingual, based on the comparison of Etruscan ritual. votive, and funerary formulas with presumably analogous formulas from epigraphic or literary texts in languages belonging to a closely connected geographic and historical environment, such as Greek, Latin, or Umbrian. Nonetheless, with the increase of reliable data, in part from more recent epigraphic discoveries (such as the gold plaques at Pyrgi mentioned above), the need to find the one right method appears to be of decreasing importance; all available procedures tend to be utilized.

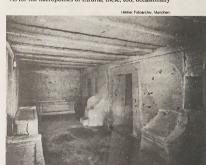

Archaeological evidence. The lack of Etruscan literature and the widely acknowledged bias and contradictory accounts of Greek and Roman writers create a situation in which the careful study of the visible remains of the Etruscans is fundamental for understanding them. The archaeological contexts and the remains themselves (including pottery, metalwork, sculpture, painting, architecture, animal and human bones, and the humblest objects of daily life) fall into three basic categories: funerary, urban, and sacred. (There is sometimes an overlapping of these categories.)

By far the largest percentage of material is funerary: thus there is a great deal of information about Etruscan ideas on the afterlife and on their attitudes toward the deceased members of their families. But there can be no doubt that the relatively scarce information about Etruscan settlements is also of great importance. The evidence of the well-preserved Etruscan city at Marzabotto (c. 500 BC) near Bologna (probably an Etruscan colony) reveals that the Etruscans were among the first in the Mediterranean to lay out a city with a grid plan; it was oriented according to the compass, emphasizing a principal north-south street and including one or more major east-west streets. The ritual involved in thus laving out a town, complete with walls, temples, and other sacred areas, was known to the Romans as the ritus etruscus. The system was commonly used by the Romans in laying out military camps and new cities and has survived in the centre of many European cities today. Such rigidly organized town plans seem to have been rare in Etruria; more often one finds an irregular pattern resulting from the coalescence of villages in Villanovan times and the adaptation to the hills normally chosen as town sites.

In a sacred context, the Etruscan temple also often revealed a careful organization, once again with a system that was passed on to the Romans. In contrast to Greek temples, those of the Etruscans frequently showed a clear differentiation of front and back, with a columniated deep front porch and a cella that was flush with the podium on which it stood. The materials were frequently perishable (timber and mud brick, on a stone foundation) except for the abundant terra-cotta sculptures that adorned the roof. Especially well-preserved are the acroteria, or roof sculptures, from the Portonaccio temple at Veii (late 6th century BC) representing Apulu (the Etruscan Apollo) and other mythological figures.

Of a different order are the spectacular finds from the site of Poggio Civitate (Murlo) near Siena, where excavations (begun in 1966) have revealed a huge building of the Archaic period with rammed earth walls, measuring about 197 feet on each side and featuring a large court in the middle. It was adorned with life-size terra-cotta figures, male and female, human and animal; some of the figures wear a huge "cowboy" hat in the regional style. Authorities still disagree over the nature of the site and are uncertain whether the building was a palace, a sanctuary, or perhaps a place of civic assembly. Ordinary Etruscan houses, known from a number of sites, include oval-shaped huts from San Giovenale and elsewhere and structures with a rectilinear plan from Veii and Acquarossa (Archaic) and Vetulonia (Hellenistic).

As for the necropolises of Etruria, these, too, occasionally

Settlement natterns

show signs of a grid plan, as at the Crocefisso del Tufo at Orvieto (second half of the 6th century BC) and at Caere. More often they have an irregular, agglutinative quality that reflects the site's long history of use. Because the Etruscans took great pains to make their relatives comfortable in a "house of the dead," the tombs suggest many details of actual Etruscan houses. Thus the tombs of Caere (especially those of the 6th century and later), carved underground out of the soft volcanic tufa so widespread in Etruria, have not only windows, doors, columns, and ceiling beams but also pieces of furniture (beds, chairs, and footstools) sculptured from the living rock. At Tarquinii, another tradition for tomb decoration led to painting the walls of the chamber with frescoes of Etruscan funerary celebrations, including banqueting, games, dancing, music, and various performances in a fresh outdoor landscape. The scenes probably served to commemorate actual funerals, but they also may have alluded to the kind of afterlife that was expected for the deceased. The Elysium-like concept of the afterlife prevailed in the Archaic period, but in the ensuing centuries one finds a growing emphasis on the darker realm of the underworld. Frescoes show its ruler, Hades (Etruscan Aita), wearing a wolf-skin cap and sitting enthroned beside his wife; demons and monsters populate this sphere. They may be seen in the remarkable Tomb of the Blue Demons (c. 400 BC), discovered at Tarquinii in 1987, or in the Francois Tomb from Vulci, where the blue-skinned devil Charu (only remotely resembling the Greek ferryman Charon) waits with his hammer to strike the deceased and take him away to the underworld. He sometimes has a gentler partner, the angelic winged figure of Vanth, who helps to ease the transition from life to death.

A perennial theme in the discussion of Etruscan material culture is its relationship to Greek models. The comparison is natural, indeed essential, in light of the massive amount of Greek artifacts, especially vases, that have been excavated in Etruria and the abundant examples of Etruscan imitations, of the pottery especially. It is also certain that Greek craftsmen sometimes settled in Etruria, as in the report by Pliny the Elder (1st century AD) about a Corinthian noble named Demaratus, who moved to Tarquinii, bringing along three of his own artists. But it is no longer appropriate to dwell naively on the "inferiority" of Etruscan art nor to insist that the Etruscans were mere imitators of the Greek art they undoubtedly prized. Instead, increasing emphasis is being placed on defining the highly original elements in Etruscan culture that exist side by side with the qualities that show their great admiration of things Greek.

Relation-

Greek and Etruscan

culture

ship between

> In addition to their distinctive modes of designing a town or of building a temple or tomb, one may note their unique native pottery, bucchero (beginning c. 680 BC), with its decorative incision in a shiny black fabric; it is radically different from standard Greek vase decoration, which regularly featured paint and a contrast of red or cream and black. In metallurgy, their bronze mirrors, sometimes described as an Etruscan "national industry, featured a convex reflecting side and a concave side adorned with engravings of themes from Greek and Etruscan mythology and daily life. Etruscan fashion also had many unique elements such as a hem-length braid down the back (7th century BC), pointed-toe shoes (c. 575-475 BC), and the mantle with the curved hem known to the Romans as the toga (6th century BC and later). Finally, the Etruscans seem to have taken an early interest in reproducing the features of their honoured relatives or officials (as in the funerary canopic urns from Clusium) and thus gave a major impetus to the development of truly realistic portraiture in Italy (especially in the Hellenistic period).

Religion and mythology. The essential ingredient in Etruscan religion was a belief that human life was but one small meaningful element in a universe controlled by gods who manifested their nature and their will in every facet of the natural world as well as in objects created by humans. This belief permeates the Etruscan representational arts, where one finds rich depictions of land, sea, and air, with man integrated into the ambient. Roman writers give repeated evidence that the Etruscans regarded every bird and every berry as a potential source of knowledge of the gods and that they had developed an elaborate lore and attendant rituals for using this knowledge. Their own myths explained the lore as having been communicated by the gods through a prophet, Tages, a miraculous child with the features of a wise old man who sprang from a plowed furrow in the fields of Tarquinii and sang out the elements of what the Romans called the Etrusca disciplina.

The literary, epigraphic, and monumental sources provide a glimpse of a cosmology whose image of the sky with its subdivisions is reflected in consecrated areas and even in the viscera of animals. The concept of a sacred space or area reserved for a particular deity or purpose was fundamental, as was the corollary theory that such designated areas could correspond to each other. Heaven reflected Earth, and macrocosm echoed microcosm. The celestial dome was divided into 16 compartments inhabited by the various divinities: major gods to the east, astrai and terrestrial divine beings to the south, infernal and inauspicious beings to the west, and the most powerful and mysterious gods of destiny to the north. The deities manifested themselves by means of natural plenomena, principally by lightning. They also revealed themselves in the microcosm of the liver of animals (typical is a bronze model of a sheep's liver found near Piacenza, bearing the incised names of divinities in its 16 outside divisions and in its internal divisions)

Bronze mirror with engraving of the soothsayer Calchas as a winged demon studying the liver of a sacrificed animal, early 4th century BC, from Vulci. In the Gregorian Museum of Etruscan Antiquities, Vatican City.

These conceptions are linked closely to the art of div- Divination ination for which the Etruscans were especially famous in the ancient world. Public and private actions of any importance were undertaken only after having interrogated the gods; negative or threatening responses necessitated complex preventive or protective ceremonies. The most important form of divination was haruspicy, or hepatoscopy-the study of the details of the viscera, especially the livers, of sacrificial animals. Second in importance was the observation of lightning and of such other celestial phenomena as the flight of birds (also important in the religion of the Umbri and of the Romans). Finally, there was the interpretation of prodigies-extraordinary and marvelous events observed in the sky or on the earth. These practices, extensively adopted by the Romans, are explicitly attributed by the ancient authors to the religion

The Etruscans recognized numerous deities (the Piacenza liver lists more than 40), and many are unknown today. Their nature was often vague, and references to them are fraught with ambiguity about number, attributes, and even gender. Some of the leading gods were eventually equated with major deities of the Greeks and Romans, deities

of the Etruscans.

about the Etruscans' as may be seen especially from the labeled representations on Etruscan mirrors. Tin or Tinia was equivalent to Zeus/Jupiter, Uni to Hera/Juno, Sethlans to Hephaestus/ Vulcan, Turms to Hermes/Mercury, Turan to Aphrodite/ Venus, and Menrya to Athena/ Minerya. But their character and mythology often differed sharply from that of their Greek counterparts. Menrva, for example, an immensely popular deity, was regarded as a sponsor of marriage and childbirth, in contrast to the virgin Athena, who was much more concerned with the affairs of males. Many of the gods had healing powers, and many of them had the authority to hurl a thunderbolt. There were also deities of a fairly orthodox Greco-Roman character, such as Hercle (Heracles) and Apulu (Apollo), who were evidently introduced directly from Greece yet came to have their designated spaces and cults.

Origins. Because the Etruscans spoke a non-Indo-European language while being surrounded in historical times by Indo-European peoples such as the Latins and Umbro-Sabelli, scholars of the 19th century examined and debated, often bitterly, the origins of this anomalous population. Their dispute continued into the 20th century but has now lost much of its intensity. The leading scholar in Etruscan studies, Massimo Pallottino, has wisely observed that such discussions have become sterile as the result of an incorrect formulation of the problem. Too much emphasis has been placed on the provenance of the Etruscans, with the expectation that there could be one simple answer. The problem is in reality exceedingly complex, and attention should be directed instead to the formation of the population, as it might be, for example, in a study of the origins of "the Italians" or "the French." Pallottino's position may be understood more clearly through a brief review of the debate.

The argument began, in fact, in antiquity with the statement by Herodotus that the Etruscans migrated from Lydia in Anatolia shortly after the time of the Trojan War: their leader was Tyrsenos, who later gave his name to the whole race. Supporters of this "Eastern" theory pointed above all to the archaeological evidence of profound Oriental influence on Etruscan culture, such as in monumental funerary architecture and exotic luxury goods of The debate gold, ivory, and other materials. But chronologically the Oriental inundation occurred nearly 500 years too late for the Herodotean migration. Further, it developed gradually provenance rather than making the sudden appearance that would have characterized the arrival of a people en masse; moreover, it is quite easily explained by reference to the trade conduits established by the Euboean Greeks in the 8th century BC. A key document in the Eastern theory is the inscription on a stone grave stela found on the island of Lemnos near the coast of Anatolia that shows remarkable lexical and structural similarities with the Etruscan language. But this curious isolated document dates only to the 6th century BC and thus cannot be interpreted as evidence of an Etruscan way station in the Herodotean migration from Anatolia to Italy. On the contrary, it has now been proposed that Lemnos may in fact have been colonized or used as a trading point by the Etruscans looking toward Anatolia in the 6th century BC rather than as a place they visited moving away from the area.

A second theory on Etruscan origins was proposed by Dionysius of Halicarnassus, who rejected the tradition of Herodotus, pointing out that the Lydian language and customs and those of the Etruscans were greatly dissimilar; he argued that the Etruscans were autochthonous (of local origin). Acceptance of this "autochthonous" theory requires that Villanovan culture be regarded as an early phase of Etruscan civilization (a hypothesis now widely endorsed) and, in addition, that there be links with an ethnic substratum of the Bronze Age in Italy (2nd millennium BC). There are indeed stray affinities with the Bronze Age culture of the "Terramara," with its cremating, sedentary habits, but also with the "Apenninic" culture, which was seminomadic and practiced inhumation. There is, however, mounting evidence of a critical transition period at the end of the Bronze Age and the beginning of the Iron Age, in which there are so many important developments that the connections between these two cultures and the Villanovan seem minor. Although the terminology is vexed for this transition period, varying from "sub-Apennine" to "Recent Bronze," "Final Bronze," and, most frequently, "Proto-Villanovan," the social and economic changes are clear. There was an increase in population and in overall wealth, a tendency to have larger, permanent settlements, an expansion of metallurgical knowledge, and a strengthening of agricultural technology. Diagnostic archaeological criteria include the use of cremation (with a biconical ash urn) and the presence of characteristic artifacts such as the fibula ("safety pin"), razor, objects of amber, the ax, and various other bronze weapons. The fact that the Proto-Villanovan archaeological horizon developed gradually rather than suddenly as the result of invasion or large migration might seem to support the theory of autochthony for the Etruscans. But once again the picture is clouded, because the Proto-Villanovan occurs in scattered areas all around Italy, including zones that definitely did not emerge as Etruscan in historical times.

To these two theories from antiquity was added a third in the 19th century to the effect that the Etruscans migrated overland into Italy from the north. This theory, without any ancient literary support, was based on similarities in customs and artifacts between the Villanovan and the Iron Age cremating cultures north of the Alps and on a dubious comparison of the name of the Rasenna with that of the Raeti, a people inhabiting the east-central Alps in the 5th century BC. The theory is basically without supporters today, though the influence or presence of certain central European weapon and helmet types and vessel forms in Etruria is not denied. These elements, however, are now put into perspective as representing simply one significant strand in the complex fabric of Etruscan culture as it developed from Villanovan to Orientalizing

These northern connections in a sense form a parallel to the Greek influences in subsequent periods, whether Euboean (8th century BC), Corinthian (7th century), Ionian (6th century), or Attic (5th century). Likewise, Oriental influences may be readily acknowledged, coming from such diverse areas as Lydia, Urartu, Syria, Assyria, Phoenicia, and Egypt. But none of these connections per se give any firm proof about Etruscan "origins," and current scholarship is much more concerned with understanding the interrelationship of these influences and the context in which the civilization in Etruria developed

Expansion and dominion. Archaeological evidence helps to develop a picture of the beginnings of Etruscan cities during the Villanovan period. Nearly every major Etruscan city of historical times has yielded Villanovan remains, but it is in the south, particularly near the coast, that the earliest signs of city formation appear. It is hypothesized that clusters of huts forming a network of villages on a single hill or on several adjacent hills coalesced into preurban settlements at this time. (The plural form of the names of some of these-Vulci, Tarquinii, and Veii-is consistent with this hypothesis.) Ash urns in the shape of oval huts with thatched roofs excavated in the area suggest what the houses of the living may have looked like, while the parity of grave goods for men and women implies a basically egalitarian society, at least in earlier stages. Cremation with ashes in a biconical vessel is commonly found as a holdover from the Proto-Villanovan; inhumation also appeared and during the Orientalizing period eventually became the prevailing rite, except in northern Etruria, where cremation persisted to the 1st century BC.

After contact was made with Greeks and Phoenicians, new ideas, materials, and technology began to appear in Etruria. In the Orientalizing period the use of writing, the potter's wheel, and monumental funerary architecture accompanied the accumulation of luxury goods of gold and ivory and exotic trade items such as ostrich eggs, tridacna shells, and faience. The Regolini-Galassi Tomb at Caere (c. 650-625 BC), discovered in 1836 in an unplundered state, dramatically revealed the full splendour of the Orientalizing period. The tomb's main chamber belonged to a fabulously wealthy lady who, inhumed with her banquet service and a wide array of jewelry made by granulation and repoussé, might well be called a queen; the word Larthia on her belongings may record her name. Even if A 19thcentury theory

The Orientalizing period

Caere did not have kings and queens at this time (as did Rome, or as Caere certainly did in the 5th century), it is clear that society had become sharply differentiated, not only in regard to wealth but also in division of labour. Many scholars hypothesize the existence of a powerful aristocratic class, and craftsmen, merchants, and seamen would have formed a middle class; it was probably at this time that the Etruscans began to maintain the elegant slaves for which they were famous. (Various Greek and Roman authors report on how Etruscan slaves dressed well and how they often owned their own homes. They easily became liberated and rapidly rose in status once they were freed.)

The dramatic growth of Etruscan civilization and influence in the 7th century is reflected in the so-called "princely" tombs, closely akin to the Regolini-Galassi Tomb, found in Etruria itself at Tarquinii, Vetulonia, and Populonia and along the Arno River (e.g., at Quinto Fiorentino) and in the south at Praeneste in Latium and at Capua and Pontecagnano in Campania. Literary sources report that Rome itself came under the rule of Etruscan kings in the late 7th century. Livy describes the arrival from Tarquinii of Tarquinius Priscus, the later king, and his ambitious, learned wife Tanaquil, a worthy counterpart to Queen Larthia of Caere. There is also archaeological evidence of Etruscan expansion northward into the Po valley in the 6th century.

True urbanization followed these developments. Mighty city-states featuring fortified walls and other public works flourished both in Etruria and in its spheres of influence. The Rome of the Etruscan kings, described in detail by Livy and known through excavation, had fortifications, a paved forum, a master drainage system (the Cloaca Maxima), a public stadium (the Circus Maximus), and a monumental Etruscan-style temple dedicated to Jupiter

Optimus Maximus.

It is at the end of the 6th century that one finds the earliest evidence for the grid system in towns and cemeteries mentioned earlier. The ample but surprisingly uniform houses and tombs imply growing regulation and cooperation and possibly signal a change in government. Etruscan cities, like Rome itself, may have begun to remove their kings at this time and to operate under an oligarchic system with elected officials from powerful noble families.

The Roman orator Cato's statement that "almost all of Italy was once under Etruscan control" best applies to this period. Undoubtedly, Etruscan maritime power and commerce played a central role in this domination. Exported Etruscan objects of the period have been found in North Africa, Greece and the Aegean, Anatolia, Yugoslavia, France, and Spain; later they even reached the Black Sea. But land routes were well under control also, especially in the corridor leading through Rome and Latium down to Capua and the other Etruscanized cities of Campania. In northern Italy, Bologna (Felsina) was the principal city, and colonies such as the ones at nearby Marzabotto and at Adria and Spina on the Adriatic Sea represented significant posts along the northern trade network.

Almost from the beginning, the Etruscans must have been rivaled in their own seas by the Greeks, who, from the founding of Pithekoussai and Cumae, settled in numerous colonies in southern Italy, and by the Phoenicians, who had established Carthage about 800 BC. The Carthaginians claimed parts of Sicily, Corsica, and Sardinia as spheres of influence and dominated the seas west of these islands to Spain. The generally salutary trading relations among these three nations and the delicate balance of power were upset, however, in the Archaic period, as new waves of Greek colonists arrived. Phocaean Greeks established a colony on Corsica at Alalia (modern Aleria) which threatened both the Etruscans at Caere and the Carthaginians and led to a naval coalition between them. The ensuing battle in the seas off Corsica (c. 535 BC) had disastrous results for the Phocaeans, who emerged as victors but lost so many ships that they abandoned their colony and moved to southern Italy. The Carthaginians and Etruscans reasserted control over Corsica, and Etruscan might was to hold firm for another quarter of a century.

Organization. From the 6th century BC onward, terri-

torial organization and political and economic initiative were concentrated in a limited number of large citystates in Etruria itself. These city-states, similar to the Greek poleis, consisted of an urban centre and a territory of fluctuating size. Numerous sources refer to a league of the "Twelve Peoples" of Etruria, formed for religious purposes but evidently having some political functions: it met annually at the chief sanctuary of the Etruscans, the Fanum Voltumnae, or shrine of Voltumna, near Volsinii, The precise location of the shrine is unknown, though it may have been in an area near modern Orvieto (believed by many to be the ancient Volsinii). As for the Twelve Peoples, no firm list of these has survived (indeed, they seem to have varied through the years), but they are likely to have come from the following major sites: Caere, Tarquinii, Vulci, Rusellae, Vetulonia, Populoniaall near the coast-and Veii, Volsinii, Clusium, Perusia (Perugia), Cortona, Arretium (Arezzo), Faesulae (Fiesole), and Volaterrae (Volterra)-all inland. There also are reports of corresponding Etruscan leagues in Campania and in northern Italy, but it is far more difficult to generate a list of Etruscan colonies or Etruscanized cities that would be likely candidates for these.

The names of some magistracies both in the league and in individual cities-such as lauchme, zilath, maru, and purth-are known, though there is little certainty as to their precise duties. Lauchme (Latin lucumo) was the Etruscan word for "king." The title of zilath . . . rasnal, translated into Latin as praetor Etruriae and meaning something like the "justice of Etruria," was evidently applied to the individual who presided over the league.

The men holding such magistracies belonged to the aristocracy, which derived its status from the continuity of the family. Onomastic formulas show that persons of free birth normally had two names. First came an individual name, or praenomen (relatively few of these are known; for men, Larth, Avle, Arnth, and Vel were frequent; for women, Larthia, Thanchvil, Ramtha, and Thana); it was followed by a family name, or nomen, derived from a personal name or perhaps the name of a god or a place. This system was in use by the second half of the 7th century, replacing the use of a single name (as in "Romulus" and "Remus") and reflecting the new complexity of relationships developing with urbanization. The Etruscans rarely used the cognomen (family nickname) employed by the Romans, but often inscriptions include the name of both the father (patronymic) and the mother (matronymic).

Etruscan women enjoyed an elevated status and a degree of liberation unknown to their counterparts in Rome and, especially, in Greece. They were allowed to own and openly display objects and clothing of a luxurious nature; they participated freely in public life, attending parties and theatrical performances; and-shocking to Greeks and Romans-they danced, drank, and rested in close physical contact with their husbands on the banqueting couches. Etruscan ladies were often literate, as one may deduce from the inscriptions on their mirrors, and even learned, if Livy's portrayal of Tanaquil as skilled in augury may be trusted. Their prominence in the family was a consistent feature of Etruscan aristocratic society and seems to have

played a role in its stability and durability.

Crisis and decline. The end of the 6th century and the beginning of the 5th was a turning point for Etruscan civilization. Several crises occurred at this time, from which the Etruscans never fully recovered and which in fact turned out to be only the first of numerous reverses they were to suffer in the ensuing centuries. The expulsion of the Tarquins from Rome (509 BC) deprived them of control over this strategic spot on the Tiber and also cut off their land route to Campania. Soon afterward, their naval supremacy also collapsed when the ships of the ambitious Hieron I of Syracuse inflicted a devastating loss on their fleet off Cumae in 474 BC. Completely out of touch with the Etruscan cities of Campania, they were unable to prevent a takeover of this area by restless Umbro-Sabellian tribes moving from the interior toward the coast.

All these reverses led to economic depression and a sharp interruption of trade for the cities on the coast and in the south and caused a redirection of commerce toward

League of the Twelve Peoples

Etruscan

Etruscan

decline

the Adriatic harbour of Spina. The situation in the south deteriorated even further as Veii experienced periodic conflict with Rome, its close neighbour, and became the first Etruscan state to fall to this growing power in central Italy (396 BC)

A measure of prosperity had come to the Po valley and the Adriatic towns, but even this Etruscan vitality in the north was short-lived. The progressive infiltration and pressure of the Celts, who had penetrated and settled in the plain of the Po, eventually suffocated and overpowered the flourishing Etruscan urban communities, almost completely destroying their civilization by the mid-4th century BC and thus returning a large part of northern Italy to a protohistoric stage of culture. Meanwhile, the Gallic Senones firmly occupied the Picenum district on the Adriatic Sea, and Celtic incursions reached on the one hand Tyrrhenian Etruria and Rome (captured and burned about 390 BC) and on the other as far as Puglia.

In the 4th century BC ancient Italy had become profoundly transformed. The eastern Italic people of Umbro-Sabellian stock diffused over most of the peninsula; the Syracusan empire and lastly the growing power of Rome had replaced the Etruscans (and the Greek colonies of southern Italy) as the dominant force. The Etruscan world had been reduced to a circumscribed, regional sphere, secluded in its traditional values; this situation determined its progressive passage into the political system of Rome.

Within this context, Etruria experienced an economic recovery and a rebounding of the aristocracy. Tomb groups once again contain riches, and the sequence of painted tombs at Tarquinii, interrupted during the 5th century, resumes. All the same, there is a new atmosphere in these tombs; now one finds images of a grim afterlife, represented as an underworld replete with demons and overhung by dark clouds.

Renewed resistance to the power on the Tiber proved futile. Roman history is filled with records of victories and triumphs over Etruscan cities, especially in the south. Tarquinii sued for peace in 351 BC, and Caere was granted a truce in 353; there were triumphs over Rusellae in 302 and over Volaterrae in 298, with the final defeat of Rusellae coming in 294. Volsinii also was attacked in this year, and its fields devastated. During this same bleak period, Etruscan society was wracked with class struggles that eventually led to the development of a substantial freedman class, especially in northern Etruria, where numerous small rural settlements sprang up in the hills. In some cities, the aristocracy looked to Rome for assistance against the restless slave class. The noble Cilnii family at Arretium called for help with a revolt of the lower classes in 302 BC, while at Volsinii the situation deteriorated so badly that the Romans marched in and razed the city (265 BC), resettling its inhabitants in Volsinii Novi (probably Bolsena).

By the mid-3rd century all Etruria appears to have been pacified and firmly subjected to Roman hegemony. In most cases, the Etruscan cities and their territories preserved a formal autonomy as independent states with their own magistrates, thus passing an uneventful period in the 2nd century BC, when the sources are largely silent about Etruria.

But the saddest chapter of all remained to be written in the 1st century BC. In 90 BC Rome granted citizenship to all Italic peoples, an act that in effect created total political unification of the Italic-Roman state and eliminated the last pretenses of autonomy in the Etruscan city-states. Northern Etruria, in addition, underwent a final devastation as it became the battleground for the opposing forces of the civil war of Marius and Sulla. Many Etruscan cities sided with Marius and were sacked and punished with all the vengeance the victorious Sulla could muster (80-79 BC). At Faesulae, Arretium, Volaterrae, and Clusium, the dictator confiscated and distributed territorial lands to soldiers from his 23 victorious legions. The new colonists brutally abused the old inhabitants and at the same time squandered their military rewards, sinking hopelessly into debt. Revolts and reprisals followed, but the agonizing process of Romanization was not actually completed until the reign of Augustus (31 BC-AD 14) brought new economic stability and reconciliation. By this time Latin had almost completely replaced the Etruscan language.

OTHER ITALIC PEOPLES

Local populations in areas colonized by Greece. The presence of the Siculi in Sicily and in the Italian peninsula is attested by the historical sources (Thucydides and Polybius). But the extent of their diffusion and their connections with other peoples of the peninsula (such as the Ligurians, the Itali, the Oenotrii, the Ausones) is more difficult to establish. A few small non-Greek inscriptions found in eastern Sicily and referable to the Siculi (the most noteworthy was found at Centuripe), coin legends, and Siculan words reported by Classical writers demonstrate the Indo-European character of the Siculan language, which seems to show an affinity with Latin and also has connections with the Umbro-Sabellian dialects. The immigration of the Siculi from the Italian peninsula into Sicily goes back to a prehistoric but not extremely early epoch; this assumption is based on the fact that there are some echoes of it in tradition and that a continental archaeological influence suddenly appears at the end of the Bronze Age. The characteristic Siculan iron culture, evident in the necropolises of Pantalica near Syracuse and of Finocchito near Noto, flourished between the 9th and the 5th centuries BC and was progressively submerged in the superior civilization of the Greeks.

Evidence is quite scarce for the Siculi in the peninsula and for the other primitive indigenous populations of what is now Calabria and of Lucania (the Oenotrii, Ausones, Chones, Morgetes, and Itali) and Campania (the Ausones and Opici). Modern scholars have hypothesized that along the Tyrrhenian coastal arc there extended in earliest times a belt of paleo-Italic peoples (so-called western Italics or Proto-Latins) originally related to the Latins and distinct from the eastern Italic peoples inhabiting the Apennine and Adriatic regions. (The archaeological documentation consists of cemeteries with Iron Age graves, but there are also traces of cremation necropolises, especially in the province of Salerno and in Calabria.) Large fortified towns arose, particularly in the interior zones of Lucania. The ethnic individuality of these ancient peoples, however, was progressively obliterated between the 8th and the 4th century BC by the Greek penetration and by the expansion of the Etruscans and the eastern Italics (Samnites, Lucanians, Bruttii).

The inhabitants of the southeastern ex-The Apulians.

Distribution of peoples of ancient Italy c. 500 BC

Western Italic peoples

The Siculi

tremity of the Italian peninsula formed a definitely characterized group of populations that the ancients often called lapyges (whence the geographic term lapygia, in which "Apulia" may be recognized). The territory included the Salentini and the Messapii peoples in the Salentine Peninsula (ancient Calabia) and the Peucetii and the Dauni farther north. (Sometimes the designations lapyges and Messapii are used with identical reference.) Ancient tradition insists upon an overseas origin for these tribes, held to be Cretan or Illyrian. The Iapygian, or more commonly, Messapian (Messapic) language is known from a considerable series of public funerary, votive, monetary, and other inscriptions written in the Greek alphabet and found in the Apulian area, especially in the Salentine Peninsula. from words reported by the ancient writers, and from toponomastic (local place-name) data. Messapian is without doubt an Indo-European language, distinct from Latin and from the Umbro-Sabellian dialects, with Balkan and central European analogies. This confirms the overseas provenance of the Iapyges from the Balkans, the more so because there existed in Illyria a tribe called the Iapodes and because a people known as the Iapuzkus lived farther north, on the Adriatic coast of Italy. Rather than a true immigration, however, there was a gradual prehistoric penetration of trans-Adriatic elements. The expansion of the lapyges must have brought them to Lucania and even to what is now Calabria, as would be deduced from traditional and archaeological indications.

Apulian civilization

Latin

culture

The Apulians' civilization, which was considerably influenced by that of the nearby Greek colonies, developed from the 9th to the 3rd centuries BC. In the most ancient period there were pit graves, sometimes in large stone tumuli. In the Siponto area, near what is now Manfredonia, the graves were accompanied by anthropomorphic stelae with geometric bas-reliefs. Geometrically painted ceramics in linear motifs persisted to the threshold of the Hellenistic age. Later graves took the form of large trunks and of catacombs with paintings on the sides. Burial was the disposition exclusively used.

Beginning in Archaic times, large cities developed, linked to each other by bonds of confederation. These included Herdonea (now Ordona), Canusium (Canosa), Rubi (Ruvo), Gnathia, Brundisium (Brindisi), Uria (Oria), Lupiae (Lecce), Rudiae, and Manduria. They preserved their independence, tenaciously defended against the Greeks,

until the age of the Roman conquest. The Latins. The Latin nation had a relatively limited territory, south of the Tiber, which was reduced, in historic times, by the invasion of the Volsci to the region between the Alban hills and the Aurunci mountains (the so-called Latium Novum). The principal Latin centres included Alba Longa, Tusculum, Lavinium, Ardea, Tibur (now Tivoli), and Praeneste (Palestrina) and the early Volscianized cities of Velitrae (Velletri), Signia (Segni), Cora (Cori), Satricum, Antium (Anzio), and Anxur (Terracina). The importance of the Latins is essentially linked with the fortunes of Rome, the forward bulwark of Latinity in the direction of the Etruscan realm. Intermixtures with the legends of the origin of Rome make the ethnographic traditions of Latium very diverse and complex. The linguistic evidence, which begins with inscriptions of the 7th to 6th century BC, indicates an individuality of the Latin world distinct from the neighbouring Etruscan and eastern

The Latins had a federal organization, centred at the sanctuary of Jupiter on Albanus Mons. Their religious heritage survived in the beliefs and cults of the Roman world. The most ancient Latin culture (9th-8th century BC) was characterized by cremation as the funeral rite, a practice it had in common with the cultures in the Etruscan and northern Italian territory, and by an iron culture showing affinities with the proto-Villanovan culture and with the cultures of Tyrrhenian southern Italy. Etruscan political control of Latium (probably 7th-6th century) coincided with an evident Etruscan cultural and artistic influence; while, from the south and from the sea, elements of Greek civilization penetrated, beginning with the alphabet.

North of Latium lived tribes ethnically akin to the Latins, with principal centres at Capena, Narce, and Falerii

(whence the name Faliscans). Their political and cultural history merges with that of the Etruscans. The Faliscan dialect, known from inscriptions, was originally Latin but was contaminated and modified by eastern Italic and Etruscan elements.

The eastern Italics. A great part of the central and southern Italian peninsula was occupied in protohistoric and historic times by populations forming a vast ethnic and linguistic unit-the eastern Italics or Umbro-Sabellians. To the south, in the mountains of the Abruzzo, lived the Samnites, who later spread into Campania, Lucania, and what is now Calabria. In the centre were the Vestini, Paeligni, Marrucini, Marsi, Aequi, Volsci, and Sabini. Farther north lived the Umbri. The origin and relationship of all these peoples is unclear. Ancient ethnographic traditions bearing on central Italy link the Samnites to the Sabines and the Sabines to the Umbri, locating their primitive centre of dispersion in the Rieti basin and in the area of Amiternum. Their diffusion was attributed to the mass emigration of an entire generation in search of a

Origin of eastern Italics

new homeland (so-called sacred spring). The linguistic data prove the unity of the group of eastern-Italic idioms, belonging to the Indo-European stock but differing from the Latin. Within this group may be distinguished a southern variant (Sabellic or Oscan) known from an abundant harvest of epigraphic documents from Samnium, Campania, and southern Italy. This variant is to be attributed to the Samnites and to a large part of the minor stocks of central Italy, including the Sabines, known from isolated inscriptions in central Italy. On the other hand, a northern (Umbrian) variant is represented by inscriptions of Umbria-principally bronze tablets from Gubbio, inscribed between the 4th and 1st century BC by a brotherhood of Umbrian priests-and by a bronze tablet from Velletri. The eastern Italic words reported by the Classical writers, as well as toponomastics, confirm these conclusions.

Notwithstanding the original unity of stock and of language, these populations had diverse histories and cultures. The Samnites from Molise (the Caraceni, the Pentri, and the Frentani) in the 5th and 4th centuries BC occupied Campania-where they vanquished Etruscans and Greeks and assumed from the local tribes the name Opici, or Osci-as well as Lucania (with the Hirpini or Lucani), reaching what is now Calabria-where they took the name Bruttii-and finally Sicily. Defeated by Rome in the Samnite wars (4th and early 3rd centuries BC), the Samnites tried for the last time, in the period of the Social War (90-83 BC), to counterpose to the Romans an Italic nationality of their own. A considerable difference existed between the culture of the mountain Samnites-organized in confederate tribes centred on fortified villages and in the 5th and 4th centuries still retaining aspects of the "iron culture"-and the high civilization of the Campani and Lucani established in the ancient cities of Capua, Nola, Nocera, and Paestum and dominated by Greek and Etruscan influence.

Some central tribes-the Marrucini, Vestini, Paeligni and Marsi-appear to be linked historically, politically, and culturally to the Samnites. The case is different with the Sabines, the Aequi, and the Volsci, whose period of expansion (6th and 5th centuries) is closely connected with earliest Rome and who had early contact with the Etrusco-

Latin civilization.

The diffusion of the Umbri toward the north and beyond The Umbri the Apennines lent credence to the ancient traditions relating to the great size of their territory. The traditions, however, are more probably based on the fact that the name Umbri is derived from that of a most ancient population, probably not Indo-European and certainly not Italic, living in the Apennine region before the diffusion of the eastern Italics. The history of the Umbrian cities-Iguvium (now Gubbio), Hispellum (Spello), Spoletium (Spoleto), Tuder (Todi), and others-is known only beginning with the period of the struggle of the Etruscans and Gauls against Rome. Umbrian civilization is revealed by the Gubbio Tablets, a document unique in its kind. The Umbrian artistic and material culture derived in large part from that of Etruria.

The populations of the Picenum. In historic times, expansion of the eastern Italic peoples placed them firmly along the Adriatic coastal tract corresponding to what is now the Marches region. Epigraphic and archaeological data give evidence also of the presence in the Picenum (an ancient region between the Apennines and the Adriatic) of the trans-Adriatic Liburni and the pre-Indo-European Asili. It is possible that elements were established here that had come by sea from Illyria (the Gubbio tablets mention the Iapuzkus, whose name recalls that of the Illyrian Iapodes and of the Apulian Iapyges). Inscriptions in the southern Piceno, however, seem to exhibit a close kinship with the Umbro-Sabellic dialects

Picenum civilization

Veneti and

Ligurians

A material civilization flowered between the 8th and 5th centuries in the northern Abruzzo and in the Marches. This civilization is represented by the rich funerary equipment of burial tombs, whose type and decoration present affinities with the iron culture of Tyrrhenian and northern Italy and with that of the Balkans and which show Greek influence. Cremation tombs of Villanovan type have been found at Fermo. Also noteworthy is the presence of stone funerary sculpture. North of Ancona is a cultural variant, particularly in the necropolis of Novilara near Pesaro, where inscriptions are in a dialect other than that of the southern Picenum and difficult to classify.

It may be held that the middle-Adriatic iron cultures expressed an early Archaic mixture of eastern Italic and trans-Adriatic peoples, influenced by the Etruscans and the Greeks. Contributing to their decline were the Gauls and Syracusans, who established themselves in this area in the 4th century BC. In the 3rd century, the Picenum was already totally conquered by the Romans.

The Veneti. Ancient tradition held the Veneti to be an Illyrian people who, coming from the east, took possession of the region named for them (Venetia). To them are linked the Histri, the Carni, and various Alpine tribes. (The name of the Veneti, or its root, is widely diffused in the ethnic onomastics of central Europe and even of Asia.) The Venetic language is known from funerary and votive inscriptions, from words cited by the Classical writers, and from onomastic and toponomastic data. It is an Indo-European language of Archaic type bearing similarities to the Latin and the Germanic.

The principal centres of the Veneti, located at the western margin of the territory, were Padua and Este. Their culture developed from the 9th century to the period of Romanization, with relationships with the Golasecca, Villanovan, and Etruscan cultures and with the transalpine Hallstatt culture. Maximum development occurred in the 6th-4th centuries BC; particularly noteworthy is the production of figured bronze situlae (conical vessels). In the final period, Gallic (Celtic) influences are found. Phenomena parallel to those of Este appear in Istria. The Veneti were horse breeders and peaceful traders and navigators; protected by the waters of the lower Po and the lower Adige, they preserved their independence against Etruscan expansion and Celtic invasion and in the 3rd century BC entered into

peaceful alliance with Rome. The Ligurians. For the ancients, the name Ligures designated the peoples of northwestern Italy, including northern Tuscany, Liguria, Piedmont, and part of what is now Lombardy. Historical tradition also placed them in central Italy, while the Classical writers and toponomastic affinities give them a broader diffusion beyond the Alps. The Ligurians also included the peoples of Corsica. The more ancient Greeks gave all the peoples of the western world the common designation of Ligyes (i.e., Ligurians).

Linguistic data-furnished by toponomastics, lexical survivals, and Ligurian words cited by Classical writersbetray the presence of a pre-Indo-European Mediterranean stratum akin to that of western Europe. Inscriptions found in upper Lombardy and in the Ticino exhibit Indo-European characteristics and in particular Celtic influences. Thus the Liguri seem to belong to an environment formed in northern Italy after the Celtic invasion and called Celto-Ligures.

The Etruscan expansion in the plain of the Po and the invasion of the Gauls confined the Ligurians between the Alps and the Apennines, where they offered such resistance to Roman penetration that they gained a reputation with the ancients for primitive fierceness. Among the more considerable Ligurian monuments are rock engravings and anthropomorphic sculptures analogous to those of southern France, found in Lunigiana and Corsica. Some of these artistic manifestations are repeated in territories farther east. But it remains doubtful whether the similar cultural imprint indicates an original identity of stock. Ligurian and Celto-Ligurian tombs of the Lombard lakes region, often holding cremations, reveal a special iron culture called the culture of Golasecca, while Ligurian sepulchres of the Italian Riviera and of Provence, also holding cremations, exhibit Etruscan and Celtic influences.

Populations of central northern Italy and of the Alps. The ethnography of the Po and Alpine regions is complex and obscure because of the early spread of Etruscan culture and colonization. The ancients record two major ethnic groups (aside from the Etruscans and the Veneti): the Euganei, inhabiting the plain and the Alpine foothills. and the Raeti, in the valleys of the Trentino and the Alto Adige. Minor peoples in the region belonged to one or the other of these stocks or to Ligurian stocks; with regard to many of these peoples, the sources speak of an Illyrian or an Etruscan origin.

Late inscriptions discovered in the Adige River valley and on the plain have a dialect showing some affinities to Etruscan, Some scholars see in this a blending of local and Etruscan elements, while others speak of an indigenous pre-Indo-European language with Indo-European influences. Primitive toponomastics confirm the existence of a linguistic stratum that could be defined as Raetian or Raeto-Euganean but distinguish it sharply from the Venetic and probably also from the Ligurian. Other inscriptions from the Val Camonica and the Garda district attest to a more noticeable Indo-European dialect, due perhaps to Celtic and Latin influences. To the west are the socalled Lepontian inscriptions.

Thus in the central Alpine and sub-Alpine area, there were original populations, different from the Veneti and the Etruscans, whose kinship with the Ligurians remains uncertain. The distinction between Euganean and Raetic tribes can be based only upon an approximate geographic criterion. To this original ethnic stratum may have belonged the most ancient inhabitants of the region, who settled there before the immigration of the Illyrian Veneti and the Etruscan conquest; certain cremation sepulchres of the Verona and Mantua regions may be attributed to them. Perhaps the existence of a Venetian goddess Reitia, recorded by Strabo and mentioned in inscriptions from Este, is some proof of a Raeto-Euganean cultural persistence in the territory occupied by the Veneti. (N.T.deG.)

Original centraland sub-Alpine populations

Ligurian

Ancient Rome

Rome must be considered one of the most successful imperial powers in history. In the course of centuries Rome grew from a small town on the Tiber River in central Italy into a vast empire that ultimately embraced England, all of continental Europe west of the Rhine and south of the Danube, most of Asia west of the Euphrates, northern Africa, and the islands of the Mediterranean. Unlike the Greeks, who excelled in intellectual and artistic endeavours, the Romans achieved greatness in their military, political, and social institutions. Roman society, during the republic, was governed by a strong military ethos. While this helps to explain the incessant warfare, it does not account for Rome's success as an imperial power. Unlike Greek city-states, which excluded foreigners and subjected peoples from political participation, Rome from its beginning incorporated conquered peoples into its social and political system. Allies and subjects who adopted Roman ways were eventually granted Roman citizenship. During the principate (see below), the seats in the Senate and even the imperial throne were occupied by persons from the Mediterranean realm outside Italy. The lasting effects of Roman rule in Europe can be seen in the geographic distribution of the Romance languages (Italian, French, Spanish, Portuguese, and Romanian), all of which evolved from Latin, the language of the Romans. The Western alphabet of 26 letters and the calendar of 12 months and 365.25 days are only two simple examples of the cultural legacy which Rome has bequeathed Western civilization.

ROME FROM ITS ORIGINS TO 264 BC

Native

Italian

neonles

Early Rome to 509 BC. Early Italy. When Italy emerged into the light of history about 700 BC, it was already inhabited by various peoples of different cultures and languages. Most natives of the country lived in villages or small towns, supported themselves by agriculture or animal husbandry (Italia means "Calf Land"), and spoke an Italic dialect belonging to the Indo-European family of languages. Oscan and Umbrian were closely related Italic dialects spoken by the inhabitants of the Apennines. The other two Italic dialects, Latin and Venetic, were likewise closely related to each other and were spoken, respectively, by the Latins of Latium (a plain of west-central Italy) and the people of northeastern Italy (near modern Venice). Iapyges and Messapii inhabited the southeastern coast. Their language resembled the speech of the Illyrians on the other side of the Adriatic. During the 5th century BC the Po valley of northern Italy (Cisalpine Gaul) was occupied by Gallic tribes who spoke Celtic and who had migrated across the Alps from continental Europe. As noted earlier, the Etruscans were the first highly civilized people of Italy and were the only inhabitants who did not speak an Indo-European language. By 700 BC several Greek colonies were established along the southern coast. Both Greeks and Phoenicians were actively engaged in

trade with the Italian natives. Modern historical analysis is making rapid progress in showing how Rome's early development occurred in a multicultural environment and was particularly influenced by the higher civilizations of the Etruscans to the north and the Greeks to the south. Roman religion was indebted to the beliefs and practices of the Etruscans. The Romans borrowed and adapted the alphabet from the Etruscans, who in turn had borrowed and adapted it from the Greek colonies of Italy. Senior officials of the Roman Republic derived their insignia from the Etruscans: curule chair, purple-bordered toga (toga praetexta), and bundle of rods (fasces). Gladiatorial combats and the military triumph (see below) were other customs adopted from the Etruscans. Rome lay 12 miles inland from the sea on the Tiber River, the border between Latium and Etruria. Because the site commanded a convenient river crossing and lay on a land route from the Apennines to the sea, it formed the meeting point of three distinct peoples: Latins, Etruscans, and Sabines. Though Latin in speech and culture, the Roman population must have been somewhat diverse from earliest times, a circumstance that may help to account for the openness of Roman society in historical times.

Historical sources on early Rome. The regal period (753-509 BC) and the early republic (509-280 BC) are the most poorly documented periods of Roman history because historical accounts of Rome were not written until much later. Greek historians did not take serious notice of Rome until the Pyrrhic War (280-275 BC), when Rome was completing its conquest of Italy and was fighting against the Greek city of Tarentum in southern Italy. Rome's first native historian, a senator named Quintus Fabius Pictor, lived and wrote even later, during the Second Punic War (218-201 BC). Thus historical writing at Rome did not begin until after Rome had completed its conquest of Italy, had emerged as a major power of the ancient world, and was engaged in a titanic struggle with Carthage for control of the western Mediterranean. Fabius Pictor's history, which began with the city's mythical Tros jan ancestry and narrated events up to his own day, established the form of subsequent histories of Rome. During the last 200 years BC, 16 other Romans wrote similarly inclusive narratives. All these works are now collectively termed "the Roman annalistic tradition" because many of them attempted to give a year-by-year (or annalistic) account of Roman affairs for the republic.

Although none of these histories are fully preserved, the first 10 books of Livy, one of Rome's greatest historians, are extant and cover Roman affairs from earliest times down to the year 293 BC (extant are also Books 21 to 45 treating the events from 218 BC to 167 BC). Since Livy wrote during the reign of the emperor Augustus (27 BC-AD 14), he was separated by 200 years from Fabius Pictor, who, in turn, had lived long after many of the events his history described. Thus, in writing about early Rome, ancient historians were confronted with great difficulties in ascertaining the truth. They possessed a list of annual magistrates from the beginning of the republic onward (the consular fasti), which formed the chronological framework of their accounts. Religious records and the texts of some laws and treaties provided a bare outline of major events. Ancient historians fleshed out this meagre factual material with both native and Greek folklore. Consequently, over time, historical facts about early Rome often suffered from patriotic or face-saving reinterpretations involving exaggeration of the truth, suppression of embarrassing facts, and invention.

The evidence for the annalistic tradition shows that the Roman histories written during the 2nd century BC were relatively brief resumes of facts and stories. Yet in the course of the 1st century BC Roman writers were increasingly influenced by Greek rhetorical training, with the result that their histories became greatly expanded in length: included in them were fictitious speeches and lengthy narratives of spurious battles and political confrontations. which, however, reflect the military and political conditions and controversies of the late republic rather than accurately portraying the events of early Rome. Livy's history of early Rome, for example, is a blend of some facts and much fiction. Since it is often difficult to separate fact from fiction in his works and doing so involves personal judgment, modern scholars have disagreed about many aspects of early Roman history and will continue to do so.

Rome's foundation myth. Although Greek historians did not write seriously about Rome until the Pyrrhic War, they were aware of Rome's existence long before then. In accordance with their custom of explaining the origin of the foreign peoples they encountered by connecting them with the wanderings of one of their own mythical heroes, such as Jason and the Argonauts, Heracles, or Odysseus, Greek writers from the 5th century BC onward invented at least 25 different myths to account for Rome's foundation. In one of the earliest accounts (Hellanicus of Lesbos), which became accepted, the Trojan hero Aeneas and some followers escaped the Greek destruction of Troy; after wandering about the Mediterranean for some years, they settled in central Italy, where they intermarried with the native population and became the Latins.

Although the connection between Rome and Troy is unhistorical, the Romans of later time were so flattered by this illustrious mythical pedigree that they readily accepted it and incorporated it into their own folklore about the beginning of their city. Roman historians knew that the republic had begun about 500 BC, because their annual list of magistrates went back that far, Before that time, they thought, Rome had been ruled by seven kings in succession. By using Greek methods of genealogical reckoning, they estimated that seven kings would have ruled about 250 years, thus making Rome's regal period begin in the middle of the 8th century BC. Ancient historians initially differed concerning the precise date of Rome's foundation, ranging from as early as 814 BC (Timaeus) to as late as 728 BC (Cincius Alimentus). By the end of the republic, it was generally accepted that Rome had been founded in 753 BC and that the republic had begun in 509 BC.

Since the generally accepted date of Troy's destruction was 1184 BC, Roman historians maintained Troy's unhistorical connection with Rome by inventing a series of fictitious kings who were supposed to have descended from the Trojan Aeneas and ruled the Latin town of Alba Longa for the intervening 431 years (1184-753 BC) until the last of the royal line, the twin brothers Romulus and Remus, founded their own city, Rome, on the Palatine Hill. According to tradition, the twins, believed to have been the children of the god Mars, were set adrift in a basket on the Tiber by the king of Alba; they survived, however, being nursed by a she-wolf, and lived to overthrow the wicked king. In the course of founding Rome the brothers quar-

Dating ancient historians

Roman annalistic tradition

reled, and Romulus slew Remus. This story was a Roman adaptation of a widespread ancient Mediterranean folktale told of many national leaders, such as the Akkadian king Sargon (c. 2300 BC), the biblical Moses, the Persian king Cyrus the Great, the Theban king Oedipus, and the twins Neleus and Pelias of Greek mythology.

The regal period, 753-509 BC. Romulus, Rome's first king according to tradition, was the invention of later ancient historians. His name, which is not even proper Latin, was designed to explain the origin of Rome's name. His fictitious reign was filled with deeds expected of an ancient city founder and the son of a war god. Thus he was described as having established Rome's early political, military, and social institutions and as having waged war against neighbouring states. Romulus was also thought to have shared his royal power for a time with a Sabine named Titus Tatius. The name may be that of an authentic ruler of early Rome, perhaps Rome's first real king; nothing, however, was known about him in later centuries, and his reign was therefore lumped together with that of Romulus.

The names of the other six kings are authentic and were remembered by the Romans, but few reliable details were known about their reigns. However, since the later Romans wished to have explanations for their early customs and institutions, historians ascribed various innovations to these kings, often in stereotypical and erroneous ways. The three kings after Romulus are still hardly more than names, but the recorded deeds of the last three kings are more historical and can, to some extent, be checked by archaeological evidence.

According to ancient tradition, the warlike founder Romulus was succeeded by the Sabine Numa Pompilius, whose reign was characterized by complete tranquility and peace. Numa was supposed to have created virtually all of Rome's religious institutions and practices. The tradition of his religiosity probably derives from the erroneous connection by the ancients of his name with the Latin word numen, meaning divine power. Numa was succeeded by Tullus Hostilius, whose reign was filled with warlike exploits, probably because the name Hostilius was later interpreted to suggest hostility and belligerence. Tullus was followed by Ancus Marcius, who was believed to have been the grandson of Numa. His reign combined the characteristics of those of his two predecessors-namely religious inno-

vations as well as warfare. Archaeological evidence for early Rome is scattered and limited because it has proven difficult to conduct extensive excavations at sites still occupied by later buildings. What evidence exists is often ambiguous and cannot be correlated easily to the ancient literary tradition; it can, however, sometimes confirm or contradict aspects of the ancient historical account. For example, it confirms that the earliest settlement was a simple village of thatched huts on the Palatine Hill (one of the seven hills eventually occupied by the city of Rome), but it dates the beginning of the village to the 10th or 9th century BC, not the mid-8th century. Rome therefore cannot have been ruled by a succession of only seven kings down to the end of the 6th century BC. Archaeology also shows that the Esquiline Hill was next inhabited, thus disproving the ancient account which maintained that the Ouirinal Hill was settled after the Palatine. Around 670-660 BC the Palatine settlement expanded down into the valley of the later Forum Romanum and became a town of artisans living in houses with stone foundations. The material culture testifies to the existence of some trade as well as to Etruscan and Greek influence. Archaeology of other Latin sites suggests that Rome at this time was a typical Latin community. In another major transition spanning the 6th century the Latin town was gradually transformed into a real city. The swampy Forum valley was drained and paved to become the city's public centre. There are clear signs of major temple construction. Pottery and architectural remains indicate vigorous trade with the Greeks and Etruscans, as well as local work done under their influence

Rome's urban transformation was carried out by its last three kings: Lucius Tarquinius Priscus (Tarquin the

A funerary urn in the shape of one of the earliest types of Roman dwelling, c. 8th century BC. In the Museum of Antiquities from the Palatine Rome

Elder), Servius Tullius, and Lucius Tarquinius Superbus (Tarquin the Proud). According to ancient tradition, the two Tarquins were father and son and came from Etruria. One tradition made Servius Tullius a Latin; another described him as an Etruscan named Mastarna. All three kings were supposed to have been great city planners and organizers (a tradition that has been confirmed by archaeology). Their Etruscan origin is rendered plausible by Rome's proximity to Etruria, Rome's growing geographic significance, and the public works that were carried out by the kings themselves. The latter were characteristic of contemporary Etruscan cities. It would thus appear that during the 6th century BC some Etruscan adventurers took over the site of Rome and transformed it into a city along Etruscan lines

Early centuries of the Roman Republic. Foundation of the republic. The ancient historians depicted Rome's first six kings as benevolent and just rulers but the last one as a cruel tyrant who murdered his predecessor Servius Tullius. usurped the kingship, terrorized the Senate, and oppressed the common people with public works. He supposedly was overthrown by a popular uprising ignited by the rape of a virtuous noblewoman, Lucretia, by the king's son. The reign of Tarquinius Superbus was described in the stereotypical terms of a Greek tyranny in order to explain the major political transition from the monarchy to the republic in accordance with Greek political theory concerning constitutional evolution from monarchy to tyranny to aristocracy. This explanation provided later Romans with a satisfying patriotic story of despotism giving way to liberty; it is probably unhistorical, however, and merely a Roman adaptation of a well-known Greek story of a love affair in Athens that led to the murder of the tyrant's brother and the tyrant's eventual downfall. According to ancient tradition, as soon as the Romans had expelled their last tyrannical king, the king of the Etruscan city of Clusium. Lars Porsenna, attacked and besieged Rome. The city was gallantly defended by Horatius Cocles, who sacrificed his life in defense of the bridge across the Tiber, and Mucius Scaecvola, who attempted to assassinate Porsenna in his own camp. When arrested before accomplishing the deed. he demonstrated his courage by voluntarily burning off his right hand in a nearby fire. As a result of such Roman heroism, Porsenna was supposed to have made peace with Rome and withdrawn his army,

One prevalent modern view is that the monarchy at Rome was incidentally terminated through military defeat and foreign intervention. This theory sees Rome as a site highly prized by the Etruscans of the 6th century BC, who are known to have extended their power and influence at the time across the Tiber into Latium and even farther south into Campania. Toward the end of the 6th century, Rome may have been involved in a war against King Porsenna of Clusium, who defeated the Romans, seized the city, and expelled its last king. Before Porsenna could establish himself as monarch, he was forced to withdraw, leaving Rome kingless. In fact, Porsenna is known to have suffered a serious defeat at the hands of the combined

Termina. tion of the monarchy

Archaeological evidence forces of the other Latins and the Greeks of Campanian Cumae. Rather than restoring Tarquin from exile to power, the Romans replaced the kingship with two annu-

ally elected magistrates called consuls.

The struggle of the orders. As the Roman state grew in size and power during the early republic (509-280 BC). new offices and institutions were created, and old ones were adapted to cope with the changing military, political, social, and economic needs of the state and its populace. According to the annalistic tradition, all these changes and innovations resulted from a political struggle between two social orders, the patricians and the plebeians, that is thought to have begun during the first years of the republic and lasted for more than 200 years. In the beginning, the patricians were supposed to have enjoyed a monopoly of power (the consulship, the Senate, and all religious offices), whereas the plebeians began with nothing except the right to vote in the assemblies. During the course of the struggle the plebeians, however, were believed to have won concessions gradually from the patricians through political agitation and confrontation, and they eventually attained legal equality with them. Thus ancient historians, such as Livy, explained all aspects of early Rome's internal political development in terms of a single sustained social movement.

As tradition has it, the distinction between patricians and plebeians was as old as Rome itself and had been instituted by Romulus. The actual historical dating and explanation of this distinction still constitutes the single biggest unsolved problem of early Roman history. The distinction existed during the middle and late republic, but modern scholars do not agree on when or how it arose; they are increasingly inclined to think that it originated and evolved slowly during the early republic. By the time of the middle and late republic, it was largely meaningless. At that point only about one dozen Roman families were patrician, all others being plebeian. Both patrician and plebeian families made up the nobility, which consisted simply of all descendants of consuls. The term "patrician." therefore, was not synonymous with "noble" and should not be confused with it: the patricians formed only a part of the Roman nobility of the middle and late republic. The only difference between patricians and plebeians in later times was that each group was either entitled to or debarred from holding certain minor offices.

The discrepancies, inconsistencies, and logical fallacies in Livy's account of the early republic make it evident that the annalistic tradition's thesis of a struggle of the orders is a gross oversimplification of a highly complex series of events that had no single cause. Tensions certainly existed; no state can experience 200 years of history without some degree of social conflict and economic unrest. In fact, legal sources indicate that the law of debt in early Rome was extremely harsh and must have sometimes created much hardship. Yet it is impossible to believe that all aspects of early Rome's internal political development resulted from one cause. Early documents, if available, would have told the later annalistic historians little more than that a certain office had been created or some law passed. An explanation of causality could have been supplied only by folklore or by the imagination of the historian himself, neither of which can be relied upon. Livy's descriptions of early republican political crises evince the political rhetoric and tactics of the late republic and therefore cannot be given credence without justification. For example, early republican agrarian legislation is narrated in late republican terms. Early republican conflicts between plebeian tribunes and the Senate are likewise patterned after the politics of the Optimates and Populares of the late republic. Caution therefore must be exercised in examining early Rome's internal development. Many of the major innovations recorded in the ancient tradition can be accepted, but the ancient interpretation of these facts cannot go unchallenged.

The consulship. The later Romans viewed the abolition of the kingship and its replacement by the consulship as marking the beginning of the republic. The king's religious functions were henceforth performed by a priest-king (rex sacrorum), who held office for life. The king's

military power (imperium) was bestowed upon two annually elected magistrates called consuls. They were always regarded as the chief magistrates of the republic, so much so that the names of each pair were given to their year of office for purposes of dating. Thus careful records were kept of these names, which later formed the chronological basis for ancient histories of the republic. The consuls were primarily generals who led Rome's armies in war. They were therefore elected by the centuriate assembly—that is, the Roman army organized into a voting body. The two consuls possessed equal power. Such collegiality was basic to almost all Roman public offices; it served to check abuses of power because one magistrate's actions could be obstructed by his colleague.

According to the annalistic tradition, the first plebeian consul was elected for 366 BC. All consuls before that time were thought to have been patrician, and one major aspect of the struggle of the orders was supposed to have been the plebeians' persistent agitation to make the office open to them. However, if the classification of patrician and plebeian names known for the middle and late republic is applied to the consular list for the years 509-445 BC, plebeian names are well represented (30 percent). It is likely that there never was a prohibition against plebeians holding the consulship. The distinction between patrician and plebeian families may have become fixed only by the middle of the 4th century BC; and the law of that time (367 BC), which specified that one of the consuls was to be plebeian, may have done nothing more than to guarantee legally that both groups of the nobility would have an equal share in the state's highest office.

equal share in the state's highest office.

The dictatorship. Despite the advantages of consular collegiality, in military emergencies unity of command was sometimes necessary. Rome's solution to this problem was the appointment of a dictator in place of the consuls. According to ancient tradition, the office of dictator was created in 501 nc, and it was used periodically down to the Second Punic War. The dictator held supreme military command for no longer than six months. He was also termed the master of the army (magister populi), and he appointed a subordinate cavalry commander, the master of horse (magister equitum). The office was thoroughly constitutional and should not be confused with the late republican dictatorships of Sulla and Caesar, which were simply legalizations of autocratic power obtained through

military usurpation. The Senate. The Senate may have existed under the monarchy and served as an advisory council for the king. Its name suggests that it was originally composed of elderly men (senes), whose age and knowledge of traditions must have been highly valued in a preliterate society. During the republic, the Senate was composed of members from the leading families. Its size during the early republic is unknown. Ancient sources indicate that it numbered about 300 during the middle republic. Its members were collectively termed patres et conscripti ("the fathers and the enrolled"), suggesting that the Senate was initially composed of two different groups. Since the term "patrician" was derived from patres and seems to have originally meant "a member of the patres," the dichotomy probably somehow involved the distinction between patricians and plebeians. During the republic the Senate advised both magistrates and the Roman people. Although in theory the people were sovereign (see below) and the Senate only offered advice, in actual practice the Senate wielded enormous power because of the collective prestige of its members. It was by far the most important deliberative body in the Roman state, summoned into session by a magistrate who submitted matters to it for discussion and debate. Whatever a majority voted in favour of was termed "the Senate's advice" (senatus consultum). These advisory decrees were directed to a magistrate or the Roman people. In most instances, they were either implemented by a magistrate or submitted by him to the people for enactment into law.

The popular assemblies. During the republic two different assemblies elected magistrates, exercised legislative power, and made other important decisions. Only adult male Roman citizens could attend the assemblies in Rome and exercise the right to vote. The assemblies were or-

Rule during military emergenganized according to the principle of the group vote. Although each person cast one vote, he did so within a larger voting unit. The majority vote of the unit became its vote, and a majority of unit votes was needed to decide an issue.

The centuriate assembly (comitia centuriata), as stated, was military in nature and composed of voting groups called centuries (military units). Because of its military character, it always met outside the sacred boundary of the city (pomerium) in the Field of Mars (Campus Martius). It voted on war and peace and elected all magistrates who exercised imperium (consuls, praetors, censors, and curule aediles). Before the creation of criminal courts during the late republic, it sat as a high court and exercised capital jurisdiction. Although it could legislate, this function was

The centuriate assembly

the plebs

usually performed by the tribal assembly. The centuriate assembly evolved through different stages during the early republic, but information exists only about its final organization. It may have begun as the citizen army meeting under arms to elect its commander and to decide on war or peace. During historical times the assembly had a complex organization. All voting citizens were placed into one of five economic classes according to wealth. Each class was allotted varying numbers of centuries, and the entire assembly consisted of 193 units. The first (and richest) class of citizens was distributed among 80 centuries; the second, third, and fourth classes were each assigned 20 units. The fifth class, comprising the poorest persons in the army, was allotted 30 centuries. In addition, there were 18 centuries of knights-men wealthy enough to afford a horse for cavalry service-and five other centuries, one of which comprised the proletarii, or landless people too poor to serve in the army. The knights voted together with the first class, and voting proceeded from richest to poorest. Because the knights and the first class controlled 98 units, they were the dominant group in the assembly, though they constituted the smallest portion of the citizen body. The assembly was deliberately designed to give the greater authority to the wealthier element and was responsible for maintaining the political supremacy of the established nobility.

The tribal assembly (comitia tributa) was a nonmilitary civilian assembly. It accordingly met within the city inside the pomerium and elected magistrates who did not exercise imperium (plebeian tribunes, plebeian aediles, and quaestors). It did most of the legislating and sat as a court for serious public offenses involving monetary fines.

The tribal assembly was more democratic in its organization than the centuriate assembly. The territory of the Roman state was divided into geographic districts called tribes, and people voted in these units according to residence. The city was divided into four urban tribes. During the 5th century BC, the surrounding countryside formed 17 rustic tribes. With the expansion of Roman territory in central Italy (387-241 BC), 14 rustic tribes were added. thus gradually increasing the assembly to 35 units, a number never exceeded.

The plebeian tribunate. According to the annalistic tradition, one of the most important events in the struggle of the orders was the creation of the plebeian tribunate. After being worn down by military service, bad economic conditions, and the rigours of early Rome's debt law, the plebeians in 494 BC seceded in a body from the city to the Sacred Mount, located three miles from Rome. There they pitched camp and elected their own officials for their future protection. Because the state was threatened with an enemy attack, the Senate was forced to allow the plebeians to have their own officials, the tribunes of the plebs.

Initially there were only 2 tribunes of the plebs, but their number increased to 5 in 471 BC and to 10 in 457 BC. Tribunes of They had no insignia of office, like the consuls, but they were regarded as sacrosanct. Whoever physically harmed them could be killed with impunity. They had the right to intercede on a citizen's behalf against the action of a consul, but their powers were valid only within one mile from the pomerium. They convoked the tribal assembly and submitted bills to it for legislation. Tribunes prosecuted other magistrates before the assembled people for misconduct in office. They could also veto the action of another tribune (veto meaning "I forbid"). Two plebeian aediles served as their assistants in managing the affairs of the city. Although they were thought of as the champions of the people, persons elected to this office came from aristocratic families and generally favoured the status quo. Nevertheless, the office could be and sometimes was used by young aspiring aristocrats to make a name for themselves by taking up populist causes in opposition to the nobility.

Modern scholars disagree about the authenticity of the annalistic account concerning the plebs' first secession and the creation of the plebeian tribunate. The tradition presented this as the first of three secessions, the other two allegedly occurring in 449 and 287 BC. The second secession is clearly fictitious. Many scholars regard the first one as a later annalistic invention as well, accepting only the last one as historical. Although the first secession is explained in terms resembling the conditions of the later Gracchan agrarian crisis (see below), given the harshness of early Roman debt laws and food shortages recorded by the sources for 492 and 488 BC (information likely to be preserved in contemporary religious records), social and economic unrest could have contributed to the creation of the office. However, the urban-civilian character of the plebeian tribunate complements the extra-urban military nature of the consulship so nicely that the two offices may have originally been designed to function cooperatively to satisfy the needs of the state rather than to be antagonistic to one another.

The Law of the Twelve Tables. The next major episode after the creation of the plebeian tribunate in the annalistic version of the struggle of the orders involved the first systematic codification of Roman law. The plebeians were supposed to have desired a written law code in which consular imperium would be circumscribed to guard against abuses. After years of tribunician agitation the Senate finally agreed. A special board of 10 men (decemviri) was appointed for 451 BC to draw up a law code. Since their task was not done after one year, a second board of 10 was appointed to finish the job, but they became tyrannical and stayed in office beyond their time. They were finally forced out of power when one commissioner's cruel lust for an innocent maiden named Verginia so outraged the people that they seceded for a second time.

The law code was inscribed upon 12 bronze tablets and publicly displayed in the Forum. Its provisions concerned legal procedure, debt foreclosure, paternal authority over children, property rights, inheritance, funerary regulations, and various major and minor offenses. Although many of its provisions became outmoded and were modified or replaced in later times, the Law of the Twelve Tables formed the basis of all subsequent Roman private law.

Because the law code seems not to have had any specific provisions concerning consular imperium, the annalistic explanation for the codification appears suspect. The story of the second tyrannical board of 10 is an annalistic invention patterned after the 30 tyrants of Athenian history. The tale of Verginia is likewise modeled after the story of Lucretia and the overthrow of Rome's last king. Thus the second secession, which is an integral part of the story, cannot be regarded as historical. On the basis of existing evidence, one cannot say whether the law code resulted from any social or economic causes. Rome was a growing city and may simply have been in need of a systematic body of law.

Military tribunes with consular power. The creation of the office of military tribunes with consular power in 445 BC was believed to have involved the struggle of the orders. The annalistic tradition portrayed the innovation as resulting from a political compromise between plebeian tribunes, demanding access to the consulship, and the Senate, trying to maintain the patrician monopoly of the office. Henceforth, each year the people were to decide whether to elect two patrician consuls or military tribunes with consular power who could be patricians or plebeians. The list of magistrates for 444 to 367 BC shows that the chief magistracy alternated between consuls and military tribunes. Consuls were more frequently elected down to 426 but rarely thereafter. At first there were three military

Provisions of the law code

tribunes, but the number increased to four in 426, and to six in 406. The consular tribunate was abolished in 367 BC and replaced by the consulship.

Livy indicates that according to some sources the consular tribunate was created because Rome was faced with three wars simultaneously. Because there is evidence that there was no prohibition against plebeians becoming consuls. scholars have suggested that the reason for the innovation was the growing military and administrative needs of the Roman state; this view is corroborated by other data. Beginning in 447 BC two quaestors were elected as financial officials of the consuls, and the number increased to four in 421 BC. Beginning in 443 BC two censors were elected about every five years and held office for 18 months. They drew up official lists of Roman citizens, assessed the value of their property, and assigned them to their proper tribe and century within the tribal and centuriate assemblies. The increase in the number of military tribunes coincided with Rome's first two major wars, against Fidenae and Veii. In 366 BC six undifferentiated military tribunes were replaced with five magistrates that had specific functions: two consuls for conducting wars, an urban praetor who handled lawsuits in Rome, and two curule aediles who managed various affairs in the city. In 362 BC the Romans began to elect annually six military tribunes as subordinate officers of the consuls.

Social and economic changes. The law reinstating the consulship was one of three tribunician bills, the so-called Licinio-Sextian Rogations of 367 BC. Another forbade citizens to rent more than 500 iugera (330 acres) of public land, and the third provided for the alleviation of indebtedness. The historicity of the second bill has often been questioned, but the great increase in the size of Roman territory resulting from Rome's conquest of Veii renders this law plausible. The law concerning indebtedness is probably historical as well, since other data suggest that debt was a problem in mid-4th-century Rome. In 352 BC a five-man commission was appointed to extend public credit in order to reduce private indebtedness. A Genucian law of 342 BC (named after Genucius, tribune of that year) temporarily suspended the charging of interest on loans. In 326 or 313 BC a Poetelian law ameliorated the harsh conditions of the Twelve Tables regarding debt servitude by outlawing the use of chains to confine debt bondsmen.

Rome's economic advancement is reflected in its replacement of a cumbersome bronze currency with silver coinage adopted from the Greek states of southern Italy. the so-called Romano-Campanian didrachms. The date of this innovation is disputed. Modern estimates range from Campanian the First Samnite War to the Pyrrhic War. Rome was no longer a small town of central Italy but rather was quickly becoming the master of the Italian peninsula and was taking its place in the larger Mediterranean world.

Romano.

didrachms

The process of expansion is well illustrated by innovations in Roman private law about 300 BC. Since legal business could be conducted only on certain days (dies fasti), knowledge of the calendar was important for litigation. In early times the rex sacrorum at the beginning of each month orally proclaimed in Rome before the assembled people the official calendar for that month. Though suited for a small agricultural community, this parochial procedure became increasingly unsuitable as Roman territory grew and more citizens lived farther from Rome. In 304 BC a curule aedile named Gnaeus Flavius upset conservative opinion but performed a great public service by erecting an inscription of the calendar in the Roman Forum for permanent display. From early times, Roman private law and legal procedure had largely been controlled and developed by the priesthood of pontiffs. In 300 BC the Ogulnian law (after the tribunes Gnaeus and Quintus Ogulnius) ended the patrician monopoly of two priestly colleges by increasing the number of pontiffs from four to eight and the number of augurs from four to nine and by specifying that the new priests were to be plebeian.

In 287 BC the third (and perhaps the only historical) secession of the plebs occurred. Since Livy's account has not survived, detailed knowledge about this event is lacking. One source suggests that debt caused the secession. Many sources state that the crisis was ended by the passage

of the Hortensian law (after Quintus Hortensius, dictator for 287), which was thought to have given enactments of the tribal assembly the same force as resolutions of the centuriate assembly. However, since similar measures were supposed to have been enacted in 449 and 339 BC. doubt persists about the meaning of these laws. It is possible that no difference ever existed in the degree of legal authority of the two assemblies. The three laws could be annalistic misinterpretations of a provision of the Twelve Tables specifying that what the people decided last should be binding. One source indicates that the Hortensian law made all assembly days eligible for legal business. If debt played a role in the secession, the Hortensian law may have been designed to reduce the backlog of lawsuits in the praetor's court in Rome.

The Latin League. Although the Latins dwelled in politically independent towns, their common language and culture produced cooperation in religion, law, and warfare. All Latins could participate in the cults of commonly worshiped divinities, such as the cult of the Penates of Lavinium, Juno of Lanuvium, and Diana (celebrated at both Aricia and Rome). Latins freely intermarried without legal complications. When visiting another Latin town, they could buy, sell, litigate, and even vote with equal freedom. If a Latin took up permanent residence in another Latin community, he became a full citizen of his new home. Although the Latin states occasionally waged war among themselves, in times of common danger they banded together for mutual defense. Each state contributed military forces according to its strength. The command of all forces was entrusted by common assent to a single person from one of the Latin towns. Sometimes the Latins even founded colonies upon hostile territory as military outposts, which became new, independent Latin states, enjoying the same rights as all the other ones. Modern scholars use the term "Latin League" to describe this col-

lection of rights and duties. According to ancient tradition, Rome's last three kings not only transformed Rome into a real city but also made it the leader of the Latin League. There is probably exaggeration in this claim. Roman historians were eager to portray early Rome as destined for future greatness and as more powerful than it actually was. Rome certainly became one of the more important states in Latium during the 6th century, but Tibur, Praeneste, and Tusculum were equally important and long remained so. By the terms of the first treaty between Rome and Carthage (509 BC), recorded by the Greek historian Polybius (c. 150 BC), the Romans (or perhaps more accurately, the Latins generally) claimed a coastal strip 70 miles south of the Tiber River as their sphere of influence not to be encroached upon by the Carthaginians.

Rome's rapid rise during the 6th century was the achievement of its Etruscan overlords, and the city quickly declined with the collapse of Etruscan power in Campania and Latium about 500 BC. Immediately after the fall of the Roman monarchy, amid Porsenna's conquest of Rome, his defeat by the Latins, and his subsequent withdrawal, the plain of Latium began to be threatened by surrounding hill tribes (Sabines, Aequi, and Volsci), who experienced overpopulation and tried to acquire more land. Thus Rome's external affairs during the 5th century largely revolved around its military assistance to the Latin League to hold back these invaders. Many details in Livy's account of this fighting are, however, unreliable. In order to have a literary theme worthy of Rome's later greatness, Livy's annalistic sources had described these conflicts in the most grandiose terms. Yet the armies, military ranks, castrametation (i.e., techniques in making and fortifying encampments), and tactics described belong to the late republic, not the Rome of the 5th century.

Roman expansion in Italy. Toward the end of the 5th century, while Rome and the Latins were still defending themselves against the Volsci and the Aequi, the Romans began to expand at the expense of Etruscan states. Rome's incessant warfare and expansion during the republic has spawned modern debate about the nature of Roman imperialism. Ancient Roman historians, who were often patriotic senators, believed that Rome always waged just

Rights and duties of the Latins

and settled Roman farmers.

Motives

imperial-

ism

cordingly, distorting or suppressing facts that did not fit this view. The modern thesis of Roman defensive imperialism, which followed this ancient bias, is now largely discredited. Only the fighting in the 5th century BC and the later wars against the Gauls can clearly be so characterized. Rome's relentless expansion was more often responsible for provoking its neighbours to fight in selfdefense. Roman consuls, who led the legions into battle, often advocated war because victory gained them perfor Roman sonal glory. Members of the centuriate assembly, which, as noted above, decided war and peace, may sometimes have voted for war in expectation that it would lead to personal enrichment through seizure and distribution of booty. The evidence concerning Roman expansion during the early republic is poor, but the fact that Rome created 14 new rustic tribes during the years 387-241 BC suggests that population growth could have been a driving force. Furthermore, Romans living on the frontier may have strongly favoured war against restless neighbours, such as Gauls and Samnites. The animal husbandry of the latter involved seasonal migrations between summer uplands and winter lowlands, which caused friction between them

wars in self-defense, and they wrote their accounts ac-

Though the Romans did not wage wars for religious ends, they often used religious means to assist their war effort. The fetial priests were used for the solemn official declaration of war. According to fetial law, Rome could enjoy divine favour only if it waged just wars-that is, wars of self-defense. In later practice, this often simply meant that Rome maneuvered other states into declaring war upon it. Then Rome followed with its declaration, acting technically in self-defense; this strategy had the effect of boosting Roman morale and sometimes swaying international public opinion.

Rome's first major war against an organized state was fought with Fidenae (437-426 BC), a town located just upstream from Rome. After it had been conquered, its land was annexed to Roman territory. Rome next fought a long and difficult war against Veii, an important Etruscan city not far from Fidenae. Later Roman historians portrayed the war as having lasted 10 years (406-396 BC), patterning it after the mythical Trojan War of the Greeks. After its conquest, Veii's tutelary goddess, Queen Juno, was solemnly summoned to Rome. The city's territory was annexed, increasing Roman territory by 84 percent and forming four new rustic tribes. During the wars against Fidenae and Veii, Rome increased the number of military tribunes with consular power from three to four and then from four to six. In 406 BC Rome instituted military pay, and in 403 BC it increased the size of its cavalry. The conquest of Veii opened southern Etruria to further Roman expansion. During the next few years, Rome proceeded to found colonies at Nepet and Sutrium and forced the towns of Falerii and Capena to become its allies. Yet, before Roman strength increased further, a marauding Gallic tribe swept down from the Po River valley, raided Etruria, and descended upon Rome. The Romans were defeated in the battle of the Allia River in 390 BC, and the Gauls captured and sacked the city; they departed only after they had received ransom in gold. Henceforth the Romans greatly feared and respected the potential strength of the Gauls. Later Roman historians, however, told patriotic tales about the commanders Marcus Manlius and Marcus Furius Camillus in order to mitigate the humiliation of the defeat.

Roman power had suffered a great reversal, and 40 years of hard fighting in Latium and Etruria were required to restore it fully. The terms of the second treaty between Rome and Carthage (348 BC) show Rome's sphere of in-

Roman expansion in Italy from 298 to 201 BC

fluence to be about the same as it had been at the time of the first treaty in 509, but Rome's position in Latium was now far stronger.

The Samnite Wars. During the 40 years after the second treaty with Carthage, Rome rapidly rose to a position of hegemony in Italy south of the Po valley. Much of the fighting during this time consisted of three wars against the Samnites, who initially were not politically unified but coexisted as separate Oscan-speaking tribes of the central and southern Apennines. Rome's expansion was probably responsible for uniting these tribes militarily to oppose a common enemy. Both the rugged terrain and the tough Samnite soldiers proved to be formidable challenges, which forced Rome to adopt military innovations that were later

important for conquering the Mediterranean.

Despite its brevity (343-341 BC), the First Samnite War resulted in the major acquisition to the Roman state of the rich land of Campania with its capital of Capua. Roman historians modeled their description of the war's beginning on the Greek historian Thucydides' account of the outbreak of the Peloponnesian War between Athens and Sparta. Nevertheless, they were probably correct in stating that the Campanians, when fighting over the town of Capua with the Samnites, allied themselves with Rome in order to utilize its might to settle the quarrel. If so, this may have been the first of many instances in which Rome went to war after being invited into an alliance by a weaker state already at war. Once invited in, Rome usually absorbed the allied state after defeating its adversary. In any event, Campania now somehow became firmly attached to Rome; it may have been granted Roman citizenship without the right to vote in Rome (civitas sine suffragio). Campania was a major addition to Rome's strength and manpower.

The absorption of Campania provoked the Latins to take up arms against Rome to maintain their independence. Since the Gallic sack of Rome in 390 BC, the city had become increasingly dominant within the Latin League. In 381 BC Tusculum was absorbed by being given Roman citizenship. In 358 BC Rome created two more rustic tribes from territory captured along the Volscian coast. The Latin War (340-338 BC) was quickly decided in Rome's favour. Virtually all of Latium was given Roman citizenship and became Roman territory, but the towns retained their local governments. The large states of Praeneste and Tibur maintained nominal independence by becoming Rome's military allies. Thus the Latin League was abolished; but the legal rights that the Latins had enjoyed among themselves were retained by Rome as a legal status, the Latin right (ius Latii), and used for centuries as an intermediate step between non-Roman status and full

Roman citizenship.

Rome was now the master of central Italy and spent the next decade organizing and pushing forward its frontier through conquest and colonization. The Romans soon confronted the Samnites of the middle Liris (modern Liri) River valley, sparking the Second, or Great, Samnite War (326-304 BC). During the first half of the war Rome suffered serious defeats, but the second half saw Rome's recovery, reorganization, and ultimate victory. In 321 BC a Roman army was trapped in a narrow canyon near the Caudine Forks and compelled to surrender, and Rome was forced to sign a five-year treaty. Later Roman historians, however, tried to deny this humiliation by inventing stories of Rome's rejection of the peace and its revenge upon the Samnites. In 315 BC, after the resumption of hostilities, Rome suffered a crushing defeat at Lautulae. Ancient sources state that Rome initially borrowed hoplite tactics from the Etruscans (used during the 6th or 5th centuries BC) but later adopted the manipular system of the Samnites, probably as a result of Samnite success at this time. The manipular formation resembled a checkerboard pattern, in which solid squares of soldiers were separated by empty square spaces. It was far more flexible than the solidly massed hoplite formation, allowing the army to maneuver better on rugged terrain. The system was retained throughout the republic and into the empire. During these same years Rome organized a rudimentary navy, constructed its first military roads (construction of the Via Appia was begun in 312 BC and of the Via Valeria in 306), and increased the size of its annual military levy as seen from the increase of annually elected military tribunes from 6 to 16. During the period 334-295 BC, Rome founded 13 colonies against the Samnites and created six new rustic tribes in annexed territory. During the last years of the war, the Romans also extended their power into northern Etruria and Umbria. Several successful campaigns forced the cities in these areas to become Rome's allies. The Great Samnite War finally ended in Rome's victory. During the final phase of this war, Rome, on another front, concluded its third treaty with Carthage (306 BC), in which the Carthaginians acknowledged all of Italy as Rome's sphere of influence.

The Third Samnite War (298-290 BC) was the last desperate attempt of the Samnites to remain independent They persuaded the Etruscans, Umbrians, and Gauls to join them. Rome emerged victorious over this formidable coalition at the battle of Sentinum in 295 and spent the remainder of the war putting down lingering Samnite resistance. They henceforth were bound to Rome by a series

The Pyrrhic War, 280-275 BC. Rome spent the 280s BC putting down unrest in northern Italy, but its attention was soon directed to the far south as well by a quarrel between the Greek city of Thurii and a Samnite tribe. Thurii called upon the assistance of Rome, whose naval operations in the area provoked a war with the Greek city of Tarentum. As in previous conflicts with Italian peoples, Tarentum summoned military aid from mainland Greece, calling upon King Pyrrhus of Epirus, one of the most brilliant generals of the ancient world. Pyrrhus arrived in southern Italy in 280 BC with 20 elephants and 25,000 highly trained soldiers. After defeating the Romans at Heraclea and stirring up revolt among the Samnites, he offered peace terms that would have confined Roman power to central Italy. When the Senate wavered, Appius Claudius, an aged blind senator, roused their courage and persuaded them to continue fighting. Pyrrhus again defeated the Romans in 279 at Asculum. His losses in the two battles numbered 7,500 (almost one-third of his entire force). When congratulated on his victory, Pyrrhus, according to Plutarch, "replied . . . that one other such would utterly undo him." This type of victory has since been referred to as Pyrrhic victory. Pyrrhus then left Italy and aided the Greeks of Sicily against Carthage; he eventually returned to Italy and was defeated by the Romans in 275 BC at Beneventum. He then returned to Greece, while Rome put down resistance in Italy and took Tarentum itself by siege in 272.

Rome was now the unquestioned master of Italy. Roman territory was a broad belt across central Italy, from sea to sea. Latin colonies were scattered throughout the peninsula. The other peoples of Italy were bound to Rome by a series of bilateral alliances that obligated them to provide Rome with military forces in wartime. According to the Roman census of 225 BC. Rome could call upon 700,000 infantry and 70,000 cavalry from its own citizens and allies. The conquest of Italy engendered a strong military ethos among the Roman nobility and citizenry, provided Rome with considerable manpower, and forced it to develop military, political, and legal institutions and practices for conquering and absorbing foreign peoples. The Pyrrhic War demonstrated that Rome's civilian army could wage a successful war of attrition against highly skilled mercenaries of the Mediterranean world.

THE MIDDLE REPUBLIC (264-133 BC)

The first two Punic Wars. Rome's rapidly expanding sphere of hegemony brought it almost immediately into conflict with non-Italian powers. In the south, the main opponent was Carthage. In violation of the treaty of 306, which (historians tend to believe) had placed Sicily in the Carthaginian sphere of influence, Rome crossed the straits of Messana (between Italy and Sicily) embarking on war. (Rome's wars with Carthage are known as the "Punic Wars": the Romans called the Carthaginians Poeni

manipular formation

The First

Samnite

War

[Phoenicians], from which derived the adjective "Punic.") First Punic War (264-241 BC). The proximate cause of the first outbreak was a crisis in the city of Messana (Messina). A band of Campanian mercenaries, the Mamertini, who had forcibly established themselves within the town and were being hard pressed in 264 by Hieron II of Syracuse, applied for help to both Rome and Carthage. The Carthaginians, arriving first, occupied Messana and effected a reconciliation with Hieron. The Roman commander, nevertheless, persisted in forcing his troops into the city; he succeeded in seizing the Carthaginian admiral during a parley and induced him to withdraw. This aggression involved Rome in war with Carthage and Syracuse. Operations began with their joint attack upon Messana, which the Romans easily repelled. In 263 the Romans advanced with a considerable force into Hieron's territory and induced him to seek peace and alliance with them. In 262 they besieged and captured the Carthaginian base at Agrigentum on the south coast of the island. The first years of the war left little doubt that Roman intentions extended beyond the protection of Messana.

In 260 the Romans built their first large fleet of standard battleships. At Mylae (Milazzo), off the north Sicilian coast, their admiral Gaius Duilius defeated a Carthaginian squadron of more maneuverable ships by grappling and boarding. This left Rome free to land a force on Corsica (259) and expel the Carthaginians, but it did not suffice to loosen their grasp on Sicily. A large Roman fleet sailed

out in 256, repelled the entire Carthaginian fleet off Cape Ecnomus (near modern Licata), and established a fortified camp on African soil at Clypea (Kélibia in Tunisia). The Carthaginians, whose citizen levy was utterly disorganized, could neither keep the field against the invaders nor prevent their subjects from revolting. After one campaign they were ready to sue for peace, but the terms offered by the Roman commander Marcus Atilius Regulus were intolerably harsh. Accordingly, the Carthaginians equipped a new army in which cavalry and elephants formed the strongest arm. In 255 they offered battle to Regulus, who had taken up position with an inadequate force near Tunis, outmaneuvered him, and destroyed the bulk of his army. A second Roman fleet, which reached Africa after defeating the full Carthaginian fleet off Cape Hermaeum (Cape Bon), withdrew all the remaining troops.

The Romans now directed their efforts once more against Sicily. In 254 they captured the important fortress of Panormus (Palermo), but when Carthage moved reinforcements onto the island, the war again came to a standstill. In 251 or 250 the Roman general Caecilus Metellus at last staged a pitched battle near Panormus, in which the enemy's force was effectively crippled. This victory was followed by a siege of the chief Punic base at Lilybaeum (Marsala), together with Drepanum (Trapani), by land and sea. In the face of resistance, the Romans were compelled to withdraw in 249; in a surprise attack upon Drepanum the Roman fleet under the command of admiral Publius Claudius Pulcher lost 93 ships. This was the Romans' only naval defeat in the war. Their fleet, however, had suffered a series of grievous losses by storm and was now so reduced that the attack upon Sicily had to be suspended. At the same time, the Carthaginians, who felt no less severely the financial strain of the prolonged struggle, reduced their forces and made no attempt to deliver a counterattack.

In 242 Rome resumed operations at sea. A fleet of 200 warships was equipped and sent out to renew the blockade of Lilybaeum. The Carthaginians hastily assembled a relief force, but in a battle fought off the Aegates, or Aegusae (Aegadian) Islands, west of Drepanum, their fleet was caught at a disadvantage and was largely sunk or captured (March 10, 241). This victory, by giving the Romans undisputed command of the sea, rendered certain the ultimate fall of the Punic strongholds in Sicily. The Carthaginians accordingly opened negotations and consented to a peace by which they ceded Sicily and the Lipari Islands to Rome and paid an indemnity of 3,200 talents. The protracted nature of the war and the repeated loss of ships resulted in an enormous loss of life and resources on both sides.

The interval between the First and Second Punic Wars

The western Mediterranean during the Punic Wars

campaign against Sicily

(241-218 BC). The loss of naval supremacy not only deprived the Carthaginians of their predominance in the western Mediterranean but exposed their overseas empire to disintegration under renewed attacks by Rome. Even the Greek historian Polybius, an admirer of Rome, considered the subsequent Roman actions against Carthage aggressive and unjustified. A gross breach of the treaty was perpetrated when a Roman force was sent to occupy Sardinia, whose insurgent garrison had offered to surrender the island (238). To the remonstrances of Carthage the Romans replied with a declaration of war and only withheld their attack upon the cession of Sardinia and

Corsica and the payment of a further indemnity. From this episode it became clear that Rome intended to use the victory to the utmost. To avoid further infringement of its hegemony, Carthage had little choice but to respond with force. The recent complications of foreign and internal strife had indeed so weakened the Punic power that the prospect of renewing the war under favourable circumstances seemed remote. Yet Hamilcar Barca sought to rebuild Carthaginian strength by acquiring a dominion in Spain where Carthage might gain new wealth and manpower. Invested with an unrestricted foreign command, he spent the rest of his life founding a Spanish empire (237-228). His work was continued by his son-in-law Hasdrubal and his son Hannibal, who was placed at the head of the army in 221. These conquests aroused the suspicions of Rome, which in a treaty with Hasdrubal confined the Carthaginians to the south of the Ebro River. At some point Rome also entered into relations with Saguntum (Sagunto), a town on the east coast, south of the Ebro. To the Carthaginians it seemed that once again Rome was expanding its interests into their sphere of hegemony. In 219 Hannibal laid siege to Saguntum and carried the town in spite of stubborn defense. The Romans responded with an ultimatum demanding that the Carthaginians surrender Hannibal or go to war. The Carthaginian council supported Hannibal and accepted the war.

Second Punic War (218-201 BC). It seemed that the superiority of the Romans at sea ought to have enabled them to choose the field of battle. They decided to send one army to Spain and another to Sicily and Africa. But before their preparations were complete. Hannibal began the series of operations that dictated the course of the war for the greater part of its duration. He realized that as long as the Romans commanded the resources of an undivided Italian confederacy, no foreign attack could overwhelm them beyond recovery. Thus he conceived the plan of cutting off their source of strength by carrying the war into Italy and causing a disruption of the league. His chances of ever reaching Italy seemed small, for the sea was guarded by the Roman fleets and the land route was

long and arduous.

But the very boldness of his enterprise contributed to its success; after a six months' march through Spain and Gaul and over the Alps, which the Romans were nowhere in time to oppose, Hannibal arrived (autumn 218) in the plain of the Po with 20,000 foot soldiers and 6,000 horses, the pick of his African and Spanish levies. At the end of the year, Hannibal, by superior tactics, repelled a Roman army on the banks of the Trebbia River, inflicting heavy losses, and thus made his position in northern Italy secure.

In 217 the campaign opened in Etruria, into which the invading army, largely reinforced by Gauls, penetrated via an unguarded pass. A rash pursuit by the Roman field force led to its being entrapped on the shore of Lake Trasimene (Trasimeno) and destroyed with a loss of at least 15,000 men. This catastrophe left Rome completely uncovered; but Hannibal, having resolved not to attack 'the capital before he could collect a more overwhelming force, directed his march toward the south of Italy, where he hoped to stir up the peoples who had formerly been the most stubborn enemies of Rome. The Italians, however, were slow everywhere to join the Carthaginians. A new Roman army under the dictator Quintus Fabius Maximus ("Cunctator") dogged Hannibal's steps on his forays through Apulia and Campania and prevented him from acquiring a permanent base of operations.

The eventful campaign of 216 was begun by a new,

aggressive move on the part of Rome. An exceptionally strong field army, variously estimated at between 48,000 of Cannae and 85,000 men, was sent to crush the Carthaginians in open battle. On a level plain near Cannae in Apulia, Hannibal deliberately allowed his centre to be driven in by the numerically superior Romans, while Hasdrubal's cavalry wheeled around so as to take the enemy in flank and rear. The Romans, surrounded on all sides, were practically annihilated, and the loss of citizens was perhaps greater than in any other defeat that befell the republic.

The effect of the battle on morale was no less momentous. The southern Italian peoples seceded from Rome, the leaders of the movement being the people of Capua, at the time the second greatest town of Italy. Reinforcements were sent from Carthage, and several neutral powers prepared to throw their weight into the scale on Hannibal's behalf. But the great resources of Rome, though terribiy reduced in respect to both men and money, were not yet exhausted. In northern and central Italy the insurrection spread but little and could be sufficiently guarded against with small detachments. In the south the Greek towns of the coast remained loyal, and the numerous Latin colonies continued to render important service by interrupting free communication between the rebels and detaining part of their forces.

In Rome itself the crisis gave way to a unanimity unparalleled in the annals of the republic. The guidance of operations was henceforth left to the Senate, which, by maintaining a persistent policy until the conflict was brought to a successful end, earned its greatest title to fame. But it also produced a severe strain, released through cruel religious rites, which were an embarrassment to later Roman authors. The disasters were interpreted as evidence of divine wrath at Roman impiety, to be propitiated by punishment (burial alive) of two offending Vestal Virgins and by the human sacrifice of a Gallic and Greek man and woman.

The subsequent campaigns of the war in Italy assumed a new character. Though the Romans contrived at times to raise 200,000 men, they could spare only a moderate force for field operations. Their generals, among whom the veterans Fabius and Marcus Claudius Marcellus frequently held the most important commands, rarely ventured to engage Hannibal in the open and contented themselves with observing him or skirmishing against his detachments. Hannibal, whose recent accessions of strength were largely discounted by the necessity of assigning troops to protect his new allies or secure their wavering loyalty, was still too weak to undertake a vigorous offensive. In the ensuing years the war resolved itself into a multiplicity of minor engagements, which need not be followed in detail. In 216 and 215 the chief seat of war was Campania, where Hannibal, vainly attempting to establish himself on the coast, experienced a severe repulse at Nola.

In 214 the main Carthaginian force was transferred from Apulia in hopes of capturing Tarentum (Taranto), a suitable harbour by which Hannibal might have secured his overseas communications. In 213-212 the greater part of Tarentum and other cities of the southern seaboard at last came into Hannibal's power, but in the meantime the Romans were suppressing the revolt in Campania and in 212 were strong enough to place Capua under blockade. They severely defeated a Carthaginian relief force and could not be permanently dislodged even by Hannibal himself. In 211 Hannibal made a last effort to relieve his allies by a feint upon Rome itself, but the besiegers refused to be drawn away from their entrenchments, and eventually Capua was starved into surrender. The Romans in 209 gained a further important success by recovering Tarentum. Though Hannibal still won isolated engagements, he was slowly being driven back into the extreme south of the peninsula.

In 207 the arrival of a fresh invading force produced a new crisis. Hasdrubal, who in 208-207 had marched over- campaign land from Spain, appeared in northern Italy with a force of 207 scarcely inferior to the army that his brother had brought in 218. After levying contingents of Gauls and Ligurians, he marched down the east coast with the object of joining his brother in central Italy for a direct attack upon Rome

The Battle

Hannibal's strategy

itself. By this time the steady drain of men and money was telling so severely upon the confederacy that some of the most loyal allies protested their inability to render further help. Nonetheless, by exerting a supreme effort, the Romans raised their war establishment to the highest total yet attained and sent a strong field army against each Carthaginian leader. Before reaching Hannibal, Hasdrubal was met in northern Italy by the army of Marcus Livius Salinator, reinforced by part of Gaius Claudius Nero's army. The battle on the banks of the Metaurus (Metauro) River was evenly contested until Nero, with a dexterous flanking movement, cut off the enemy's retreat. The bulk of Hasdrubal's army was destroyed, and he himself was killed. His head was tossed into his brother's camp as an announcement of his defeat.

The campaign of 207 decided the war in Italy. Though Hannibal still maintained himself for some years in southern Italy, this was chiefly due to the exhaustion of Rome. In 203 Hannibal, in accordance with orders received from home, sailed back to Africa; and another expedition under his brother Mago, which had sailed to Liguria in 205 and endeavoured to rouse the slumbering discontent of the people in Cisalpine Gaul and Etruria, was forced

to withdraw

Campaigns in Sicily and Spain. Concurrently with the great struggle in Italy, the Second Punic War was fought on several other fields. To the east King Philip V of Macedon began the First Macedonian War (214-205) in concert with the Carthaginians, when the Roman power seemed to be breaking up after Cannae, Although this compelled the Romans to stretch their already severely strained resources still further by sending troops to Greece, the diversions Roman diplomacy provided for Philip in Greece and the maintenance of a Roman patrol squadron in the Adriatic Sea prevented any effective cooperation between Philip and Hannibal.

Agriculture in Italy had collapsed, and the Romans had to look to Sardinia and Sicily for their food supply. Sardinia was attacked by Carthaginians in 215, but a small Roman force was enough to repel the invasion. In Sicily the death of Hieron II, Rome's steadfast friend, in 215 left the realm of Syracuse to his inexperienced grandson Hieronymus. The young prince abruptly broke with the Romans, but before hostilities commenced he was assassinated. The Syracusan people now repudiated the monarchy and resumed their republican constitution. When the Romans threatened terrible punishment, the Syracusans found it necessary to cooperate with the Carthaginians.

The Roman army and fleet under Marcus Claudius Marcellus, which speedily appeared before the town, were completely baffled by the mechanical contrivances that the Syracusan mathematician Archimedes had invented in 213 for the defense of the city. Meanwhile, the revolt against Rome spread in the interior of the island, and a Carthaginian fleet gained control of towns on the south coast. In 212 Marcellus at last broke through the defense of Syracuse and, in spite of the arrival of a Carthaginian relief force, took control of the whole town in 211. By the end of 210 Sicily was wholly under the power of Rome.

The conflict in Spain was second in importance only to the Italian war. From this country the Carthaginians drew large supplies of troops and money that might serve to reinforce Hannibal; hence it was in the interest of the Romans to challenge their enemy within Spain. Though the force that Rome at first spared for this war was small in numbers and rested entirely upon its own resources, the generals Publius Cornelius and Gnaeus Cornelius Scipio, by skillful strategy and diplomacy, not only won over the peoples north of the Ebro and defeated the Carthaginian leader Hasdrubal Barca in his attempts to restore communication with Italy but also carried their arms along the east coast into the heart of the enemy's domain.

But eventually the Roman successes were nullified by a rash advance. Deserted by their native contingents and cut off by Carthaginian cavalry, among which the Numidian prince Masinissa rendered conspicuous service, the Roman generals were killed and their troops destroyed (211).

Disturbances in Africa prevented the Punic commanders from exploiting their success. Before long the fall of Capua enabled Rome to transfer troops from Italy to Spain; and in 210 the best Roman general of the day, the young son and namesake of Publius Scipio, was placed in command by popular vote, despite his youth and lack of the prerequisite senior magistracies. He signalized his arrival by a bold and successful coup de main upon the great arsenal of Carthago Nova (Cartagena) in 209. Though after an engagement at Baecula (Bailen; 208) he was unable to prevent Hasdrubal Barca from marching away to Italy, Scipio profited by his opponent's departure to push back the remaining hostile forces the more rapidly. A last effort by the Carthaginians to retrieve their losses with a fresh army was frustrated by a great Roman victory at Ilipa, near Seville, and by the end of the year 206 the Carthaginians had been driven out of Spain.

The war in Africa. In 205 Scipio, who had returned to Rome to hold the consulship, proposed to follow up his victories by an attack on the home territory of Carthage. Though the presence of Hannibal in Italy deterred Fabius and other senators from sanctioning this policy, Scipio gradually overbore all resistance. He built up a force, which he organized and supplemented in Sicily, and in 204 sailed across to Africa. He was met there by a combined levy of Carthage and King Syphax of Numidia and for a time was penned to the shore near Utica. But in the spring he extricated himself by a surprise attack on the enemy's camp, which resulted in the total loss of the allied

force by sword or fire.

In the campaign of 203 a new Carthaginian force was destroyed by Scipio on the Great Plains 75 miles from Utica, their ally Syphax was captured, and the renegade Masinissa was reinstated in the kingdom from which Syphax had recently expelled him. These disasters induced the Carthaginians to sue for peace; but before the very moderate terms that Scipio offered could be definitely accepted, a sudden reversal of opinion caused them to recall Hannibal's army for a final trial of war and to break off negotiations. In 202 Hannibal assumed command of a composite force of citizen and mercenary levies reinforced by a corps of his veteran Italian troops.

After negotiations failed, Scipio and Hannibal met in the Battle of Zama. Scipio's force was somewhat smaller in numbers but well trained throughout and greatly superior in cavalry. His infantry, after evading an attack by the Carthaginian elephants, cut through the first two lines of the enemy but was unable to break the reserve corps of Hannibal's veterans. The battle was ultimately decided by the cavalry of the Romans and their new ally Masinissa. who by a maneuver recalling the tactics of Cannae took Hannibal's line in the rear and destroyed it.

The Carthaginians again applied for peace and accepted the terms that Scipio offered. They were compelled to cede Spain and the Mediterranean islands still in their hands, to surrender their warships, to pay an indemnity of 10,000 talents within 50 years, and to forfeit their independence

in affairs of war and foreign policy.

The Second Punic War, by far the greatest struggle in which either power engaged, had thus ended in the complete triumph of Rome, although not because of any faultiness in the Carthaginians' method of attack. Carthage could only hope to win by invading Italy and using the enemy's home resources against him. The failure of Hannibal's brilliant endeavour was ultimately due to the stern determination of the Romans and to the nearly inexhaustible manpower from their Italian confederacy, which no shock of defeat or strain of war could entirely disintegrate. Although Rome and its allies suffered casualties of perhaps one-fifth of their adult male population, they continued fighting. For Polybius, the Second Punic War illustrated the superiority of the strong Roman constitution over Hannibal's individual genius.

(M.Car./H.H.S./R.P.Sa.) The establishment of Roman hegemony in the Mediterranean world. Roman expansion in the eastern Mediterranean. Just before the Second Punic War, Rome had projected its power across the Adriatic Sea against the Illyrians. As noted, Philip V of Macedon in turn had joined the Carthaginians for a time during the war in an attempt to stem the tide of Roman expansion but had

The Battle of Ilipa

Roman attack on Syracuse

The Second Macedonian War agreed to terms of peace with Rome's allies, the Aetolians. in 206 and then with Rome in the Peace of Phoenice of 205. Immediately after the Second Punic War the Roman Senate moved to settle affairs with Philip, despite the warweary centuriate assembly's initial refusal to declare war. Historians have debated Rome's reasons for this momentous decision, with suggestions ranging from a desire to protect Athenians and other Greeks from Philip out of philhellenism to fear of a secret alliance between Philip and the Seleucid king Antiochus III. Yet these suggestions are belied by the fact that Rome later treated the Greek cities callously and that no fear is apparent in Rome's increasing demands on Philip and in its refusal to negotiate seriously with him through the course of the war. Rather, the Second Macedonian War (200-196) fits the long pattern of Roman readiness to go to war in order to force ever more distant neighbours to submit to superior Roman power.

In the winter of 200-199, Roman legions marched into the Balkans under the command of Publius Sulpicius Galba. During the next two years there was no decisive battle, as the Romans gathered allies among the Greeks-not only their previous allies, the Aetolians, but also Philip's traditional allies, the Achaeans, who recognized Roman military superiority. The consul of 198, Titus Quinctius Flamininus, took over the command and defeated Philin at the battle of Cynoscephalae in 197. The terms of settlement allowed Philip to remain king of Macedon but stipulated payment of an indemnity and restrictions on campaigning beyond the borders of his kingdom. Flamininus then sought to win the goodwill of the Greeks with his famous proclamation of their liberation at the Isthmian Games of 196. To lend credibility to this proclamation, he successfully argued against senatorial opposition for the withdrawal of Roman troops from all Greece, including the strategically important "Fetters" (the key garrisons of Acrocorinth, Chalcis, and Demetrias).

Even before the Romans withdrew, the seeds had been sown for their recentry into the East. As an active king, Antiochus III set out to recover the ancestral possessions of his kingdom on the western coast of Anatolia and in Thrace. In response to the Roman demand that he stay out of Europe, the king attempted to negotiate. When the Romans showed little interest in compromise, Antiochus accepted the invitation of Rome's former allies, the Aetolians, who felt they had not been duly rewarded with additional territory after the victory over Philip, to liberate the Greeks. Upon crossing into Greece, however, the king found no enthusiasm among the other Greeks for a war of liberation and was defeated at Thermopylae in 191 by legions under the command of Manius Acilius Glabrio.

Antiochus returned home to gather a larger army. In 190 Lucius Cornelius Scipio was elected consul in Rome and was authorized to recruit a force for a campaign against Antiochus. Accompanying Lucius as a legate was his brother, the great general Scipio Africanus. In an attempt to avert war. Antiochus offered to accept the earlier Roman terms, only to find that the Romans had now extended their demands to keep Antiochus east of the Taurus Mountains of Anatolia. Unable to accept, Antiochus fought and lost to Scipio's army at Magnesia ad Sipylum in the winter of 190-189. In the following Treaty of Apamea (188), the Seleucid kingdom was limited to Asia east of the Taurus range and was required to pay an indemnity of 15,000 talents and to give up its elephants and all but 10 ships. Rome punished its opponents, the Aetolians, and rewarded its supporters, notably Pergamum and Rhodes, which were granted new territories, including Greek cities, at the expense of "the liberation of the "Greeks." The consul of 189, Gnaeus Manlius Vulso, came east with reinforcements, took command of the legions, and proceeded to plunder the Galatians of Anatolia on the pretext of restoring order.

The withdrawal of Roman legions this time did not entail the withdrawal of a Roman presence from the Hellenistic East. On the contrary, according to Polybius, the Romans now "were displeased if all matters were not referred to them and if everything was not done in accordance with their decision." Continuing jealousies and disputes in the

Greek world offered Rome opportunities to adjudicate and ultimately to intervene once again. In the Peloponnese the Achaean League was at odds with Sparta, wishing to bring Sparta into the league and to suppress the radical social program of its king, Nabis, Flamininus in 195 supported the independence of Sparta, but in 192 the Achaean leader, Philopoemen, induced Sparta to join the league with a promise of no interference in its internal affairs. When an infringement of the promise prompted the Spartans to secede, Philopoemen in 188 led an Achaean army to take Sparta, kill the anti-Achaean leaders, and force the city back into the league. Although the Senate heard complaints, it took no immediate action. Then, in 184, the Senate reasserted its own terms for settlement but was circumvented by Philopoemen, who reached a separate agreement with the Spartans. The independent-minded Philopoemen died the following year in a campaign by the league to suppress a revolt of Messene. His death led to a change of leadership, as the pro-Roman Callicrates (regarded by Polybius as a sycophant) began a policy of

obeying Rome's every wish. Meanwhile, tensions between Rome and Philip were increasing. Philip had supported Rome's war with Antiochus in the hope of recovering Thessalian and Thracian territory, but in this he was disappointed by the Romans. They did, however, return Philip's younger son, Demetrius, taken to Rome as a hostage in 197—a reward with tragic consequences. During his years as a hostage, Demetrius had made senatorial friendships, which aroused suspicions at home that the Romans would prefer to see Demetrius rather than his elder brother, Perseus, succeed Philip, Philip ordered the death of Demetrius in 181 and then died in 179, leaving his throne to Perseus, the last king of Macodon.

Perseus' activism started a stream of complaints to the Senate from neighbouring Greek powers from 175 onward. The king's real intentions are unclear; perhaps Polybius was right that he wished to make the Romans "more cautious about delivering harsh and unjust orders to Macedonians." The Senate listened to the unfavourable interpretations of Perseus' enemies, who claimed that the king's actions revealed an intent to attack Rome. Like his father, Perseus campaigned to extend Macedonian power to the northeast and south and marched through Greece as far as Delphi. He solicited alliances with the Achaean League and other Greek states, which some of the leaders hostile to Rome would have liked to accept. He arranged dynastic marriages with other Hellenistic kings, taking the daughter of Seleucus IV as his wife and giving the hand of his sister to Prusias II of Bithynia. Although these actions could have been viewed as the behaviour expected of a Hellenistic monarch, Eumenes of Pergamum suggested to the Senate that Perseus was preparing for war against Rome. After the Senate decided on war, it sent Quintus Marcius Philippus to propose a truce and to give Perseus false hopes of negotiation in order to allow the consul of 171, Publius Licinius Crassus, to land his army on the Illyrian coast unhindered-a ploy decried by some older senators as "the new wisdom."

Perseus' initial success against the Roman army in Thessaly in 171 did not alter the massive imbalance of power; the Romans again refused the king's offer to negotiate. Over the next three years Roman commanders devoted more effort to plunder than to the defeat of Perseus. In a notorious incident, the praetor Lucius Hortensius anchored his fleet at Abdera, a city allied with Rome, and demanded supplies; when the Abderitans asked to consult the Senate, Hortensius sacked the town, executed the leading citizens, and enslaved the rest. When complaints reached the Senate, weak attempts were made to force the Roman commanders to make restitution. In 168 the experienced Lucius Aemilius Paullus was reelected consul and sent out to restore discipline. He quickly brought the Third Macedonian War to an end by defeating Perseus in the Battle of Pydna in June 168. Perseus was deposed, and Macedonia was divided into four republics, which were forbidden to have relations with one another; they paid tribute to Rome at half the rate they had previously paid to the king.

Philopoemen and the

League

The defeat of Perseus The rise of

piracy

In 167 Rome proceeded to punish those who had sided with Perseus (such as the Illyrian Genthius), those whose loyalty had wavered (such as Eumenes), and even those who had contemplated acting as mediators in the war (such as the Rhodians). In Illyria, Paullus, on instructions from the Senate, swept through the countryside enslaving 150,000 inhabitants from 70 Epirote towns. In Achaea, 1,000 leading men suspected of Macedonian sympathies were taken as hostages to Rome. (Among them was Polybius, who befriended the noble Scipionic family and wrote his great history of the rise of Rome with the aid of privileged access to the views of the senatorial leadership.) Eumenes was refused a hearing before the Senate on his visit to Italy; his fall from favour prompted his enemies to dispute his territory, and in 164 a Roman embassy in Anatolia publicly invited complaints against the king. Rhodes had thrived as the leading trade centre of the eastern Mediterranean, using its considerable resources to control piracy; now Rome undermined its economy and power by making the island of Delos a free port, thereby depriving Rhodes of its income from harbour dues. Territory in Lycia and Caria on the mainland, granted to Rhodes in 189, was now taken away. But the far harsher proposal in the Senate to declare Rhodes an enemy and to destroy it was opposed by senior senators such as Cato the Censor and was voted down. As a result of the weakening of Rhodes, piracy became rampant in the eastern Mediterranean (the young Julius Caesar was captured by pirates). During the next century Roman senators did not find the political will to suppress the piracy, perhaps in part because it served their interests; pirates supplied tens of thousands of slaves for their Italian estates and disrupted the grain trade, thus raising prices for their produce in Rome.

The arrangements of 167 served the Roman policy of weakening the powers of the eastern Mediterranean. In the previous year Rome had also intervened to stop Seleucid expansion into Egypt. In a famous episode, the Roman ambassador Gaius Popillius Laenas delivered to Antiochus IV the Senate's demand that the king withdraw from Egypt. When the king requested time for consultation. Popillius "drew a circle around the king with a stick he was carrying and told him not to leave the circle until he gave his response. The king was astonished at this occurrence and the display of superiority, but, after a brief time, said he would do all the Romans demanded."

The power vacuum fostered by the Romans was not ultimately conducive to stability. An adventurer, Andriscus, claiming to be descended from the Macedonian dynasty, was able to enter the Macedonian republics without serious resistance. He was successful enough in raising an army to defeat the first Roman force sent against him in 149 under the command of the praetor Publius Iuventius Thalna (who was killed). A second Roman army under Quintus Caecilius Metellus defeated the pretender in 148, With the death of Callicrates, leadership of the Achaean League passed to Critolaus and Diaeus, outspoken proponents of Greek independence from Rome. In 147 a Roman embassy was sent to intervene in the affairs of the league by supporting the secession of Sparta and also by calling for the detachment of Corinth and Argos from the league. The embassy provoked a violent reply. When further negotiations were blocked by Critolaus, Rome declared war on the Achaeans in 146, citing as reason the ill-treatment of their embassy. Metellus (now with the appellation of "Macedonicus"), having delayed with his army, marched against Critolaus and defeated him in Locris. Then Lucius Mummius Archaicus, consul of 146, took over the command and defeated Diaeus and the remaining Achaeans. The Senate ordered Mummius to teach a lesson to the Greeks: the venerable city of Corinth was sacked, its treasures taken to Rome, and its buildings burned to the ground.

The nature of Roman domination in the East began to change decisively after these wars: in place of influence through embassies, arbitration of disputes, and the occasional military incursion came direct rule. Macedonia was annexed as a province, to be governed and taxed by a Roman proconsul, who also watched over the Greek cities to the south, where the leagues were disbanded. Farther east, the kingdom of Pergamum was added as the province of Asia, as a bequest to the Roman people from Attalus III in 133.

Roman expansion in the western Mediterranean. If Roman military intervention in the east was sporadic in the 2nd century, campaigning in northern Italy and Spain was nearly continuous. During Hannibal's invasion of Italy, the Insubres and Boii, Gallic peoples in the Po valley, had joined the Carthaginians against Rome. In 200 the Gauls and Ligurians combined forces and sacked the Latin colony of Placentia in an attempt to drive the Romans out of their lands. In the following years consular armies repeatedly attacked the Gauls. In 194 Lucius Valerius Flaccus won a decisive victory over the Insubres; in 192 the leading Boii under severe pressure went over to the Roman side, signaling the coming defeat of their tribe. Following their victories, the Romans sent thousands of new colonists to the Po valley to reinforce the older colonies of Placentia and Cremona (190) and to establish new colonies, notably Bononia (189) and Aquileia (181).

During the same period the Romans were at war with the Ligurian tribes of the northern Appennines. The serious effort began in 182, when both consular armies and a proconsular army were sent against the Ligurians. The wars continued into the 150s, when victorious generals celebrated two triumphs over the Ligurians. Here also the Romans drove many natives off their land and settled colonies in their stead (e.g., Luna and Luca in the 170s).

As a result of the Second Punic War, Roman legions had marched into Spain against the Carthaginians and remained there after 201. The Romans formalized their rule in 197 by creating two provinces, Nearer and Further Spain. They also exploited the Spanish riches, especially the mines, as the Carthaginians had done. In 197 the legions were withdrawn, but a Spanish revolt against the Roman presence led to the death of one governor and required that the two praetorian governors of 196 be accompanied by a legion each. The situation was serious enough for the consul of 195, Cato the Censor, to be sent to Spain with two legions. From Cato comes the earliest extant firsthand account of Roman conquest. His comments show that he prided himself on his bravery and lack of greed as compared with other Roman commanders. Yet his narrative must overstate the extent and decisiveness of his success because fighting persisted for years to come, as later Roman governors sought to extend Roman control over more Spanish peoples-the Celtiberi of northeastern Spain, the Lusitani of modern-day Portugal, and the Vettones and Vaccaei of northwestern Spain. In 177 Tiiberius Sempronius Gracchus celebrated a triumph over the Celtiberi. The size of the Roman forces was probably then reduced from four to two legions; from 173 to 155 there was a lull in the regular campaigning. During these decades Spanish peoples brought complaints to Rome about corrupt governors

Annual warfare resumed in Spain in 154, being perhaps in part a violent reaction to corrupt administration, and dragged on until 133. Labeled a "fiery war" (really wars), these struggles acquired a reputation for extreme cruelty; they brought destruction to the native population (e.g., 20,000 Vaccaei were killed in 151 after giving themselves up to Lucius Licinius Lucullus) and made recruiting legionaries in Italy difficult. In Further Spain the Lusitanian leader Viriathus enjoyed some successes, including the surrender of a Roman army in 141-140 and a favourable treaty with Rome, but the next governor of the province, Quintus Servilius Caepio, arranged for his assassination in 139. Two years later in Nearer Spain, the Numantines also forced the surrender of an army under Gaius Hostilius Mancinus; the Senate later disavowed the agreement of equal terms and handed Mancinus, bound and naked, over to the Spaniards to absolve themselves of responsibility before the gods. The wars in Spain were brought to a conclusion in 133 by Publius Cornelius Scipio Aemilianus, who took Numantia after a long siege, enslaved the population, and razed the city.

It was Scipio Aemilianus (b. 185/184) who in the previous decade had imposed a similar final solution on Carthage in the Third Punic War (149-146). After the A "fiery

Direct Roman rule in the East Second Punic War, Carthage had recovered to the point that in 191 it offered to repay the remainder of the 50-year tribute of 200 talents per year in one lump sum. Rome's refusal of the offer suggests that beyond its monetary value the tribute had the symbolic importance of signifying subjection. Carthage's neighbour, the Numidian king Masinissa, had been granted as a reward for his support of Rome at the Battle of Zama his paternal kingdom and the western Numidian kingdom ruled by Syphax. During the next half century Masinissa periodically tried to exploit his favour in Rome by encroaching on Carthaginian territory. Initially, the Carthaginians submissively sought the arbitration of Rome in these disputes, but more often than not Roman judgment went in favour of Masinissa After a series of losses, the Carthaginians in 151 decided to act on their own and raised an army to ward off the Numidian attacks. When a Roman delegation observed the Carthaginian army raised in breach of the treaty of 201, Rome was provided with the casus belli for a declaration of war in 149; Polybius, however, claims that the Senate had decided on this war "long before." The elderly Cato had been ending his speeches in the Senate since 153 with the notorious exhortation that "Carthage must be destroyed." Carthage desperately and pathetically tried to make amends, executing the generals of the expedition against the Numidians, surrendering to Rome, and handing over hostages, armour, and artillery. Only then did the Romans deliver their final demand: Carthage must be abandoned and the population moved to a new site inland. Such extreme terms could not be accepted.

The war against Carthage, with its prospects of rich booty, presented no recruiting problems for the Romans: huge land and naval forces were sent out under both consuls of 149. Lucius Marcius Censorinus and Manius Manilius. The imbalance of resources meant that the outcome was never in doubt, but the fortifications of Carthage delayed the Roman victory. The young Scipio Aemilianus was elected consul for 147, and by popular vote he was assigned the task of bringing the war to an end. He blockaded the city by land and sea, inflicting terrible suffering. Finally, in 146, the Roman army took Carthage, enslaved its reof Carthage maining 50,000 inhabitants, burned the buildings to the ground, and ritually sowed the site with salt to guarantee that nothing would ever grow there again. Carthaginian territory was annexed as the province of Africa.

The

destruction

Explanations of Roman expansion. As one of the decisive developments in western history, Roman expansion has invited continual reinterpretation by historians, Polybius, who wrote his history in order to explain to other Greeks the reasons for Roman success, believed that after their victory over Hannibal the Romans conceived the aim of dominating all before them and set out to achieve it in the Second Macedonian War. If one accepts the Roman view that they fought only "just wars"-that is, only when provoked-then Roman conquest emerges as "one of the most important accidents in European history," as Rome had to defend itself from threats on all sides. Historians have suggested other motives for empire, such as a desire to profit from war, an interest in commercial expansion, or a love of the Greeks, who asked for protection against Hellenistic monarchs.

Major historical phenomena of this kind rarely receive final, decisive interpretations, but several assertions may be ventured. Some of the interpretations are anachronistic impositions on the ancient world; ancient testimony, for example, gives no support to commercial or mercantile explanations. Cultural and economic interpretations seem more appropriate. Roman culture placed a high value on success in war: virtus (courage and qualities of leadership) was displayed, above all, in war, and the triumph, a parade through Rome celebrating a major victory over an enemy, was the honour most highly prized by the senatorial generals who guided Roman decisions about war and peace. Moreover, these leaders, and the whole Roman people, were fully aware of the increasing profits of victory; in the 2nd century commanders and soldiers, as well as the city itself, were enriched by the glittering booty from Africa and the Greek East.

Yet, it is rightly pointed out, Roman intervention in the

East was sporadic, not systematic, and the Romans did not annex territory in the Balkans, Anatolia, or North Africa for more than 50 years after their initial victories. The latter point, however, is not telling, since the Romans regarded defeated states allied to them as part of their imperium, whether or not they were under Roman provincial administration. The sporadic timing of the wars The issue would seem to support the Romans' claim that they only of "just reacted, justly, to provocations. But attention to the individual provocations should not blind the historian to the larger pattern of Roman behaviour. From 218 the Romans annually fielded major armies decade after decade. Rome was able to go to war every year in response to provocations only because it chose to define its interests and make alliances farther and farther afield. Polybius as noted, reveals how the Romans were the masters of manipulation of circumstances to force opponents to behave in a way they could interpret as provocative. Therefore the Roman interpretation of "just wars" and the Polybian interpretation of a universal aim to conquer need not be contradictory. The concept of "just war" may have justified any given war but does not explain the perpetual Roman readiness to go to war. For that the historian must look to Polybius' universal aim or to general political, social, economic, and cultural features of Rome. Finally, it must be remembered that in some instances it was clearly the Roman commander who provoked the war in order to plunder and to win a triumph (e.g., Licinius Lucullus, governor of Nearer Spain, in 151).

Beginnings of provincial administration. Rome dominated its Latin and Italian neighbours by incorporating some into the Roman citizen body and by forming bilateral alliances with most of the Italian city-states. After the Punic Wars, Rome undertook to rule newly acquired territories directly as subject provinces. In 241 Sicily became Rome's first province, followed by Sardinia-Corsica in 238, and Spain, divided into two provinces, in 197. After a 50-year hiatus, Macedonia and Africa were annexed in 146, and the province of Asia (northwestern Anatolia) in 133. In principle, each province was to be administered in accordance with its lex provinciae, a set of rules drawn up by the conquering commander and a senatorial embassy. The lex provinciae laid down the organization of taxation, which varied from province to province.

The provincial administrative apparatuses were minimal and unprofessional, as the Romans relied heavily on the local elites as mediators. Each year a senatorial magistrate was sent out to govern with nearly unfettered powers. Because initially the governors were usually praetors, the addition of new provinces required the election of more praetors (increased to four in 227 and to six in 197). The assignments to provinces were done by lot. The governor took with him one of the quaestors to oversee the finances of provincial government and senatorial friends and relatives to serve as deputies and advisors (legati). Among the humbler functionaries assisting the governor were scribes to keep records and lictors with fasces (bundles of rods and axes) to symbolize gubernatorial authority and to execute sentences pronounced by the governor in criminal cases.

The governor's main duties were to maintain order and security and to collect revenues. The former often entailed command of an army to ward off external threats and to suppress internal disorders such as banditry. When not commanding his army, the governor spent his time hearing legal cases and arbitrating disputes. During the republic, revenue collection was left to private companies of publicani, so called because they won by highest bid the contract to collect the revenues. It was the governor's responsibility to keep the publicani within the bounds of the lex provinciae so that they did not exploit the helpless provincials too mercilessly, but this was difficult. Governors expected to make a profit from their term of office, and some collaborated with the publicani to strip the provinces of their wealth.

THE TRANSFORMATION OF ROME AND ITALY

DURING THE MIDDLE REPUBLIC The Greek historian Polybius admired Rome's balanced constitution, discipline, and strict religious observance as

Gubernatorial duties

Compe-

tition for

high office

the bases of the republic's success and stability. Yet Rome's very successes in the 2nd century undermined these features, leading to profound changes in the republic's poli-

tics, culture, economy, and society. Citizenship and politics in the middle republic. The Romans organized their citizenry in a way that permitted expansion. This was regarded as a source of strength by contemporaries such as Philip V, who noted that Rome replenished its citizen ranks with freed slaves. The extension of citizenship continued in the early 2nd century, as in the grant of full citizen rights to Arpinum, Formiae, and Fundi in 188. Yet Rome's glittering successes made such openness ever more problematic. For one, the city attracted increasing numbers of Latins and allies, who wished to use their ancient right to migrate and take up Roman citizenship. The depletion of Latin and Italian towns prompted protests, until in 177 Rome took away the right of migration and forced Latin and Italian migrants to return to their hometowns to register for military service. Such measures were sporadically repeated in the following years. In addition, the flood of slaves into Rome from the great conquests increased the flow of foreign-born freedmen into the citizen body. Sempronius Gracchus (father of the famous tribunes) won senatorial approbation as censor in 168 by registering the freedmen in a single urban tribe and thus limiting their electoral influence. Despite these efforts, the nature and meaning of Roman citizenship were bound to change, as the citizen body became ever more diffuse and lived dispersed from Rome, the only place where the right of suffrage could be exercised.

Polybius greatly admired Rome's balanced constitution, with its elements of monarchy (magistrates), aristocracy (Senate), and democracy (popular assemblies). According to Greek political theory, each form of constitution was believed to be unstable and susceptible to decline until replaced by another. Yet Rome's system of balance, Polybius thought, was a check on the cycle of decline. By forcing the Roman constitution into the mold of Greek political theory, however, he exaggerated the symmetry of checks and balances. In reality, the Senate enjoyed a period of steady domination through the first two-thirds of the 2nd century, having emerged from the Second Punic War with high prestige. Only occasionally did the developing ten-

sions and contradictions surface during these decades Politics during the period was largely a matter of senatorial families competing for high office and the ensuing lucrative commands. Because offices were won in the centuriate and tribal assemblies, senators had to cultivate support among the populus. Yet the system was not as democratic as it might appear. Senators with illustrious names and consular ancestors dominated the election to the highest offices, increasing their share of the consulates from about one-half to two-thirds during the 2nd century. These proportions can be interpreted in two ways: the Senate was not a closed, hereditary aristocracy but was open to new families, who usually rose through the senatorial ranks in the course of generations with the patronal support of established families; yet a small circle of prominent families (e.g., the Aemilii, Claudii, and Cornelii) were disproportionately successful, surprisingly so in view of the popular electoral process. Since the campaigning was not oriented toward issues, the great families were able to maintain their superiority over the centuries by their inherited resources: their famous names, their wealth, and their clienteles of voters.

While aristocratic electoral competition was tradition during the republic, this period began to exhibit the escalation in competitiveness that was later fatal to the republic. For example, Publius Cornelius Scipio Africanus emerged from the Second Punic War as the Roman whose dignitas (prestige) far surpassed that of his peers. Nonetheless, a number of senators attacked him and his brother Lucius Cornelius with legal charges until he finally retired from Rome to end his life at his Campanian villa at Liternum. For younger senators, however, Scipio's spectacular achievement was something to emulate. The ambitious young Flamininus moved swiftly through the senatorial cursus honorum ("course of honors") to win the consulship and command against Philip V at the age of 30. Such cases prompted laws to regulate the senatorial cursus: iteration in the same magistracy was prohibited, the praetorship was made a prerequisite for the consulship, and in 180 the lex Villia annalis (Villian law on minimum ages) set minimum ages for senatorial magistrates and required a two-year interval between offices. The consulship (two elected to it per year) could be held from age 42, the praetorship (six per year) from age 39, and the curule aedileship from 36. Patricians, still privileged in this area, were probably allowed to stand for these offices two years earlier. The senatorial career was preceded by 10 years of military service, from age 17, and formally began with a quaestorship, the most junior senatorial magistracy (eight per year), at age 30 or just under. The offices between the quaestorship and praetorship, the aedileship (four per year) and the plebeian tribunate (10 per year), were not compulsory but provided opportunities to win popularity among the voters by staging aedilician games and supporting popular causes, respectively. Here again, excess elicited restraint, and legal limits were placed on the lavishness of the games. More broadly, from 181 legislation designed to curb electoral bribery was intermittently introduced.

The problems of electoral competition did not disappear. In the late 150s second consulships were prohibited altogether, but within decades the rules were broken. Scipio Aemilianus, grandson by adoption of Scipio Africanus, challenged the system. Returning from the Carthaginian campaign to Rome to stand for the aedileship, he was elected instead to the consulship, even though he was underage and had not held the prerequisite praetorship. He was then elected to a second consulship for 134. Scipio had no subversive intent, but his career set the precedent for circumventing the cursus regulations by appeal to the popular assemblies.

While the 2nd century was a time of heated competition among senators, it was generally a period of quiescence of the plebs and their magistrates, the tribunes. Nevertheless, signs of the upheaval ahead are visible. For one, the long plebeian struggle against arbitrary abuse of magisterial power continued. A series of Porcian laws were passed to protect citizens from summary execution or scourging, asserting the citizen's right of appeal to the assembly (ius provocationis). A descendant of the Porcian clan later advertised these laws on coins as a victory for freedom. Moreover, the massive annual war effort provoked occasional resistance to military service. In 193 the tribunes started to investigate complaints about overly long military service. Interpreting this as a challenge to magisterial authority, the Senate responded with a declaration of an emergency levy, and the tribunes stopped their activity. In 151 the tribunes tried to protect some citizens from the levy for the unpopular war in Spain. A confrontation between the tribunes and the recruiting consuls ensued, in which the tribunes briefly imprisoned the consuls until a compromise relieved the crisis. The scene of tribunes taking consuls to jail was repeated in 138 during a period of renewed difficulties over recruiting.

Since the Hortensian law of 287, the plebs had the constitutional power to pass laws binding on the entire state without senatorial approval. During the next century and a half few attempts were made to use the power for purposes of major reform against the Senate's will, in part because the plebeian tribunes, as members of the senatorial order, generally shared the Senate's interests and in part because the plebeians benefited from Rome's great successes abroad under senatorial leadership. Yet senatorial fear of unbridled popular legislative power is perceptible in the Aelian and Fufian law of about 150. This law, imperfectly known from later passing references, provided that a magistrate holding a legislative assembly could be prevented from passing a bill on religious grounds by another magistrate claiming to have witnessed unfavourable omens in a procedure called obnuntiatio. In addition, the days of the year on which legislative assemblies could be held were reduced. As conservative senators worked to restrain the democratic element in the political processes, the plebeians sought to expand their freedom. Voting in electoral and judicial assemblies had been public, allowing

The Porcian laws

powerful senators more easily to manage the votes of their clients. The Gabinian law (139) and Cassian law (137) introduced secret written ballots into the assemblies, thus loosening the control of patrons over their clients. Significantly, the reform was supported by Scipio Aemilianus. the sort of senator who stood to benefit by attracting the clients of other patrons through his personal popularity. These reforms, together with the changing composition of the electorate in the city, carried the potential, soon to be realized, for more volatile assemblies.

Culture and religion. Expansion brought Rome into contact with many diverse cultures. The most important of these was the Greek culture in the eastern Mediterranean with its highly refined literature and learning. Rome responded to it with ambivalence; although Greek doctring was attractive, it was also the culture of the defeated and enslaved. Indeed, much Greek culture was brought to Rome in the aftermath of military victories, as Roman soldiers returned home not only with works of art but also with learned Greeks who had been enslaved. Despite the ambivalence, nearly every facet of Roman culture was influenced by the Greeks, and it was a Greco-Roman culture that the Roman empire bequeathed to later European civilization.

As Roman aristocrats encountered Greeks in southern Italy and in the East in the 3rd century, they learned to speak and write in Greek. Scipio Africanus and Flamininus, for example, are known to have corresponded in Greek. By the late republic it became standard for senators to be bilingual. Many were reared from infancy by Greek-speaking slaves and later tutored by Greek slaves or freedmen. Nonetheless, despite their increasing fluency in Greek, senators continued to insist on Latin as the official language of government; visiting dignitaries from the East addressing the Senate in Greek had their speeches translated-as a mark of their subordination.

Because Greek was the lingua franca of the East, Romans had to use Greek if they wished to reach a wider audience. Thus the first histories by Romans were written in Greek. The patrician Fabius Pictor, who, as noted above. founded the Roman tradition of historiography during the Second Punic War, wrote his annalistic history of Rome in Greek partly in order to influence Greek views in favour of Rome, and he emphasized Rome's ancient ties to the Greek world by incorporating in his history the legend that the Trojan hero Aeneas had settled in Latium. Because Roman history was about politics and war, the writing of history was always judged by Romans to be a suitable pastime for men of politics-i.e., for senators

such as Fabius. Rome had had a folk tradition of poetry in the native Saturnian verse with a metre based on stress, but not a formal literature. Lucius Livius Andronicus was regarded as the father of Latin literature, a fact that illustrates to what extent the development of Roman literature was bound up with conquest and enslavement, Livius, a native Greek speaker from Tarentum, was brought as a slave to Rome, where he remained until his death (c. 204). Becoming fluent in Latin, he translated the Homeric Odyssey into Latin in Saturnian verse. Thus Latin literature began with a translation from Greek into the native metre. Livius reached wider audiences through his translations of Greek plays for public performance. Gnaeus Naevius, the next major figure (c. 270-c. 201), was again not a native Roman but an Oscan speaker from Campania. In addition to translating Greek drama, he wrote the first major original work in Latin, an epic poem about the First Punic War. Naevius' successors, Quintus Ennius from Calabria (239-169) and Titus Maccius Plautus from Umbria (c. 254-184), transformed the Latin poetic genres by importing Greek metrical forms based on the length of syllables rather than on stress. Ennius was best known for his epic history of Rome in verse, the Annales, but he also wrote tragedies and satires. Plautus produced comedies adapted from Greek New Comedy. He is the only early author whose work is well represented in the corpus of surviving literature (21 plays judged authentic by Marcus Terentius Varro, Rome's greatest scholar). None of the plays of his younger contemporaries, Caecilius Statius (c. 210-168) and Marcus Pacuvius (c. 220-130), survive, nor do the once highly esteemed tragedies of Lucius Accius (170-c. 86). The six extant comedies of Terence (Publius Terentius Afer; c. 190-159) provide a sense of the variation in the comic tradition of the 2nd century. These authors also were outsiders, coming from the Celtic Po valley. Brundisium, Umbria, and North Africa, respectively. Thus, while assorted foreigners, some of servile origin, established a Latin literature by adapting Greek genres, metrical forms, and content, native Roman senators began to write history in Greek Other forms of Greek learning were slower to take root

in Rome. Later Romans remembered that a Greek doctor established a practice in Rome for the first time just before the Second Punic War, but his reputation did little to stimulate Roman interest in the subject. Like doctors. Greek philosophers of the 2nd century were regarded with interest and suspicion. In the early 3rd century Romans had erected in public a statue of Pythagoras, a 6thcentury Greek philosopher who had founded communities of philosophers in southern Italy. In the mid and century some senators displayed an interest in philosophy. Scipio Aemilianus, Gaius Laelius (consul 140), and Lucius Furius Philus (consul 136) were among those who listened to the lectures of the three leaders of the Athenian philosophical schools visiting Rome on a diplomatic mission in 155-the academic Carneades, the peripatetic Critolaus, and the stoic Diogenes. On an official visit to the East in 140, Scipio included in his entourage the leading stoic Panaetius. In the same period, another stoic, Blossius of Cumae, was said to have influenced the reforming tribune Tiberius Sempronius Gracchus. Yet the philosophical influence should not be exaggerated; none of these senators was a philosopher or even a formal student of philosophy. Moreover, the sophisticated rhetoric of the philosophers-in 155 Carneades lectured in favour of natural justice one day and against it the next-was perceived by leading Romans such as Cato the Censor as subversive to good morals. At his urging the Senate quickly concluded the diplomatic business of Carneades, Critolaus, and Diogenes in 155 and hurried them out of Rome. This was part of a broader pattern of hostility to philosophy; in 181 the (spurious) Books of Numa, falsely believed to have been influenced by Pythagoras, were burned, and the following decades witnessed several expulsions of philosophers from the city. In comedies of the period, the discipline was held up for ridicule.

The hostility toward philosophy was one aspect of a wider Roman sense of unease about changing mores. Cato, a "new man" (without senatorial ancestors) elected consul (195) and censor (184), represented himself as an austere champion of the old ways and exemplifies the hardening Roman reaction against change under foreign influence. Although Cato knew Greek and could deploy allusions to Greek literature, he advised his son against too deep a knowledge of the literature of that "most worthless and unteachable race." Cato despised those senatorial colleagues who ineptly imitated Greek manners. He asserted the value of Latin culture in the role of father of Latin prose literature. His treatise on estate management, the De agricultura (c. 160), has survived with its rambling discourse about how to run a 200-iugera (124-acre) farm, including advice on everything from buying and selling slaves to folk medicine. Cato's greater, historical work, the Origines, survives only in fragments: it challenged the earlier Roman histories insofar as it was written in Latin and emphasized the achievements of the Italian peoples rather than those of the few great senatorial families of Rome (whose names were conspicuously omitted).

Elected censor in 184 to protect Roman mores, Cato vowed "to cut into pieces and burn like a hydra all luxury and voluptuousness." He expelled seven men from the Senate on various charges of immorality and penalized through taxation the acquisition of such luxuries as expensive clothing, jewelry, carriages, and fancy slaves. The worry about luxury was widespread, as evidenced by the passage of a series of sumptuary laws supported by Cato. During the depths of the Second Punic War the Oppian law (215) was passed to meet the financial crisis by re-

Hostility to philosophy

Literature

stricting the jewelry and clothing women were allowed to wear; in 195, after the crisis, the law was repealed despite Cato's protests. Later sumptuary laws were motivated not by military crisis but by a sense of the dangers of luxury; the Orchian Jaw (182) limited the lavishness of banquets; the Fannian law (161) strengthened the Orchian provisions, and the Didian law (143) extended the limits to all Italy. A similar sense of the dangers of wealth may also have prompted the lex Vecconia (169), which prohibited Romans of the wealthiest class from naming women as being in their wills.

The laws and censorial actions ultimately could not restrain changes in Roman mores. Economic conditions had been irreversibly altered by conquest; the magnitude of conspicuous consumption is suggested by a senatorial decree of 161 that restricted the weight of silver tableware in a banquet to 100 pounds-10 times the weight for which Publius Cornelius Rufinus was punished in 275. Moreover, the very competitiveness that had traditionally marked the senatorial aristocracy ensured the spread of cultural innovations and new forms of conspicuous consumption among the elite. In contrast to the austere Cato, other senators laid claim to prestige by collecting Greek art and books brought back by conquering armies, by staging plays modeled on Greek drama, and by commissioning literary works, public buildings, and private sculptural monuments in a Greek style.

Whereas the influence of Greek high culture was felt principally in a small circle of elite Romans who had the wealth to acquire Greek art and slaves and the leisure and education to read Greek authors, the influence of religions from the eastern Mediterranean was perceived as potentially subversive to a far wider audience. Polybius praised the Romans for their conscientious behaviour toward the gods. Romans were famous for their extreme precision in recitation of vows and performance of sacrifices to the gods, meticulously repeating archaic words and actions centuries after their original meanings had been forgotten. Guiding these state cults were priestly colleges; and priestly offices such as of pontifix and augur were filled by senators, whose dominance in politics was thus replicated in civic religion.

In earlier centuries Rome's innate religious conservatism was, however, counterbalanced by an openness to foreign gods and cults. As Rome incorporated new peoples of Italy into its citizen body, it accepted their gods and religious practices. Indeed, among the most authoritative religious texts, consulted in times of crisis or doubt, were the prophetic Sibylline Books, written in Greek and imported from Cumae. The receptivity appears most pronounced in the 3rd century: during its final decades temples were built in the city for Venus Erycina from Sicily and for the Magna Mater, or Great Mother, from Pessinus in Anatolia; games were instituted in honour of the Greek god Apollo (212) and the Magna Mater after the war. The new cults were integrated into the traditional structure of the state religion, and the "foreignness" was controlled (i.e., limits were placed on the orgiastic elements in the cult of the Great Mother performed by her eunuch priests).

The openness, never complete or a matter of principle, tilted toward resistance in the early 2nd century. In 186 Roman magistrates, on orders from the Senate, brutally suppressed Bacchic worship in Italy. Associations of worshipers of the Greek god Bacchus (Dionysus) had spread across Italy to Rome. Their members, numbering in the thousands, were initiated into secret mysteries, knowledge of which promised life after death; they also engaged in orgiastic worship. The secrecy soon gave rise to reports of the basest activities, such as uncontrolled drinking, sexual promiscuity, forgery of wills, and poisoning of kin. According to Livy, more than 7,000 were implicated in the wrongdoing; many of them were tried and executed, and the consuls destroyed the places of Bacchic worship throughout Italy. For the future, the (extant) senatorial decree prohibited men from acting as priests in the cult, banned secret meetings, and required the praetor's and Senate's authorization of ceremonies to be performed by gatherings of more than five people. The terms of the decree provide a sense of what provoked the harsh senatorial reaction. It was not that the Bacchic cult spread heretical beliefs about the gods—Roman civic religion was never based on theological doctrine with pretensions to exclusive truth; rather, the growing secret cult led by male priests the properties of the properties of the properties of senators in state religion. The decree did not aim to ellminate Bacchic worship but to bring it under the supervision of senatoral authorities. The following centuries witnessed sporadic official actions against foreign cults; it happens to be recorded that a praetor of 139 removed private altars built in public areas and expelled astrologers and Jews from the city. Thus the reaction to eastern religions paralleled that to Greek philosophy; both were perceived as new ways of thinking that threatened to undermine traditional mores and the relations of authority implicit in them.

Economy and society. It seems certain that the economy and society of Italy were transformed in the wake of Rome's conquest of the Mediterranean world, even though the changes can be described only incompletely and imprecisely, owing to the dearth of reliable information for the preceding centuries. Romans of the 1st century BC believed that their ancestors had been a people of small farmers in an age uncorrupted by wealth. Even senators who performed heroic feats were said to have been of modest means-men such as Lucius Quinctius Cinncinatus, who was said to have laid down his plow on his tiny farm to serve as dictator in 458 BC. Although such legends present an idealized vision of early Rome, it is probably true that Latium of the 5th and 4th centuries was densely populated by farmers of small plots. Rome's military strength derived from its superior resources of manpower levied from a pool of small landowning citizens (assidui). A dense population is also suggested by the emigration from Latium of scores of thousands as colonists during the 4th and 3rd centuries. The legends of senators working their own fields seem implausible, but the disparity in wealth was probably much less noticeable than in the late republic. The 4th-century artifacts uncovered by archaeologists display an overall high quality that makes it difficult to distinguish a category of luxury goods from the pottery and terra-cottas made for common use.

the pottery and terra-cottas made for common use. War and conquest altered this picture, yet certain fundamental features of the economy remained constant. Until its fall, the Roman Empire retained agriculture as the basis of its economy, with probably four-fifths of the population tilling the soil. This great majority continued to be needed in food production because there were no labour-saving technological breakthroughs. The power driving agricultural and other production was almost entirely supplied by humans and animals, which set modest limits to economic growth. In some areas of Italy, such as the territory of Capena in southern Etruria, archaeologists have found traditional patterns of settlement and land division continuing from the 4th to the end of the 1st century—evidence that the Second Punic War and the following decades did not bring a complete break with the past.

Economic change came as a result of massive population shifts and the social reorganization of labour rather than technological improvement. The Second Punic War, and especially Hannibal's persistent presence in Italy, inflicted a considerable toll, including loss of life on a staggering scale, movement of rural populations into towns, and destruction of agriculture in some regions. Although the devastation has been overestimated by some historians, partial depopulation of the Italian countryside is evident from the literary and archaeological records: immediately after the war enough land stood vacant in Apulia and Samnium to settle between 30,000 and 40,000 of Scipio's veterans, while areas of Apulia, Bruttium, southern Campania, and south-central Etruria have yielded no artifacts indicating settlement in the postwar period.

Populations have been known to show great resilience in recovering from wars, but the Italian population was given no peace after 201. In subsequent decades Rome's annual war effort required a military mobilization unmatched in history for its duration and the proportion of the population involved. During the 150 years after Hannibal's surrender, the Romans regularly fielded armies of more than 100,000 men, requiring on average about 13

A people of small farmers

Openness to foreign cults percent of the adult male citizens each year. The attested casualties from 200 to 150 add up to nearly 100,000. The levy took Roman peasants away from their land. Many never returned. Others, perhaps 25,000, were moved in the years before 173 from peninsular Italy to the colonies of the Po valley. Still others, in unknown but considerable numbers, migrated to the cities. By the later 2nd century some Roman leaders perceived the countryside to be depopulated.

To replace the peasants on the land of central and southern Italy, slaves were imported in vast numbers. Slavery was well established as a form of agricultural labour before the Punic Wars (slaves must have produced much of the food during the peak mobilization of citizens from 218 to 201). The scale of slavery, however, increased in the 2nd and 1st centuries as a result of conquests. Enslavement was a common fate for the defeated in ancient warfare: the Romans enslaved 5,000 Macedonians in 197; 5,000 Histri in 177; 150,000 Epirotes in 167; 50,000 Carthaginians in 146; and in 174 an unspecified number of Sardinians, but so many that "Sardinian" became a byword for "cheap" slave. These are only a few examples for which the sources happen to give numbers. More slaves flooded into Italy after Rome destabilized the eastern Mediterranean in 167 and gave pirates and bandits the opportunity to carry off local peoples of Anatolia and sell them on the block at Delos by the thousands. By the end of the republic Italy was a thoroughgoing slave society with well over one million slaves, according to the best estimates. No census figures give numbers of slaves, but slaveholding was more widespread and on a larger scale than in the antebellum American South, where slaves made up about one-third of the population. In effect, Roman soldiers fought in order to capture their own replacements on the land in Italy, although the shift from free to servile labour was only a partial one.

The influx of slaves was accompanied by changes in patterns of landownership, as more Italian land came to be concentrated in fewer hands. One of the punishments meted out to disloyal allies after the Second Punic War was confiscation of all or part of their territories. Most of the ager Campanus and part of the Tarentines' landsperhaps two million acres in total-became Roman ager publicus (public land), subject to rent. Some of this property remained in the hands of local peoples, but large tracts in excess of the 500-iugera limit were occupied by wealthy Romans, who were legally possessores (i.e., in possession of the land, although not its owners) and as such paid a nominal rent to the Roman state. The trend toward concentration continued during the 2nd century, propelled by conquests abroad. On the one side, subsistance farmers were always vulnerable in years of poor harvests that could lead to debt and ultimately to the loss of their plots. The vulnerability was exacerbated by army service, which took peasants away from their farms for years at a time. On the other side, the elite orders were enriched by the booty from the eastern kingdoms on a scale previously unimaginable. Some of the vast new wealth was spent on public works and on new forms of luxury and part was invested to secure future income. Land was the preferred form of investment for senators and other honourable men: farming was regarded as safer and more prestigious than manufacture or trade. For senators, the opportunities for trade were limited by the Claudian law of 218 prohibiting them from owning large ships. Wealthy Romans thus used the proceeds of war to buy out their smaller neighbours. As a result of this process of acquisition, most senatorial estates consisted of scattered small farms. The notorious latifundia, the extensive consolidated estates. were not widespread. Given the dispersion of the property, the new landlord was typically absentee. He could leave the working of the farms in the hands of the previous peasant owners as tenants, or he could import slaves.

peasant owners as tenants, or the could import suspensible the estate-owning class of this period come from Cato's De agricultura. Although based on Greek handbooks discussing estate management, it reflects the assumptions and thinking of a 2nd-century senator. Cato envisaged a medium-sized, 200-ingera farm with a permanent staff of 11 slaves. As

with other Roman enterprises, management of the farm was left to a slave bailiff, who was helped by his slave wife. While Cato, like the later agricultural writers Varro and Lucius Junius Columella, assumed the economic advantage of a slave work force, historians today debate whether estates worked by slaves were indeed more profitable than smaller peasant farms. Cato had his slaves use much the same technology as the peasants, although a larger estate could afford large processing implements, such as grape and olive crushers, which peasants might have to share or do without. Nor did Cato bring to bear any innovative management advice; his suggestions aimed to maximize profits by such commonsense means as keeping the slave work force occupied all year round and buying chean and selling dear. Nevertheless, larger estates had one significant advantage in that the slave labour could be bought and sold and thus more easily matched to labour needs than was possible on small plots worked by peasant families.

Cato's farm was a model representing one aspect of the reality of the Italian countryside. Archaeologists have discovered the villas characteristic of the Catenian estate beginning to appear in Campania in the 2nd century and later in other areas. The emergence of slave agriculture did not exclude the continuing existence in the area of peasants as owners of marginal land or as casual day labourers or both. The larger estates and the remaining peasants formed a symbiotic relationship, mentioned by Cato: the estate required extra hands to help during peak seasons, while the peasants needed the extra wages from day labour to supplement the meagre production of their plots. Yet in many areas of Italy the villa system made no inroads during the republic, and traditional peasant farming continued. Other areas, however, underwent a drastic change: the desolation left by the Second Punic War in the central and southern regions opened the way for wealthy Romans to acquire vast tracts of depopulated land to convert to grazing. This form of extensive agriculture produced cattle, sheep, and goats, herded by slaves. These were the true latifundia, decried as wastelands by Roman imperial authors such as the elder Pliny.

The marketplace took on a new importance as both the Catonian estate and the *latifundium* aimed primarily to produce goods to sell for a profit. In this sense, they represented a change from peasant agriculture, which aimed above all to feed the peasant's family. The buyers of the new commodities were the growing cities—another facet of the complex economic transformation. Rome was swelled by migrants from the countryside and became the largest city of preindustrial Europe, with a population of about one million in the imperial era; other Italian cities grew to a lesser extent.

The mass of consumers created new, more diverse demands for foodstuffs from the countryside and also for manufactured goods. The market was bipolar, with the poor of the cities able to buy only basic foodstuffs and a few plain manufactured items and the rich demanding increasingly extravagant luxury goods. The limitations of the poor are reflected in the declining quality of humble temple offerings. The craftsmen and traders produced mainly for the rich minority. The trading and artisanal enterprises in Rome were largely worked by slaves and freedmen imported to Rome by the wealthy. Although honourable, freeborn Romans considered it beneath their dignity to participate directly in these businesses, they willingly shared in the profits through ownership of these slaves and through collection of rents on the shops of humbler men. Thus, manufacturing and trading were generally small-scale operations, organized on the basis of household or family. Roman law did not recognize business corporations with the exception of publican companies holding state contracts; nor were there guilds of the medieval type to organize or control production. Unlike some later medieval cities, Rome did not produce for export to support itself; its revenues came from booty, provincial taxes, and the surplus brought from the countryside to the city by aristocratic Roman landlords. Indeed, after 167 provincial revenues were sufficient to allow for the abolition of direct

taxes on Roman citizens.

Building projects were the largest enterprises in Rome

and offered freeborn immigrants jobs as day labourers. In addition to the private building needed to house the growing population, the early and middle 2nd century witnessed public building on a new scale and in new shapes. The leading senatorial families gained publicity by sponsoring major new buildings named after themselves in the Forum and elsewhere. The Basilica Porcia (built during Marcus Porcius Cato's censorship of 184), the Basilica Aemilia et Fulvia (179), and the Basilica Sempronia (170-169) were constructed out of the traditional tufa blocks but in a Hellenized style.

New infrastructures were required to bring the necessities of life to the growing population. The Porticus Aemilia (193), a warehouse of 300,000 square feet on the banks of the Tiber, illustrates how the new needs were met with a major new building technology, concrete construction. Around 200 BC in central Italy it was discovered that a wet mixture of crushed stone, lime, and sand (especially a volcanic sand called pozzolana) would set into a material of great strength. This construction technique had great advantages of economy and flexibility over the traditional cut-stone technique: the materials were more readily available, the concrete could be molded into desired shapes, and the molds could be reused for repetitive production. The Porticus Aemilia, for example, consisted of a series of roughly identical arches and vaults-the shapes so characteristic of later Roman architecture. The new technology also permitted improvements in the construction of the aqueducts needed to increase the city's water supply.

The economic development outside of Rome encompassed some fairly large-scale manufacturing enterprises and export trade. At Puteoli on the Bay of Naples the ironworks industry was organized on a scale well beyond that of the household, and its goods were shipped beyond the area. Puteoli flourished during the republic as a port city, handling imports destined for Rome as well as exports of manufactured goods and processed agricultural products. In their search for markets, the large Italian landowners exported wine and olive oil to Cisalpine Gaul and more distant locations. Dressel I amphoras, the threefoot pottery jars carrying these products, have been found in substantial quantities in Africa and Gaul. Yet the magnitude of the economic development should not be exaggerated: the ironworks industry was exceptional, and most pottery production continued to be for local use.

Major social changes and dislocations accompanied the demographic shifts and economic development. Relations between rich and poor in Rome had traditionally been structured by the bond existing between patron and client. In the daily morning ritual of the salutatio, humble Romans went to pay their respects in the houses of senators. who were obligated to protect them. These personal relationships lent stability to the social hierarchy. In the 2nd century, however, the disparity between rich and poor citizens grew. While this trend increased the personal power of individual senators, it weakened the social control of the elite as a whole; the poor had become too numerous to be controlled by the traditional bond of patron and client.

Until the end of the 170s the impoverishment of humble citizens had been counterbalanced to some extent by the founding of colonies, because dispossessed peasants were given new lands in outlying regions. During the middle decades of the 2nd century, however, colonization ceased, and the number of dispossessed increased, to judge from the declining number of small landowners in the census. The problem created by a growing proletariat was recognized by a few senators. Gaius Laelius, probably during his consulship of 140, proposed a scheme of land redistribution to renew the class of smallholders, but it was rejected by the Senate.

Some of the dispossessed went to Rome, where, together with the increasing numbers of slaves and freedmen, they contributed to the steadily growing population. This density led to the miseries associated with big cities, which were exacerbated by the absence of regulation. By 200 BC the pressure of numbers necessitated apartment buildings of three stories. Constructed without a building code, these structures were often unsound and prone to collapse. Moreover, closely placed and partly made of wood, they were tinderboxes, ever ready to burst into flame. The population density also increased the vulnerability to food shortages and plagues. In 188 fines were levied against dealers for withholding grain, attesting to problems of supply. The 180s and 170s witnessed repeated outbreaks of plague. The state, which could use its power to increase the grain supply, was helpless against diseases. In general, the republican state developed few new institutions to manage the growing urban problems: until the reign of Augustus matters were left to the traditional authority of urban magistrates, who were unaided by a standing fire brigade or police force. Consequently, Rome held an increasing potential for social discontent and conflicts without a corresponding increase in means of control.

The family, regarded by Romans as a mainstay of the social order, also was affected by the wider economic and social transformations of the 2nd century BC. In the early republic the family had formed a social, economic, and legal unity. The woman generally married into her husband's family and came under his legal authority (or that of his father if he was still alive), and her dowry merged with the rest of the estate under the ownership of the husband. The husband managed the family's affairs outside the house, while the wife was custodian within. Marriage was an arrangement for life; divorces were rare and granted only in cases of serious moral infractions, such as adultery or wine-tippling on the part of the wife. The children of the couple were subject to the father's nearly absolute legal powers (patria potestas), including the power of life and death, corporal punishment, and a monopoly of ownership of all property in the family. The father's power lasted until his death or, in the case of a daughter, until her marriage. When the father died, his sons, his wife, and his unmarried daughters became legally independent, and all inherited equal shares of the family's property unless otherwise specified in a will. The imperial authors idealized the early republic as a time of family harmony and stability, which was lost through the corruption of the later republic.

When family life emerged into the full light of history in the 2nd century BC, it had changed in significant ways. A form of marriage, commonly called "free marriage," becoming prevalent. Under this form, the wife no longer came into her husband's power or property regime but remained in that of her father; upon her father's death she became independent with rights to own and dispose of property. But she was not a member of the family of her husband and children and had no claim to inheritance from them, even though she lived with them in the same house. Because many women inherited part of their fathers' estates, they could use their independent fortunes to exert influence on husbands, children, and people outside the house. In the same period divorce became far more common; moral infractions were no longer needed to justify divorce, which could be initiated by either side. Frequent divorce and remarriage went hand in hand with the separation of marital property. There is plausibility in the suggestion that these changes were brought on by a desire of the women's fathers to avoid having their daughters' portions of the larger family estates slip irrevocably into the hands of their husbands. Although the changes in law and practice were not motivated by any movement to emancipate women, the result was that propertied women of the late republic, always excluded from the public sphere of male citizens, came to enjoy a degree of freedom and social power unusual before the 20th century

Slaves came to permeate the fabric of family life and altered relationships within the household. They were regularly assigned the tasks of child-rearing, traditionally the domain of the mother, and of education, until then the responsibility of both the father and the mother. Whereas children had acquired the skills needed for their future roles by observing their parents in a kind of apprenticeship, in wealthy houses sons and, to a lesser extent, daughters were now given a specialized education by slaves or freedmen. The management of aristocratic households was entrusted to slaves and freedmen, who served as secretaries, accountants, and managers. The wife was no longer needed as custodian of the household, though domestic marriage"

Social changes guardianship remained an element in the idealization of her role. Later moralists attributed a decline in Roman virtue and discipline to the intrusion of slaves into familial relationships and duties.

Rome and Italy. During the middle republic the peoples of Italy's began to coalesce into a fairly homogeneous and cohesive society. Polybius, however, does not give insight into this process, because, living in Rome, he too little appreciated the variety of Italian cultures under Roman sway, from the Gallic peoples in the mountains of the north to the urbane Greeks on the southern coasts. Other evidence, though meagre, nonetheless suggests several processes that contributed to the increasing cohesion.

First, the Romans built a network of roads that facilitated communication across Italy. As stated above, the first great road was the Via Appia, which was Islad out by Appius Claudius Caecus in 312 to connect Rome to Capua. Between the First and Second Punic Wars roads were built to the north: the Via Aurelia (2417) along the Tyrthenian coast, the Via Flaminia (220) through Umbria, and the Via Clodia through Etruria. Then, in the 2nd century, Roman presence in the Po valley was consolidated by the Via Aemilia (187) from Ariminum on the Adriatic coast to the Latin colony of Placentia and by the Via Postumia (148) running through Transpadane Gaul to Aquileia in the east and Genua in the west.

Second, internal migration-Italians moving to Rome and Romans being sent to Latin colonies throughout Italy-promoted social and cultural homogeneity. Some of these colonies were set alongside existing settlements; others were founded on new sites. The colonies re-created the physical and social shape of Rome; the town plans and architecture, with forums including temples to Jupiter, were modeled on those of Rome. The imposition of a Latin colony on the Greek city of Paestum in Lucania (273) entailed the implantation of a Roman-style forum in the centre of the existing city in a way that rudely intruded on the old sanctuary of Hera. The initial system governing the distribution of land to Latin colonists aimed to replicate the Roman social hierarchy differentiated by wealth: it is recorded of the colonists sent to Aquileia in 181 that the 3,000 infantrymen each received 50 iugera (31 acres), the centurions 100 jugera (62 acres), and the cavalrymen 140 iugera (86 acres). The unifying effect of the colonies is evident in Paestum's notable loyalty to Rome during the Second Punic War.

Latin

colonies

in Italy

Third, although Rome did not seek to govern Italy through a regular administration, it influenced local affairs through formal bonds of personal friendship (amicitia) and hospitality (hospitium) between the Roman elite and their local counterparts. Through these ties the leading men of Italy were gradually drawn into the ruling class in Rome. The most prominent example of the 2nd century is that of Gaius Marius of Arpinum, who, only two generations after his town had received full citizen rights, began his meteoric senatorial career under the patronage of the great Roman nobles, the Metelli.

Fourth, the regular military campaigns brought together Romans and Italians of all classes under the command of Roman magistrates. The Italian troops appear to have been levied in a fashion similar to the one used for the Romans, which would have required a Roman-style census as a means of organizing the local citizenies. In the absence of direct administration, military service was the context in which Italians most regularly experienced Roman authority.

Fifth, Rome occasionally deployed its troops in Italy to maintain social order. Rome suppressed an uprising of serfs in Eruscan Volsimi in 265 and a sedition in Patavium in 175. When the massive influx of slaves raised the spectre of rebellions across Italy, Roman troops were deployed to put down uprisings: in 195, 5,000 slaves were executed in Latin Setia; in 196 the practor was sent with his urban legion to Etruria to fight a pitched battle in which many slaves were killed; and the practor of 185 dealt with rebellious slaves in Apulia, condemning 7,000 to death. The later slave revolt in Sicily (c. 135–132) was not contained so effectively and grew to include perhaps 70,000. The slaves defeated the first consular army sent

in 134; the efforts of two more consuls were required to restore order. The revolts, unusual for their frequency and size, are not to be explained by abolitionist programs (nonexistent in antiquity) nor by maltreatment. The causes lay in the enslavement and importation of entire communities with their native leadership and in the free reign given to slave shepherds who roamed armed around the countryside serving as communication lines between slave plantations. These uprisings made it clear that the social fabric of Italy, put under stress by the transformations brought about by conquest, had to be protected by Roman force.

While the exercise of Roman authority and force was sometimes resented by Italians, Rome's power made its mores and culture worthy of imitation. The Latin language and Roman political institutions slowly spread. A request from the old Campanian city of Cumae in 180 that it be allowed to change its official language from Oscan to Latin was a sign of things to come. (R.P.Sa.)

THE LATE REPUBLIC (133-31 BC)

The aftermath of the victories. The fall of Carthage and Corinth did not even mark a temporary end to warfare. War and military glory were an essential part of the Roman aristocratic ethos and, hence, of Roman political life. Apart from major wars still to come, small wars on the frontiers of Roman power-never precisely fixed-continued to provide an essential motive in Roman history; in Spain, Sardinia, Illyria, and Macedonia, barbarians could be defeated and triumphs won. Thus the limits of Roman power were gradually extended and the territories within them pacified, while men of noble stock rivaled the virtus of their ancestors and new men staked their own competing claims, winning glory essential to political advancement and sharing the booty with their officers and soldiers. Cicero could still depict it as a major disgrace for Lucius Piso (consul; 58 BC) that he had won no triumph in the traditionally "triumphal" province of Macedonia. Nonetheless, the coincidence of the capture of Corinth and Carthage was even in antiquity regarded as a turning point in Roman history: it was the end (for the time being) of warfare against civilized powers, in which the danger was felt to be greater and the glory and the booty were superior to those won against barbarian tribes. Changes in provincial administration. The first immediate effect was on the administration of the empire. The military basis of provincial administration remained: the governor (as he is called) was in Roman eyes a commander with absolute and unappealable powers over all except Roman citizens, within the limits of the territory (his provincia) assigned to him (normally) by the Senate. He was always prepared-and in some provinces expectedto fight and win. But it had been found that those unlimited powers were often abused and that Senate control could not easily be asserted at increasing distances from Rome. For political and perhaps for moral reasons, excessive abuse without hope of a remedy could not be permitted. Hence, when the decision to annex Carthage and Macedonia had been made in principle (149 BC), a permanent court (the quaestio repetundarum) was established at Rome to hear complaints against former commanders and, where necessary, to assure repayment of illegal exactions. No penalty for offenders was provided, and there was no derogation from the commander's powers during his tenure; nevertheless, the step was a landmark in the recognition of imperial responsibility, and it was also to have important effects on Roman politics.

Another result of the new conquests was a major administrative departure. When Africa and Macedonia became provinciae to be regularly assigned to commanders, it was decided to break with precedent by not increasing the number of senior magistrates (praetors). Instead, prorogation—the device of leaving a magistrate in office promagistrate, in place of a magistrate, bate his term had expired, which had hitherto been freely used when emergencies had led to shortages of regular commanders—was established as part of the administrative system: thenceforth, every year at least two praetors would have to be retained as promagistrates. This was the beginning of the

Recognition of imperial responsibility

dissociation between urban magistracy and foreign command that was to become a cardinal principle of the system of Sulla and of the developed Roman Empire.

Social and economic ills. It is not clear to what extent the temporary end of the age of major wars helped to produce the crisis of the Roman Republic. The general view of thinking Romans was that the relaxation of external pressures led to internal disintegration. (This has happened in other states, and the view is not to be lightly dismissed.) Moreover, the end of large-scale booty led to economic recession in Rome, thus intensifying poverty and discontent. But the underlying crisis had been building up over a long period.

The reform movement of the Gracchi (133-121 BC). From the state's point of view, the chief effect was a decline in military manpower. The minimum property qualification for service was lowered and the minimum age (17) ignored; resistance became frequent, especially to the distant and unending guerrilla war in Spain.

The program and career of Tiberius Sempronius Gracchus. Tiberius Gracchus, grandson of Scipio Africanus and son of the Gracchus who had conquered the Celtiberi and treated them well, was quaestor in Mancinus' army when it faced annihilation; on the strength of his family name, he personally negotiated the peace that saved it. When the Senate-on the motion of his cousin Scipio Aemilianus, who later finished the war-renounced the peace, Tiberius felt aggrieved; he joined a group of senior senators hostile to Aemilianus and with ideas on reform. Elected tribune for 133, in Scipio's absence, Tiberius attempted to find a solution for the social and military crisis, with the political credit to go to himself and his backers. Tiberius had no intention of touching private property; his idea was to enforce the legal but widely ignored limit of 500 iugera (309 acres) on occupation of public land and to use the land thus retrieved for settling landless citizens, who would both regain a secure living and be liable for service. The slave war in Sicily, which had lasted several years and had threatened to spread to Italy, had underlined both the danger of using large numbers of slaves on the land and the need for a major increase in military citizen manpower.

Tiberius' proposal was bound to meet with opposition in the Senate, which consisted of large landowners. On the advice of his eminent backers, he took his billwhich made various concessions to those asked to obey the law and hand back excess public land-straight to the Assembly of the Plebs, where it found wide support. This procedure was not revolutionary; bills directly concerning the people appear to have been frequently passed in this way. But his opponents persuaded another aristocratic tribune, Marcus Octavius, to veto the bill. Tiberius tried the constitutional riposte; an appeal to the Senate for arbitration. But the Senate was unwilling to help, and Octavius was unwilling to negotiate over his vetoan action apparently unprecedented, though not (strictly speaking) unconstitutional. Tiberius had to improvise a way out of the impasse. He met Octavius' action with a similarly unprecedented retort and had Octavius deposed by the Assembly. He then passed his bill in a less conciliatory form and had himself, his father-in-law, and his brother appointed commissioners with powers to determine boundaries of public land, confiscate excess acreage, and divide it in inalienable allotments among landless citizens. As it happened, envoys from Pergamum had arrived to inform the Senate that Attalus III had died and made the Roman people his heirs (provided the cities of his kingdom were left free). Tiberius, at whose house the envoys were lodging, anticipated Senate debate and had the inheritance accepted by the people and the money used to finance his agrarian schemes.

Tiberius' opponents now charged him with aiming at tyranny, a charge that many may well have believed: redistribution of land was connected with demagogic tyranny in Hellenistic states, and Tiberius' subsequent actions had been high-handed and beyond the flexible borderline of what was regarded as mos majorum (constitutional custom). Fearing prosecution once his term in office was over, he now began to canvass for a second tribunateanother unprecedented act, bound to reinforce fears of tyranny. The elections took place in an atmosphere of violence, with nearly all his tribunician colleagues now opposed to him. When the consul Publius Scaevola, on strict legal grounds, refused to act against him, Publius Scipio Nasica, the chief pontiff, led a number of senators and their clients to the Assembly, and Tiberius was killed in a resulting scuffle. Widespread and bloody repression followed in 132. Thus political murder and political martyrdom were introduced into Roman politics.

The land

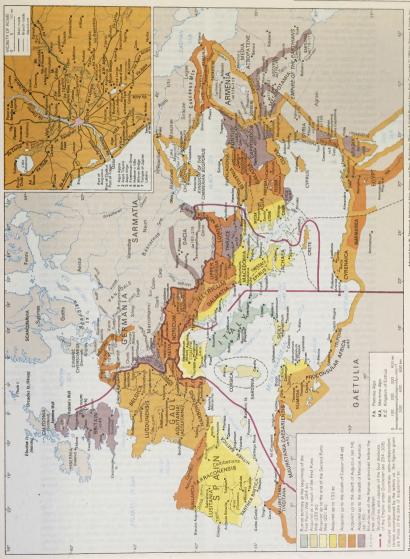

commis-

sion

The land commission, however, was allowed to continue because it could not easily be stopped. Some evidence of its activities survives. By 129, perhaps running out of available land held by citizens, it began to apply the Gracchan law to public land held by Italian individuals or communities. This had probably not been envisaged by Tiberius, just as he did not include noncitizens among the beneficiaries of distributions. The Senate, on the motion of Scipio Aemilianus, upheld the Italians' protests. transferring decisions concerning Italian-held land from the commission to a consul. This seriously hampered the commission's activities. Marcus Fulvius Flaccus, chairman of the commission and consul in 125, tried to solve the problem by offering the Italians the citizenship (or alternatively the right to appeal against Roman executive acts to the Roman people) in return for bringing their holdings of public land under the Gracchan law. This aroused fears of uncontrollable political repercussions. Flaccus was ordered by the Senate to fight a war in southern France (where he gained a triumph) and had to abandon his proposal. There is no sign of widespread Italian interest in it at this time, though the revolt of the Latin colony Fregellae (destroyed 125) may be connected with its failure.

The program and career of Gaius Sempronius Gracchus. In 123 Gaius Gracchus, a younger brother of Tiberius, became tribune. He had served on Tiberius' land commission and had supported Flaccus' plan. Making the most of his martyred brother's name, Gaius embarked on a scheme of general reform in which, for the first time in Rome, Greek theoretical influences may be traced. Among many reforms-including provision for a stable and chean wheat price and for the foundation of colonies (one on the site of Carthage), to which Italians were admitted-two major ideas stand out: to increase public revenues (both from the empire and from taxes) and pass the benefit on to the people; and to raise the wealthiest nonsenators (particularly the equites, holders of the "public horse"-who received state financial aid for the purchase and upkeep of their horses-and next to senators in social standing) to a position from which, without actually taking part in the process of government, they could watch over senatorial administration and make it more responsible. The idea was evoked by Tiberius' death. As early as 129 a law compelled senators to surrender the "public horse" (which hitherto they had also held) and possibly in other ways enhanced the group consciousness and privileges of the equites. Regarding the increase of public revenue, Gaius put the publicani (public contractors, hitherto chiefly concerned with army and building contracts and with farming minor taxes) in charge of the main tax of Asia-a rich province formed out of Attalus' inheritance, which would henceforth provide Rome with the major part of its income. This was expected both to reduce senatorial corruption and to improve efficiency. Gaius also put eminent nonsenators (probably defined by wealth, but perhaps limited to the equites, or equestrian class) in charge of the quaestio repetundarum, whose senatorial members had shown too much leniency to their colleagues, and he imposed severe penalties on senators convicted by that court. Finally, in a second tribunate, he hoped to give citizenship to Latins and Latin rights to other Italians, with the help of Flaccus who, though a distinguished former consul, took the unique step of becoming tribune. But a consul and a tribune of 122 together persuaded the citizen voters that it was against their interests to share the privileges of citizenship: the bill was defeated, and Gaius failed in his attempt to be re-elected once more. In 121, preparing (as private citizens) to use force to oppose the cancellation of some of their laws, Gaius and Flaccus were killed in a riot, and many of their followers were executed.

Plan to settle landless citizens

During the next decade the measures benefiting the people were largely abolished, though the Gracchan land distributions, converted into private property, did temporarily strengthen the Roman citizen peasantry. The provisions giving power to wealthy nonsenators could not be touched, for political reasons, and they survived as the chief effect of Gaius' tribunates. The court seems to have worked better than before, and, during the next generation, several other standing criminal courts were instituted, as were occasional ad hoc tribunals, always with the same class of jurors. In 106 a law adding senators to the juries

was passed, but it remained in force for only a short time. The republic (c. 121-91 BC). War against Jugurtha. Since Roman historians were no more interested in polities than (on the whole) in social or economic developments, the struggles of the aristocratic families must be pieced together from chance information. It would be mere paradox to deny the importance in republican Rome, as in better known aristocratic republics, of family feuds, alliances, and policies, and parts of the picture are known-e.g., the central importance of the family of the Metelli, prominent in politics for a generation after the Gracchi and dominant for part of that time. In foreign affairs the client kingdom of Numidia-loyal ever since its institution by Scipio Africanus-assumed quite unwarranted importance when a succession crisis developed there soon after 120, as a bastard, Jugurtha, relying on superior ability and aristocratic Roman connections, sought to oust his two legitimate brothers from their shares of the divided kingdom. Rome's usual diplomatic methods failed to stop Jugurtha from disposing of his brothers, but the massacre of Italian settlers at Cirta by his soldiers forced the Senate to declare war (112). The war was waged reluctantly and ineffectively, with the result that charges of bribery were freely bandied about by demagogic tribunes taking advantage of suspicion of aristocratic political behaviour that had smoldered ever since the Gracchan crisis. Significantly, some eminent men, hated from those days, were now convicted of corruption. The Metelli, however, emerged unscathed, and Ouintus Metellus, consul in 109, was entrusted with the war in Africa. He waged it with obvious competence but failed to finish it and thus gave Gaius Marius, a senior officer, his chance,

The career of Gaius Marius. Marius, born of an equestrian family at Arpinum, had attracted the attention of Scipio Aemilianus as a young soldier and, by shrewd political opportunism, had risen to the praetorship and married into the patrician family of the Julii Caesares. Though Marius had deeply offended the Metelli, once his patrons, his considerable military talents had induced Quintus Metellus to take him to Africa as a legatus. Marius intrigued against his commander in order to gain a consulship; he was elected (chiefly with the help of the equites and antiaristocratic tribunes) for 107 and was given charge of the war by special vote of the people. He did little better than Metellus had, but in 105 his quaestor Lucius Sulla, in delicate and dangerous negotiations, brought about the capture of Jugurtha, opportunely winning the

During the preceding decade a serious threat to Italy had developed in the north. Starting in 125, several Roman commanders (Marcus Flaccus has been noted) had fought against Ligurian and Gallic tribes in southern France and had finally established a Roman sphere of influence there: a road had been built linking Italy with Spain, and some garrison posts probably secured it; finally, a colony was settled at Narbonne, an important road junction (c. 118). in southern But, unwilling to extend administrative responsibilities, the Senate had refused to establish a regular provincia. Then some migrating German tribes, chief of them the Cimbri, after defeating a Roman consul, invaded southern France, attracting native sympathy and finding little effective Roman opposition. Two more consular armies suffered defeat, and in October 105 a consul and proconsul with their forces were destroyed at Orange. There was

war for Marius and Rome.

panic in Rome, allayed only by the firm action of the other consul, Publius Rutilius Rufus. At this moment news of Marius' success in Africa arrived. and he was at once dispensed from legal restrictions and again elected consul for 104. After a brilliant triumph that restored Roman morale, he took over the army prepared and trained by Rutilius. He was reelected consul year after year, while the German tribes delayed attacking Italy. Finally, in 102-101, he annihilated them at Aquae Sextiae (Aix-les-Bains) and, with his colleague, Quintus Catulus, on the Campi Raudii (near the Po delta), Another triumph and a sixth consulship (in 101) were his reward.

In his first consulship, Marius had taken a step of great (and probably unrecognized) importance: aware of the difficulties long endemic in the traditional system of recruitment, he had ignored property qualifications in enrolling his army and, as a result, had recruited ample volunteers among men who had nothing to lose. This radical solution was thenceforth generally imitated, and conscription became confined to emergencies (such as the Social and Civil wars). He also enhanced the importance of the legionary eagle (the standard), thus beginning the process that led to each legion's having a continuing corporate identity. At the same time, Rutilius introduced arms drill and reformed the selection of senior officers. Various tactical reforms in due course led to the increasing prominence of the cohort (one-tenth of a legion) as a tactical unit and the total reliance on non-Roman auxiliaries for light-armed and cavalry service. The precise development of these reforms cannot be traced, but they culminated in the much more effective armies of Pompey and Caesar,

Marius' African army had been unwilling to engage in another war, and Marius preferred to use newly levied soldiers (no longer difficult to find). But neither he nor the Senate seemed aware of any responsibilities to the veterans. In 103 a tribune, Lucius Saturninus, offered to pass a law providing land in Africa for them in return for Marius' support for some anti-oligarchic activities of his own. Marius agreed, and the large lots distributed to his veterans (both Roman and Italian) turned out to be the beginning of the Romanization of Africa. In 100, with the German wars ended, Saturninus again proved a welcome ally, arranging for the settlement of Marius' veterans in Gaul. An incidental effect was the departure of Marius' old commander and subsequent enemy, Quintus Metellus, who refused to recognize the validity of Saturninus' law and, choosing martyrdom, went into exile. But this time Saturninus exacted a high price. With his ally, the praetor Gaius Glaucia, he introduced laws to gain the favour of plebs and equites and proceeded to provide for the settlement of veterans of wars in Macedonia and Sicily in the same way as for those of Marius' war. He planned to seek reelection for 99, with Glaucia illegally gaining the consulship. Violence and even murder were freely used to accomplish these aims.

Marius now had to make a choice. Saturninus and Glaucia might secure him the continuing favour of the plebs and perhaps the equites, though they might also steal it for themselves. But as the saviour of his country and six times consul, he now hoped to become an elder statesman (princeps), accepted and honoured by those who had once looked down on him as an upstart. To this end he had long laboured, dealing out favours to aristocrats who might make useful allies. This was the reward Marius desired for his achievement; he never thought of revolution or tyranny. Hence, when called on to save the state from his revolutionary allies, he could not refuse. He imprisoned them and their armed adherents and did not prevent their being lynched. Yet, having saved the oligarchy from revolution, he received little reward; he lost the favour of the plebs, while the oligarchs, in view of both his birth and his earlier unscrupulous ambition, refused to accept him as their equal. Metellus was recalled; this was a bitter blow to Marius' prestige, and he preferred to leave Rome and visit Asia.

Before long a face-saving compromise was found, and Marius returned; but in the 90s he played no major part. Though he held his own when his friends and clients were attacked in the courts, his old aristocratic protégés now found more promising allies. Sulla is typical: closely associated with Marius in his early career, he was by 91 ready to take the lead in attacking Marius and (significantly) found eager support. The oligarchy could not forgive Marius.

Marius' opposition to Saturninus and Glancia

Wars and dictatorship (c. 91-80 BC). Events in Asia. In foreign affairs the 90s were dominated by Asia, Rome's chief source of income. Mithradates VI, king of Pontus, had built a large empire around the Black Sea and was probing and intriguing in the Roman sphere of influence. Marius had met him and had given him a firm warning. temporarily effective: Mithradates had proper respect for Roman power. Scheming to annex Cappadocia, he had been thwarted by the Senate's instructing Sulla, as proconsul to install a pro-Roman king there in 96-95 (It was on this occasion that Sulla received a Parthian embassythe first contact between the two powers.) But dissatisfaction in the Roman province of Asia gave new hope to Mithradates. Ineffectively organized after annexation and corrupt in its cities' internal administration, it was soon overrun with Italian businessmen and Roman tax collectors. When the Senate realized the danger, it sent its most distinguished jurist, Quintus Mucius Scaevola (consul in 95 and pontifex maximus), on an unprecedented mission to reorganize Asia (94). He took Publius Rutilius Rufusjurist, stoic philosopher, and former consul-with him as his senior officer, and after Scaevola's return Rutilius remained behind, firmly applying the new principles they had established. This caused an outcry from businessmen, whose profits Scaevola had kept within bounds; he was prosecuted for "extortion" in 92 and convicted after a trial in which Roman publicani and businessmen unscrupulously used their power among the class that provided criminal juries. The verdict revealed the breakdown of Gaius Gracchus' system: the class he had raised to watch over the Senate now held irresponsible power, making orderly administration impossible and endangering the empire. Various leading senators were at once vexatiously prosecuted, and political chaos threatened.

Developments in Italy. The 90s also saw dangerous developments in Italy. In the 2nd century BC, Italians as a whole had shown little desire for Roman citizenship and had been remarkably submissive under exploitation and ill-treatment. The most active of their governing class flourished in overseas business, and the more traditionally minded were content to have their oligarchic rule supported by Rome. Their admission to citizenship had been proposed as a by-product of the Gracchan reforms. By 122 it had become clear that the Roman people agreed with the oligarchy in rejecting it. The sacrifices demanded of Italy in the Numidian and German wars probably increased dissatisfaction among Italians with their patently inferior status. Marius gave citizenship to some as a reward for military distinction-illegally, but his standing (auctoritas) sufficed to defend his actions. Saturninus admitted Italians to veteran settlements and tried to gain citizenship for some by full admission to Roman colonies. The censors of 97-96, aristocrats connected with Marius, shared his ideas and freely placed eminent Italians on the citizen registers. This might have allayed dissatisfaction, but the consuls of 95 passed a law purging the rolls and providing penalties for those guilty of fraudulent arrogation. The result was insecurity and danger for many leading Italians. By 92 there was talk of violence and conspiracy among

Insecurity

and danger

for leading

Italians

desperate men. It was in these circumstances that the eminent young noble, Marcus Livius Drusus, became tribune for 91 and hoped to solve the menacing accumulation of problems by means of a major scheme of reforms. He attracted the support of the poor by agrarian and colonial legislation and tried to have all Italians admitted to citizenship and to solve the jury problem by a compromise: the courts would be transferred to the Senate, and 300 equites would be admitted to it. (To cope with the increase in business it would need this expansion in size.) Some leading senators, frightened at the dangerous situation that had developed, gave weighty support. Had Drusus succeeded, the poor and the Italians might have been satisfied; the equites, deprived of their most ambitious element by promotion, might have acquiesced; and the Senate, always governed by the prestige of the noble principes rather than by votes and divisions, could have returned, little changed by the infusion of new blood, to its leading position in the process of government. But Drusus failed. Some members of

each class affected were more conscious of the loss than of the gain; and an active consul, Lucius Philippus, provided leadership for their disparate opposition. After much violence, Drusus' laws were declared invalid. Finally he himself was assassinated. The Italians now rose in revolt (the Social War), and in Rome a special tribunal, manned by the Gracehan jury class, convicted many of Drusus' supporters until the Senate succeeded in suspending its sittings because of the military danger.

The first year of the Social War (90) was dangerous: the tribes of central and southern Italy, traditionally among the best soldiers in Rome's wars, organized in a confederacy for the struggle that had been forced upon them. Fortunately all but one of the Latin cities—related to Rome by blood and tradition and specially favoured by Roman law—remained loyal: their governing class had for some time had the privilege of automatically acquiring Roman citizenship by holding local office. Moreover, Rome now showed its old ability to act quickly and wisely in emergencies: the consul Lucius Caesar passed a law giving citizenship to all Italians who wanted it. The measure came in time to head off major revolts in Umbria and Etruria, which accepted at once.

Civil war and the rule of Lucius Sulla. In 89 the war in central Italy was won, and Gnaeus Pompeins Strabo celebrated a triumph. Attention now turned to the East, where Mithradates had taken advantage of Rome's troubles to expel the kings of Cappadocia and Bithynia. A Roman embassy restored them, and he withdrew. However, when the envoys incited Bithynian incursions into his territory, whith the work of the contract of the con

In Rome, various men, including Marius, had hoped for the Eastern command. But it went to Sulla, elected consul for 88 after distinguished service in the Social War. Publius Sulpicius, a tribune in that year and an old friend of Drusus, tried to continue the latter's policy of justice to the Italians by abolishing the gerrymandering that in practice deprived the new citizens of an effective vote. Finding the oligarchy firmly opposed, he gained the support of Marius (who still commanded much loyalty) for his plans by having the Eastern command transferred to him. After much street-fighting, the consuls escaped from Rome, and Sulpicius' bills were passed. Sulla's response was totally unforeseen: he appealed to the army he had led in the Social War, which was still engaged in mopping-up operations in Campania, and persuaded them to march on Rome. He occupied the city and executed Sulpicius; Marius and others escaped. Significantly, Sulla's officers left him. It was the first time a private army of citizens had occupied Rome-an effect of Marius' army reform, which had ended by creating a "client army" loyal chiefly to its commander, and of the Social War, which had made the use of force within Italy seem commonplace. The end

of the republic was foreshadowed. Having cowed Rome into acquiescence and having passed some legislation, Sulla left for the East. Cinna, one of the consuls of 87, at once called for the overthrow of Sulla's measures. Resisted by his colleague Octavius, he left Rome to collect an army and, with the help of Marius, occupied the city after a siege. Several leading men were killed or condemned to death, Sulla and his supporters were outlawed, and (after Marius' death early in 86) another commander was sent to Asia. The policy now changed to one of reconciliation: the Social War was wound up, and the government gained wide acceptance until Cinna was killed by multious soldiers (84).

Sulla meanwhile easily defeated Mithradates' forces in two battles in Boeotia, took Athens, which under a revolutionary regime had declared for Mithradates, and cleared the king's army out of Greece. While negotiating with Cinna's government, Sulla also entered upon negotiations with Mithradates and, when he heard of Cinna's death, quickly made peace and an alliance with Mithradates, driving the government's commander in Asia to suicide. After wintering his troops in the rich cities of Asia, Sulla

attempt to restore

crossed into Greece and then into Italy, where his veteran army broke all resistance and occupied Rome (82). Sulla was elected dictator and, while Italy and all the provinces except Spain were quickly reduced, began a reign of terror (the "proscriptions"), in which hundreds of his enemies or those of his adherents were killed without trial, while their property went to enrich him and his friends. Wherever in Italy he had met resistance, land was expropriated and

given to his soldiers for settlement. While the terror prevailed, Sulla used his powers to put through a comprehensive program of reform (81). Although he had twice taken Rome with a private proletarian army, he had earlier had connections with the inner circles of the oligarchy, and after Cinna's death some eminent men who had refused to collaborate with Cinna joined Sulla. By the time Sulla's success seemed certain, even most of those who had collaborated were on his side, and he was acclaimed as the defender of the nobility who had defeated an illegal revolutionary regime. His reforms aimed chiefly at stabilizing Senate authority by removing alternative centres of power. The tribunate was emasculated; the censors' powers were reduced; provincial governors were subjected to stricter Senate control; and the equites, who had been purged of Sulla's opponents by the proscriptions, were deprived of some symbols of dignity and made leaderless by the inclusion of 300 of Sulla's chief supporters in the Senate. The jury reform of Gaius Gracchus, seen by some leading senators as the prime cause of political disintegration, could now be undone, and the criminal courts could once more become a monopoly of senators.

Sulla's measures were by no means merely reactionary. His program was basically that of Marcus Drusus. His overriding aim was the restoration of stable government, and this could only come from the Senate, directed by the principes (former consuls and those they chose to consult). Sulla accepted and even extended recent developments where they seemed useful: the Italians retained full citizenship; the system of standing criminal courts was expanded; the practice of praetors normally spending their year of office in Rome and then going to provinces for a second year was extended to consuls and became an integral part of his system. To prevent long command of armies (which might lead to careers like his own), Sulla increased the number of praetors so that, in principle and in normal circumstances, each province might have a new governor every year. As for the overriding problem of poverty, his contribution to solving it was to settle tens of thousands of his veterans on land confiscated from enemies in Italy; having become landowners, the veterans would be ready to defend the social order, in which they now had a stake, against the dispossessed.

At the beginning of 80 Sulla laid down his dictatorship and became merely consul, with the senior Metellus (Quintus Metellus Pius), a relative of his wife, as his colleague. The state of emergency was officially ended. At the end of the year, after seeing to the election of two reliable consuls, Sulla retired to Campania as a private citizen; he hoped that the restored oligarchy would learn to govern the state he had handed over to them. For 78 Marcus Lepidus, an ambitious patrician whom Sulla disliked and distrusted, was elected consul. Sulla did not intervene. Within a few months, Sulla was dead. Lepidus at once attacked his system, using the grievances of the expropriated as a rallying cry and his province of Gaul as a base. But he was easily defeated by his former colleague Quintus Catulus, assisted by young Gnaeus Pompeius (Pompey).

The Roman state in the two decades after Sulla (79-60 BC). The early career of Pompey. Pompey was the son of Gnaeus Pompeius Strabo, who had triumphed after the Social War but had incurred general hatred because of cold-blooded duplicity during the troubles of 88 and 87. After Strabo's death, young Pompey, who had served under him and inherited his dubiously won wealth, was protected by Cinna's government against his father's enemies. Following in his father's footsteps, he deserted the government after Cinna's death, raised a force among his father's veterans in central Italy, and helped to conquer Italy and, in a lightning campaign, Sicily and the province of Africa for Sulla. Though not old enough to hold any regular magistracy (he was born in 106), he had, from these military bases, blackmailed Sulla into granting him a triumph (81) and had married into the core of the Sullan oligarchy. Out of pique against Sulla, he had supported Lepidus' election for 78, but he had too great a stake in the Sullan system to permit Lepidus to overthrow it.

Meanwhile a more serious challenge to the system had arisen in Iberia. Quintus Sertorius, a former praetor of tough Sabine gentry stock, had refused to follow most of his social betters in joining Sulla; instead he had left for Spain, where he claimed to represent the legitimate government. Although acting throughout as a Roman proconsul, with a "counter-Senate" of eminent Roman citizens. Sertorius won the enthusiastic support of the native population by his fairness, honesty, and charisma, and he soon held most of the Iberian Peninsula, defending it successfully even against a large force under Quintus Metellus Pius. When the consuls of 77 would have nothing to do with this war, Pompey was entrusted by the Senate, through the efforts of his eminent friends and sponsors, with the task of assisting Metellus. The war dragged on for years, with little glory for the Roman commanders. Although Sertorius had many sympathizers in Italy, superior numbers and resources finally wore him down, and he was assassinated by a Roman officer. Pompey easily defeated the remnants of Sertorius' forces in 72

The death of Nicomedes IV of Bithynia (74) led to another major war. Like Attalus of Pergamum, Nicomedes left his kingdom to Rome, and this provoked Mithradates, who was in contact with Sertorius and knew of Rome's difficulties, to challenge Rome again. The Eastern command again led to intrigues in Rome. The command finally went to Lucius Lucullus, a relative of Sulla and consul in 74, who hoped to build up a countervailing power in the East.

At the same time, Marcus Antonius, father of the later Triumvir, was given a command against the pirates in the eastern Mediterranean (whom his father had already fought in 102-100), partly, perhaps, as further reinsurance against Pompey. With Italian manpower heavily committed, a minor slave rising led by Spartacus (73) assumed threatening dimensions, until Marcus Crassus (an old Sullan and profiteer in the proscriptions) volunteered to accept a special command and defeated the slaves. At this point (71) Pompey returned from Spain with his army, crucified the remnants of the slave army, and claimed credit for the victory.

Pompey and Crassus. He and Crassus now confronted each other, each demanding the consulship for 70, though Pompey had held no regular magistracy and was not a senator. Agreeing to join forces, both secured it.

During their consulship, the political, though not the administrative, part of the Sullan settlement was repealed. The tribunes' powers were fully restored; criminal juries were divided between senators and wealthy nonsenators; and, for the first time since Sulla, two censors-both supporters of Pompey-were elected, who purged the Senate and, in compiling the registers, at last fully implemented the Italians' citizenship. The year 70 also saw the prosecution of Verres (son of a "new man" and Sullan profiteer), who had surpassed the liberal Roman conventions in exploiting his province of Sicily. For future impunity he relied on his aristocratic connections (especially the Metelli and their friends), his fortune, and the known corruptibility of the Sullan senatorial juries. But Verres was unlucky. First, he had ill-treated some of Pompey's important Sicilian clients, thus incurring Pompey's displeasure; next, his case coincided with the anti-Sullan reaction of 70; finally, the Sicilians succeeded in persuading Ciceroan ambitious young "new man" from Arpinum hoping to imitate the success of his fellow citizen Marius by means of his rhetorical ability-to undertake the prosecution. Despite obstruction from Verres' friends, Cicero collected massive evidence against him, presented his case to fit into the political context of the year, and obtained Verres' conviction as an act of expiation for the shortcomings of the Sullan order.

The year 70 thus marked the loss of control by the Sul-

Revolt of Sertorius

Loss of control by the Sullan establishment

lan establishment. The nobility (families descended from consuls) continued to gain most of the consulships, with the old patriciate (revived by Sulla after a long decline) stronger than for generations; the Senate still supervised administration and made ordinary political decisions; the system continued to rely essentially on mos majorum (constitutional custom) and auctoritas (prestige)-potent forces in the status society of the Roman Republic. The solid bases of law and power that Sulla had tried to give it had been surrendered, however. The demagogue-tribune or consul-could use the legal machinery of the popular assembly (hence such men are called populares), while the commander could rely on his army in the pursuit of private ambition. The situation that Sulla had tried to remedy now recurred, made worse by his intervention. His massacres and proscriptions had weeded out the defenders of lawful government, and his rewards had gone to the timeservers and the unscrupulous. The large infusion of equites into the Senate had intensified the effect. While eliminating the serious friction between the two classes. which had made the state ungovernable by 91, it had filled the Senate with men whose tradition was the opposite of that sense of mission and public service that had animated the best of the aristocracy. Few men in the new ruling class saw beyond self-interest and self-indulgence.

One result was that massive bribery and civil disorder in the service of ambition became endemic. Laws were repeatedly passed to stop them, but they remained ineffective because few found it in their interest to enforce them. Exploitation of the provinces did not decrease after Verres: governors (still with unlimited powers) feathered their own nests and were expected to provide for all their friends. Extortion cases became a political ritual, with convictions impossible to obtain. Cicero, thenceforth usually counsel for the defense, presented hair-raising behaviour as commonplace and claimed it as acceptable. The Senate's. traditional opposition to annexation faded out. Pompey made Syria into a province and added a large part of Pontus to Bithynia (inherited in 74 and occupied in 70); the demagogue Clodius annexed Cyprus-driving its king to suicide-to pay for his massive grain distributions in Rome; Caesar, finally, conquered Gaul by open aggression and genocide and bled it white for the benefit of his friends and his ambitions. Crassus would have done the same with Parthia, had he succeeded. Opposition to all this in the Senate, where it appeared, was based on personal or political antagonism. If the robber barons were attacked on moral grounds, it was because of the use they made of their power in Rome.

Politically, the 60s lay under the shadow of Pompey. Refusing to take an ordinary province in 69, he waited for his chance. It came in 67 when his adherent Gabinius, as tribune, secured him, against the opposition of all important men, an extraordinary command with unprecedented powers to deal with the pirates. Pompey succeeded within a few months where Antonius and others had failed. The equites and the people were delighted because trade, including Rome's food imports, would now be secure. Meanwhile Lucullus had driven Mithradates out of Anatolia and into Armenia; but he had offended Roman businessmen by strict control and his own soldiers and officers by strict discipline. Faced with mutinies, he suffered a reverse and became vulnerable to attacks in Rome. In 66 another tribunician law appointed Pompey, fresh from his naval victories, to take over supreme command in the East, which he did at once, studiously insulting his predecessor. He quickly defeated Mithradates and procured his death, then spent some time in a total reorganization of the East, where Asia (the chief source of revenue) was protected by three further provinces and a ring of client states beyond the frontier. The whole of the East now stood in his clientela (clientship), and most of it owed him money as well. He returned by far the wealthiest man in Rome.

Political suspicion and violence. Meanwhile Roman politics had been full of suspicion and violence, much of it stirred up by Crassus who, remembering 71, feared Pompey's return and tried to make his own power impregnable. There was much material for revolution, with poverty (especially in the country, among families dispossessed by Sulla) and debt (among both the poor and the dissolute rich) providing suitable issues for unscrupulous populares. One such man, the patrician Catiline, after twice failing to gain the consulship by traditional bribery and intrigue, put himself at the head of a movement planning a coup d'état in Rome to coincide with an armed rising in Italy (late 63). Cicero, as consul, defeated these efforts and, relying on the doubtful legality of a Senate vote in support, had Catiline's eminent Roman associates executed. Catiline himself fell in a desperate battle.

For Cicero-the "new man" who had made his way to Isolation of the top by his own oratorical and political skill, obliging everyone by unstinting service, representing Pompey's interests in Rome while avoiding offense to Pompey's enemies-this was the climax of his life. Like his compatriot Marius, he had saved the state for its rulers: he had taken resolute action when those rulers were weak and vacillating; and, like Marius, he got small thanks for it. Pompey was miffed at having to share his fame with a municipal upstart, and eminent gentlemen could not forgive that upstart for having driven patricians to their death,

Pompey's return was peaceful. Like Marius, he wanted recognition, not tyranny. He dismissed his army, to the surprise of Crassus and others, and basked in the glory of his triumph and the honours voted to him. But having given up power, he found himself caught in a net of constitutional obstruction woven by his politically experienced enemies and was unable to have either of his principal demands met: land for his veterans and the ratification of his arrangements in the East. It was at this point that Caesar returned from Spain.

Gaius Julius Caesar, descended (as he insisted) from kings and gods, had shown talent and ambition in his youth; he opposed Sulla but without inviting punishment, married into the oligarchy but advocated popular causes, vocally defended Pompey's interests while aiding Crassus in his intrigues and borrowing a fortune from him, flirted with Catiline but refused to dabble in revolution, then worked to save those whom Cicero executed. In 63 he won a startling success: defeating two distinguished principes, he. who had not yet been practor, was elected pontifex maximus-a post of supreme dignity, power, and patronage, Despite some cynicism among Roman aristocrats toward the state religion, its ceremonial was kept up and was a recognized means of political manipulation; thus priesthoods could give more lasting power than magistracies, in addition to the cachet of social success. Young Caesar was now head of the hierarchy. After his praetorship (62). Caesar successfully governed Spain, clearing a surplus sufficient to pay off his debts. On returning to Rome, he naturally hoped for the consulship of 59; but his enemies, by legal chicanery, forced him to choose between standing for office and celebrating a triumph. He gave up the triumph and easily became consul.

The final collapse of the Roman Republic (59-44 BC). Caesar, Pompey, and Crassus. For his consulship Caesar fashioned an improbable alliance: his skill in having won the trust of both Crassus and Pompey enabled him to unite these two enemies in his support. Crassus had the connections, Pompey had the soldiers' vote, and Caesar was consul and pontifex maximus. The combination (often misleadingly called the "first Triumvirate") was invincible, especially since the consul Caesar had no scruples about countering legal obstruction with open force. Pompey got what he wanted, and so did Crassus (whose immediate need was a concession to the Asian tax farmers, in whose companies he probably had much of his capital). In return, Caesar got a special command in Cisalpine Gaul and Illyricum for five years by vote of the people; the Senate itself, on Pompey's motion, extended it to Transalpine Gaul. Marriage alliances sealed the compact, chief of them Pompey's marriage to Caesar's daughter Julia.

Caesar left for Gaul, but Rome was never the same; the shadow of the alliance hung over it, making the old-style politics impossible. In 58 Publius Clodius, another aristocratic demagogue, was tribune and defended Caesar's interests. Cicero had incurred Clodius' enmity and was now sacrificed to him; he was driven into exile as having unlawfully executed citizens in 63. By 57 Caesar's allies

Alliance of Caesar Pompey, Crassus

Defeat and death of Mithradates VI End of

the pact

had drifted back into rivalry. Pompey secured Cicero's return, and Cicero at once tried to break up the alliance by attracting Pompey to the Senate's side. Just when he seemed about to succeed, the three dynasts secretly met and revived their compact (56). Rome had to bow once more. In 55 Pompey and Crassus were consuls, and the contents of their secret agreement were slowly revealed. Caesar, whom his enemies had made efforts to recall, was prolonged in his command for five years and (it later appeared) had been promised another consulship straight after, to secure him against prosecution and give him a chance of another army command. Pompey was given a special command over all of Spain, which he exercised through deputies while he himself remained just outside Rome to keep an eye on the city. Crassus, who now needed glory and new wealth to equal those of his allies. was to attack Parthia with a large army. Thus the three dynasts would practically monopolize military power for the foreseeable future.

Cicero, among others, had to submit and was thenceforth their loyal spokesman. After his achievement of 63 he had dreamed of leading a coalition of all "right-thinking" men in Italy in defending the traditional oligarchy, but he had found little support among the oligarchy. He now used this fact to rationalize his surrender. His brother took

The dynasts' pact did not even bring peace. Clodius, as

tribune, had created a private army, and there was no state

force to counter it. Pompey could have done it by calling his soldiers in, but the Senate did not trust him enough to

service in Gaul under Caesar.

request this, and Pompey did not wish to parade himself as an unashamed tyrant. Other men formed private armies in opposition to Clodius, and one Milo at last managed to have him killed after a scuffle (52). By then, however, Roman politics had radically and unexpectedly changed. Political maneuvers. Julia died in 54, breaking the ties between Caesar and Pompey. Caesar pressed Pompey to renew them, but Pompey held off, preserving his freedom of action. Crassus' Parthian campaign ended in disaster and in Crassus' death (53), By 52 Pompey and Caesar stood face to face, still nominally friends but with no personal link between them and no common interests. Caesar, by conquering the whole of Gaul, had almost equaled Pompey's prestige and, by his utterly ruthless way of waging war, Pompey's wealth. Unlike Pompey, he used his wealth to dispense patronage and buy useful friends. At this point Pompey cautiously offered the oligarchy his support. It had much to give him that he wanted-control of the administrative machine, respectability, and the seal of public approval. Its leaders (even the intransigent young Cato, who had led opposition to the three individually long before their alliance and to their joint oppression of the state ever since) now recognized that acceptance of Pompey's terms and surrender to his protection was their only chance of survival. Pompey at once turned firmly against Milo, who presented a political threat: if Milo could use the force that had killed Clodius to keep firm control of Rome, he-an ambitious man of known conservative views-might in due course offer an alternative and more trustworthy champion to the oligarchy. But he was not yet ready. Pompey forced them to make their choice at once, and they chose Pompey in preference. He was made sole consul and had Milo convicted by an intimidated court. Meanwhile he had made a marriage alliance with the noblest man in Rome, Quintus Metellus Scipio, who became his colleague in the consulship. The state had captured Pompey (or vice versa), and Caesar stood alone in opposition to both of them. During the next two years there were a series of maneuvers: the Senate leaders, with Pompey's silent support, worked for Caesar's recall, which would have meant his instantly sharing the fate of Milo; while Caesar and his agents in Rome tried to strike some bargain that would ensure his safety and his future in politics. Finally, Pompey declared himself, and, early in 49, the Senate voted to outlaw Caesar. Two tribunes supporting him (one of them Mark Antony) had to flee.

By the time they reached him, Caesar had already crossed the Rubicon: he now had a cause. Civil war. Pompey had exuded confidence over the outcome if it came to war. In fact, however, Caesar's veterans were unbeatable, and both men knew it. To the disgust of his followers, Pompey evacuated Rome, then Italy, His plan was to bottle Caesar up in Italy and starve him out. But Caesar, in a lightning sweep, seized Massilia and Spain from Pompey's commanders, then crossed into Greece. where a short campaign ended in Pompey's decisive defeat at Pharsalus (48). Pompey fled to Egypt, where he was assassinated by a man hoping thus to curry Caesar's favour. This was by no means the end of the war. Almost at once Caesar was nearly trapped at Alexandria, where he had intervened in a succession dispute; but he escaped and installed Cleopatra on the throne, for personal as well as political reasons. In Africa the Pompeian forces and their native allies were not defeated until Caesar himself moved against them and annihilated them at Thapsus. Cato, disdaining the victor's pardon, committed suicide at Utica (46). In Spain, where Pompey's name was still powerful, his sons organized a major rising, which Caesar himself again had to defeat at Munda (45) in the bloodiest battle of the war. By the time he returned, he had only a few months to live.

The dictatorship and assassination of Caesar. In Rome the administrative machine had inevitably been disrupted, and Caesar had always remained in control, as consul or as dictator. Those who had feared proscriptions, or hoped for them, were proved wrong. Some of Caesar's enemies had their property confiscated, but it was sold at fair value; most were pardoned and suffered no loss. One of these was Cicero, who, after much soul-searching, had followed his conscience by joining Pompey before Pharsalus. Poverty and indebtedness were alleviated, but there was no wholesale cancellation of debts or redistribution of property, and many of Caesar's adherents were disappointed. Nor was there a general reform of the republic, (Caesar's only major reform was of the calendar: indeed, the Julian calendar proved adequate for centuries.) The number of senators and magistrates was increased, the citizenship was more freely given, and the province of Asia was relieved of some of its tax burden. But Caesar had no plan for reforming the system-not even to the extent that Sulla had tried to do, for Sulla had at least planned for his own retirement. For a time, honourable men, such as Cicero, hoped that the "Dictator for Settling the Constitution" (as Caesar called himself) would produce a real constitution-some return to free institutions. By late 45 that hope was dead. Caesar was everywhere, doing everything to an almost superhuman degree. He had no solution for the crisis of the republic except to embody it in himself and none at all for the hatred of his peers, which he knew this was causing. He began to accept more and more of the honours that a subservient Senate invidiously offered, until finally he reached a position perilously close to kingship (an accursed term in Rome) and even deification. Whether he passed those hazy boundary lines is much debated and not very important. He had put himself in a position in which no Roman ought to have been and which no Roman aristocrat could tolerate. As a loyal friend of his was later to say: "With all his genius, he saw no way out." To escape the problem or postpone it, he prepared for a Parthian war to avenge Crassus-a project most likely to have ended in similar disaster. Before he could start on it, about 60 men-former friends and old enemies, honourable patriots and men with grievancesstruck him down in the Senate on March 15, 44 BC

The Triumvirate and Octavian's achievement of sole power. Brutus and Cassius, the organizers of the conspiracy, expected all Romans to rejoice with them in the rebirth of "freedom." But to the Roman people the freedom of the governing class had never meant very much; the armies (especially in the west) were attached to Caesar, and the Senate was full of Caesarians at all levels, cowed but biding their time. Mark Antony, the surviving consul, whom Brutus had been too scrupulous to assassinate with his master, gradually gained control of the city and the official machinery, and the "liberators" withdrew to the East. But a challenger for the position of leader of the Caesarians soon appeared in the person of Octavian, Caesars's son by adoption and now his heir. Though not

Changes under Caesar Formation of the Triumvirate yet 20, Octavian proved an accomplished politician: he attracted loyalty as a Caesarian while cooperating against Antony with the Senate, which, under Cicero's vigorous leadership, now turned against the consul. Cicero hoped to fragment and thus defeat the Caesarian party, with the help of Brutus and Cassius, who were making good progress in seizing control of the eastern provinces and armies. In 43 the two consuls (both old Caesarian officers) and Octavian defeated Antony at Mutina, and success seemed imminent. But the consuls died, and Octavian demanded and, by armed force, obtained the consulship; and the armies of Italy, Spain, and Gaul soon showed that they would not fight against one another. Octavian, Antony, and Lepidus (the senior Caesarian with an army) now had themselves appointed "Triumvirs for Settling the Constitution" for five years and secured control of Italy by massive proscriptions and confiscations (Cicero, Antony's chief enemy, was among the first to die). They then defeated and killed Brutus and Cassius at Philippi (42) and divided the Roman world among themselves, with Lepidus, a weak man accidentally thrust into prominence, getting the smallest share. Octavian, who was to control Italy, met armed opposition from Antony's brother and wife, but they got no help from Antony and were defeated at Perusia (41). Octavian and Antony sealed their alliance with a marriage compact: Antony married Octavia. Octavian's sister. Octavian then confronted Pompey's son Sextus Pompeius, who had seized control of the islands off Italy. After much diplomatic maneuvering (including another meeting with Antony), Octavian attacked and defeated Sextus; when Lepidus tried to reassert himself, Octavian crushed him and stripped him of his office of Triumvir (while with conspicuous piety leaving him the chief pontificate, now an office without power). Octavian now controlled the West and Antony the East, still officially as Triumvirs (their term of office had been extended), even though Lepidus had been eliminated in 36.

Each of the two leaders embarked on campaigns and reorganization in his half-Octavian in Illyricum, Antony particularly on the Parthian frontier. But Antony now married Cleopatra and tried to make Egypt his military and political base. In a war of propaganda, Octavian gradually convinced the western provinces, Italy, and most of the Roman upper class that Antony was sacrificing Roman interests, trying to become a Hellenistic king in Alexandria, and planning to rule the Roman world from there with Cleopatra. In 32, though he now held no legal position. Octavian intimidated most of Antony's remaining aristocratic friends into joining him, made the whole West swear allegiance to himself, and in 31, as consul, crossed into Greece to attack Antony. On September 2 he defeated Antony and Cleopatra in a naval battle at Actium. Though in itself not a major victory, it was followed by the disintegration of Antony's forces, and Antony and Cleopatra finally committed suicide in Alexandria (30). (E.Ba./R.P.Sa.)

INTELLECTUAL LIFE OF THE LATE REPUBLIC

The late Roman Republic, despite its turmoil, was a period of remarkable intellectual ferment. Many of the leading political figures were men of serious intellectual interests and literary achievement; foremost among them were Cicero, Caesar, Cato, Pompey, and Varro, all of them senators. The political upheaval itself leavened intellectual life; imperial senators were to look back to the late republic as a time when great political struggles stimulated great oratory, something the more ordered world of the emperors could no longer do.

The seeds of intellectual development had been sown in the late 3rd and early 2nd centuries; the flowering came in the last generation of the republic. As late as the 90s ne the Romans still appear relatively unsophisticated. Greek intellectuals were absorbed in debates among themselves, giving only passing nods to Romans by dedicating untechnical works to them. In 92 the censors issued an edict closing down the schools of Latin rhetoric in Rome. Serious students such as Cierce had to go east in the 80s to receive their higher education from leading Greek philosophers and rhetoricians. The centre of intellectual life began to shift toward the West after the 90s. As a result of the Mithradatic wars, libraries were brought from the East to Italy. The Helenistic kingdoms, which had provided the patronage for much intellectual activity, were dismantled by Pompey and Octavian, and Greek intellectuals increasingly joined the retinues of great Roman senators such as Pompey. Private Roman houses, especially senatorial villas on the Bay of Naples, became the focus of intellectual life; it was there that libraries were reassembled and Greek teachers kept as dependents.

Roman traditions favoured the development of certain disciplines, creating a pattern that was distinct from the Greek, Disciplines related to the public life of senators prospered—notably oratory, law, and history; certain fields of study were judged fit for diversions in leisure hours, and still others were considered beneath the dignity of an honourable Roman. Areas such as medicine and architecture were left to Greeks and others of lower status, and mathematics and the sciences aroused little interest. Greek slaves especially played an important role in the intellectual life of the late republic, serving in roles as diverse as teachers, copyists of manuscripts, and oral readers to aristocrats.

By the beginning of the imperial era the maturing of Roman intellectual culture was evident. Caesar had commissioned Varro to organize the first public library in Rome, and Greek scholars such as the geographer Strabo moved west to pursue their studies in Rome.

Grammar and rhetoric. The education of the Roman elite was dominated by training in language skills, grammar, and rhetoric. The grammatici, who taught grammar and literature, were lower-class and often servile dependents. Nevertheless, they helped to develop a Roman consciousness about "proper" spelling and usage that the elite adopted as a means of setting themselves off from humbler men. This interest in language was expressed in Varro's work on words and grammar, De Lingua Latina (43?), with its prescriptive tone. Rhetoric, though a discipline of higher status, was still taught mainly by Greeks in Greek. The rhetoricians offered rules for composition: how to elaborate a speech with ornamentation and, more important, how to organize a work through the dialectical skills of definition and division of the subject matter into analytical categories. The Romans absorbed these instructions so thoroughly that the last generation of the republic produced an equal of the greatest Greek orators in Cicero. The influence on Roman culture of dialectical thinking, instilled through rhetoric, can hardly be overstated; the result was an increasingly disciplined, well-organized habit of thinking. This development can be seen most clearly in the series of agricultural works by Roman authors: whereas Cato's 2nd-century De agricultura is rambling and disorganized, Varro's three books on Res rusticae (37), with their division of soils into 99 types, seem excessively organized.

Law and history. Roman law, though traditional in content, was also deeply influenced by Greek dialectic. For centuries the law had been passed down orally by pontifical priests. It emerged as an intellectual discipline only in the late republic, when men who saw themselves as legal specialists began to write treatises aimed at organizing existing law into a system, defining principles and concepts, and then applying those principles systematically. Quintus Mucius Scaevola was a privatal figure: a pontifiex in the traditional role, he published the first systematic legal treatise, De time civili, in the 80s. Ciercor credited his contemporary Servius Sulpicius Rufus with being the jurist who transformed law into a discipline (ars).

The decisive events of the late republic stimulated the writing of history. The first extant historical works in Latin (rather than in Greek) date from this period: Sallust's Bellum Iugurinum (Iugurthine Wan) and Bellum Catilinae (Catilinarian Conspiracy) and Caesar's memoirs about his Gallic and civil wars. The rapid changes also prompted antiquarian studies as Roman senators looked back to archaic institutions and religious rituals of the distant past to legitimize or criticize the present. Varro's 41 books (now lost) on Antiquitates terum humanarum et divinarum ("Antiquities of things human and divine") were

Roman

influential in establishing the traditions of early Rome for future generations.

Philosophy and poetry. Philosophy and poetry were suitable as pastimes for senators; few, however, were as serious about philosophy as the younger Cato and Cicero. Even Cicero's philosophical works were not technical treatises by Greek standards; rather, they were presented as dialogues among leading senators in their leisure. Similarly, Lucretius' De rerum natura (On the Nature of Things: 50s) offered, in verse, a nontechnical explanation of Epicureanism. The technical philosophical works were written by humbler men and are now lost. A survey of their names and titles, however, shows that stoicism was not yet the dominant philosophical school it later became; more in evidence were the Epicureans, peripatetics, and academics. There also were revivals of Aristotelian and Pythagorean studies in this period.

The best-known poets of the late republican and civil war periods came from well-to-do Italian families. Catullus from Verona (c. 84-c. 54) had a reputation as doctus (learned) for his exquisitely crafted poems full of literary allusions in the Alexandrian style. Far from cumbersome, however, were many of his short, witty poems that challenged traditional Roman mores and deflated senatorial pretensions. Rome's greatest poets, Virgil (70-19) and Horace (65-8), were born during the republic, came of age during the civil wars, and survived to celebrate the victory of their patron, Augustus, Virgil's Eclogues one and nine, written during the civil wars, poignantly evoke the suffering of the upheaval that ironically inspired Rome's highest intellectual and artistic achievements. (R.P.Sa.)

THE EARLY ROMAN EMPIRE (31 BC-AD 193)

The consolidation of the empire under the Julio-Claudians. The establishment of the principate under Augustus. Actium left Octavian the master of the Roman world. This supremacy, successfully maintained until his death The first of more than 40 years later, made him the first of the Roman emperors. Suicide removed Antony and Cleopatra and the Roman their potential menace in 30 BC, and the annexation of Egypt with its Ptolemaic treasure brought financial independence. With these reassurances Octavian could begin the task of reconstruction.

Law and order had vanished from the Roman state when its ruling aristocrats refused to curb their individual ambitions, when the most corrupt and violent persons could gain protection for their crimes by promising their support to the ambitious, and when the ambitious and the violent together could thus transform a republic based on disciplined liberty into a turbulent cockpit of murderous rivalries. Good government depended on limits being set to unrestrained aspirations, and Octavian was in a position to impose them. But his military might, though sufficiently strong in 31 BC to guarantee orderly political processes, was itself incompatible with them; nor did he relish the role of military despot. The fate of Julius Caesar, an eagerness to acquire political respectability, and his own esteem for ancestral custom combined to dissuade Octavian from it. He wished to be, in his own words, "the author of the best civilian government possible." His problem was to regularize his own position so as to make it generally acceptable, without simultaneously reopening the door to violent lawlessness. His pragmatic responses not only ensured stability and continuity but also respected republican forms and traditions so far as possible.

Large-scale demobilization allayed people's fears; regular consular elections raised their hopes. In 29-28 BC Octavian carried out, with Marcus Vipsanius Agrippa, his powerful deputy, the first census of the Roman people since 70: and this involved drawing up an electoral roll for the Centuriate Assembly. Elections followed, and Octavian was inevitably chosen consul. Then, on Jan. 13, 27 BC, he offered to lay down his powers. The Roman Senate rejected this proposal, charging him instead to administer (besides Egypt) Spain, Gaul, and Syria for the next 10 years, while it itself was to supervise the rest of the empire. Three days later, among other honours, it bestowed upon him the name by which he has ever since been known, Augustus. As most of the troops still under arms were in the regions

entrusted to Augustus' charge, the arrangements of 27 BC hardly affected his military strength. Moreover, so long as he was consul (he was reelected every year until 23 BC), he was civilian head of government as well. In other words, he was still preeminent and all-powerful, even if he had, in his own words, placed the res publica at the disposal of the Senate and the Roman people. Augustus particularly wished to conciliate the senatorial class, without whose cooperation civilian government was impossible. But his monopolization of the consulship offended the Senate. making a different arrangement clearly necessary. Accordingly, in 23 Augustus made a change; he vacated the consulship and never held it again (except momentarily in 5 BC and again in 2 BC, for a limited, specific purpose). In its place he received the tribunician power (tribunicia potestas). He could not become an actual plebeian tribune, because Julius Caesar's action of making him a patrician had disqualified him for the office. But he could acquire the rights and privileges pertaining to the office; and they were conferred upon him, apparently by the Senate, whose action was then ratified by the popular assembly. He had already been enjoying some of a tribune's privileges since 36; but he now acquired them all and even some additional ones, such as the right to convene the Senate whenever he chose and to enjoy priority in bringing business before it, Through his tribunician power he could also summon the popular assembly and participate fully in its proceedings. Clearly, although no longer consul, he still retained the

legal right to authority in civilian affairs. The arrangement of 23 entailed an additional advantage. The power of the plebeian tribune was traditionally associated with the protection of citizens, and Augustus' acquisition of it was therefore unlikely to rouse resentment. Indeed, Augustus thenceforth shrewdly propagated the notion that, if his position in the state was exceptional (which it clearly was), it was precisely because of his tribunician power. Although he held it for only one year at a time, it was indefinitely renewable and was pronounced his for life. Thus, it was both annual and perpetual and was a suitable vehicle for numbering the years of his supremacy. His era (and this is true also of later emperors) was counted officially from the year when he acquired the tribunician power.

The year 23 likewise clarified the legal basis for Augustus' control of his provincia (the region under his jurisdiction) and its armed forces. The Senate invested him with an imperium proconsulare (governorship and high command), and, while this had a time limit, it was automatically renewed whenever it lapsed (usually every 10 years). This proconsular imperium, furthermore, was pronounced valid inside Italy, even inside Rome and the pomerium (the boundary within which only Roman gods could be worshiped and civil magistrates rule), and it was superior (majus) to the imperium of any other proconsul. Thus, Augustus could intervene legally in any province, even in one entrusted to someone else.

The network of favours owed him that Augustus had cultivated within the state, among people of the greatest authority over their own networks, made his position virtually unassailable, but he avoided provoking this high class of his supporters, senatorial and equestrian, by not drawing attention to the most novel and autocratic of the many grants of power he had received, the imperium proconsulare majus. Instead, he paraded the tribunician power as the expression of his supreme position in the

After 23 no fundamental change in Augustus' position occurred. He felt no need to hold offices that in republican times would have conferred exceptional power (e.g., dictatorship, lifetime censorship, or regular consulship), even though these were offered him. Honours, of course, came his way: in 19 BC he received some consular rights and prerogatives, presumably to ensure that his imperium was in no particular inferior to a consul's; in 12, when Lepidus died, he became pontifex maximus (he had long since been elected into all of the priestly colleges); in 8 BC the 8th month of the year was named after him; in 2 BC he was designated pater patriae ("father of his country"). a distinction that he particularly esteemed because it sugAugustus' tribunician

emperors

Augustus' honours

gested that he was to all Romans what a pater/familiat was to his own household. He also accepted special commissions from time to time: e.g., the supervision of the supply of grain and water, the maintenance of public buildings (including temples), the regulation of the Tiber, the superintendence of the police and fire-fighting services, and the upkeep of Italy's roads. Such behaviour advertised his will and capacity to improve the lives of people dependent on him. Of that capacity, manifest on a grand scale, his tribunician power and proconsular imperium were only the formal expression. He was a charismatic leader of unrivaled prestige (auctoritas), whose merest suggestions were binding.

Like an ordinary Roman, he contented himself with three names. His, however, Imperator Caesar Augustus. were absolutely unique, with a magic all their own that caused all later emperors to appropriate them, at first selectively but after AD 69 in their entirety. Thereby they became titles, reserved for the emperor (or, in the case of the name Caesar, for his heir apparent); from them derive the titles emperor, kaiser, and tsar. Yet, as used by Augustus and his first four successors, the words Imperator Caesar Augustus were names, not titles-that is, respectively, praenomen, nomen (in effect), and cognomen. One title that Augustus did have was princeps (prince); this, however, was unofficial-a mere popular label, meaning Rome's first citizen-and government documents such as inscriptions or coins do not apply it to Augustus. But because of it the system of government he devised is called the principate.

The Roman Senate and the urban magistracies. Augustus regarded the Senate, whose leading member (princeps senatus) he had become in 28, as a body with important functions; it heard fewer overseas embassies than formerly, but otherwise its dignity and authority seemed unimpaired; its members filled the highest offices; its decrees, although not formally called laws, were just as binding; it soon became a high court, whose verdicts were unappealable; it supervised the older provinces and nominally the state finances as well, and it also in effect elected the urban magistrates; formally, even the emperor's powers derived from the Senate. Nevertheless, it lacked real power, Its provinces contained few troops (and by AD 40 it had ceased to control even these few). Hence, it could hardly dispute Augustus' wishes. In fact, real power rested with Augustus, who superintended state finances and above all controlled membership in the Senate; every senator's career depended on his goodwill. But he valued the Senate as the repository of the true Roman spirit and traditions and as the body representing public opinion. He was considerate toward it, shrewdly anticipated its reactions, and generally avoided contention with it. He regularly kept it informed about his activities; and an imperial council (Consilium Principis), which he consulted on matters of policy, in the manner of a republican magistrate seeking the opinion of his advisory committee, consisted of the consuls, certain other magistrates, and 15 senators-not handpicked by him but chosen by lot every six months.

To rid the Senate of unworthy members, he reduced its numbers by successive reviews to about 600 (from the triumviral 1,000 or more). Sons of senators and men of good repute and substance who had served in the army and the vigintiviri ("board of twenty," minor magistracy) could become members by being elected, at age 25 or over, to the quaestorship. Their subsequent rank in the Senate depended on what other magistracies they managed to win; these were, in ascending order, the aedileship (or plebeian tribunate), the praetorship, and the consulship. No one disliked by Augustus could expect to reach any of them, while anyone whom he nominated or endorsed was sure of election. Despite the emperor's control, there were usually enough candidates for keen contests. By AD 5 destinatio seems to have been the practice-that is, a special panel of senators and equites selected the praetors and consuls, and the comitia centuriata automatically ratified their choice. In about AD 5, likewise, the consulship was shortened to six months. This not only gratified senators and increased the number of high-ranking qualified officials but also showed that the consuls' duties were be-

coming largely ceremonial. This was also true, but to a far lesser degree, of the other unpaid magistrates. A senator really made his mark in between his magistracies, when he served in important salaried posts, military or civilian or both, sometimes far from Rome.

The equestrian order. Senators, however, were either too proud or too few to fill all the posts. Some posts were considered menial and went to the emperor's freedmen or slaves. Others were entrusted to equites, and the equestrian order soon developed into one of the great institutions of the empire. Augustus decided that membership in the order should be open to Roman citizens of means and reputation but not necessarily of good birth. Ultimately, there were thousands of equites throughout the empire. Although this was a lower aristocracy, a good career was available to them. After tours of duty as an army officer (the so-called militiae equestres), an aspiring eques might serve as the emperor's agent (procurator) in various capacities and eventually become one of the powerful prefects (of the fleet, of the vigiles, or fire brigade, of the grain supply, of Egypt, or of the Praetorian Guard). This kind of an equestrian career became standardized only under Claudius I; but Augustus began the system and, by his use of equites in responsible posts, founded the imperial civil service, which later was headed chiefly by them. The equites also performed another function: the senatorial order had difficulty in maintaining its numbers from its own ranks and depended on recruitment from below, which meant from the equestrian order. Because this order was not confined to Rome or even to Italy, the Senate gradually acquired a non-Italian element. The western provinces were already supplying senators under Augustus.

Administration of Rome and Italy. Ordinary Roman citizens who were neither senators nor equites were of lesser consequence. Although still used, the old formula senatus populusque Romanus ("the Senate and the Roman people") had changed its meaning: in effect, its populusque Romanus portion now meant "the emperor." The "Roman people" had become the "Italian people," and it was embodied in the person of Augustus, himself the native of an Italian town. To reduce the risk of popular demonstrations in Rome, the emperor provided grain doles, occasional donatives, and various entertainments; but he allowed the populace no real power. After AD 5 the Roman people's participation in public life consisted in the formality of holding occasional assemblies to ratify decisions made elsewhere. Ultimately, this caused the distinction between the Roman citizens of Italy and the provincial inhabitants of the overseas empire to disappear; under Augustus, however, the primacy of Italy was insistently emphasized.

Indeed, Italy and justice for its inhabitants were Augustus' first cares. Arbitrary triumviral legislation was pronounced invalid after 29 BC, and ordinary Roman citizens everywhere had access to Augustus' own court of appeal (his appellate jurisdiction dated from 30 BC and in effect replaced the republican appeal to the people). His praetorian and urban cohorts provided physical security; his officials assured grain supplies; and he himself, with help from such aides as Agrippa, monumentalized Italian towns. The numerous Augustan structures in Italy and Rome (as he boasted, a city of brick before his time and of marble afterward) have mostly perished, but impressive ruins survive (e.g., aqueduct, forum, and mausoleum in Rome; bridge at Narni; arch at Fano; gate at Perugia). Doubtless their construction alleviated unemployment, especially among the proletariat at Rome. But economic considerations did not influence Augustus' policies much (customs tariffs, for instance, were for fiscal, not protective, purposes), nor did he build harbour works at Ostia, Rome's port. Italian commerce and industry-notably fine pottery, the so-called terra sigillata, and wine-nevertheless flourished in the conditions he created. Public finances, mints, and coinage issues, chaotic before him, were placed on a sound basis, partly by the introduction of a sales tax and of a new levy (inheritance taxes) on Roman citizens-who hitherto had been subject only to harbour dues and manumission (see below) charges-and partly by means of repeated subventions to the public treasury (aerarium Saturni) from

Rise of equites to a privileged

Augustus' relationship with the Senate

> The primacy of Italy

Augustus' own enormous private resources (patrimonium Caesaris). His many highways also contributed to Italy's economic betterment.

Augustus' great achievement in Italy, however, was to restore morale and unify the country. The violence and self-aggrandizement of the 1st century BC had bred apathy and corruption. To reawaken a sense of responsibility, especially in official and administrative circles, Augustus reaffirmed traditional Italian virtues (by laws aimed against adultery, by strengthening family ties, and by stimulating the birth rate) and revived ancestral religion (by repairing temples, building new shrines, and reactivating moribund cults and rituals). To infuse fresh blood and energy into disillusioned Roman society, he promoted the assimilation of Italy: the elite of its municipal towns entered the Roman Senate, and Italy became firmly one with Rome. To keep the citizen body pure, he made manumission of slaves difficult, and from those irregularly manumitted he

Two types of provinces

withheld the citizenship. Administration of the provinces. Sharply distinguished from Italy were the provinces of the empire. From 27 BC on they were of two types. The Senate supervised the long-established ones, the so-called public provinces: their governors were chosen by lot, usually served for a year, commanded no troops, and were called proconsuls (although only those superintending Asia and Africa were in fact former consuls, the others being former practors). The emperor supervised all other provinces, and collectively they made up his provincia: he appointed their governors, and these served at his pleasure, none with the title of proconsul because in his own provincia proconsular imperium was wielded by him alone. These imperial provinces might be "unarmed," but many of them were garrisoned, some quite heavily. Those containing more than one legion were entrusted to former consuls and those with a legion or less to former praetors; in both cases their governors were called legati Augusti pro praetore ("legates of Augustus with authority of a praetor"). There were also some imperial provinces governed not by senators but by equites (usually styled procurators but sometimes prefects); Judaea at the time of Christ's crucifixion was such an equestrian province, Pontius Pilate being its governor. An entirely exceptional imperial province was Egypt, so jealously guarded that no senator could visit it without express permission; its prefect was unique in being an equestrian in command of legions.

The provinces paid tribute, which helped to pay for the armed services, various benefactions to supporters. a growing palace staff, and the public-works programs. Periodical censuses, carefully listing provincial resources, provided the basis for the two direct taxes: tributum soli, exacted from occupiers of provincial soil, and tributum capitis, paid on other forms of property (it was not a poll tax, except in Egypt and in certain backward areas). In addition, the provinces paid indirect taxes, such as harbour dues. In imperial provinces the direct taxes (tributa) were paid to the emperor's procurator, an equestrian official largely independent of the governor. In senatorial provinces, quaestors supervised the finances; but, increasingly, imperial procurators also appeared. The indirect taxes (vectigalia) were still collected by publicani, who were now much more rigorously controlled and gradually replaced by imperial civil servants.

To reward his troops after faithful service, Caesar had settled them on lands mostly in the provinces, in veteran towns; and Augustus, for the same reason and to reduce the dangerous military presence in the state generally, resorted to the same procedure on a vast scale. Thus, in the space of a single generation, more than 120 new centres were organized across the empire in an explosion of urbanizing energy never equaled or even approached in later times. In the settlements called coloniae all residents were to be Roman citizens, and the form of government and many other aspects of life specified in their charters bore a thoroughly Roman character. Some coloniae, in further approximation to Italian models, enjoyed exemption from tribute. In the municipia only persons elected as magistrates were awarded Roman citizenship (after Hadrian, in Africa, admission was sometimes extended to the whole of the local senate); but the whole of the local aristocracy in the course of time would be in this way gradually incorporated fully into the state. In municipia, too, charters specified Roman forms of government. Urban centres that were wholly noncitizen, called civitates, enjoyed autonomy in their own affairs, under the governor's eye; they paid taxes and administered the rural territory around them. In the west, many of them were eventually granted the status of municipia, and they adopted the originally Italian magistracies (duoviri and aediles, collectively quattuorviri) and senate (curia or ordo), normally numbering 100 members. The entire West rapidly came under the administration of urban centres of these three forms, without which the central government could never have done its job. Moreover. these centres radiated economic and cultural influence around them and so had an immense effect, particularly on the way of life of the more backward areas. In the east, however, urban centres, though equally important for government purposes, had already been in existence and long settled into their own culture and forms of government,

The provinces were generally better off under the empire. Appointment over them as governor was now and henceforth generally granted with the emperor's approval, Because he thought of himself as in some ways the patron and defender of the provincial population, lax or extortionate officials could expect some loss of imperial favour, an end to their careers, or an even more severe

Emperor worship. For this priceless gift of peace many individuals and even whole communities, in Italy and elsewhere, expressed their thanks spontaneously by worshiping Augustus and his family. Emperor worship was also encouraged officially, however, as a focus of common loyalty for the polyglot empire. In the provinces, to emphasize the superiority of Italy, the official cult was dedicated to Roma et Augustus; to celebrate it, representatives from provincial communities or groups of communities met in an assembly (Consilium Provinciae), which incidentally might air grievances as well as satisfactions. (This system began in the Greek-speaking provinces, long used to wooing their rulers with divine honours. It penetrated the west only slowly, but from 12 BC an assembly for the three imperial Gallic provinces existed at Lugdunum.) In Italy the official cult was to the genius Augusti (the life spirit of his family); it was coupled in Rome with the Lares Compitales (the spirits of his ancestors). Its principal custodians (seviri Augustales) were normally freedmen. Both the Senate and the emperor had central control over the institution. The Senate could withhold a vote of posthumous deification. and the emperor could acknowledge or refuse provincial initiatives in the establishment of emperor worship, in the construction for it, or in its liturgical details. The energy, however, that infused emperor worship was to be found almost wholly among the local nobilities.

The army. It was Augustus' soldiers, however, not his worshipers, who made him all-powerful. Their allegiance, like the name Caesar, was inherited from his "father, the deified Julius. The allegiance was to the emperor personally, through a military oath taken in his name every January 1; and the soldiers owed it after his death to his son or chosen successor. This preference of theirs for legitimacy could not be ignored because they were now a standing army, something that the republic had lacked. Demobilization reduced the 60 legions of Actium to 28, a number hardly sufficient but all that Augustus' prudence or economy would countenance. These became permanent formations, each with its own number and name; the soldiers serving in them were called legionaries. Besides the legionaries there was a somewhat smaller body of auxiliaries, or supporting troops. The two corps together numbered more than a quarter of a million men. To them must be added the garrison of Italy-the praetorian cohorts, or emperor's bodyguard, about 10,000 strongand the marines of the imperial fleet, which had its main headquarters at Misenum and Ravenna in Italy and subsidiary stations and flotillas on seas and rivers elsewhere (the marines, however, were not reckoned good combat forces). All these troops were long-service professionalsthe praetorians serving 16 years; legionaries, 20; auxil-

Allegiance of the to the emperor

Types of urban centres

iaries, 25; and marines, 28-with differing pay scales, the praetorians' being the highest. In addition to their pay, the men received donatives, shares of booty, and retirement bonuses from a special treasury (aerarium militare) established in AD 6 and maintained out of the sales tax and Roman citizens' death duties. Under Augustus the praetorians were normally Italians, but many legionaries and virtually all auxiliaries were provincials, mainly from the imperial provinces in the west, the legionaries coming from municipal towns and the auxiliaries from tribal areas. The tendency to use provincials grew, and by the year 100 the Roman imperial army was overwhelmingly non-Italian. Nevertheless, it helped greatly to Romanize the empire. The legionaries were Roman citizens from the day they enlisted, if not before, and the auxiliaries (after Claudius anyway) from the day they were discharged; and though serving soldiers could not legally marry, many had mistresses whose children often became Roman citizens. The troops, other than praetorians and marines, passed their years of service in the "armed" imperial provinces the auxiliaries in forts near the frontier and the legionaries at some distance from it in camps that showed an increasing tendency, especially after AD 69, to become permanent (some of them, indeed, developed into great European cities). There was no central reserve, because, although desirable for emergencies, it might prove dangerous in peacetime.

The officers were naturally Roman citizens. In the legions those of the highest rank (legati and tribuni) were senators or equites; lower officers (centuriones) might enter directly from Italian or provincial municipalities or might rise through the ranks; by the time they retired, if not sooner, many of them were equites. In the auxiliaries the unit commanders (praefecti) were equites, often of provincial birth. On retirement the soldiers frequently settled in the provinces where they had served, made friends, and perhaps acquired families. Imperial policy favoured this practice. Thus the army, which had done much to intro-duce into the provinces Romans of all ranks, with their own way of life, through veteran settlements of the 40s, 30s, and 20s BC, continued in the same role on a more modest and casual scale throughout the Augustan reign

and for two centuries or so afterward.

Foreign policy. After Actium and on two other occasions, Augustus solemnly closed the gates of the shrine of Janus (a gesture of peace) to show that Rome had peace as well as a princeps. These well-publicized gestures were purely temporary; the gates were swiftly reopened. His proconsular imperium made Augustus the arbiter of peace and war, and an ostensible search for defensible frontiers made his a very warlike reign. While the republic had left the limits of Roman territorial claims rather vague and indefinite, he planned conquests stretching to the boundaries defined by nature (deserts, rivers, and ocean shores), not always, however, with immediate annexation in mind. When annexation did occur, it was followed by the construction of solidly built military roads, paved with thick stone blocks: these also served the official post system (cursus publicus) and were provided with rest stages and overnight lodges at regular intervals.

Areas where subjugation looked arduous and where Romanization seemed problematic were left to client kings, dependent on the emperor's support and goodwill and under obligation to render military aid to Rome. Such satellite kingdoms spared Augustus the trouble and expense of maintaining strong defenses everywhere; nevertheless, their ultimate and intended destiny was incorporation as soon as it suited their overlord's convenience. Usually, territory was gained more easily by creating and subsequently incorporating a client kingdom than by launching

an expansionist war. In the south, Augustus found suitable frontiers quickly. In 25 BC an expedition under Aelius Gallus opened the Red Sea to Roman use and simultaneously revealed the Arabian Desert as an unsurpassed and, indeed, unsurpassable boundary. The same year Gaius Petronius, the prefect of Egypt, tightened Rome's grip as far as the First Cataract and established a broad military zone beyond it. The vast region north of the Sahara and the Atlas Mountains was also secured (c. 25) after a series of punitive raids against native tribes and the annexation of one client kingdom (Numidia) and the creation of another (Mauretania). Three legions, two in Egypt and one in Africa (a senatorial province), policed the southern shore of the

In the west, consolidation was extended to the Atlantic. Gaul, Julius Caesar's conquest, was organized as four provinces: senatorial Narbonensis and the imperial three Gauls (Aquitania, Belgica, and Lugdunensis). In Spain, after Agrippa successfully ended in 19 BC the last campaien that Augustus had launched in person in 26, three provinces were formed: senatorial Baetica and imperial Lusitania and Tarraconensis. Three legions enforced Roman authority from Gibraltar to the mouth of the Rhine Augustus ignored the advice of court poets and others to

advance still farther and annex Britain.

In the east, Parthia had demonstrated its power against Crassus and Antony, and Augustus proceeded warily. He retained Antony's ring of buffer client kingdoms, although he incorporated some, including the most celebrated of in the east them, Judaea; he made it a province in AD 6, especting. however, some of the customs of its Jewish inhabitants Augustus stationed four legions in Syria and obviously envisaged the Euphrates River and the northern extension of the Arabian Desert as the desirable frontier with Mesopotamia. Farther north, however, no such natural line existed. North of the Black Sea the client kingdom of the Cimmerian Bosporus, under its successive rulers Asander and Polemo, helped to contain southward and westward thrusts by the Scythians, an Iranian people related to the Parthians, and this provided protection in the north for Anatolia and its provinces (senatorial Asia and Bithynia-Pontus and imperial Cilicia and Galatia, the latter a large new province created in 25 BC out of Amyntas' client kingdom). By a show of force, Augustus' stepson Tiberius, in 20 BC, recovered the standards lost at Carrhae and installed Tigranes as client king of Armenia. Although Augustan propaganda depicted this as a famous victory, strategic considerations inevitably obliged the Parthians, once they settled their internal, dynastic dissensions, to dispute Roman control of Armenia. Thus it can hardly be said that Augustus settled the eastern frontier. Missions were sent to the East repeatedly (Agrippa, 17-13 BC; Gaius Caesar, AD 1-4; Germanicus, 18-19), and Armenia remained a problem for Augustus' successors: Tiberius successfully maintained Roman influence there, but Gaius and Claudius failed to do so, leaving Nero with a difficult situation.

In the north, too, there was difficulty. The Alps and their passes were finally subjugated early in Augustus' reign. This enabled Tiberius and his brother Drusus between 16 and 8 BC to conquer all the way to the great rivers of central Europe. New provinces were created in the Alps and Tyrol (Maritime and Pennine Alps, Raetia, Noricum) and also farther east (Pannonia, Moesia). Stability along the Danube was precariously maintained, under Augustus and later, by means of periodical alliances with Maroboduus and his successors, who ruled Germanic tribes such as the Marcomanni and Quadi in Bohemia to the north of the river, and by the existence of a Thracian client kingdom to the south of its lowest course. The push across the Rhine began in 12 BC; although it reached the Elbe, consolidation beyond the Rhine proved elusive. A revolt in Pannonia (AD 6-9) interrupted it, and, in AD 9, German tribes under Arminius annihilated Quinctilius Varus and three legions in the Teutoburg Forest. This disaster reduced the number of legions to 25 (it did not reach 28 again until half a century later), and it disheartened Augustus. Old and weary, he withdrew to the Rhine and decided against all further expansion, a policy he urged upon his successor. For the watch on the Rhine the military districts of Upper and Lower Germany were created, containing eight legions between them. Another seven garrisoned the Danubian provinces. These figures reveal imperial anxiety for the northern frontier.

Economic life. Although widespread, Augustus' wars chiefly affected the frontier districts. Elsewhere, peace prevailed. Indeed, never before had so large an area been peace

Difficulties and north

Territorial expansion under Augustus

free of war for so long. This state of affairs helped trade. The suppression of piracy and the use of military roads, which the frontier warfare itself brought into being, provided safe arteries of commerce. Stable currency also aided economic growth. Activity directly connected with the soil predominated; but there were also many establishments, usually small, engaged in manufacturing, and such products as textiles, pottery, tiles, and papyrus were turned out in surprising quantities. Advanced techniques were also known: glassblowing, for example, dates from the Augustan age. Most products were consumed locally, but the specialties or monopolies from any region usually exceeded local needs, and the surplus was sold elsewhere, generating a brisk interchange of goods. Some traveled great distances, even beyond the empire: trade with India, for example, reached respectable proportions once the nature of the monsoon was understood, and the Red Sea was opened to Roman shipping. Merchants, especially Levantines, traveled everywhere, and fairs were frequent. The Mediterranean world was linked together as never before, and standardization made considerable headway. In Augustus' day Italy was economically the most important part of the empire. It could afford to import on a large scale, thanks partly to provincial tribute but above all to its own large productivity. The eastern provinces, for their part, recovered rapidly from the depredations of the civil wars and were industrially quite advanced. The other provinces were less developed, but they soon ceased being mere suppliers of raw materials; they learned to exploit their natural resources by using new techniques and then began overtaking the more advanced economies of Italy and the Greek-speaking regions. The importance of trade in unifying the empire should not be underestimated.

Augustan art and literature. In 17 BC Rome held Secular Games, a traditional celebration to announce the entry into a new epoch (saeculum). New it was, for, though Augustus preserved what he could of republican institutions, he added much that was his own. His Rome had become very Italian, and this spirit is reflected in the art and literature of his reign. Its greatest writers were native Italians, and, like the ruler whose program they glorified, they used the traditional as the basis for something new. Virgil, Horace, and Livy, as noted above, imitated the writing of classical Greece, but chiefly in form, their tone and outlook being un-Hellenic. It was the glory of Italy and faith in Rome that inspired Virgil's Georgics and Aeneid,

Horace's Odes, and the first 10 books of Livy's history. In Augustan art a similar fusion was achieved between the prevailing Attic and Hellenistic models and Italian naturalism. The sculptured portraits on the Ara Pacis Augustae (Altar of the Augustan Peace) of 9 BC, for all their lifelike quality, are yet in harmony with the classical poise of the figures, and they strike a fresh note: the stately converging processions (Rome's imperial family and magistrates on one side; senators, equites, and citizens on the other) became the prototypes for all later processional reliefs. Augustan painting likewise displays a successful combination of Greek and Roman elements, to judge from the frescoes in the house of Livia on the Palatine. In Augustan architecture, decidedly conservative and Hellenic, the potentialities of curving and vaulted spaces that had been revealed in the earlier 1st century BC were not realized. Building was, however, very active and

widespread. The culture of the age undoubtedly attained a high level of excellence, dominated by the personality of the emperor and his accomplishments. Imperial art had already reached full development, a matter of no small moment, because Rome's political predominance made the spread of its influence inevitable. The Mediterranean world was soon assuming a Roman aspect, and this is a measure of Augustus' extraordinary achievement. Yet it was an achievement with limitations. His professed aimto promote stability, peace, security, and prosperity-was irreproachable, but perhaps it was also unexciting. Emphasizing conservatism by precept and his own example, he encouraged the simpler virtues of a less sophisticated age, and his success made this sedate but rather static outlook fashionable. People accepted the routine of his continuing

rule, at the cost, however, of some loss of intellectual energy and moral fervour. The great literature, significantly, belongs to the years near Actium, when people's imagination still nursed heady visions of Roman victory and Italian destiny. After the Secular Games the atmosphere became more commonplace and produced the frivolities of Ovid and the pedestrian later books of Livy.

Appraisal of Augustus. Augustus' position as princeps cannot be defined simply. He was neither a Roman king (rex) nor a Hellenistic monarch (basileus), nor was he, as the 19th-century German historian Theodor Mommsen thought, a partner with the Senate in a dyarchy. He posed as the first servant of an empire over which the Roman Senate presided, and it would appear that his claim to have accepted no office inconsistent with ancestral custom was literally true. Proconsular imperium was a republican institution, and, although tribunician power was not, it contained nothing specifically unrepublican. But, while precedents can be cited for Augustus' various powers, their concentration and tenure were absolutely unparalleled. Under the republic, powers like his would have been distributed among several holders, each serving for a limited period with a colleague. Augustus wielded them all, by himself, simultaneously and without any time limit (in practice, at least). This fact made him an emperor, but it did not necessarily make him a military tyrant.

In discharging both military and civilian functions, Augustus was no different from republican consuls or practors. Admittedly his military power was overwhelming; but, if he chose not to brandish it, the tone of his reign could remain essentially civilian. Constitutional safeguards were indeed lacking; everything was at the emperor's discretion, and even Augustus passed legislation that made anti-imperial behaviour, real or suspected, treasonable (men were, in fact, executed for conspiracy during his reign). But there had been no constitutional safeguards in the republic, under Sulla, Pompey, the triumvirs, or even Julius Caesar. Augustus' improved police services probably made lowerclass Romans at least feel safer under him. The senatorial class, however, contained a minority resentful of the sheer undeniable preponderance of the princeps' power, and he was the target of several unsuccessful plots against his life.

The principate was something personal, what the emperor chose to make it, and the relations prevailing between emperor and Senate usually indicated what a reign was like. In Augustus' case they reveal a regime that was outwardly constitutional, generally moderate, and certainly effective. But, as he himself implied at the end of his life, he was a skillful actor in life's comedy. Later emperors lacked his sureness of touch.

When Augustus died, the Senate unhesitatingly pronounced him divus-the deified one who had restored peace, organized a standing army to defend the frontiers, expanded those frontiers farther than any previous Roman, improved administrative practices everywhere, promoted better standards of public and private behaviour. integrated Rome and Italy, embellished Rome, reconciled the provinces, expedited Romanization, and above all maintained law and order while respecting republican traditions.

Augustus' luck was hardly inferior to his statecraft. Despite indifferent health, he headed the Roman state in one capacity or another for 56 years. His rule, one of the longest in European history, consolidated the principate so firmly that what might have been an episode became an epoch. At his death there was practically no one left with any personal memory of the republic, and Augustus' wish came true: he had fashioned a lasting as well as constitutional government. The principate endured with only minor changes for about 200 years.

The succession. Like any great Roman magnate, Augustus owed it to his supporters and dependents to maintain the structure of power which they constituted together and which would normally pass from father to son. In accepting the heritage from Caesar, he had only done the right thing, and he was respected for it by his peers. None of them would have advised him later to dismantle what he had since added to it. When, for instance, he was away from Rome, rather than accepting a diminution in his preAugustus' accomplish-

Cultural excellence of the Augustan age

rogatives of administration, a senator as city prefect was deputed to represent him. Consequently, Augustus began thinking early about who should follow him. The soldiers' views on legitimacy reinforced his own natural desire to found a dynasty, but he had no son and was therefore obliged to select his successor. Death played havoc with his attempts to do so. His nephew Marcellus, his sonin-law Agrippa, his grandsons Gaius and Lucius (Julia's children by Agrippa), were groomed in turn; but they all predeceased him. Augustus, finally and reluctantly, chose a member of the republican nobility, his stepson Tiberius, a scion of the ultra-aristocratic Claudii. In AD 4 Augustus adopted Tiberius as his son and had tribunician power and probably proconsular imperium as well conferred upon him. This arrangement was confirmed in 13, and, when Augustus died the following year, Tiberius automatically became emperor.

Tiberius (ruled 14-37), during whose reign Christ was crucified, was a soldier and administrator of proved capability but of a reserved and moody temperament that engendered misunderstanding and unpopularity. Slander blamed him for the death in 19 of his nephew and heir apparent, the popular Germanicus; and, when informers (delatores), who functioned at Rome like public prosecutors, charged notables with treason, Tiberius was thought to encourage them. By concentrating the praetorian cohorts in a camp adjoining Rome, he increased the soldiers' scope for mischief-making without building any real security, and in 26 he left Rome permanently for the island of Capreae (Capri), entrusting Rome to the care of the city prefect. Tiberius heeded the aged Augustus' advice and did not extend the empire. (The annexation of Cappadocia, a client kingdom, represented no departure from Augustan policy.) In general he took his duties seriously; however, by administering the empire from Capreae he offended the Senate and was never fully trusted, much less really liked. At his death he was not pronounced divus. His great-nephew, Germanicus' son Gaius, succeeded him.

Gaius (better known by his nickname, Caligula, meaning Little Boot) ruled from 37 to 41 with the absolutism of an Oriental monarch; his short reign was filled with reckless spending, callous murders, and humiliation of the Senate, Gaius' foreign policy was inept. Projected annexation proved abortive in Britain; it touched of heavy fighting in Mauretania. In Judaea and Alexandria, Gaius' contemptuous disregard of Jewish sentiment provoked hear rebellion. When assassination ended his tyranny, the Senate contemplated restoration of the republic but was obliged by the Praetorian Guard to recognize Claudius, Germanicus' burders and therefore Gaius' suche as empression.

Central-

ization and

expansion

under Claudius I

brother and therefore Gaius' uncle, as emperor. Claudius I (ruled 41-54) went far beyond Augustus and Tiberius in centralizing government administration and, particularly, state finances in the imperial household. His freedmen secretaries consequently acquired great power; they were in effect directors of government bureaus. Claudius himself displayed much interest in the empire overseas; he enlarged it significantly, incorporating client kingdoms (Mauretania in 42; Lycia, 43; Thrace, 46) and, more important, annexing Britain. Conquest of Britain began in 43, Claudius himself participating in the campaign; the southeast was soon overrun, a colonia established at Camulodunum (Colchester) and a municipium at Verulamium (St. Albans), while Londinium (London) burgeoned into an important entrepôt. Claudius also promoted Romanization, especially in the western provinces, by liberally granting Roman citizenship, by founding coloniae, and by inducting provincials directly into the Senate-he became censor in 47 and added to the Senate men he wanted, bestowing appropriate quaestorian or praetorian rank upon them to spare the maturer ones among them the necessity of holding junior magistracies; lest existing senators take offense, he elevated some of them to patrician status (a form of patronage often used by later emperors). Claudius' provincial policies made the primacy of Italy less pronounced, although that was hardly his aim. In fact, he did much for Italy, improving its harbours, roads, and municipal administration and draining its marshy districts. The execution of many senators and equites, the insolence and venality of his freedmen,

the excessive influence of his wives, and even his bodily infirmities combined to make him unpopular. Nevertheless, when he died (murdered probably by his fourth wife, Agrippina, Augustus' great-granddaughter, who was impatient for the succession of the 16-year-old Nero, her son by an earlier marriage), he was pronounced drives.

Nero (ruled 54-68) left administration to capable advisers for a few years but then asserted himself as a vicious despot. He murdered successively his stepbrother Britannicus, his mother Agrippina, his wife Octavia, and his tutor Seneca. He also executed many Christians, accusing them of starting the great fire of Rome in 64 (this is the first recorded Christian persecution). In Rome his reliance on Oriental favourites and his general missovernment led to a conspiracy by Gaius Calpurnius Piso in 65, but it was suppressed, leading to yet more executions; the victims included the poet Lucan. The empire was not enlarged under this unwarlike emperor, but it was called upon to put down serious disorders. In Britain in 60-61 the rapacity and brutality of Roman officials provoked a furious uprising under Queen Boudicca; thousands were slaughtered, and Camulodunum, Vernulamium, and Londinium were destroyed. In the east a major military effort under Corbulo, Rome's foremost general, was required (62-65) to reestablish Roman prestige; a compromise settlement was reached, with the Romans accepting the Parthian nominee in Armenia and the Parthians recognizing him as Rome's client king. In 66, however, revolt flared in Judaea, fired by Roman cruelty and stupidity, Jewish fanaticism, and communal hatreds; the prefect of Egypt, Julius Alexander, prevented involvement of the Jews of the Diaspora. An army was sent to Judaea under Titus Flavius Vespasianus to restore order; but it had not completed its task when two provincial governors in the west rebelled against Nero-Julius Vindex in Gallia Lugdunensis and Sulpicius Galba in Hispania Tarraconensis. When the praetorians in Rome also renounced their allegiance, Nero lost his nerve and committed suicide. He brought the Julio-Claudian dynasty to an ignominious end by being the first emperor to suffer damnatio memoriae-his reign was officially stricken from the record by order of the Senate.

Growth of the empire under the Flavians and Antonines. The year of the four emperors. Nero's death ushered in the so-called year of the four emperors. The extinction of the Julio-Claudian imperial house robbed the soldiers of a focus for their allegiance, and civil war between the different armies ensued. The army of Upper Germany, after crushing Vindex, urged its commander, Verginius Rufus, to seize the purple for himself. But he elected to support Galba-scion of a republican patrician family claiming descent from Jupiter and Pasiphae-who was recognized as emperor by the Senate. However, the treasury, emptied by Nero's extravagance, imposed a stringent economy, and this bred unpopularity for Galba; his age (73) was also against him, and unrest grew. Early in January 69 the Rhineland armies acclaimed Aulus Vitellius, commander in Lower Germany; at Rome the praetorians preferred Marcus Salvius Otho, whom Galba had alienated by choosing a descendant of the old republican aristocracy for his successor. Otho promptly procured Galba's murder and obtained senatorial recognition; this ended the monopoly of the purple for the republican nobility.

Otho, however, lasted only three months; defeated at Bedriacum, near Cremona in northern tally, by Vitelluis' powerful Rhineland army, he committed suicide (April 69). The Senate thereupon recognized Vitelluis; but the soldiers along the Danube and in the east supported Vespasianus, the commander in Judaea. In a second battle near Bedriacum, the Rhineland troops were defeated in their turn, and on Vitellius' death soon afterward an accommodating Senate pronounced Vespasian emperor.

The Flavian emperors. On Dec. 22, 69, the Senate conferred all the imperial powers upon Vespasian en blocwith the famous Lex de Imperio Vespasiani ("Law Regulating Vespasian's authority"), and the Assembly ratified the Senate's action. This apparently was the first time that such a law was passed; a fragmentary copy of it is preserved on the Capitol in Rome.

Vespasian (ruled 69-79) did not originate from Rome or

The reign of Nero

its aristocracy. His family came from the Sabine municipality Reate, and with his elevation the Italian bourgeoisie came into its own. He and his two sons, both of whom in turn succeeded him, constituted the Flavian dynasty (69-96). Vespasian faced the same difficult task as Augustusthe restoration of peace and stability. The disorders of 69 had taken troops away from the Rhine and Danube frontiers. Thereupon, the Danubian lands were raided by Sarmatians, a combination of tribes who had overwhelmed and replaced the Scythians, their distant kinsmen, in eastern Europe. The assailants were repelled without undue difficulty; but the Sarmatian Iazyges, now firmly in control of the region between the Tisza and Danube rivers, posed a threat for the future.

Developments in the Rhineland were more immediately serious. There in 69 a certain Civilis incited the Batavians serving as auxiliaries in the Roman army to rebel. Gallic tribes joined the movement, and the insurgents boldly overran all but two of the legionary camps along the Rhine. Vespasian sent his relative Petilius Cerealis to deal with the rebels, who, fortunately for Rome, were not united in their aims; by 70 Cerealis had restored order. That same year Vespasian's elder son, Titus, brought the bloody war in Judaea to its end by besieging, capturing,

and destroying Jerusalem.

Vesna-

policies

sian's

To rehabilitate the public finances, Vespasian introduced new imposts, including a poll tax on Jews, and practiced stringent economies. With the Senate he was courteous but firm. He allowed it little initiative but used it as a reservoir from which to obtain capable administrators. To that end he assumed the censorship and added senators on a larger scale than Claudius had done, especially from the municipalities of Italy and the western provinces. Already before 69 an aristocracy of service had arisen, and the provincialization of the Roman Senate had begun; thereafter this development made rapid headway. Besides the censorship, Vespasian also often held the consulship, usually with Titus as his colleague. His object presumably was to ensure that his own parvenu Flavian house outranked any other. In this he succeeded; the troops especially were ready to accept the Flavians as the new imperial family. On Vespasian's death in 79, Titus, long groomed for the succession, became emperor and immediately had his fa-

Titus (ruled 79-81) had a brief reign, marred by disasters (the volcanic eruption that buried Pompeii and Herculaneum and another great fire in Rome); but his attempts to alleviate the suffering and his general openhandedness won him such popularity that he was unhesitatingly dei-

fied after his early death.

Domitian (ruled 81-96), Titus' younger brother, had never been formally indicated for the succession; but the praetorians acclaimed him, and the Senate ratified their choice. Throughout his reign Domitian aimed at administrative efficiency, but his methods were high-handed. For him the Senate existed merely to supply imperial servants. He also used equites extensively, more than any previous emperor. He held the consulship repeatedly, was censor perpetuus from 85 on, and demanded other extravagant honours. On the whole, his efficiency promoted the welfare of the empire. Above all, he retained the allegiance of the troops. Although scornful of the Senate's dignity, he insisted on his own and mercilessly punished any act of disrespect, real or fancied, toward himself. He became even more suspicious and ruthless when Saturninus, commander in Upper Germany, attempted rebellion in 89. He crushed Saturninus; executions and confiscations ensued, and delatores flourished. The tyranny was particularly dangerous to senators, and it ended only with Domitian's assassination in 96. The Flavian dynasty, like the Julio-Claudian, ended with an emperor whose memory was officially damned.

The disorders in 69 were the cause of some military reforms. Under the Flavians, auxiliaries usually served far from their native hearths under officers of different nationality from themselves. At the same time, the tasks assigned to them came increasingly to resemble those performed by the legionaries. The latter grew less mobile, as camps with stone buildings came to be the rule; and it

became common for detachments from a legion (vexillationes), rather than the entire legion, to be used for field operations. This army of a new type proved its mettle in Britain, where the advance halted by Boudicca's revolt was now resumed. Between 71 and 84 three able governors-Petilius Cerealis, Julius Frontinus, and Julius Agricola, the latter Tacitus' father-in-law-enlarged the province to include Wales and northern England; Agricola even reached the Scottish highlands before Domitian recalled him.

Along the Rhine, weaknesses revealed by Civilis' revolt were repaired. Vespasian crossed the river in 74 and annexed the Agri Decumates, the triangle of land between the Rhine, Danube, and Main rivers. To consolidate the position, he and Domitian after him penetrated the Neckar River valley and Taunus mountains, and fortifications began to take shape to the east of the Rhine, a military boundary complete with strongpoints, watchtowers, and, later, a continuous rampart of earthworks and palisades. Once Saturninus' revolt in 89 had been suppressed, Domitian felt the situation along the Rhine sufficiently stable to warrant conversion of the military districts of Upper and Lower Germany into regular provinces and the transfer of some Rhineland troops to the Danube. To the north of this latter river, the Dacians had been organized into a strong kingdom, ruled by Decebalus and centring on modern Romania; in 85 they raided southward across the Danube, and in the next year they defeated the Roman punitive expedition. Domitian restored the situation in 88. but Saturninus' rebellion prevented him from following up his success. Domitian and Decebalus thereupon came to terms: Decebalus was to protect the lower Danube against Sarmatian attack, and Domitian was to pay him an annual subsidy in recompense. The Danubian frontier, however, remained disturbed, and Domitian wisely strengthened its garrisons; by the end of his reign it contained nine legions, as against the Rhineland's six, and Pannonia was soon to become the military centre of gravity of the empire.

The Flavians also took measures to strengthen the eastern frontier. In Asia Minor, Vespasian created a large "armed" province by amalgamating Cappadocia, Lesser Armenia, and Galatia; and the whole area was provided with a network of military roads. South of Asia Minor, Judaea was converted into an "armed" province by getting legionary troops; and two client kingdoms-Commagene and Transjordan-were annexed and added to Syria. Furthermore, the legionary camps seem now to have been established right on the Euphrates at the principal river crossings. This display of military strength kept the empire

and Parthia at peace for many years

The Antonine emperors. Marcus Cocceius Nerva, an elderly senator of some distinction, was the choice of Domitian's assassins for emperor; and the Senate promptly recognized him. The soldiers, however, did so much more reluctantly, and, because the year 69 had revealed that emperors no longer needed to be Roman aristocrats and could be chosen in places other than Rome, their attitude imposed caution

Nerva, who ruled from 96 to 98, adopted a generally lavish and liberal policy, but it failed to win the soldiers over completely, and he proved unable to save all Domitian's murderers from their vengeance. Unrest subsided only when, overlooking kinsmen of his own, he adopted an outstanding soldier, Marcus Ulpius Trajanus, who was governor of Upper Germany, as his successor. Nerva him-

self died a few months later.

Trajan (ruled 98-117) was the first and perhaps the only emperor to be adopted by a predecessor totally unrelated to him by either birth or marriage. He was also the first in a series of "good" rulers who succeeded one another by adoption and for most of the 2nd century provided the empire with internal harmony and careful government; they are collectively, if somewhat loosely, called the Antonine emperors. More significantly still, Trajan, a Spaniard, was also the first princeps to come from the provinces; with the greater number of provincials now in the Senate, the elevation of one of them, sooner or later, was practically inevitable. Throughout his reign, Trajan generally observed constitutional practices. Mindful of the susceptibilities of the Senate, he regularly consulted and Strengthening of the eastern frontier

Military reforms under the Flavians

reported to it. Modest in his bearing, he did not claim ostentatious honours such as frequent consulships or numerous imperial salutations, and he mixed easily with senators on terms of cordial friendship. This reestablished mutual respect between princeps and Senate. Empire and liberty, in Tacitus' words, were reconciled, and the atmosphere of suspicion, intrigue, and terror surrounding the court in Domitian's day disappeared. Traian endeared himself also to the populace at large with lavish building programs, gladiatorial games, and public distributions of money. Above all, he was popular with the armed forces; he was the soldier-emperor par excellence. Understandably, he received the title Optimus (Best), officially from 114 on (and unofficially for many years earlier).

Yet Trajan was a thoroughgoing autocrat who intervened without hesitation or scruple even in the senatorial sphere, whenever it seemed necessary. His aim was efficiency; his desire was to promote public welfare everywhere. He embellished Rome with splendid and substantial structures and he showed his care for Italy by refurbishing and enlarging the harbours at Ostia, Centumcellae, and Ancona, He sent officials called curatores to Italian municipalities in financial difficulties and helped to rehabilitate them. He greatly expanded an ingenious charity scheme probably begun by Nerva: money was loaned to farmers on easy terms, and the low interest they paid went into a special fund for supporting indigent children. Nor did Trajan neglect Italy's highway network: he built a new road (Via Traiana) that soon replaced the Via Appia as the main thoroughfare between Beneventum and Brundisium.

Interest in Italy implied no neglect of the provinces. Curatores were also sent to them; to rescue Achaea and Bithynia, senatorial provinces, from threatened bankruptcy. Trajan made them both temporarily imperial, sending special commissioners of his own to them. His correspondence with his appointee in Bithynia, the younger Pliny, has survived and reveals how conscientiously the emperor responded on even the smallest details. At the same time, it reveals how limited was access to the central government and, consequently, how great a latitude for independent decisions must be left to the governors who lacked some special claim on the emperor's attention. Trajan's day was too short to hear every speech of every delegation from the provinces, every recommendation to bestow favour or grant promotion, and every appeal to himself as supreme judiciary. To assist him, he had a "bureaucracy" of only a few hundred in Rome and a few more hundred serving in various capacities in the provinces-to direct the lives of some 60 million people. Clearly, most government must in fact rest in the hands of local aristocracies.

In the military sphere, Trajan's reign proved a most dynamic one. He decided to strengthen the dangerous Danube frontier by converting Dacia into a salient of Roman territory north of the river in order to dismember the Sarmatian tribes and remove the risk of large, hostile combinations to a safer distance. Bringing to bear a force of 100,000 men, he conquered Decebalus in two hardfought wars (101-102; 105-106) and annexed Dacia, settling it with people from neighbouring parts of the empire. On the eastern frontier he planned a similar operation, evidently in the conviction, shared by many eminent Romans both before and after him, that only conquest could solve the Parthian problem. Possibly, too, he wished to contain the menace of the Sarmatian Alani in the Caspian region. In a preliminary move, the Nabataean kingdom of Arabia Petraea was annexed in 105-106. Then, in 114, Trajan assembled another large army, incorporated the client kingdom of Armenia, and invaded Parthia.

Expansion

of the

empire

under

Trajan

After spectacular victories in 115 and 116, he created additional provinces (Northern Mesopotamia, Assyria) and reached the Persian Gulf. But he had merely overrun Mesopotamia; he had not consolidated it, and, as his army passed, revolts broke out in its rear. The Jews of the Diaspora and others seized their chance to rebel, and before the end of 116 much of the Middle East besides Parthia was in arms (Cyrene, Egypt, Cyprus, Anatolia). Trajan proceeded resolutely to restore the situation, but death found him still in the East.

Before his last illness he had not formally indicated his

successor. But high honours and important posts had been accorded his nearest male relative, Publius Aelius Hadrianus, the governor of Syria; and, according to Trajan's widow, Hadrian had actually been adopted by Trajan on his deathbed. Accordingly, both Senate and soldiers recognized him. Trajan's posthumous deification was never in

Hadrian (ruled 117-138), also a Spaniard, was an emperor of unusual versatility. Unlike Trajan, he was opposed to territorial expansion. Being himself in the East in 117, he renounced Trajan's conquests there immediately and contemplated evacuating Dacia as well. Furthermore. four of the consular generals particularly identified with Trajan's military ventures were arrested and executed "for conspiracy"; Hadrian claimed later that the Senate ordered their deaths against his wishes. The only heavy fighting during his generally peaceful reign occurred in Judaea-or Syria Palaestina, as it was thenceforth called-where Bar Kokhba led a furious, if futile, Jewish revolt (132-135) against Hadrian's conversion of Jerusalem into a Roman colony named Aelia Capitolina.

The extent of the Roman Empire in AD 117

Instead of expansion by war, Hadrian sought carefully delimited but well-defended frontiers, with client states bevond them where possible. The frontiers themselves, when not natural barriers, were strongly fortified; in Britain, Hadrian's Wall, a complex of ditches, mounds, forts, and stone wall, stretched across the island from the Tyne to the Solway; Germany and Raetia had a limes (fortified boundary) running between Mainz on the Rhine and Regensburg on the Danube. Within the frontiers the army was kept at full strength, mostly by local recruiting of legionaries and apparently of auxiliaries, too (so that Vespasian's system of having the latter serve far from their homelands gradually ceased). Moreover, the tendency for auxiliaries to be assimilated to legionaries continued; even the officers became less distinguishable, because equites now sometimes replaced senators in high posts in the legions. To keep his essentially sedentary army in constant readiness and at peak efficiency (no easy task), Hadrian carried out frequent personal inspections, spending about half his reign in the provinces (121-125; 128-134).

Hadrian also was responsible for significant developments on the civilian side. Under him, equites were no longer required to do military service as an essential step in their career, and many of them were employed in the imperial civil service, more even than under Domitian. By now the formative days of the civil service were over; its bureaucratic phase was beginning, and it offered those equites who had no military aspirations an attractive, purely civilian career. Formal titles now marked the different equestrian grades of dignity: a procurator was vir egregius; an ordinary prefect, vir perfectissimus; a praetorian prefect, vir eminentissimus, the latter title being obviously parallel to the designation vir clarissimus for a senator. Thenceforth, equites replaced freedmen in the Hadrian's policies

reign of quiet

prosperity

imperial household and bureaus, and they even appeared in Hadrian's imperial council.

Hadrian also improved legal administration. He had his expert jurists codify the edictum perpetuum (the set of rules gradually elaborated by the praetors for the interpretation of the law). He also appointed four former consuls to serve as circuit judges in Italy. This brought Italy close to becoming a province; Hadrian's intent, however, was not to reduce the status of Italy but to make all parts of the empire important. For one part of his realm, he was exceptionally solicitous: he spent much time in Greece and lavishly embellished Athens.

Hadrian maintained good relations with but was never fully trusted by the Senate. His foreign policy seemed to be unheroic, his cosmopolitanism to be un-Roman, and his reforms to encroach on activities traditionally reserved for senators. Moreover, in his last two years he was sometimes capricious and tyrannous. Like Augustus, he had no son of his own and conducted a frustrating search for a successor. After executing his only male blood relative, his grandnephew, in 136, he adopted Lucius Ceionius Commodus, renaming him Lucius Aelius Caesar. The latter, however, died shortly afterward, whereupon Hadrian in 138 chose a wealthy but sonless senator, the 51-year-old Titus Aurelius Antoninus; but, evidently intent on founding a dynasty, he made Antoninus in his turn adopt two youths, 16 and 7 years old, respectively-they are known to history as Marcus Aurelius (the nephew of Antoninus' wife) and Lucius Verus (the son of Aelius Caesar). When Hadrian died soon thereafter, Antoninus succeeded and induced a reluctant Senate to deify the deceased emperor. According to some, it was this act of filial piety that won for Antoninus his cognomen, Pius.

Antoninus'

Antoninus Pius (ruled 138-161) epitomizes the Roman Empire at its cosmopolitan best. He himself was of Gallic origin; his wife was of Spanish origin. For most men his was a reign of quiet prosperity, and the empire under him deserves the praises lavished upon it by the contemporary writer Aelius Aristides. Unlike Hadrian, Antoninus traveled little; he remained in Italy, where in 148 he celebrated the 900th anniversary of Rome, Princeps and Senate were on excellent terms, and coins with the words tranquillitas and concordia on them in Antoninus' case mean what they say. Other of his coins not unreasonably proclaim felicitas temporum ("the happiness of the times"). Yet raids and rebellions in many of the borderlands (in Britain, Dacia, Mauretania, Egypt, Palaestina, and elsewhere) were danger symptoms, even though to the empire at large they seemed only faraway bad dreams, to use the expression of Aelius Aristides. Antoninus prudently pushed the Hadrianic frontiers forward in Dacia, the Rhineland, and Britain (where the Antonine Wall from the Firth of Forth to the River Clyde became the new boundary) and carefully groomed his heir apparent for his imperial responsibilities.

Marcus Aurelius (ruled 161-180) succeeded the deified Antoninus and more than honoured Hadrian's intentions by immediately co-opting Lucius Verus as his full coemperor. Because Verus' competence was unproved, this excess of zeal was imprudent. Fortunately, Verus left decision making to Marcus. Marcus' action was also dangerous for another reason; it represented a long step away from imperial unity and portended the ultimate division of the empire into Greek- and Latin-speaking halves. Nor was this the only foreboding development in Marcus' reignformidable barbarian assaults were launched against the frontiers, anticipating those that were later to bring about the disintegration of the empire. Marcus himself was a stoic philosopher; his humanistic, if somewhat pessimistic. Meditations reveal how conscientiously he took his duties. Duty called him to war; he responded to the call and spent far more of his reign in the field than had any previous emperor.

At Marcus' very accession the Parthians turned aggressive, and he sent Verus to defend Roman interests (162). Verus greedily took credit for any victories but left serious fighting to Avidius Cassius and the army of Syria. Cassius succeeded in overrunning Mesopotamia and even took Ctesiphon, the Parthian capital; he was therefore able to conclude a peace that safeguarded Rome's eastern provinces and client kingdoms (166). In the process, however, his troops became infected with plague, and they carried it back with them to the west with calamitous results. The Danube frontier, already weakened by the dispatch of large detachments to the East, collapsed under barbarian assault. Pressed on from behind by Goths. Vandals, Lombards, and others, the Germanic Marcomanni and Ouadi and the Sarmatian Jazyges poured over the river: the Germans actually crossed Raetia, Noricum, and Pannonia to raid northern Italy and besiege Aquileia. Marcus and Verus relieved the city shortly before Verus' death (169). Then, making Pannonia his pivot of maneuver. Marcus pushed the invaders back; by 175 they were again beyond the Danube. At that moment, however, a false report of Marcus' death prompted Avidius Cassius. by now in charge of all eastern provinces, to proclaim himself emperor. The news of this challenge undid Marcus' achievements along the Danube because it took him to the East and reopened the door to barbarian attacks. Fortunately, Cassius was soon murdered, and Marcus could return to central Europe (177). But he had barely restored the frontier again when he died at Vindobona (Vienna) in 180, bequeathing the empire to his son, the 19-yearold Commodus, who had actually been named coemperor three years earlier.

Commodus (ruled 180-192), like Gaius and Nero, the vouthful emperors before him, proved incompetent, conceited, and capricious. Fortunately, the frontiers remained intact, thanks to able provincial governors and to barbarian allies, who had been settled along the Danube with land grants and who gave military service in return. But Commodus abandoned Marcus' scheme for new trans-Danubian provinces, preferring to devote himself to sensual pleasures and especially to the excitements of the arena in Rome, where he posed as Hercules Romanus and forced the Senate to recognize his godhead officially. He left serious business to his favourites, whose ambitions and intrigues led to plots, treason trials, confiscations, and insensate murders. Commodus' assassination on the last day of 192 terminated a disastrous reign; thus the Antonines, like the Julio-Claudians, had come to an ignominious end. And there was a similar sequel. Commodus' damnatio memoriae, like Nero's, was followed by a year

of four emperors.

The empire in the 2nd century. The century and threequarters after Augustus' death brought no fundamental changes to the principate, although so long a lapse of time naturally introduced modifications and shifts of emphasis. By Flavian and Antonine times the principate was accepted universally. For the provinces, a return to the republic was utterly unthinkable; for Rome and Italy, the year 69 served as a grim warning of the chaos to be expected if, in the absence of a princeps, the ambitions of a few powerful individuals obtained unfettered scope. A princeps was clearly a necessity, and people were even prepared to tolerate a bad one, although naturally they

always hoped for a good one.

The princeps, moreover, did not have to be chosen any longer from the Julio-Claudians. The great achievement of the Flavians was to reconcile the soldiers and the upper classes everywhere to the idea that others were eligible. The Flavians' frequent tenure of consulship and censorship invested their family, though not of the highest nobility, with the outward trappings of prestige and the aristocratic appearance of an authentic imperial household. The deification of the first two Flavians contributed to the same end, and so did the disappearance of old republican families that might have outranked the reigning house (by 69 most descendants of the republican nobility had either died of natural causes or been exterminated by imperial persecution). After the Flavians, the newness of a man's senatorial dignity and the obscurity of his ultimate origin, whether it was Italian or otherwise, no longer forbade his possible elevation. Indeed, Domitian's successors and even Domitian himself in his last years did not need to enhance their own importance by repeated consulships. The Antonine emperors, like the Julio-Claudians, held the office infrequently. They did, however, continue the Flavian practice of emphasizing the loftiness of their families

Barbarian assaults

Eligibility for the principate by deifying deceased relatives (Trajan deified his sister, his niece, and his father; Antoninus, his wife; and so forth)

Trend to absolute monarchy. Glorification of the reigning house, together with a document such as Vespasian's Lex de Imperio, helped to advertise the emperor's position; and under the Flavians and Antonines the principate became much more like an avowed monarchy. Proconsular imperium began to be reflected in the imperial titulary, and official documents started calling the emperor domi-

nus noster ("our master"). The development of imperial law-making clearly illustrates the change. From the beginnings of the principate, the emperor had had the power to legislate, although no law is known that formally recognized his right to do so; by Antonine times, legal textbooks stated unequivocally that whatever the emperor ordered was legally binding. The early emperors usually made the Senate their mouthpiece and issued their laws in the form of senatorial decrees: by the 2nd century the emperor was openly replacing whatever other sources of written law had hitherto been permitted to function. After 100 the Assembly never met formally to pass a law, and the Senate often no longer bothered to couch its decrees in legal language, being content to repeat verbatim the speech with which the ruler had advocated the measure in question. After Hadrian. magistrates ceased modifying existing law by their legal interpretations because the praetors' edictum perpetuum had become a permanent code, which the emperor alone could alter. By 200, learned jurists had lost the right they had enjoyed since the time of Augustus of giving authoritative rulings on disputed points (responsa prudentium). Meanwhile, the emperor more and more was legislating directly by means of edicts, judgments, mandates, and rescripts-collectively known as constitutiones principum. He usually issued such constitutiones only after consulting the "friends" (amici Caesaris) who composed his imperial council. But a constitutio was nevertheless a fiat. The road to the later dominate (after 284) lay open.

Political life. Nevertheless, the autocratic aspect of the Flavian and Antonine regimes should not be overstressed. Augustus himself had been well aware that it was impossible to disguise permanently the supremacy that accumulation of powers gained piecemeal conferred; his deportment in his last years differed little from that of Vespasian, Titus, and the so-called five good emperors who followed them. Nor had other Julio-Claudians hesitated to parade their predominance-Claudius, by centralizing the imperial powers, reduced their apparent diversity to one allembracing imperium; Gaius and Nero revealed the autocracy implicit in the principate with frank brutality

What impresses perhaps as much as the undoubtedly autocratic behaviour of the Flavians and Antonines is the markedly civilian character of their reigns. They held supreme power, and some of them were distinguished soldiers; yet they were not military despots. For this the old republican tradition-whereby a state official might serve in both a civilian and a military capacity-was largely responsible. Matters, however, were open to change after Hadrian separated the two realms of service. Actually, the 3rd century soon showed what it meant to have a princeps whose whole experience had been confined to camps and barracks.

Civilian

of the

reigns

Flavian and

Antonine

character

As imperial powers became more concentrated, republican institutions decayed; the importance of imperial officials grew, while the authority of urban magistrates declined. Quaestorship, praetorship, and consulship (the last-named now reduced to a two-month sinecure) became mere stepping stones to the great imperial posts that counted most in the life of the empire. Governors of imperial provinces and commanders of legions were Roman senators; but they were equally imperial appointees. Clearly, the emperor was the master of the Senate; and it was disingenuous for him to get impatient, as some emperors did, with the Senate's lack of initiative and reluctance to take firm decisions of its own. The emperor might not even consult the Senate much, preferring to rely on his imperial council, in which equestrian bureau chiefs over the course of the 2nd century came to constitute an established element.

The Senate, however, at least until the reign of Commodus, was treated courteously by most Flavians and Antonines. They recognized its importance as a lawcourt, as the body that formally appointed a new emperor, and as a sounding board of informed opinion. Senators came increasingly from the provinces, and, although this meant preeminently the western provinces (the Greek-speaking East being underrepresented), the Senate did reflect to some extent the views of the empire at large.

The equites, meanwhile, steadily acquired greater importance as imperial officials. In newly created posts they invariably became the incumbents, and in posts of long standing they replaced freedmen and publicani. During the 2nd century equestrian procurators increased markedly in numbers as the direction of imperial business came to be more tidily subdivided. Four grades of service distinguished by salary were established. While the government assumed a more rational flow and outline, its total number of employees nevertheless remained quite tiny, compared with that of the 4th and later centuries.

Rome and Italy. By the 2nd century the city of Rome had attracted freeborn migrants from all over the empireit housed, additionally, large numbers of manumitted slaves. These newcomers were all assimilated and diluted the city's Italian flavour. The vast majority of them were poor, the handful of opulent imperial freedmen being entirely exceptional. But many were energetic, enterprising, and lucky, able to make their way in the world. Freedmen laboured under a social stigma, although some of them managed to become equites. Their sons, however, might overcome discrimination, and their grandsons were even

eligible for membership in the Senate. Inevitably, there was extensive trade and commerce (much of it in freedman hands) in so large a city, which was also the centre of imperial administration. There was little industry, however, and the urban poor had difficulty finding steady employment. Theirs was a precarious existence, dependent on the public grain dole and on the private charity of the wealthy. Large building programs gave Flavian and Antonine emperors the opportunity not only to repair the damage caused by fire and falling buildings (as stated, a frequent hazard among the densely packed and flimsily built accommodations for the urban plebs) but also to relieve widespread urban unemployment. They also made imperial Rome a city of grandeur. Augustus' building program had been vast but mostly concerned with repairing or rebuilding structures already existing, and his Julio-Claudian successors had built relatively little until the great fire made room for the megalomaniac marvels of Nero's last years. It was under the Flavians and Antonines that Rome obtained many of its most celebrated structures: the Colosseum, Palatine palaces, Trajan's Forum, the Pantheon, the Castel Sant' Angelo (Hadrian's mausoleum), the Temple of Antoninus and Faustina, Aurelius' Column, as well as the aqueducts whose arches spanned across Campagna to keep the city and its innumerable fountains supplied with water.

Italy was much less cosmopolitan and sophisticated and, according to literary tradition, much more sober and straitlaced than was Rome. It was the mistress of the empire, although the gap between it and the provinces was narrowing. Hadrian's policies especially helped to reduce its privileged position. His use of circuit judges was resented precisely because with them Italy resembled a province; actually. Italy badly needed them, and their abolition by Antoninus Pius was soon reversed by Marcus Aurelius. Also, in Aurelius' reign a provincial fate overtook Italy in the form of barbarian invasion; a few years later the coun-

try got its first legionary garrison under Septimius Severus. The economic importance of Italy also declined. By the end of Augustus' reign, the ascendancy of its wine, oil, marble, and fine pottery in the markets of Gaul and Germany had already begun to yield to the competition of local production in the West; and, by Flavian times, Italy was actually importing heavily not only from Gaul (witness the crates of yet-unpacked Gallic bowls and plates caught in the destruction of Pompeii) but also from Spain. The latter province was especially represented by its extraordinarily popular condiment, garum; its olive oil, too,

The urban

was a sizable item on Italian tables after AD 100, only to yield its primacy there, by the mid-2nd century, to oil from northern Africa. By then, Spanish, Gallic, and African farm products all outweighed Italian ones in Ostia and Rome. Against such tendencies, the emperors did what they could: Domitian, for example, protected Italian viticulture by restricting vine growing in the provinces; Trajan and his successors forced Roman senators to take an interest in the country, even though it was no longer the homeland of many of them, by investing a high proportion of their capital in Italian land (one-third under Trajan, one-quarter under Aurelius).

Attempts to achieve stability in the provinces

Developments in the provinces. The 18th-century historian Edward Gibbon's famous description of the 2nd century as the period when men were happiest and most prosperous is not entirely false. Certainly, by then people had come to take for granted the unique greatness and invincibility of the empire; even the ominous events of Aurelius' reign failed to shatter their conviction that the empire was impregnable; and the internal disturbances of the preceding reign had not given cause for much alarm. The credit for the empire's success lay less with what its rulers did and could do than with what they did not do: they did not interfere too much. The empire was a vast congeries of peoples and races with differing religions, customs, and languages, and the emperors were content to let them live their own lives. Imperial policy favoured a veneer of common culture transcending ethnic differences, but there was no deliberate denationalization. Ambitious men striving for a career naturally found it helpful, if not necessary, to become Roman in bearing and conduct and perhaps even in language as well (although speakers of Greek often rose to exalted positions). But local selfgovernment was the general rule, and neither Latin nor Roman ways were imposed on the communities composing the empire. The official attitude to religion illustrates this-in line with the absolutist trend, emperor worship was becoming slowly but progressively more theocratic (Domitian relished the title of god, Commodus demanded it); yet this did not lead to the suppression of non-Roman or even outlandish cults, unless they were thought immoral (like Druidism, with its human sacrifice) or conducive to public disorder (like Christianity, with its uncompromising dismissal of all gods other than its own as mere demons, and wicked and hurtful ones at that-hence its liability to become a target for riots).

While there is no indication that the central authorities consciously opposed the increase of governmental personnel, the number of government employees certainly grew very slowly. Thus the responsibilities of the magnates in provincial cities were correspondingly great. In parts of southern Spain or in the area south of the Black Sea, for example, where the extent of the territories dependent on cities stretched out over many scores of miles into the surrounding landscape, city senators had not only to collect taxes but also to build roads and carry out much rural police work. Within their cities, too, senators had to see to the collection of taxes and tolls; as a group, they had to oversee and assign the income from municipal lands or buildings rented out and from endowments established by generous citizens; they had to authorize the plans and financing of sometimes very elaborate civic structuresan aqueduct, an amphitheatre, or a temple to the imperial family-or of great annual festivals and fairs or of ongoing amenities serving the public baths (free oil for anointing oneself, heating, and upkeep) or the public markets. In the eastern provinces, they had to replenish from time to time the stock of small local bronze coins; and they had to insure that magistracies were effectively staffed, even though there usually was no salary of any sort to attract candidates. Magistrates and city senators generally had to pay handsomely for their election and thereafter make further handsome contributions, as need arose and so far as they could afford, toward the adornment of their community.

What attracted candidates in adequate numbers were most often three inducements: the feeling of community approval and praise, offered in the most public ways (described by writers of the time with striking psychological penetration); the enhancement of personal influence (meaning power) through the demonstration of great financial means; and finally, the social and political advancement that might follow on local prominence through attracting the attention of a governor or of the emperor himself. It was from the provincial elite that new Roman senators were made.

Cities, through their elite families, competed with each other across entire regions. City rivalries in northern Italy or western Anatolia happen to be especially well reported. Within individual cities, elite families were often in competition as well. In consequence, the standards of municipal beneficence rose, encouraged by a populace who on public occasions assembled in large numbers in the theatre demanding yet more expenditure from their leaders. The emperors, who realized that the well-being of cities, the jewels of their realm, depended on such munificence, increasingly intervened to insure a continued flow of good things from the rich of a community to their fellow citizens. Legislation might, for example, specify the binding nature of electoral campaign promises or of formerly voluntary contributions connected with public service. As a consequence, in the 2nd century consideration must for the first time be given to the local aristocrat unwilling to serve his city; the series of imperial pronouncements exerting compulsion on such a person to serve was to stretch far into the future, with increasing severity. Attempts to stabilize the benefits arising from ambitious rivalries thus had an oppressive aspect.

As to the lower orders, their voice is rarely heard in surviving sources, except in acclamation. So long as the rich voluntarily covered the bulk of local expenses and so long as they commanded the leisure and knowledge of the world to give to administration unsalaried, the poor could not fairly claim much of a right to determine the city's choices. Thus they acclaimed the candidacies of the rich and their gifts and otherwise gave vent to their wishes only by shouting in unison in the theatre or amphitheatre (in between spectacles) or through violent mob actions.

As noted above, the poor routinely solved the problems of daily life by appealing to someone of influence locally; this was true whether in Palestine, as indicated in the Talmud, or in Italy, as is evident from Pliny's correspondence. The higher one looked in society, the more it appeared crisscrossed and interconnected by ties of kinship or of past services exchanged. It was at these higher levels that answers to routine problems were to be sought. Appeal was not directed to one's peers, even though trade associations, cult groups of social equals, and burial insurance clubs with monthly meetings could be found in every town. Such groups served social, not political or economic, purposes, at least during the principate.

Accordingly, society was ordinarily described by contemporaries simply in terms of two classes, the upper and the lower, rich and poor, powerful and dependent, well known and nameless. The upper classes consisted of little more than 600 Roman senators, 25,000 equites, and 100,000 city senators; hence, a total amounting to 2 percent of the population. This stratum, from the mid-2nd century defined in law as "the more honourable," honestiores, was minutely subdivided into degrees of dignity, the degrees being well advertised and jealously asserted; the entire stratum, however, was entitled to receive specially tender treatment in the courts. The remaining population was lumped together as "the more lowly," humiliores, subject to torture when giving witness in court; to beatings, not fines; and to execution (in increasingly savage forms of death) rather than exile for the most serious crimes. Yet because of the existing patterns of power, which directed the humiliores to turn for help to the upper stratum, the lower classes did not form a revolutionary mass but constituted a stable element.

The pyramidal structure of society suggested by the statistics given above is somewhat obscured by the reality and prominence of the urban scene. In the cities the harsh outlines of the distribution of wealth were moderated by a certain degree of social mobility. No class offers more success stories than that of freedmen. Especially in the West, freedmen are astonishingly prominent in the record The social

of inscriptions and proverbial for what the upper classes called unprincipled enterprise and vulgar moneygrubbing. Artisans and tradespeople-lowly folk, in the eyes of someone like Cicero-in fact presented themselves with a certain dignity, even some financial ease. At the bottom, slaves were numerous, constituting perhaps one-tenth of the population in at least the larger towns outside of Italy and considerably more in Italy-as much as one-quarter in Rome. But in the cities many of them at least enjoyed security from starvation and had a good roof over their heads. When one turns to the rural scene, however, one encounters a far larger, harsher world. In the first place, nine-tenths of the empire's people lived on the land and from its yield. Where details of their lives emerge with any clarity, they most often tell of a changeless and bleak existence. The city looked down on the countryside with elaborate scorn, keeping the rural population at arm's length. Very often people in the country had their own language-such as Gallic, Syriac, Libyphoenician, or Coptic, which further isolated them-and their own religion. marriage customs, and forms of entertainment. In time, the very term "country dweller," paganus, set the rural population still further apart from the empire's Christianized urban population.

In the overall context of Western history, the degree to which the Mediterranean world during the period of the empire became one single system, one civilization, is a matter of the greatest importance. Clearly, one must distinguish between the life of the rural masses and that of the urban minority. The former retained many traits of a way of life predating not only Roman conquest but, in the East, the conquests of Alexander the Great centuries earlier. However, the device of organizing conquered territories under cities responsible for their surrounding territory proved as successful under the Romans as under the Greeks. The intent of both conquerors may have been limited to ensuring political control and the yield of tribute; however, in fact, they achieved much more: an approach to uniformity, at least in the cities.

The first thing to strike the traveler's eye, in any survey of the 2nd-century empire, would have been the physical appearance of urban centres; as already noted, whatever the province, many of the same architectural forms could be observed: the suburbs tended to have aqueducts and racetracks and the cities a central grand market area surrounded by porticoes, temples, a records office, a council hall, a basilica for judicial hearings and public auctions, and a covered market hall of a characteristic shape for perishable foods (a macellum, as in Pompeii, in Perge on the southern coast of modern Turkey, or in North African Lepcis); there also would have been public baths with several separate halls for cold or hot bathing or exercise, a covered or open-air theatre, grand fountains, monumental arches, and honorific statues of local worthies by the dozens or even hundreds. Eastern centres would have gymnasia, occasionally Western ones as well; and Western cities would have amphitheatres, occasionally Eastern ones as well, for the imported institution of gladiatorial combats. Throughout the Western provinces, public buildings were likely to be arranged according to a single planmore or less the same everywhere-in which a grid of right-angle streets was dominant, at least toward the central part of the city.

In the West, as opposed to the East, a great deal of urbanization remained to be done and was accomplished by the Romans. The grid plan, its particular mark, can be detected at the heart of places such as Turin, Banasa (Morocco), and Autun, all Augustan foundations, as well as in Nicopolis (Bulgaria), Budapest, and Silchester, all later ones. As noted above, orthogonal town planning was not a Roman invention, but the Romans introduced it to new regions and with a particular regularity of their own. Moreover, the grid of the central part of the city was matched, and sometimes extended on the same lines, by another grid laid across the surrounding territory. The process, referred to as centuriation, typically made use of squares of 2,330 feet (710 metres) on a side, intended for land distribution to settlers and general purposes of inventory. Signs of it were first detected in northern Africa in the 1830s, through surviving crop marks and roads, and have since (especially through air photography) been traced in the environs of Trier and Homs (Syria) and large areas of northern Italy, Tunisia, and elsewhere. In the placing of cities and roads and property boundaries, the Romans of the empire therefore left a nearly indelible stamp of their organizing energies on the map of Europe; they

The hot room of the imperial baths at Trier, Ger

also established the lives of conquered populations inside their own characteristic framework.

The special burst of energy in the Augustan colonizing spread abroad not only the visible elements of a ruling civilization but the invisible ones as well. Colonies and municipalities received Roman forms of government according to their charters, they were administered by Roman law in Latin, and they diffused these things throughout the general population within and around them. In frontier areas such lessons in an alien civilization were pressed home by garrison forces through their frequent contacts with their hosts and suppliers. By the 2nd century considerable Latinization had occurred in the West. Modern Spanish, Portuguese, and French show that this was particularly true of the Iberian peninsula, which had been provincial soil ever since the Second Punic War, and of Gaul, where Latin enjoyed the advantage of some relationship to Celtic. In these regions, except in the less accessible rural or mountainous parts, even the lower orders adopted Latin. Today one can find in Romania the tongue that is the closest to its parent, Latin, even at so great a distance from its home. And Latin can be found not only in Romance languages; it has left its mark on languages such as Basque and German.

Inscriptions represent the most frequent testimony to linguistic allegiance; more than a quarter of a million survive in Latin from the period of the empire, the vast majority of them being funerary. The number of inscriptions per year increases slowly during the 1st century and a half AD, thereafter ascending in a steep line to a point in the second decade of the 3rd and then falling off even more steeply. The curve is best explained as reflecting pride in "Romanness"-in possessing not only Latin but full citizenship as well and, thereby, admission to a group for whom commemoration of the deceased was a legal as well as a moral duty. Over the course of time, by individual gift from the emperors, by army service, and by election to magistracies or simply to the city senates of colonies and municipalities, a growing proportion of the empire's population had gained citizenship; moreover, their children were citizens, whose descendants in turn were Romans in the legal sense. By AD 212 this accelerating process had advanced so far that the emperor Caracalla could offer the gift of incorporation to the entirety of his subjects without much notice being taken of his generosity-it was already in the possession of most of the people who counted and whose reactions might be recorded. Once citizenship was universal, it ceased to constitute a distinction; thus the declaration of it through the custom of funerary commemoration rapidly passed out of favour.

One great flaw in the picture of the empire as one single civilization by 212, triumphantly unified in culture as in its political form, has already been pointed out: what was achieved within the cities' walls did not extend with any completeness to the rural population, among whom local ways and native languages persisted. Peasants in 4thcentury Syria spoke mostly Syriac, in Egypt mostly Coptic, in Africa often Punic or Libyphoenician, and in the Danube and northwestern provinces other native tongues. There was still another great flaw; the empire was half Roman (or Latin), half Greek. The latter was hardly touched by the former except through what may be called official channels-that is, law, coinage, military presence, imperial cult, and the superposition of an alien structure of power and prestige, to which the elite of the Eastern provinces might aspire. On the other hand, the Roman half was steeped in Greek ways. Apuleius, for example. though born and reared in a small North African town of the 2nd century, was sent to Athens to study rhetoric; on his return he could find not only an audience for his presentations in Greek but ordinary people in the marketplace able to read a letter in that language. In Rome the Christian community used Greek as its liturgical language well into the 3rd century, and the crowds in the Circus Maximus could enjoy a pun in Greek; an aristocrat such as the emperor Marcus Aurelius could be expected to be as bilingual as was Cicero or Caesar before him or even. like the emperor Gallienus, help the Greek philosopher Plotinus found a sort of Institute for Advanced Studies in the Naples area. Greece continued to supply a great deal of sculpture for Western buyers or even the teams of artisans needed for the decoration of public buildings in 3rd-century northern Africa. By such various means the division between the two halves of the empire was for a time covered over.

Among the institutions most important in softening the edges of regional differences was the cult of the emperors. In one sense, it originated in the 4th century BC, when Alexander the Great first received veneration by titles and symbols and forms of address as if he were a superhuman being. Indeed, he must have seemed exactly that to contemporaries in Egypt, where the pharaohs had long been worshiped, and to peoples in the Middle East, for similar reasons of religious custom. Even the Greeks were quite used to the idea that beings who lived a human life of extraordinary accomplishment, as "heroes" in the full sense of the Greek word, would never die but be raised into some higher world; they believed this of heroes such as Achilles, Hercules, Pythagoras, and Dion of Syracuse in the mid-4th century BC. Great Roman commanders, like Hellenistic rulers, had altars, festivals, and special honours voted to them by Greek cities from the start of the 2nd century BC. It was not so strange, then, that a freedman supporter of Caesar's erected a pillar over the ashes of the dead dictator in the Forum in April 44 BC and offered cult to him as a being now resident among the gods. Many citizens joined in. Within days Caesar's heir Octavian pressed for the declaration of Caesar as divine-which the Senate granted by its vote in 42. By 25 BC the city of Mytilene had organized annual cult acts honouring Augustus and communicated their forms and impulse to Tarraco in Spain as well as to other Eastern Greek cities; and by 12 BC divine honours to Caesar and Augustus' genius were established through the emperors' initiative both in the Gallic capital, Lugdunum, and in the neighbourhood chapels to the crossroads gods in Rome. From these various points and models, emperor worship spread rapidly. Within a few generations, cities everywhere had built in its service new temples that dominated their forums or had assigned old temples to the joint service of a prior god and the imperial family. Such centres served as rallying points for the citizenry to express its devotion to Rome and the emperor. To speak for whole provinces. priests of the cult assembled during their year of office in central shrines, such as Lugdunum, as delegates of their cities, where they formulated for the emperor their complaints or their views on the incumbent governor's administration. Whether these priests were freedmen in urban neighbourhoods, municipal magnates in local temples, or still grander leaders of the provinces, they perceived the imperial cult as something of high prestige and invested it and Roman rule with glory.

The emotional and political unification of the empire was further promoted by submissive or flattering forms of reference or address, adopted even by the highest personages when speaking of the emperor, and by portraits of the emperors or their families with attendant written messages. Of these two most obvious means of propaganda, the first survives in the texts of many panegyrics delivered to the throne, rhetorical disquisitions on monarchy, and prefatory announcements accompanying the publication of government edicts. They established a tone in which it was proper to think of Roman rule and government. Portraits, the second means of propaganda, included painted ones on general display in cities, sculpted ones, especially in the early years of each reign, based on official models available in a few major cities (hundreds of these survive. including at least one in gold), and engraved ones on coins. Imperial coins offered a more rapidly changing exhibition of images than even postage stamps in the modern world. Because the dies soon wore out, many scores of issues had to be brought out each year, in gold, silver, and bronze. While the images ("types") and words ("legends") on them tended to repetition, there was much conscious inculcation of topical messages: for example, in the short and rocky reign of Galba in AD 69, one finds the legends "All's well that ends well" (bonus eventus), "Rome reborn," "Peace for Romans," and "Constitutional government restored"

The cult of the emperors

Portraits of the emperor (libertas restituta, with iconographic reference to Brutus' coins of 43 BC) and superlative portraits of Galba himself; or, in other reigns, the legends, enriched with suitable symbolism, read "the soldiers loyal," "Italy well fed," and fecunditas of the royal family and its progeny. So far as it is possible to comprehend the mind of the empire's populace, there was no significant opposition to the government by the 2nd century; instead, there prevailed a great deal of ready veneration for the principate as an institution.

Economic factors, to the extent that they were favourable, played an obvious part in promoting both cultural and political unity. So far as acculturation was concerned, a limit to its achievement was clearly set by the amount of disposable capital among non-Romanized populations. The cost of such luxuries as schooling in Latin or frescoes on one's walls were high. But more and more people could afford them as the benefits of Roman occupation were spreading. The rising levels of prosperity did not, however, result from a special benevolence on the part of the conquerors, intent as they were (and often cruelly intent) on the pleasures and profits of physical mastery over the conquered. Rather, they can be explained, first, by the imposition of the Pax Romana, which gave urban centres surer access to the surrounding rural areas and rural producers access in turn to convenient, centralized markets; second, by the sheer attractiveness of imported articles, which intensified efforts to increase the power to buy them; third, by the economic stimulation afforded by taxes, which had to be paid on new earnings but which remained in the provinces where they were raised. In the fourth place, prosperity also rose in the regions least Romanized. This can be explained by the fact that they tended to be heavily garrisoned and the soldiers spent their wages locally. So far as they could, they bought goods and services of a Roman sort and generally attracted concentrations of people likely to develop into cities of a Roman sort. The economic impact of army payrolls was all the greater because of the cash added to them from taxes raised in other, more developed provinces in the East. Much of the urbanization and enrichment of the western and northern provinces can be explained by these four factors.

Until the 1950s or '60s the sources for studying the economy of the empire were insufficient. The archaeological sources were too scarce and heterogeneous to be of much help, and the written ones contained barely usable amounts of quantified data; economic analysis without quantification, however, is almost a contradiction in terms. Thus discussion was obliged to limit itself to rather general remarks about the obviously wide exchange of goods, the most famous points of production or sale of given articles, techniques of banking, or commercial law. This is still the case with regard to the Eastern half of the Mediterranean world, where excavation has made relatively little headway; but, for the West, archaeological data have greatly increased in recent decades in both quantity and intelligibility. As a result, a growing number of significant statements based on quantification can now be made. They are of special value because they bear on what was economically most important-namely, agriculture. Like any preindustrial economy, that of the empire derived the overwhelming bulk of its gross national product from food production. One would therefore like to know what regions in what periods produced what rough percentage of the chief comestibles-wine, oil, wheat, garum or legumes. Thanks to techniques such as neutron activation analysis or X-ray fluorescence spectrometry, the contents of large samples of amphorae at certain market junctures can be identified, dated by shape of vessel, and occasionally ascribed to certain named producers of the vessel, and the information drawn into a graph; or, the numbers and find-spots of datable fine "china" (so-called Arretine ware or later equivalents) or ceramic oil lamps from named producers can be indicated on a map of, say, Spain or France. The yield of such data underlies statements made above regarding, for example, the supersession of Italy as producer of several essential agricultural products by the mid-1st century AD, the concurrent transformation of Gaul from importer to exporter, and the emergence by

the 3rd century of northern Africa as a major exporter of certain very common articles. Information of this general nature provides some sense of the shift in prosperity in the Western provinces.

In the age of the Antonines, Rome's empire enjoyed an obvious and prosperous tranquility; modern consensus has even settled on about AD 160 as the peak of Roman civilization. Whatever measurement may be used in this identification, however, an economic one does not fit very well. Evidence, as it accumulates in more quantifiable form, does not seem to show any perceptible economic decline in the empire as a whole after roughly 160. Rather, Italy had probably suffered some decrease in disposable wealth in the earlier 1st century. Gaul's greatest city, Lugdunum, had begun to shrink toward the end of the 2nd, and various other regions in the West suffered setbacks at various times, while all of Greece continued to be poor. Other regions, however, had more wealth to spend, and as is manifest in major urban projects of utility and beautification or in the larger rooms and increasingly expensive decoration of rural villas. Roman rule also brought extraordinary benefits to the economies of Numidia and Britain, to name its two most obvious successes.

To the extent the empire grew richer, modern observers are likely to look for an explanation in technology. As noted above, in Augustus' reign a new mode of glassblowing spread rapidly from Syria to other production centres; Syria in the 3rd century was also the home of new and more complicated weave patterns. Such rather minor items, however, only show that technical improvements in industry were few and insignificant. The screw press for wine and olive oil was more efficient than the levered variety, but it was not widely adopted, even within Italy. Waterwheels for power, known in Anatolia in Augustus' reign, were little used; a few examples in Gaul belong only to the later empire. Similarly, the mechanical reaper was found only in Gaul of the 4th century. Perhaps the most significant advances were registered in the selective breeding of strains of grains and domestic animals: for example, the "Roman" sheep (which had originated in the Greek East) spread throughout Europe, banishing the inferior Iron Age species to a merited exile in the Outer Hebrides (the Soay sheep of St. Kilda island). What is vastly more significant, however, than these oddments of technological history is the minute subdivision of productive skills and their transmission from father to son in populations adequate to the demand-for iron ore from Noricum, most notably, or for glass and paper from Alexandria, Specialization in inherited skills produced a remarkably high level of proficiency, requiring only the security of the Pax Romana for the spreading of its products everywheretransport itself being one of those skills.

The health of the economy no doubt helps to explain the political success of the empire, which was not disturbed by frequent revolts or endemic rural or urban unrest. On the other hand, there were limits in the economy, which expressed themselves through resistance to taxation. Tax levels settled at the enforceable maximum; but revenue fell far short of what one might expect, given the best estimates of the empire's gross national product. The basic problem was the tiny size of the imperial government and the resulting inefficiency of its processes. Moreover, it could not make good its inadequacies by borrowing in times of special need; Nero's need to harry his millionaire subjects with false charges of treason in order to pay for his incredibly expensive court and spendthrift impulses reflects the realities of raising revenue. So do the very cautious experiments of Augustus in setting army pay and army size. Ultimately, the military strength of the empire was insufficient-inadequate for emergencies-because of these realities.

The army. The army that enforced the Pax Romana had expanded little beyond the size envisaged for it by Augustus, despite the enlargement of the empire by Claudius, the Flavians, and Trajan. It reached 31 legions momentarily under Trajan, but it usually numbered 28 under the Flavians and Antonines until the onset of the frontier crisis in Aurelius' reign brought it to 30. Without raising pay rates to attract recruits more easily, a large force was

Archaeological sources for studying the economy

seemingly beyond reach-which probably explains why Hadrian, and later Commodus, halted further expansion.

The army was used not to prop up a militarist government but to defend the frontiers. Shifts in enemy pressures, however, caused the legions to be distributed differently than in Julio-Claudian times. Under Antoninus Pius, the Danubian provinces (Pannonia, Moesia, Dacia) had 10, and the East (Anatolia, Syria, Palestine, Egypt) had 9, and both regions also had supporting naval flotillas; of the remaining 9 legions, Britain contained 3 and the Rhineland 4. Tacitus in his Annals (4.5) rates the auxiliary troops near the turn of the era as being about as numerous as the legionaries. But they soon outnumbered them: that is, whereas legions contained somewhat more than 5,000 men each if they were at full strength and thus totaled roughly 150,000 in the mid-2nd century, the auxiliaries numbered 245,000-again, if at full strength. Recent estimates put the actual figure for the entire army at 375,000 to 400,000.

Two reasons, military and financial, explain the growing use of nonlegionaries. Mustered in units mostly of 500, they were easier to move around and could be encouraged to maintain the special native skills of their inheritanceas slingers from the Balearic Islands or Crete, in camel corps from Numidia, or as light cavalry from Thrace. In addition, they could be recruited for lower wages than legionaries. As regards recruitment for the legions, even that higher rate proved less and less attractive. Whereas legions in the early empire could be largely filled with men born in Italy and southern Gaul, by the second half of the 1st century most of the men had to be drawn from the provinces: after Trajan, they were largely natives of the frontier provinces. Young men from the inner parts of the empire, growing up in successive generations of continual peace, no longer looked on military service as a natural part of manhood, and the civilian economy appeared attractive compared to the rewards at some frontier posting. Peace and prosperity thus combined to make the army less and less Roman, less and less of the centre, and more and more nearly barbarous.

The troops' loyalty did not suffer on that account. The men were no more ready to mutiny or to support a pretender around AD 200 than they had been in the early empire. However, experience especially in the year of the four emperors (AD 69) did suggest the desirability of splitting commands into smaller units, which, in turn, involved splitting up provinces, the number of which was constantly growing; by Hadrian's day subdivision began to anticipate the fragmentation later carried out by Diocletian.

Cultural life. The literature of the empire is both abundant and competent, for which the emperors' encouragement and financing of libraries and higher education were perhaps in part responsible. The writers, however, with the possible exception of Christian apologists, were seldom excitingly original and creative. As Tacitus said, the great masters of literature had ceased to be. Perhaps Augustus' emphasis on tradition affected more than political ideals and practice. At any rate, men of letters, too, looked often backward. At the same time, they clearly reveal the success of the empire in spreading Greco-Roman culture, for the majority of them were natives of neither Italy nor Greece. Of the writers in Latin, the two Senecas, Lucan, Martial, Columella, Hyginus, and Pomponius Mela came from Spain; Fronto, Apuleius, and probably Florus and Aulus Gellius, from Africa. Tacitus was perhaps from Gallia Narbonensis. The Latin writers in general sought their models less in Greece than in Augustus' Golden Age, when Latin literature had reached maturity. Thus, the poets admired Virgil and imitated Ovid; lacking genuine inspiration, they substituted for it an erudite cleverness, the fruit of an education that stressed oratory of a striking but sterile kind. Authentic eloquence in Latin came to an end when, as Tacitus put it, the principate "pacified" oratory. Under the Flavians and Antonines, an artificial rhetoric, constantly straining after meretricious effects, replaced it. The epigrammatic aphorism (sententia) was especially cultivated; the epics of Lucan, Valerius Flaccus, Silius Italicus, and Statius are full of it, and it found a natural outlet in satirical writing, of which the Latin instinct for the mordant always ensured an abundance. In fact, Latin satire excelled: witness Martial's epigrams, Petronius' and Juvenal's pictures of the period, and Persius' more academic talent. For that matter, Tacitus' irony and pessimism were not far removed from satire.

In the East the official status of Greek and the favour it enjoyed from such emperors as Hadrian gave new life to Greek literature. It had something in common with its Latin counterpart in that it looked to the past but was chiefly written by authors who were not native to the birthplace of the language. The so-called Second Sophistic reverted to the atticism of an earlier day but often in a Roman spirit; its products from the Asian pens of Dio Chrysostom and Aelius Aristides are sometimes limpid and talented tours de force but rarely great literature. In Greek, too, the best work was in satire, the comic prose dialogues of the Syrian Lucian being the most noteworthy and original literary creations of the period. Among minor writers the charm of Arrian and Pausanias, Asians both, and above all of Plutarch abides (although Plutarch's talents were mediocre, and his moralizing was shallow, his biographies, like those of his Latin contemporary Suetonius, are full of information and interest).

Imperial encouragement of Greek culture and a conviction, no longer justified, of its artistic and intellectual superiority caused the East to resist Latinization. This attitude was bound to lead to a divided empire, and thoughtful observers must have noted it with misgivings. The split, however, was still far in the future. Meanwhile, there was a more immediate cause for disquiet. The plethora of summaries and anthologies that appeared implies a public progressively indifferent to reading whole works of literature for themselves. In other words, the outlook for letters was poor, and this had an unfortunate effect on the scientific literature of the age, which was in itself of firstclass quality. Dioscorides on botany, Galen on medicine. and Ptolemy on mathematics, astronomy, and geography represent expert scholars expounding carefully, systematically, and lucidly the existing knowledge in their respective fields. But their very excellence proved fatal because, as the reading public dwindled, theirs remained standard works for far too long; their inevitable errors became enshrined. and their works acted as brakes on further progress.

Stoicism was the most flourishing philosophy of the age. In the East a sterile scholasticism diligently studied Plato and Aristotle, but Epictetus, the stoic from Anatolia, was the preeminent philosopher. In the West, stoicism permeates Seneca's work and much of Pliny's Natural History. Evidently, its advocacy of common morality appealed to the traditional Roman sense of decorum and duty, and its doctrine of a world directed by an all-embracing providence struck a responsive chord in the 2nd-century emperors, though they deeply disapproved of its extremist offshoots, the cynics: Marcus Aurelius, as noted, was himself a stoic.

Imperial art, dealing above all with man and his achieve- Imperial ments, excelled in portraits and commemoration of events; Roman sculpture and presumably Roman painting, also, owed much to Greek styles and techniques. It emerged, however, as its own distinctive type. The Augustan age had pointed the way that Roman art would go: Italian taste would be imposed on Hellenic models to produce something original. The reliefs of the Augustan Ara Pacis belong to Rome and Italy, no matter who actually carved them. By Flavian times this Roman artistic instinct had asserted itself and with it the old Roman tendency toward lively and accurate pictorial representation. It can be seen from the reliefs illustrating the triumph over Judaea in the passageway of the Arch of Titus in the Roman Forum. The narrative description dear to Roman art found its best expression in the great spiral frieze on Trajan's Column, where the emperor can be seen among his soldiers at various times in the Dacian campaigns; the story of the war plays a most important part, although, like most imperial monuments, the column is meant to exalt the leader. Under Hadrian a reaction made sculpture less markedly Italian, as if to be in conformity with the slow decline of Italy toward quasi-provincial status. Also under Hadrian,

the figure of the emperor was more prominent-bigger

Imperial literature and more frontal than the other figures-as if to illustrate the growing monarchical tone of the principate. This tendency continued under the Antonines, when there was a magnificent flowering of sculpture on panels, columns, and sarcophagi; but its exuberance and splendour fore-

shadow the end of classical art

The artistic currents that flowed in Rome were felt throughout the empire, the less developed areas being influenced most. In the West, provincial sculpture closely resembled Roman, although it sometimes showed variations, in Gaul especially, owing to local influences (the native element, however, is not always easy to identify). The Roman quality of portraits painted on Egyptian mummy cases shows that the Greek-speaking regions were also affected, although generally they maintained their own traditions. But by now the Greek East had become rather barren; much of its production was imitative rather than vitally creative. Greece proper contributed little, the centre of Hellenism having shifted to Anatolia, to places such as Aphrodisias, where there was a flourishing school of sculpture.

In at least one respect the East was heavily influenced by Rome. The use of concrete and cross vault enabled Roman architects and engineers to span wide areas; their technological achievements included the covered vastness of the huge thermal establishments, the massive solidity of the amphitheatres, and the audacity of the soaring bridges and aqueducts. The East was greatly impressed. Admittedly, the agoras and gymnasiums in Greek towns are hardly Roman in aspect, but, for most structures of a practical utilitarian kind, the Greek debt to Rome was heavy. Sometimes Roman influence can be seen not only in the fundamental engineering of such buildings as market gateways, theatres, and amphitheatres but even in such decorative details as composite capitals as well. Roman features abound in exotic Petra, Palmyra, Gerasa, and Baalbek, and even in Athens itself. (E.T.S./R.MacM.)

THE LATER ROMAN EMPIRE

The dynasty of the Severi (AD 193-235). Septimius Severus. After the assassination of Commodus on Dec. 31, AD 192, Helvius Pertinax, the prefect of the city, became emperor. In spite of his modest birth, he was well respected by the Senate, but he was without his own army. He was killed by the praetorians at the end of March 193, after a three-month reign. The praetorians, after much corrupt bargaining, designated as emperor an old general. Didius Julianus, who had promised them the largest donativum (a donation given to each soldier on the emperor's accession). The action of the praetorians roused the ire of the provincial armies. The army of the Danube, which was the most powerful as well as the closest to Rome, appointed Septimius Severus in May 193. Severus soon had to face two competitors, supported, like himself, by their own troops: Pescennius Niger, the legate of Syria, and Clodius Albinus, legate of Britain. After having temporarily neutralized Albinus by accepting him as Caesar (heir apparent), Septimius marched against Niger, whose troops, having come from Egypt and Syria, were already occupying Byzantium. The Danubian legions were victorious, and Niger was killed at the end of 194; Antioch and Byzantium were pillaged after a long siege. Septimius even invaded Mesopotamia, for the Parthians had supported Niger. But this campaign was quickly interrupted: in the West, Albinus, disappointed at not being associated with the empire, proclaimed himself Augustus in 196 and invaded Gaul. He was supported by the troops, by the population, and even by the senators in Rome. In February 197 he was defeated and killed in a difficult battle near his capital of Lugdunum, which, in turn, was almost devastated. Septimius Severus remained the sole master of the empire, but the pillagings, executions, and confiscations left a painful memory. A few months later, in the summer of 197, he launched a second Mesopotamian campaign, this time against the Parthian king Vologases IV, who had attacked the frontier outpost Nisibis conquered two years previously by the Romans. Septimius Severus was again victorious. Having arrived at the Parthian capitals (Seleucia and Ctesiphon), he was defeated near Hatra but in 198

obtained an advantageous peace: Rome retained a part of Mesopotamia, together with Nisibis, the new province being governed by an eques. After having inspected the East, the emperor returned to Rome in 202. He spent most of his time there until 208, when the incursions of Caledonian rebels called him to Britain, where he carried out a three-year campaign along Hadrian's Wall. He died at Eboracum (York) in February 211.

Septimius Severus belonged to a Romanized Tripolitan family that had only recently attained honours. He was born in Leptis Magna in North Africa and favoured his native land throughout his reign. He was married to Julia Domna of Emesa, a Syrian woman from an important priestly family, and was surrounded by Easterners. He had pursued a senatorial career and had proved himself a competent general, but he was above all a good administrator and a jurist. Disliking Romans, Italians, and senators, he deliberately relied on the faithful Danubian army that had brought him to power, and he always showed great concern for the provincials and the lower classes. Although he had sought to appropriate the popularity of the Antonines to his own advantage by proclaiming himself the son of Marcus Aurelius and by naming his own son Marcus Aurelius Antoninus, he in fact carried out a totally different policy-a brutal yet realistic policy that opened careers to new social classes. Indifferent to the prestige of the Senate, where he had a great many enemies, he favoured the equites. The army thus became the seedbed of the equestrian order and was the object of all of his attentions. The ready forces were increased by the creation of three new legions commanded by equites, and one of these, the Second Parthica, was installed near Rome. Unlike Vespasian, who also owed his power to the army but who knew how to keep it in its proper place, Septimius Severus, aware of the urgency of external problems, established a sort of military monarchy. The praetorian cohorts doubled their ranks, and the dismissal of the old staff of Italian origin transformed the Praetorian Guard into an imperial guard, in which the elite of the Danube army were the most important element. The auxiliary troops were increased by the creation of 1,000-man units (infantry cohorts) and cavalry troops, sometimes outfitted with mail armour in the Parthian manner. The careers of noncommissioned officers emerging from the ranks now opened onto new horizons: centurions and noncommissioned grades could attain the tribunate and enter into the equestrian order. Thus, a simple Illyrian peasant might attain high posts: this was undoubtedly the most significant aspect of the "Severan revolution." This "democratization" was not necessarily a barbarization, for the provincial legions had long been Romanized. Their salaries were increased, and donativa were distributed more frequently; thenceforth, soldiers were fed at the expense of the provincials. Veterans received lands, mostly in Syria and Africa. The right of legitimate marriage, previously refused by Augustus, was granted to almost all of the soldiers, and the right to form collegia (private associations) was given to noncommissioned officers. Because more than a century had passed since the last raise in pay for the troops, despite a steady (if slow) rise in the level of prices, Severus increased the legionary's base rate from 300 to 500 denarii, with, no doubt, corresponding increases in other ranks. The reflection of this step in the content of precious metal in silver coinage (see below) recalls a point made earlier: the imperial revenues were constrained within the narrow limits of political and administrative reality

The administrative accomplishments of Septimius Severus were of great importance: he clearly outlined the powers of the city prefect; he entrusted the praetorian prefecture to first-class jurists, such as Papinian; and he increased the number of procurators, who were recruited for financial posts from among Africans and Easterners and for government posts (praesides) from among Danubian officers. Italy lost its privileges and found itself subjected, like all the other provinces, to the new annona, a tax paid in kind, which assured the maintenance of the army and of the officials. The consequent increase in expendituresfor administration, for the salaries and the donativa of the soldiers, for the maintenance of the Roman plebs, and for

The growth of the equestrian

Severus' campaigns

> Severus' administrative accomplishments

construction-obliged the emperor to devalue the denarius in 194. But the confiscations increased his personal fortune, the res privata, which had been previously created by Antoninus.

Severus' social policy favoured both the provincial recruitment of senators (Easterners, Africans, and even Egyptians), causing a sharp decrease in the percentage of Italian senators, and the elevation of the equestrian order, which began to fill the prince's council with its jurists. The cities, which had been favoured by the Antonines, were more and more considered as administrative wheels in the service of the state: the richest decuriones (municipal councillors) were financially responsible for levying the taxes, and it was for this purpose that the towns of Egypt finally received a houle (municipal senate).

The burden of taxes and forced government service was made weightier by numerous transport duties for the army and for the annona service and was regulated by the jurists through financial, personal, or mixed charges. The state was watchful to keep the decuriones in the service of their cities and to provide a control on their administration through the appointment of curatores rei publicae, or officials of the central government. The lower classes were, in principle, protected against the abuses of the rich, but in fact they were placed at the service of the state through the restrictions imposed on shipping and commercial corporations. Membership might entail forced contributions of capital or labour to such public necessities as the supply of food to Rome. The state became more and more a policeman, and the excesses of power of numerous grain merchants (frumentarii) weighed heavily on the little man.

Imperial power, without repudiating the ideological themes of the principate, rested in fact on the army and sought its legitimacy in heredity: the two sons of Septimius Severus, Caracalla and Geta, were first proclaimed Caesars, the former in 196, the latter in 198; later, they were directly associated with imperial power through bestowal of the title of Augustus, in 198 and 209, respectively. Thus, during the last three years of Septimius Severus' reign, the

empire had three Augusti at its head.

Caracalla, Caracalla, the eldest son of Septimius Severus, reigned from 211 to 217, after having assassinated his younger brother. Geta, He was a caricature of his father: violent, megalomaniacal, full of complexes, and, in addition, cruel and debauched. He retained the entourage of the equites and jurists who had governed with his father but enforced to an even greater degree his father's militaristic and egalitarian policy. He increased the wages of the army even further and, at the same time, began a costly building program that quickly depleted the fortune left him by his father. He forced the senators to pay heavy contributions, doubled the inheritance and emancipation taxes, and often required the aurum coronarium (a contribution in gold), thereby ruining the urban middle classes. To counter the effects of a general upward drift of prices and the larger and better-paid army of his own and his father's making, he created a new silver coin, the antoninianus. It was intended to replace the basic denarius at double its value, though containing only about one and a half times its worth in precious metal. The only historical source to suggest Caracalla's motive for his gift of universal citizenship, Dio Cassius, states that it was meant to increase revenues by bringing new elements of the population under tax obligations formerly limited to Romans only

Although little endowed with military qualities, Caracalla adopted as his patron Alexander the Great, whom he admired greatly, and embarked on an active external policy. He fought successfully against the Teutonic tribes of the upper Danube, among whom the Alamanni, as well as the Capri of the middle Danube, appeared for the first time; he often prudently mixed military operations with negotiation and gave important subsidies and money (in sound currency) to the barbarians, thus arousing much discontent. His ambition was to triumph in the East like his hero of old and, more recently, Trajan and his own father. He invaded Armenia and Adiabene and annexed Osroëne in northwest Mesopotamia, joining it to the part of Mesopotamia taken by Septimius Severus. In April 217, while pursuing his march on the Tigris, he was assassinated on the order of one of his practorian prefects, Marcus Opellius Macrinus.

Macrinus. Macrinus was accepted as emperor by the soldiers, who were unaware of the role he had played in the death of his predecessor. For the first time an eques had acceded to the empire after having been no more than a manager of financial affairs. The senators reluctantly accepted this member of the equestrian order, who, nevertheless, proved to be moderate and conciliatory: but the armies despised him as a mere civilian, and the ancient authors were hostile to him. His reign was brief, and little is known of him. He concluded an inglorious peace with the Parthians, which assured Mesopotamia to Rome through the payment of large sums of money. And to make himself popular, he canceled Caracalla's tax increases and reduced military expenditures. A plot against him was soon organized: two young grandnephews of Septimius Severus were persuaded by their mothers and especially by their grandmother, Julia Maesa, the sister of Julia Domna (who had recently died), to reach for imperial power. The eldest, Bassianus, was presented to the troops of Syria, who had been bought with gold, and was proclaimed in April 218. Shortly afterward, Macrinus was defeated and killed, as was his son (whom he had associated with him on the throne).

Elagabalus and Severus Alexander. The new emperor was presented as the son of Caracalla, whose name he took (Marcus Aurelius Antoninus). He is better known. however, under the name Elagabalus, the god whose high priest he was and whom he quickly and imprudently attempted to impose on the Romans, in spite of his grandmother's counsel of moderation. Fourteen years old, he caused himself to be detested by his heavy expenditures. his orgies, and the dissolute behaviour of his circle. The praetorians killed him in 222 and proclaimed as emperor his first cousin, Alexianus, who took the name of Severus

Alexander.

Although well educated and full of good intentions. Severus Alexander showed some weakness of character by submitting to the counsel of his mother, Mamaea, and of his grandmother, Maesa. The Scriptores historiae Augustae, a collection of biographies of the emperors, attributes to him a complete program of reforms favourable to the Senate, but these reforms are not mentioned elsewhere. As in the time of Septimius Severus, his counselors were equites. Ulpian, the praetorian prefect, was the greatest jurist of this period, and the basic policies of the founder of the dynasty were carried on, but with less energy. This weakening of energy had disastrous results: in Persia, the Arsacids were replaced in 224 by the more ambitious Sāsānid dynasty, who hoped to recover the former possessions of the Achaemenids in the East. Their initial attacks were stopped in 232 by a campaign that was, however, poorly conducted by the emperor and that alienated the army as a result of its ineptitude. In Rome there were frequent disorders, and, as early as 223, Ulpian had been killed by the praetorians. While gathered on the Rhine to fight the Teutons, the soldiers once again revolted and killed Severus Alexander and his mother. A coarse and uneducated but energetic soldier, Maximinus the Thracian, succeeded him without difficulty in March 235. The

Severan dynasty had come to an end. Religious and cultural life in the 3rd century. On the right bank of the Tiber in Rome, in the least fashionable section of town among Lebanese and Jewish labourers, Elagabalus built an elegant temple to his ancestral god; he was no doubt in those precincts very well received when he presided personally at its inauguration. Yet the world that counted, the world of senators and centurions, reacted with indignation. Within the capital the ruler was expected to honour the gods of the capital, the ancient Roman ones. At the same time, it was deemed appropriate that he reverently recognize other gods, in their place; for this reason a biography presenting Severus Alexander for the reader's admiration records how scrupulously he offered worship on the Capitoline to Jupiter, while also having, in a chapel attached to his domestic quarters, the images of his lares (household gods), of the deified emperors of most

Rise of the Sāsānids in

The antoninianus

The issue of an offical religion beloved memory, and of such superhuman beings as the Greeks would have called "heroes," including Apollonius the holy man of Tyana, Christ, Abraham, and Orpheus. The furnishing of the chapel is described by a most dubious source; but if it is not history, it is at least revealing of ideals. A Roman ruler was to express not only the piety of the capital and its citizens but also that of all his people throughout his empire. Imperial religion was properly compounded of both Roman and non-Roman piety.

Official religion can hardly be said to have existed in the sense of being pressed on people by the state. But the statement needs qualification. The cults of Rome were certainly official in the city itself; they were supported out of the state treasury and by the devotion of the emperor, at least if he lived up to what everyone felt were his responsibilities. In the army, too, camps had shrines in which portraits of the emperor were displayed for veneration on certain days of the year. A 3rd-century calendar has been found in an Eastern city that specifies for the garrison regiment the religious ceremonies to be carried out during the year, including a number of the oldest and most traditional ones in Rome. Many Western cities accorded special size and prominence to a temple in which Jupiter or the imperial family or both together were worshiped not by orders from on high, it is true, but spontaneously. The ubiquity of the imperial cult has already been emphasized. All these manifestations of piety gave some quality of "Romanness" to the religion of the empire.

On the other hand, the empire had been assembled from a great number of parts, whose peoples already had their own way of life fully matured; they were not about to surrender it nor, in fact, were they ever asked to do so by their conquerors. What characterized the religious life of the empire as a whole was the continued vitality of local cults in combination with a generally reverent awareness of one's neighbours' cults. The emperor, for example, might openly offer personal veneration to his favourite god, a god outside the traditional Roman circle, while also practicing a more conventional piety. When he was on his travels, he would offer cult at the chief shrines of all the localities he visited. What was expected of the emperor was expected of everyone: respectful toleration of all components in the religious amalgam. Of course, there were differences according to individual temperament and degree of education; approaches to religion might be literal or philosophical, fervent or relaxed. Rural society was more conservative than urban. But the whole can fairly be called an integrated system.

Just as the special power of the Greek gods had gained recognition among the Etruscans and, subsequently, among the Romans in remote centuries BC or as Sarapis in Hellenistic times had come to be worshiped in scattered parts of the Ptolemies' realm-Macedonia and Ionia, for example-so at last the news of unfamiliar gods was carried by their worshipers to distant places in the Roman Empire where, too, they worked their wonders, attracted reverent attention, and received a pillared lodging, a priesthood, and daily offerings. The Pax Romana encouraged a great deal more than commerce in material objects. It made inevitable the exchange of ideas in a more richly woven and complex fabric than the Mediterranean world had ever seen, in which the Phrygian Cybele was at home also in Gaul and the Italian Silvanus in northern Africa.

Religious developments in the Eastern provinces during the centuries from Augustus to Severus Alexander followed a somewhat different course from those in the West. In the East the further jumbling together of already wellmixed traditions encouraged a tolerance that eroded their edges. It became possible to see predominant similarities in Selene, Artemis, and Isis, in Zeus, Iarhibol, Helios, and Sarapis, or in Cybele, Ma, and Bellona. From recognition of basic similarities one might reason to a sort of monotheism, by the lights of which, for persons given to theology, local deities were no more than narrow expressions of greater truths. A juncture was then natural with Neoplatonism, the school of philosophy that later came to be held in high regard.

On the other hand, in Italy, the Danube provinces, and the Western provinces, religious change and development can be more easily seen in the immigration of worshipers of Easter deities. Those took root and became popularnone more so than Mithra, though Isis, Cybele, and Jupiter of Doliche were close behind. Apuleius in the closing chapters of his novel usually called The Golden Ass in English describes how a young man is brought from mere consciousness of Isis as a famous goddess with certain well-known rites and attributes, to a single-minded devotion to her. Aelius Aristides, a famous rhetorician of the time, recounts in his spiritual diary the development of a similar devotion in himself to Asclepius. Both the fictional and the factual account give a central place to benefits miraculously granted. It was by such means that piety was ordinarily warmed to a special fervour, whether or not that process should be called conversion. In any case, it produced the testimonies-votive inscriptions, temples, and so forth-through which it is possible to trace the spread of foreign cults. Eastern cults, however, also introduced to the West complex liturgies, beliefs underlying beliefs that could be explained in especially dramatic ways to special devotees ("mysteries"), and much rich symbolism. Of no cult was this more true than Mithraism, known to the 20th century through excavation of the underground shrines that it preferred.

The rise of Christianity. During the 1st and 2nd centuries, Christianity spread with relative slowness. The doctrines of Jesus, who was crucified about AD 30, first took root among the Jews of Palestine, where a large number of sects were proliferating-orthodox sects, such as the Sadducees and the Pharisees, as well as dissident and sometimes persecuted sects such as the Essenes, whose ascetic practices have been illuminated by the discovery of the Dead Sea Scrolls in the mid-20th century. At the end of Tiberius' reign, Christianity had spread to the gentiles as a result of the preaching of St. Paul in Anatolia and in Greece. At the same time, Christianity continued to make progress among the Jews of Jerusalem, Alexandria, and Syria and quickly reached even Osroëne and the Parthian towns of the Euphrates, where Jewish colonies were numerous. The Roman authorities at first had difficulty in distinguishing the "Christos" believers from the orthodox Jews, but the religion of the former, on leaving its original milieu, quickly became differentiated.

A familiar charge against the Jews, however, continued to pursue the Christians: that they felt a hatred of mankind. Their expectation of the end of the world aroused a suspicion that that was what they indeed desired; moreover, they were also suspect for their aloofness-they cut themselves off from family and community-and for their meetings, whose purpose was obscure. Their 2nd-century spokesmen had to dispel the belief, often recorded, that they practiced magic involving cannibalism; further, that they indulged in sex orgies, incestuous to boot; and, the most common accusation of all, that they were atheistspeople who denied the existence of the gods and rejected accepted cults. This last charge, which was, of course, exactly on the mark, must be set in the context of occasional episodes of mob violence against (non-Christian) atheists or doubters. Here the association of Christians with Jews, equally monotheistic, might have provided some protection for the Christians, but the Jews were faithful to a cult of the greatest antiquity and, moreover, had long made their peace with Caesar, Augustus, and their successors. It was a peace that could not extend to people who had (it would be alleged) apostasized from their own Judaism. Christians did not participate in the Jewish revolt of 66-73, and, under the Flavians, Christianity completely severed itself from its origins.

At this time the East was the centre of the new religion, whose followers grew in numbers from Egypt to the Black Sea and were beginning to be noticed in Bithynia and in Greece. Christians seemed fairly numerous in Rome as early as the end of the 1st century. When the age of the Apostles ended, the age of the church began, with its bishops, presbyters, and deacons, with its catechism, preaching, and celebration of the Eucharist. In the 2nd century, Christianity began to reach the intellectuals. Hellenistic culture offered educated Christians the resources of philosophical dialectic and of sophist rhetoric. The ex-

Beginnings Christian organizaample of Philo of Alexandria had shown in the 1st century that it was possible to reconcile the Bible with the great Platonic ideas. By the 2nd century the Christian "apologists" tried to show that Christianity was in harmony with Greco-Roman humanism and that it was intellectually,

and above all morally, superior to paganism.

But the Christians did not succeed in convincing the authorities. The first persecution, that of Nero, was related to a devastating fire in the capital in 64, for which the Christians were blamed or, perhaps, only made the scapegoats. In any case, their position as bad people (mali homines of the sort a governor should try to suppress) had been established, and later suppressions could be justified by reference to "the Neronian practice." So far as criminal law was concerned, such a precedent had considerable authority, of the sort that Pliny, as governor, was looking for in his handling of the Christians of Bithynia-Pontus in 111. His master, the emperor Trajan, told him not to seek them out but to execute those who, being informed against, refused to abjure their religion. Hadrian and other successors hewed to the same line thereafter. Thus, the persecutions remained localized and sporadic and were the result of private denunciations or of spontaneous popular protests. Under Marcus Aurelius, the difficulties of the times often caused the Christians, who refused to sacrifice to the state gods and to participate in the imperial cult, to be accused of provoking the wrath of the gods: martyrs appeared in the East, in Rome, in Gaul, and in Africa. Commodus' reign was more favourable to them, perhaps because certain members of his circle, not a very edifying one in other respects, were Christians or Christian sympathizers. This reprieve, however, was short-lived: Septimius Severus inaugurated the first systematic persecution. In 202 an edict forbade Christian (and Jewish) proselytism. Members of extremist sects were persecuted for preaching continence (which violated Augustus' laws against celibacy), for holding the state in contempt, and especially for refusing military service. Under Caracalla, the situation quieted, and the church continued to progress, favoured perhaps by the relative freedom that the law granted to funerary collegia (whence the first catacombs).

Cultural life from the Antonines to Constantine. Latin literature enjoyed its "Silver Age" under the Antonines, with the majority of great authors, such as Tacitus, Juvenal, and Pliny the Younger, having begun their careers under Domitian. They had no heirs: after Tacitus, Roman history was reduced to biography. It was only in the 4th century that history began to flourish again, with Ammianus Marcellinus, a Greek writing in Latin. Satire, the Roman genre par excellence, came to an end with Juvenal; and Pliny the Younger, a diligent rhetorician but with a lesser degree of talent, had only the mediocre Fronto as a successor. More original was the aforementioned rhetorician, scholar, and picaresque novelist Apuleius of Madauros.

A Greek renaissance, however, took place during the 2nd century. The Second Sophistic school reigned in every area: in rhetoric, history, philosophy, and even in the sciences. Schools of rhetoric and philosophy prospered in the East-in Smyrna, Ephesus, Pergamum, Rhodes, Alexandria, and even in Athens-protected and subsidized by the emperors, from Vespasian to Marcus Aurelius. The great sophists were Herodes Atticus, a multimillionaire from Athens; Polemon; and Aelius Aristides, a valetudinarian devotee of Asclepius. Dio Cassius and Herodian were conscientious and useful historians (first half of the 3rd century), as was later Dexippus the Athenian, whose work survives only in fragments. Science was represented by the mathematician Nicomachus of Gerasa; medicine, by Galen of Pergamum; astronomy, by the Alexandrian Ptolemy. Law remained the only Roman science, exemplified under the Antonines by Salvius Julianus and Gaius (the Institutiones) and rising to its zenith in the 3rd century as a result of the works of three jurists: Papinian, Ulpian, and Modestinus. Philosophy, heavily influenced by rhetoric and ethics, was represented under Domitian and Trajan by Dio (or Chrysostom) of Prusa, who outlined the stoical doctrine of the ideal sovereign. The biographer Plutarch and Lucian of Samosata were more eclectic, especially Lucian, who resembled Voltaire in his caustic skepticism. Under Marcus Aurelius, one of Lucian's friends. Celsus wrote the first serious criticism of Christianity. "The True Word," known through Origen's refutation of it in the 3rd century. At this time philosophy leaned toward religious mysticism; under the Severans, Ammonius Saccas created the school of Alexandria, and his disciple Plotinus founded the Neoplatonist school, which was to fight bitterly against Christianity. After the apologists and, above all. Tertullian (c. 160-after 222), Christian thought deepened, and theology made its appearance. Clement and Origen (c. 185-c. 254), the greatest theologian of the time, were the luminaries of the church of Alexandria; the Roman church still wrote in Greek and was represented by the slightly old-fashioned Hippolytus; and the church of Africa had a powerful personality, St. Cyprian, bishop of Carthage.

The disappearance of the great lyric and poetic styles, the fossilizing of education as it came to be completely based on rhetoric (paideia), and the growing importance of philosophical and religious polemical literature among both pagans and Christians were the basic traits that as early as the 3rd century, foreshadowed the intellectual life

of the late empire.

Military anarchy and the disintegration of the empire (235-270). Succession of emperors and usurpers. The period from the death of Severus Alexander to the time of Claudius II Gothicus was marked by usurpations and barbarian invasions. After Maximinus the Thracian, who bravely fought the Alemanni but showed great hostility toward the Senate and the educated elite, the Gordians rose to power as a result of a revolt by wealthy African landowners. A senatorial reaction first imposed civilian emperors. Pupienus and Balbinus together, and then named Gordian III, a youth backed by his father-in-law, the praetorian prefect Timesitheus. Gordian III was murdered by the soldiers during a campaign against the Persians and was replaced, first by Philip the Arabian and then by Decius. both soldiers. Decius tried to restore Roman traditions and also persecuted the Christians, but he was killed by the Goths in 251 in a battle near the Black Sea, From 253 to 268 two Roman senators, Valerian and his son Gallienus, reigned, Valerian revived the persecution of the Christians, but he was captured by the Persians during a disastrous campaign and died in captivity (260). His son then reigned alone, facing multiple invasions and several usurpations. He moved constantly between the Rhine and the Danube, achieving brilliant victories (Milan in 262. the Nestus in 267), but the Pannonian army raised several competitors against him (Ingenuus, Regalianus, Aureolus). Too busy to protect the Gauls against the Franks and the Alemanni and the East against the Persians, he had to tolerate the formation of the Gallic empire under the praetorian prefect Marcus Cassianius Postumus (259-268) and the Palmyrene kingdom of Odenathus (260-267). Some of his reforms were a foreshadowing of the future: the senators were practically excluded from the army; the equites received the majority of commands and of provincial governorships; and the composition of the army was modified by the creation of new army corps and especially of a strong cavalry, which was placed under the command of a single leader and charged with closing the breaches that the barbarians were opening along the frontiers. Upon his father's death Gallienus had put an end to the persecution of the Christians, preferring to fight the new religion through intellectual means; to that end, he favoured the ancient Greek cults (Demeter of Eleusis) and protected the Neoplatonist philosopher Plotinus. These initiatives increased the number of his enemies, particularly among the patriotic senators and the Pannonian generals. While Gallienus was in Milan besieging the usurper Aureolus, he was killed by his chiefs of staff, who proclaimed Claudius II (268), the first of the Illyrian emperors. The new emperor won a great victory against the Alemanni on the Garda lake and overwhelmed the Goths in Naissus (269) but died of the plague in 270. This fatal period brought to light one of the major defects of the empire: the lack of a legitimate principle of succession and the preponderant role of the army in politics. The structures that had

The Christian theologians

Decline of Latin literature

> Victories over the Germans

created the strength of the principate were weakened, and the empire required deep reforms. Gallienus had felt their necessity but had been too weak to impose them

The barbarian invasions. The Goths were Germans coming from what is now Sweden and were followed by the Vandals, the Burgundians, and the Gepidae. The aftereffect of their march to the southeast, toward the Black Sea, was to push the Marcomanni, the Quadi, and the Sarmatians onto the Roman limes in Marcus Aurelius' time. Their presence was brusquely revealed when they attacked the Greek towns on the Black Sea about 238. Timesitheus fought against them under Gordian III, and under Philip and Decius they besieged the towns of Moesia and Thrace, led by their kings, Ostrogotha and Kniva. Beginning in 253, the Crimean Goths and the Heruli appeared and dared to venture on the seas, ravaging the shores of the Black Sea and the Aegean as well as several Greek towns. In 267 Athens was taken and plundered despite a strong defense by the historian Dexippus. After the victories of Gallienus on the Nestus and Claudius at Naissus (Nish), there was for a time less danger. But the countries of the middle Danube were still under pressure by the Marcomanni, Quadi, lazyges, Sarmatians, and the Carpi of free Dacia, who were later joined by the Roxolani and the Vandals. In spite of stubborn resistance, Dacia was gradually overwhelmed, and it was abandoned by the Roman troops, though not evacuated officially. When Valerian was captured in AD 259/260, the Pannonians were gravely threatened, and Regalianus, one of the usurpers proclaimed by the Pannonian legions, died fighting the invaders. The defense was concentrated around Sirmium and Siscia-Poetovio, the ancient fortresses that had been restored by Gallienus, and many cities were burned.

In the West the invasions were particularly violent. The Germans and the Gauls were driven back several times by the confederated Frankish tribes of the North Sea coast and by the Alemanni from the middle and upper Rhine. Gallienus fought bitterly, concentrating his defense around Mainz and Cologne, but the usurpations in Pannonia prevented him from obtaining any lasting results. In 259-260 the Alemanni came through the Agri Decumates (the territory around the Black Forest), which was now lost to the Romans. Some of the Alemanni headed for Italy across the Alpine passes; others attacked Gaul, devastating the entire eastern part of the country. Passing through the Rhône Valley, they eventually reached the Mediterranean; and some bands even continued into Spain. There they joined the Franks, many of whom had come by ship from the North Sea, after having plundered the western part of Gaul. Sailing up the estuaries of the great rivers, they had reached Spain and then, crossing the Strait of Gibraltar, had proceeded to Mauretania Tingitana. Gallienus, outflanked, entrusted Gaul and his young son Saloninus to Postumus, who then killed Saloninus and proclaimed himself emperor. The several invasions had so frightened the people that the new emperor was readily accepted, even in Spain and Britain. He devoted himself first to the defense of the country and was finally considered a legitimate emperor, having established himself as a rival to Gallienus, who had tried in vain to eliminate him but finally had to tolerate him. Postumus governed with moderation, and, in good Roman fashion, minted excellent coins. He, too, was killed by his soldiers, but he had successors who lasted until 274.

Difficulties in the East. In the East the frontiers had been fixed by Hadrian at the Euphrates. But under Nero, the Romans had claimed control over the kings of Armenia, and under Caracalla they had annexed Osroëne and Upper Mesopotamia. The Parthian empire had been weak and often troubled, but the Sasanids were more dangerous. In 241, Shāpūr I (Sapor), an ambitious organizer and statesman, mounted the throne: he united his empire by bringing the Iranian lords into line and by protecting the Zoroastrian religion. He also tolerated the Manichaeans and put an end to the persecutions of the Christians and Jews, thereby gaining the sympathy of these communities. In 252, with a large army at his command, Shāpūr imposed Artavasdes on Armenia, attacked Mesopotamia, and took Nisibis. In 256 his advance troops entered Cap-

The surrender of the emperor Valerian to the Persian king Shāpūr, rock relief, AD 260, in the province of Fārs, Iran.

padocia and Syria and plundered Antioch, while Doura-Europus, on the middle Euphrates, was likewise falling to him. Valerian had rushed to its aid, but he could not remedy the situation; and in 259 or 260 he was imprisoned by Shapur during operations about which little is known. Mesopotamia was lost and Rome was pushed back to the Euphrates. Cappadocia, Cilicia, and Syria were again plundered, and a puppet emperor was appointed in Antioch, But these victories were transitory: in Osroëne, Edessa had shown resistance, a defense was organized in Cappadocia and Cilicia, and Odenathus, the prince of Palmyra, took Shāpūr by surprise and forced him back to Iran. Having thus aided the Roman cause, Odenathus then began to act in his own interest: he continued the fight against the Persians and took the title "King of Kings." The Romans officially entrusted him with the defense of the East and conferred on him the governorship of several provinces; the "kingdom" of Palmyra thus extended from Cilicia to Arabia. He was murdered in 267 without ever having severed his ties with Gallienus. His widow Zenobia had her husband's titles granted to their son Vaballathus. Then in 270, taking advantage of the deaths of Gallienus and Claudius II, she invaded Egypt and a part of Anatolia. This invasion was followed by a rupture with Rome. and in 271 Vaballathus was proclaimed Imperator Caesar Augustus. The latent separatism of the Eastern provinces and, undoubtedly, some commercial advantages caused them to accept Palmyrene domination without difficulty, as they had, in the past, supported Avidius Cassius and Pescennius Niger against the legitimate emperors. In 272 unity was restored by Aurelian, but Mesopotamia was lost, and the Euphrates became the new frontier of the empire.

Economic and social crisis. The invasions and the civil wars worked in combination to disrupt and weaken the empire over a span of half a century. Things were at their worst in the 260s, but the entire period from 235 to 284 brought the empire close to collapse. Many regions were laid waste (northern Gaul, Dacia, Moesia, Thrace, and numerous towns on the Aegean); many important cities had been pillaged or destroyed (Byzantium, Antioch, Olbia, Lugdunum); and northern Italy (Cisalpine Gaul) had been overrun by the Alemanni. During the crisis, the emperor either focused his forces on the defense of one point, inviting attack at another, or he left some embattled frontier altogether to its own devices; any commander who proved successful had the emperorship thrust upon him, on the very heels of his victories over the invaders. Counting several sons and brothers, more than 40 emperors thus established themselves for a reign of some sort, long or (more often) short. The political destabilization fed on itself, but it also was responsible for heavy expenditure of economic life and treasure. To keep pace with the latter, successive damage emperors rapidly and radically reduced the percentage of precious metal in the standard silver coins to almost nothing so as to spread it over larger issues. What thus became

destabilization and

Alemanni invasions

The severity of damage done to the empire by the political and economic destabilization is not easily estimated since for this period the sources of every sort are extremely poor. Common sense would suggest that commerce was disrupted, taxes collected more harshly and unevenly, homes and harvests destroyed, the value of savings lost to inflation, and the economy in general badly shaken. A severe plague is reported that lasted for years in midcentury, producing terrible casualties. In some western areas, archaeology provides illustration of what one might expect: cities in Gaul were walled, usually in much reduced circuits; villas here and there throughout the Rhine and Danube provinces also were walled; road systems were defended by lines of fortlets in northern Gaul and adjoining Germany; and a few areas, such as Brittany, were abandoned or relapsed into pre-Roman primitiveness. Off the coasts of that peninsula and elsewhere, too, piracy reigned; on land, brigandage occurred on a large scale. The reentrant triangle of land between the upper Danube and upper Rhine had to be permanently abandoned to the barbarians around it in about 260. The Pax Romana had then, in all these manifest ways, been seriously disrupted. On the other hand, in Egypt, where inflation is most amply documented, its harmful effects cannot be detected. The Egyptian economy showed no signs of collapse. Furthermore, some regions-most of Britain, for example-emerged from the half-century of crisis in a more prosperous condition than before. A summary of the effects of crisis can only underline one single fact that is almost self-evident; the wonders of civilization attained under the Antonines required an essentially political base. They required a strong, stable monarchy in command of a strong army. If either or both were seriously disturbed, the economy would suffer, along with the civilization's ease and brilliance. If, on the other hand, the political base could be restored, the health of the empire as a whole was not beyond recovery.

In the meantime, certain broad changes unconnected with the political and economic crisis were going forward in the 3rd century. Civilians increasingly complained of harassment and extortion by troops stationed among them; exaction of taxes intended for the army also became the target of more frequent complaint; and demands by soldiers to interfere in civilian government, foremost by those stationed in the capital, grew more insolent. The choice of emperor became more and more openly the prerogative of the military, not the Senate; and, as mentioned, in the 260s senators were being largely displaced from high military commands. The equestrian rank, in which persons risen from military careers were often to be found, was the beneficiary of the new policy. In sum, the power of the military, high and low, was asserting itself against that of the civilians. From this change, further, there flowed certain cultural consequences; for, continuing the tendencies detectable even in the 1st century, the army was increasingly recruited from the most backward areas, above all, from the Danubian provinces. Here, too-indeed, throughout the whole northern glacis of the empire-it had been state policy to allow entire tribes of barbarians to immigrate and to settle on vacant lands, where they dwelled, farmed, paid taxes, and offered their sons to the army. Such immigrants, in increasingly large numbers from the reign of Marcus Aurelius on, produced, with the rural population, a very non-Romanized mix. From the midst of just such people, Maximinus mounted to the throne in 235, and later, likewise, Galerius (Caesar from 293). It is quite appropriate aesthetically, from Aurelian on, that these later 3rd-century rulers chose to present themselves to their subjects in their propaganda with stubbly chin, set jaw, and close-cropped hair on a

The recovery of the empire and the establishment of the dominate (270-337). The Illyrian emperors. After Claudius II's unexpected death, the empire was ruled from 270 to 284 by several "Illyrian" emperors, who

were good generals and who tried in an energetic way to restore equilibrium. The most remarkable was Aurelian. He first gained hard-won victories over the Alemanni and the Juthungi, who had invaded the Alpine provinces and northern Italy. To cheer the inhabitants of Rome, who had succumbed to panic, he began construction of the famous rampart known as Aurelian's Wall. And while crossing the Danubian provinces, before marching against Palmyra, he decided on an orderly evacuation of Dacia, an undefendable region that had been occupied by the barbarians since the time of Gallienus. In the East, he defeated Zenobia's troops easily and occupied Palmyra in 272. Shortly afterward, an uprising broke out in Egypt under the instigation of a rich merchant, who, like a great part of the population, was a partisan of the Palmyrene queen. In response, Aurelian undertook a second campaign, plundering Palmyra and subjugating Alexandria. These troubles, however, along with the devastation of the great caravan city, were to set back Roman trade seriously in the East. Later, rounding back on the Gallic empire of Postumus' successors, he easily defeated Tetricus, a peaceful man not very willing to fight, near Cabillonum The unity of the empire was restored, and Aurelian celebrated a splendid triumph in Rome. He also reestablished discipline in the state, sternly quelled a riot of artisans in the mints of Rome, organized the provisioning of the city by militarizing several corporations (the bakers, the pork merchants), and tried to stop the inflation by minting an antoninianus of sounder value. His religious policy was original: in order to strengthen the moral unity of the empire and his own power, he declared himself to be the protégé of the Sol Invictus (the Invincible Sun) and built a magnificent temple for this god with the Palmyrene spoils. Aurelian was also sometimes officially called dominus et deus: the principate had definitely been succeeded by the "dominate." In 275 Aurelian was murdered by certain officers who mistakenly believed that their lives were in danger.

For once, his successor, the aged senator Tacitus, was chosen by the Senate-at the army's request and on short notice; he reigned only for a few months. After him. Probus, another Illyrian general, inherited a fortified empire but had to fight hard in Gaul, where serious invasions occurred in 275-277. Thereafter, Probus devoted himself to economic restoration; he attempted to return abandoned farmland to cultivation and, with the aid of military labour, undertook works of improvement. To remedy the depopulation, he admitted to the empire, as had Aurelian. a great number of defeated Goths, Alemanni, and Franks and permitted them to settle on plots of land in Gaul and in the Danubian provinces. After the assassination of Probus in 282 by soldiers, Carus became emperor and immediately associated with himself his two sons, Carinus and Numerian. Carus and Numerian fought a victorious campaign against the Persians but died under unknown circumstances. Carinus, left behind in the West, was later defeated and killed by Diocletian, who was proclaimed emperor in November 284 by the army of the East.

Diocletian. Diocletian may be considered the real founder of the late empire, though the form of government he established-the tetrarchy, or four persons sharing power simultaneously-was transitory. His reforms, however, lasted longer. Military exigencies, not the desire to apply a preconceived system, explain the successive nomination of Maximian as Caesar and later as Augustus in 286 and of Constantius and Galerius as Caesars in 293. The tetrarchy was a collegium of emperors comprising two groups: at its head, two Augusti, older men who made the decisions; and, in a secondary position, two Caesars, younger, with a more executive role. All four were related either by adoption or by marriage, and all were Illyrians who had attained high commands after a long military career. Of the four, only Diocletian was a statesman. The unity of the empire was safeguarded, despite appearances. for there was no territorial partitioning. Each emperor received troops and a sector of operation; Maximian, Italy and Africa; Constantius, Gaul and Britain; Galerius, the Danubian countries; and Diocletian, the East. Practically all governmental decisions were made by Diocletian, from

whom the others had received their power. He legislated. designated consuls, and retained precedence. After 287 he declared his kinship with the god Jupiter (Jove), who Diocletian claimed was his special protector. Diocletian, together with his Caesar Galerius, formed the "Jovii" dynasty, whereas Maximian and Constantius, claiming descent from the mythical hero Hercules, formed the "Herculii," This "Epiphany of the Tetrarchs" served as the divine foundation of the regime. The ideological recourse to two traditional Roman divinities represented a break with the Orientalizing attempts of Elagabalus and Aurelian. Even though he honoured Mithra equally, Diocletian wanted to be seen as continuing the work of Augustus. In dividing power, Diocletian's aim was to avoid usurpations, or at least to stifle them quickly-as in the attempt of Carausius, chief of the army of Britain, who was killed (293), as was his successor, Allectus (296), after a landing by Constantius.

The deification of the imperial function, marked by elaborate rituals, tended to set the emperors above the rest of mankind. But it was still necessary to avoid future rivalries and to assure the tetrarchy a legitimate and regular succession. Some time between 300 and 303 Diocletian found an original solution. After the anniversary of their 20-year reign the two Augusti abdicated (Maximian quite unwillingly), and on the same day (May 1, 305) the two Caesars became Augusti. Two new Caesars were chosen, Severus and Maximinus Daia, both friends of Galerius, whose strong personality dominated Constantius. In repudiating the principle of natural heredity (Maximian and Constantius each had an adult son), Diocletian took a great risk: absolute divine monarchy, which Diocletian largely established, implies the hereditary transmission of power, and the future was soon to demonstrate the attachment of the troops and even of the population to the hereditary principle.

In order to create a more efficient unity between subjects and administrators, Diocletian multiplied the number of provinces; even Italy was divided into a dozen small units of the provincial type. Rome, moreover, was no longer the effective capital of the empire, each emperor having his own residence in the part of the empire over which he ruled (Trier, Milan, Sirmium, Nicomedia). Although a few

provinces were still governed by senators (proconsuls or consuls), the majority were given to equestrian praesides usually without any military power but with responsibility for the entirety of civil administration (justice, police, finances, and taxes). The cities lost their autonomy, and the curiales administered and collected the taxes under the governor's direct control. The breaking up of the provinces was compensated for by their regrouping into a dozen dioceses, under equestrian vicars who were responsible to the emperor alone. The two praetorian prefects had less military power but played an important role in legislative. iudicial, and above all, financial matters: the administration of the annona, which had become the basis of the fiscal system, in fact gave them management of the entire economy. Within the central administration the number of offices increased, their managers being civilians who carried out their functions as a regular career. All officials were enrolled in the militia, whose hierarchy was to be outlined during the 4th century.

Great efforts were devoted to strengthening the borders. and the limes were outfitted with fortresses (castella) and small forts (burgi), notably in Syria. The army's strength was increased to 60 legions (but with reduced personnel); and, in principle, each border province received a garrison of two legions, complemented by subsidiary troops. Adopting one of Gallienus' ideas, Diocletian created an embryonic tactical army under the direct orders of the emperor whose escort (comitatus) it formed. The troops were most often commanded by duces and praenositi rather than by provincial governors and were mainly recruited from among the sons of soldiers and from barbarians who enlisted individually or by whole tribes. In addition, the landowners had to provide either recruits or a corresponding sum of money. All of these reforms were instituted gradually, during defensive wars whose success demonstrated the regime's efficiency. Constantius put down Carausius' attempted usurpation and fought the Alemanni fiercely near Basel; Maximian first hunted down the Bagaudae (gangs of fugitive peasant brigands) in Gaul, then fought the Moorish tribes in Africa, in 296-298, triumphing at Carthage; and on the Danube, Diocletian, and later Galerius, conquered the Bastarnae, the Iazyges, and the Carpi, deporting them in large numbers to the provinces. In the East, however, the opposition of the Persians, led by the enterprising Narses, extended from Egypt to Armenia. The Persians incited uprisings by both the Blemmyes nomads in southern Egypt and the Saracens of the Syrian desert and made use of anti-Roman propaganda by the Manichaeans and Jews. Diocletian succeeded in putting down the revolt in Egypt and fortified the south against the Blemmyes. But in 297, Narses, the heir to Shāpūr's ambitions, precipitated a war by taking Armenia, Osroëne, and part of Syria, After an initial defeat, Galerius won a great victory over Narses, and in 298 the peace of Nisibis reinstated a Roman protégé in Armenia and gave the empire a part of Upper Mesopotamia that extended even beyond the Tigris. Peace was thus assured

for some decades The wars, the reforms, and the increase in the number of officials were costly, and inflation reduced the resources of the state. The annona, set up by Septimius Severus, had proved imperfect, and Diocletian now reformed it through the jugatio-capitatio system: henceforth, the land tax, paid in kind by all landowners, would be calculated by the assessment of fiscal units based on extent and quality of land, type of crops grown, number of settlers and cattle, and amount of equipment. The fiscal valuation of each piece of property, estimated in juga and capita (interchangeable terms whose use varied by region and period of time), required a number of declarations and censuses similar to those practiced long before in Egypt. Each year, the government established the rate of tax per fiscal unit; and every 15 years, beginning in 312, taxes were reassessed. This complicated system was not carried out uniformly in every region. Nevertheless, it resulted in an improved accounting of the empire's resources and a certain progress in fiscal equity, thus making the administration's heavy demands less unbearable. In addition, Diocletian wished to reorganize the coinage and stabilize

opposition

Changes in provincial organization

Late

Roman

society

inflation. He thus minted improved sterling coins and fixed their value in relation to a gold standard. Nevertheless, inflation again became disturbing by the end of the century, and Diocletian proclaimed his well-known Edictum de Maximis Pretiis, fixing price ceilings for foodstuffs and for goods and services, which could not be exceeded under pain of death. The edict had indifferent results and was scarcely applied, but the inscriptions revealing it have

great economic interest. Diocletian's reforms adumbrated the principal features of late Roman society: a society defined in all parts that could be useful to the state by laws fixing status and, through status, responsibility. The persons owning grain mills in Rome were (to anticipate developments that continued to unfold throughout the next two or three generations) responsible for the delivery of flour for the dole and could not bequeath or withdraw any part of their capital from their enterprise. Several other labour groups were similarly restricted, such as owners of seagoing vessels that served the supply of Rome, bargees in the Tiber, Ostian grain handlers, distributors of olive oil and pork for the dole, bath managers, and limeburners. A ban on moving to some other home or job along with production quotas were placed on people in trades serving state factories that made imperial court and army garments, cavalry equipment, and arms. Diocletian built a number of such factories, some in his capital Nicomedia, others in cities close to the groups whose needs they served. The laws imposing these obligations affected only labour groups serving the army and the capital (or capitals, plural, after the promotion of Constantinople); and, to identify them, induce them to serve, and hold them in their useful work, emperors as early as Claudius had offered privileges and imposed controls. Diocletian, however, greatly increased the weight and complexity of all these obligations.

Diocletian also changed the administrative districts in Egypt, in keeping with the model found elsewhere, by designating in each a central city to take responsibility for the whole. The last anomalous province was thus brought into line with the others. Everywhere, the imperial government continued to count on the members of the municipal senate to serve it, above all in tax collection but also in the supply of recruits, in rural police work, billeting for troops, or road building. As had been the case for centuries, they had to have a minimum of landed property to serve as surety for the performance of their administrative duties as well as to submit to nomination as senator, if it was so determined by the Senate. There had never been any one law to that effect, but by Diocletian's time the emperor had at his command a body of long-established custom and numerous imperial decisions that served just as well. Local elites were thus hereditary, compulsory agents of his purpose, exactly like the Tiber bargees.

Two other groups were frozen into their roles in the same fashion: soldiers and farmers. The sons of soldiers were required to take up their fathers' occupation (a law to that effect was in operation at least by 313); and the natural tendency of tenant farmers (coloni) to renew their lease on land that they, and perhaps their fathers and grandfathers. had worked was confirmed by imperial decisions-to such effect that, in 332, Constantine could speak of tenants on his Sardinian estates as bound to the acres they cultivated. This is the earliest explicit pronouncement on what is called the "colonate." Soon the institution was extended beyond imperial estates to tie certain categories of tenants to private estates as well. The emperors wanted to ensure tax revenue and, for that, a stable rural labour supply.

The empire, as it is seen in abundant legislation for the period of Diocletian and beyond into the 5th century, has been called a "military dictatorship" or even a sort of totalitarian prison, in which every inhabitant had his own cell and his own shackles. This may well have been the rulers' intent. By their lights, such a system was needed to repair the weaknesses revealed in the 3rd-century crisis. The principle of hereditary obligations was not, after all, so very strange, set against the natural tendencies of the economy and the practices that had developed in earlier. easier times. Yet Diocletian's intentions could not be fully realized, given the limits on governmental effectiveness.

After a period of initial indifference toward the Christians. Diocletian ended his reign by unleashing against them, in 303, the last and most violent of their persecutions. It was urged on him by his Caesar Galerius and prolonged in the East for a decade (until 311) by Galerius as Augustus and by other emperors. As in earlier persecutions, the initiative arose at the heart of government; some emperors, as outraged by the Christians as many private citizens, considered it their duty to maintain harmony with the gods, the pax deorum, by which alone the empire flourished. Accordingly, Decius and Valerian in the 250s had dealt severely with the Christians, requiring them to demonstrate their apostasy by offering sacrifice at the local temples, and for the first time had directly struck the church's clergy and property. There were scores of Christians who preferred death, though the great majority complied or hid themselves. Within a matter of months after he had begun his attacks, however, Decius had died (251), and the bloody phase of Valerian's attacks also lasted only months (259/260). His son Gallienus had issued an edict of tolerance, and Aurelian was even appealed to by the church of Antioch to settle an internal dispute. Christianity had now become open and established, thanks to the power of its God so often, it seemed, manifested in miraculous acts and to the firmness with which converts were secured in a new life and community. The older slanders-cannibalism and incest-that had troubled the Apologists in the 2nd century no longer commanded credence. A measure of respectability had been won, along with recruits from the upper classes and gifts of land and money. By the end of the 3rd century Christians actually predominated in some of the smaller Eastern towns or districts, and they were well represented in Italy, Gaul, and Africa around Carthage; all told, they numbered perhaps as many as 5 million out of the empire's total population of 60 million. Occasional meetings on disputed matters might bring together dozens of bishops, and it was this institution or phenomenon that the Great Persecutions sought to defeat. The progress of a religion that could not accept the religious basis of the tetrarchy and certain of whose members were imprudent and provocative, as in the incidents at Nicomedia (where a church was built across from Diocletian's palace), finally aroused Galerius' fanaticism. In 303-304 several edicts, each increasingly stringent, ordered the destruction of the churches, the seizure of sacred books, the imprisonment of the clergy, and a sentence of death for all those who refused to sacrifice to the Roman gods. In the East, where Galerius was imposing his ideas more and more on the aging Diocletian, the persecution was extremely violent, especially in Egypt, Palestine, and the Danubian regions. In Italy, Maximian, zealous at the beginning, quickly tired: and in Gaul, Constantius merely destroyed a few churches without carrying reprisals any further. Nevertheless, Christianity could no longer be eradicated, for the people of the empire and even some officials no longer felt the blind

hatred for Christians that had typified previous centuries. Struggle for power. The first tetrarchy had ended on May 1, 305; the second did not last long, After Constantius died at Eboracum in 306, the armies of Britain and Gaul, without observing the rules of the tetrarchic system, had hastened to proclaim Constantine, the young son of Constantius, as Augustus. Young Maxentius, the son of Maximian (who had never wanted to retire), thereupon had himself proclaimed in Rome, recalled his father into service, and got rid of Severus. Thus, in 307-308 there was great confusion. Seven emperors had, or pretended to have, the title of Augustus: Maximian, Galerius, Constantine, Maxentius, Maximinus Daia, Licinius (who had been promoted Augustus in 308 by Galerius against Con-

stantine), and, in Africa, the usurper Domitius Alexander. This situation was clarified by successive eliminations. In 310, after numerous intrigues, old Maximian was killed by his son-in-law Constantine, and in the following year Alexander was slain by one of Maxentius' praetorian prefects. In 311 Galerius died of illness a few days after having admitted the failure of his persecutions by proclaiming an edict of tolerance. There remained, in the West, Constantine and Maxentius and in the East, Licinius and Maximinus Daia. Constantine, the best general, invaded Italy with Persecutions of Christians

a strong army of faithful Gauls and defeated Maxentius near the Milvian Bridge, not far from Rome. While attempting to scape, Maxentius drowned. Constantine then made an agreement with Licinius, and the two rallied the Eastern Christians to their side by guaranteeing them religious tolerance in the Edict of Milan (313). This left Maximius Daia, now isolated and regarded as a persecutor, in a weak position; attacked by Licinius near Adrianople, he fell ill and died soon afterward, in 313. This left the empire with two leaders, Constantine and Licinius, allied in outward appearances and now brothers-in-law as a result of Licinius' marriage to Constantine's sister.

The reign of Constantine. Constantine and Licinius soon disputed among themselves for the empire. Constantine attacked his adversary for the first time in 316, taking the dioceses of Pannonia and Moesia from him. A truce between them lasted 10 years. In 316 Diocletian died in Salona, which he had never felt a desire to leave despite the collapse of his political creation. Constantine and Licinius then reverted to the principles of heredity, designating three potential Caesars from among their respective sons, all still infants, with the intention of securing their dynasties (two sons of Constantine and one of Licinius). The dynastic concept, however, required the existence of only a single emperor, who imposed his own descendance. Although Constantine favoured the Christians, Licinius resumed the persecutions, and in 324 war erupted once again. Licinius, defeated first at Adrianople and then in Anatolia, was obliged to surrender and, together with his son, was executed. Next, Constantine's third son, Constantius, was in turn named Caesar, as his two elder brothers, Crispus and Constantine the Younger. had been some time before. The second Flavian dynasty was thus founded, and Constantine let it be believed that his father, Flavius Constantius (Chlorus), was descended from Claudius Gothicus.

Constantine's conversion to Christianity had a far-reaching effect. Like his father, he had originally been a votary of the Sun; worshiping at the Grand Temple of the Sun in the Vosges Mountains of Gaul, he had had his first vision-albeit a pagan one. During his campaign against Maxentius, he had had a second vision-a lighted cross in the sky-after which he had painted on his men's shields a figure that was perhaps Christ's monogram (although he probably had Christ confused with the Sun in his manifestation as summa divinitas ["the highest divinity"]). After his victory he declared himself Christian. His conversion remains somewhat mysterious and his contemporaries-Lactantius and Eusebius of Caesarea-are scarcely enlightening and even rather contradictory on the subject. But it was doubtless a sincere conversion, for Constantine had a religious turn of mind. He was also progressive and greatly influenced by the capable bishops who surrounded him from the very beginning.

Until 320–322 solar symbols appeared on Constantine's monuments and coins, and he was never a great theologian. Yet his favourable policy toward the Christians never faltered. Christianity was still a minority religion in the empire, especially in the West and in the countryside (and consequently within his own army), thus excluding the possibility of any political calculation on his part. But it was enthusiastically welcomed in the East, and thanks to Constantine the new religion triumphed more rapidly, his official support led to the conversion of numerous pagans, although with doubful sincertity because they were indifferent in their moral conviction.

The church, so recently persecuted, was now suddenly showered with favours: the construction of magnificent churches (Rome, Constantinople), donations and grants, exemptions from decurial duties for the clergy, juridical competences for the bishops, and exceptional promotions for Christian officials. Pagans were not persecuted, however, and Constantine retained the title of ponitive maximus. But he spoke of the pagan gods with contempt and forbade certain types of worship, principally nocturnal sacrifices. In 331 he ordered an inventory of pagan property, despoiled the temples of their treasure, and finally destroyed a few Eastern sanctuaries on the pretext of immorality.

The churches were soon to feel the burden of imperial solicitude: the "secular arm" (i.e., the government) was placed at the service of a fluctuating orthodoxy, for the emperor was impressionable to arguments of various coteries and became quite lost in theological subtleties. In 314 the Council of Arles had tried in vain to stop the Donatist schism (a nationalistic heretical movement questioning the worthiness of certain church officials) that arose in Africa after Diocletian's persecutions. The Arian heresy raised even more difficulties: Arius, an Alexandrian priest and disciple of Lucian of Antioch, questioned the dogma of the Trinity and of the Godhead of Christ, and his asceticism, as well as the sharpness of his dialectics. brought him many followers; he was convicted several times, but the disorders continued. Constantine, solicited by both sides and untroubled by doctrinal nuances that were, moreover, foreign to most believers in the West wished to institute a universal creed; with this in mind he convened the general Council of Nicaea, or Nicene Council, in 325. He condemned Arius and declared, in spite of the Easterners, that Jesus was "of one substance" with God the Father. Nevertheless, the heresy continued to exist, for Constantine changed his mind several times; he was influenced by Arian or semi-Arian bishops and was even baptized on his deathbed, in 337, by one of them, Eusebius of Nicomedia.

Between 325 and 337 Constantine effected important reforms, continuing Diocletian's work. The division between the limitanei border troops and the tactical troops (comitatenses and imperial guard) led by magistri militum was clarified, and military careers became independent of civil careers. At the same time, however, he lodged an increasing number of troops in or next to cities, a process whose objective was ease and economy of supply; however, training and discipline were harder to enforce because of it, and the men hung about in idleness. It was also under Constantine that a barbarian commander in the Roman army attained a historical significance. He was Crocus the Alaman, who led the movement among the troops that resulted in Constantine's seizure of the rank of Augustus in 306 immediately after his father Constantius' death. A similar figure was the great commander Bonitus, a Frank, in the years 316-324; and Constantine credited his victories against Maxentius in 311-312 principally to his barbarian troops, who were honoured on the triumphal Arch of Constantine in Rome. In opposition to him, Licinius mustered drafts of Goths to strengthen his army. Goths were also brought in by Constantine, to the number of 40,000, it is said, to help defend Constantinople in the latter part of his reign, and the palace guard was thenceforward composed mostly of Germans, from among whom a great many high army commands were filled. Dependence on immigrants or first-generation barbarians in war was to increase steadily, at a time when conventional Roman troops were losing military value.

Constantine raised many equestrians to senatorial rank, having in his earlier reign the still rapidly increasing ranks of the civil service to fill-it was at least 50 times the size of the civil service under Caracalla-and having in his later reign a second senate to fill, in Constantinople (see below). A rapid inflation in titles of honour also took place. As a result of these several changes, the equestrian order ceased to have meaning, and a new nobility of imperial service developed. Constantine gave first rank in the central administration to the palace quaestor, the magister officiorum, and the counts of finance (comes sacrarum largitionum, comes rei privatae). The diocesan vicars were made responsible to the praetorian prefects, whose number was increased and whose jurisdictions were now vast territories: the prefectures of Gaul, Italy, Illyricum, and the East. The unification of political power brought with it a corresponding decentralization of administration.

In order to reorganize finances and currency, Constantine minted two new coins: the silver miliarensis and, most importantly, the gold solidus, whose stability was to make it the Byzantine Empire's basic currency. And by plundering Licinius' treasury and despoling the pagan temples, he was able to restore the finances of the state. Even so, he still had to create class taxes: the globa for

Constantine's conversion to Christian-

itv

senators, and the chrysargyre, which was levied in gold and silver on merchants and craftsmen in the towns.

Constantine's immortality, however, rests on his founding of Constantinople. This "New Rome," established in 324 on the site of Byzantium and dedicated in 330, rapidly increased in population as a result of favours granted to immigrants. A large number of churches were also built there, even though former temples were not destroyed; and the city became the administrative capital of the empire, receiving a senate and proconsul. This choice of site was due not to religious considerations, as has been suggested, but rather to reasons that were both strategic (its proximity to the Danube and Euphrates frontiers) and economic (the importance of the straits and of the junction between the great continental road, which went from Boulogne to the Black Sea, and the eastern commercial routes, passing through Anatolia to Antioch and Alexandria). Constantine died on May 22, 337.

The Roman Empire under the 4th-century successors of Constantine. The rule of Constantine's sons. After some months of confusion, Constantine's three surviving sons (Crispus, the eldest son, had been executed in mysterious circumstances in 326), supported by the armies faithful to their father's memory, divided the empire among themselves and had all the other members of their family killed. Constantine II kept the West, Constantius the East, and Constans, the youngest brother, received the central prefecture (Italy, Africa, and Illyricum). In 340 Constantine II tried to take this away from Constans but was killed. For the next 10 years there was peace between the two remaining brothers, and Constans won acceptance for a religious policy favourable to the Niceans, whose leader, Athanasius, had received a triumph in Alexandria, In 350 a mutiny broke out in Autun; Constans fled but was killed in Lugdunum by Magnentius, a usurper who was recognized in Gaul, Africa, and Italy. Constantius went out to engage Magnentius, and the Battle of Mursa (351) left the two strongest armies of the empire-those of Gaul and of the Danube-massacred, thus compromising the empire's defense. Magnentius retreated after his defeat and finally committed suicide in 353.

Thenceforth, Constantius reigned alone as Augustus, aided by a meddlesome bureaucracy in which mission deputies (agentes in rebus), informers, and spies played an important role. He named two Ceasrs in succession, his two young surviving cousins, Gallus in the East and Julian in Gaul. Constantius eventually had to get rid of Gallus, who proved incompetent and cruel and soon terrorized Antioch. Julian, however, was a magnificient success, a fact that aroused Constantius' jealousy and led to Julian's usurpation; for the latter was proclaimed Augustus, in spite of Constantius' opposition, at Lutetia in 361. Civil war was averted when Constantius died in November 361, leaving the empire to Julian, the last ruler of the Constantinian family (see below).

At the time of his death in 337 Constantine had been preparing to go to war against the Persians. This legacy weighed heavily on the shoulders of Constantius, a military incompetent when compared to the energetic Sāsānian king Shāpūr II. Nearly every year the Persians attacked and pillaged Roman territory; the Mesopotamian towns were besieged, and Nisibis alone resisted. There was a lull between 350 and 357, while Shapur was detained by troubles in the eastern regions of his own kingdom. The war resumed, however, and Mesopotamia was partly lost when the emperor had to leave in order to fight Julian. Constantius had fought Shāpūr conscientiously, but his generals were mediocre, except for Urisicinus, and he himself was clumsy. In the meantime, the Rhine and Danube were threatened frequently, because the troops had been withdrawn from there and sent to the East. Constantius. moreover, had made a mistake in sending Chnodomar, the Alemannic king, against Magnentius in 351, for his tribes had gone on to ravage Gaul. Julian, however, soon revealed himself to be a great military leader by winning several well-fought campaigns between 356 and 361, most notably at Strasbourg in 357, and by restoring approximately 70 plundered villages. His abandonment, in AD 358, of the district of Toxandria, roughly equivalent to modern Belgium, to its barbarian squatters, on condition of their defending it against other invaders, was no doubt a realistic decision. Constantius defeated the Quadi and the Goths on the Danube in 359, but court intrigues, Magnentius' usurpation, and the interminable war against the Persians allowed the barbarians to wreak great havoe.

Constantius was primarily interested in religious affairs. His interventions created a "caesaro-papism" that was unfavourable to the church, for after the Battle of Mursa the emperor had become violently Arian. The Christological problem had moved to the forefront. In 360 Constantius obtained a new creed by force from the Council of Constantinople, which, rejecting the notion of "substance" as too risky, declared only that the Son was like the Father and thus left the problem unresolved. Pagans as well as orthodox Nicaeans (Homoousians) and extremist Arians (Anomoeans) were persecuted, for in 356-357 several edicts proscribed magic, divination, and sacrifices and ordered that the temples be closed. But when Constantius visited Rome in 357, he was so struck by its pagan grandeur that he apparently suspended the application of these measures.

The reign of Julian. Julian, who had been spared because of his tender age from the family butchering in 337, had been brought up far from the court and was undoubtedly intended for the priesthood. Nevertheless, he had been allowed to take courses in rhetoric and philosophy at Ephesus and later at Athens; he developed a fondness for Hellenic literature, and he secretly apostatized around 351. When he became sole emperor at the end of 361, he proclaimed his pagan faith, ordered the restitution of the temples seized under Constantius, and freed all the bishops who had been banished by the Arians, so as to weaken Christianity through the resumption of doctrinal disputes. The religion he himself espoused was compounded of traditional non-Christian elements of piety and theology, such as might have been found in any fairly intellectual person in the preceding centuries, along with elements of Neoplatonism developed by Porphyry and Jamblichus of two or three generations earlier, and, finally, much of the organization and social ethic of the church. From Neoplatonism he learned the techniques of direct communication with the gods (theurgy) through prayer and invocation; from the church he adopted, as the church itself had adopted from the empire's civil organization, a hierarchy of powers: provincial, metropolitan, urban, with himself as supreme pontiff. His deep love of traditional higher culture, moreover, provoked his war on Christian intellectuals and teachers who, he protested, had no right to Homer or Plato. Many Christians both before and later concurred with him, being themselves troubled by the relation between Christianity and inherited literature and thought, steeped as both were in pagan beliefs

In the latter part of his 18-month reign, Julian forbade Christians from teaching, began the rebuilding of the Temple at Jerusalem, restored many pagan shrines, and displayed an exagegrated piety. Whereas Constantine (and his sons to a lesser degree) had introduced a huge number of coreligionists into the upper ranks of the army and government, achieving a rough parity between the members of the two reigions, Julian began to reverse the process. Within a short while Julian was successful enough in his undertaking to have aroused the fear and hatted of the Christians, who for a long time thought of him as the Antichrist.

In the political realm, Julian wished to return to the liberal principate of the Antonines—to a time before the reforms of Diocletian and Constantine, whom he detested. He put an end to the terrorism of Constantius' enunchs and agentes in rebus and reduced the personnel and expenditures of the court, while he himself lived like an ascetic. In the provinces he lightened the financial burden on individuals by reducing the capitatio, and on cities, by reducing the aurum coronarium and restoring the municipal properties confiscated by Constantius. On the other hand, he increased the number of curiales by reinstating numerous clerks in an attempt to return the ancient lustre to municipal life. Thus, he earned the gratitude of pagan intellectuals, who were enamoured of the past of

Constantius'

The reign of Constantius Julian's attempt to defeat Persia

free Greece; and Ammianus made him the central hero of his history

Taking up Trajan's dream, Julian wished to defeat Persia definitively by engaging the empire's forces in an offensive war that would facilitate a national reconciliation around the gods of paganism. But his army was weak-corrupted perhaps by large numbers of hostile Christians. After a brilliant beginning, he was defeated near Ctesiphon and had to retrace his steps painfully; he was killed in an obscure encounter on June 26, 363.

Julian's successor, Jovian, chosen by the army's general staff, was a Christian, but not a fanatic. He negotiated a peace with Shapur, by which Rome lost a good part of Galerian's conquests of 298 (including Nisibis, which had not surrendered) and abandoned Armenia. He also restored tolerance in religious affairs, for he neither espoused any of the heresies nor persecuted pagans. In February 364 he

died accidentally.

The reign of Valentinian and Valens. Once again the general staff unanimously chose a Pannonian officer-Valentinian, an energetic patriot and, like Jovian, a moderate Christian-but he had to yield to the rivalry of the armies by dividing authority. Taking the West for himself Valentinian entrusted the East to his brother Valens, an inexperienced man whom he raised to the rank of Augustus. For the first time the two parts of the empire were truly separate, except for the selection of consuls, in which

Valentinian had precedence.

Although he served the state with dedication, Valentinian could be brutal, choleric, and authoritarian. His foreign policy was excellent: all the while he was fighting barbarians (the Alemanni in Gaul, the Sarmatians and Quadi in Pannonia) and putting down revolts in Britain and Africa (notably that of the Berber Firmus) with the aid of his top general. Theodosius the Elder, he was taking care to improve the army's equipment and to protect Gaul by creating a brilliant fortification. His domestic measures favoured the curiales and the lower classes: from then on, taxes would be collected exclusively by officials; the protection of the poor was entrusted to "defenders of the plebs," chosen from among retired high officials (honorati). Nevertheless, needs of state obliged him to accentuate social immobility, to reinforce corporation discipline and official hierarchization, and to demand taxes ruthlessly. At first he was benevolent to the Senate of Rome, supervised the provisioning of the city, and legislated in favour of its university, the nursery of officials (law of 370). But beginning in 369, under the influence of Maximin, the prefect of Gaul, he initiated a period of terror, which struck the great senatorial families. Meanwhile, religious peace reigned in the West, tolerance was proclaimed, and after some difficulty, Rome found a great pope in Damasus, who, beginning in 373, actively supported the new bishop of Milan, St. Ambrose, an ardent defender of orthodoxy.

In the East, Valens, who was incapable and suspicious, had fallen under the influence of legists, such as the praetorian prefect Modestus. The beginning of Valens' reign was shadowed by the attempted usurpation of Procopius (365-366), a pagan relative of Julian's who failed and was killed by the army, which remained faithful to Valens. Modestus instituted harsh persecutions in Antioch of the educated pagan elite. Valens was a fanatic Arian, who exiled even moderate Nicaean bishops and granted to Arians favours that aroused violent reactions from the orthodox, whose power had increased in the East. Valens' policies

made the East prey to violent religious passions. On the Danube, Valens fought the Visigoths and made a treaty with their king, Athanaric, in 369; but in 375 the Ostrogoths and the Greutingi appeared on the frontiers, pushed from their home in southern Russia by the powerful Huns. In 376 Valens authorized the starving masses to enter Thrace; but, being exploited and mistreated by the officials, they soon turned to uncontrollable pillaging. Their numbers continually increased by the addition of new bands, until finally they threatened Constantinople itself. Valens sent for aid from the West, but without waiting for it to arrive he joined battle and was killed n the Adrianople disaster of 378, which to some critics foreshadowed the approaching fall of the Roman Empire.

The Goths, who were also stirring up Thrace and Macedonia, could no longer be driven out. The provinces subject to their pillaging soon included Pannonia farther up the Danube, where Gratian agreed with a cluster of three tribal armies to settle them as a unit under their own chiefs on vacant lands (380). By a far more significant arrangement of the same sort two years later, Theodosius assigned to the Goths a large area of Thrace along the Danube as, in effect, their own kingdom; there they enjoyed autonomy as well as a handsome subsidy from the emperor, exactly as tribes beyond the empire had done in previous treaties. They were expected to respond to calls on their manpower if the Roman army needed supplementing, as it routinely did. Although the Goths considered this treaty ended with Theodosius' death and resumed their lawless wanderings for a while, it nevertheless represented the model for subsequent ones, again struck with the Goths under their king Alaric (from 395; see below) and with later barbarian tribes. The capture of the empire had begun.

The reign of Gratian and Theodosius I. Following Valentinian's sudden death in 375, the West was governed by his son Gratian, then 16 years old, who had been given the title of Augustus as early as 367. The Pannonian army, rife with intrigue, quickly proclaimed Gratian's halfbrother, Valentinian II, only four years old. The latter received Illyricum under his older brother's guardianship. and this arrangement satisfied everybody. Valentinian's advisers were executed: Maximian was sacrificed to the spite of the Senate, and Theodosius the Elder became the victim of personal jealousies. Gratian announced a liberal principate, supported in Gaul by the wealthy family of the Bordeaux poet Ausonius and in Rome by the Symmachi and the Nicomachi Flaviani, representatives of the pagan aristocracy. His generals defeated the Alemanni and the Goths on the Danube but arrived too late to save Valens.

On Jan. 19, 379, before the army, Gratian proclaimed Theodosius, the son of the recently executed general, as Eastern emperor. Theodosius was chosen for his military ability and for his orthodoxy (Gratian, extremely pious, had come under the influence of Damasus and Ambrose). The East was enlarged by the dioceses of Dacia and Macedonia, taken from Valentinian II. Gratian and Theodosius agreed to admit the Goths into the empire, and Gratian applied the policy also to the Salian Franks in Germany. Theodosius soon dominated his weak colleague and entered the battle for the triumph of orthodoxy. In 380 the Arians were relieved of their churches in Constantinople, and in 381 the Nicaean faith was universally imposed by a council whose canons established the authority of the metroplitan bishops over their dioceses and gave the bishop of the capital a primacy similar to that of the bishop of Rome.

In ecclesiastical affairs, the separation between East and West was codified. The Westerners bowed to this policy, satisfied with the triumph of orthodoxy. Gratian then permitted Ambrose and Damasus to deal harshly with the Arians, with the support of the state. Paganism also was hounded: following Theodosius' lead, Gratian refused the chief priesthood, removed the altar of Victory from the hall of the Roman Senate, and deprived the pagan priests and the Vestal Virgins of their subsidies and privileges. The pagan senators were outraged, but their protests were futile because Gratian was watched over by Ambrose.

This militantly orthodox policy aroused the displeasure of the pagans and of the Western Arians: thus, when Gratian left Trier for Milan, the army of Gaul and Britain proclaimed its leader, Maximus, in 383. He conquered Gaul without difficulty, and Gratian was killed in Lyons. Maximus, who, like Theodosius, was Spanish and extremely orthodox, was recognized by the latter. In the meantime, the third Augustus, Valentinian II, had taken refuge in Milan after suffering defeat in Pannonia. He was effectively under the domination of his mother, Justina, an Arian who sought support for her son among the Arians and pagans of Rome and even among the African Donatists (a Christian heresy). In 388 Maximus, after arriving in Italy, first expelled Valentinian and then prepared to attack Theodosius. The latter, accepting the inevitability of

Influx of Goths and Franks

peace in the West. persecutions in the East

Religious

Sole rulership of Theodosius war, strengthened his resolve and gained several victories. Maximus was killed at Aquileia in 388, and theneoforth Theodosius ruled both West and East, he was represented in the East by his son Arcadius, an Augustus since 383. Valentinian II was sent to Trier, accompanied by the Frankish general Arbogast to control him.

After a few years' respite, during the prefectureships of Nicomachus Flavianus in Rome and Tatian in the East, paganism waged its last fight: Theodosius, influenced by Ambrose, who had dared to inflict public penance on him in 390 after the massacre at Thessalonica, had determined to eliminate the pagans completely. After a few hostile clashes, the law of Nov. 8, 392, proscribed the pagan religion. Then Arbogast, after Valentinian II's death in 392 under shadowy circumstances, proclaimed as emperor the rhetorician Eugenius. When Theodosius refused to recognize him, Eugenius was thrown into the arms of the pagans of Rome. But this last "pagan reaction" was shortlived; in 394, with his victory at the Frigidus (modern Vipacco) River, between Aquileia and Emona, Theodosius put an end to the hopes of Eugenius and his followers. His intention was to place his son Honorius, proclaimed Augustus in 393, over the West, while returning his eldest son, Arcadius, to the East. But Theodosius' sudden death in January 395 precipitated the division of the empire.

Theodosius had successfully dealt with the danger of the Goths, although not without taking risks, and had both established a dynasty and imposed the strictest orthodoxy. A compromise peace with the Persians had given Rome, in 387, a small section of Armenia, where he had founded Theodosiopolis (Erzurum). He had survived two pretenders in the West. These military successes were, however, won with armies in which barbarians were in the majority, which was not a good sign. The barbarian presence is reflected in the names of his commanding officers, including such Franks as Richomer, Merovech, and Arbogast, and the half-Vandad Stilicho, who through his marriage to Serena, Theodosius' niece, had entered the imperial family.

Social and economic conditions. During the 4th century the emperor's power was theoretically absolute, the traditions of the principate having given way to the necessities of defense.

The emperor was both heir to the Hellenistic basileus (absolute king) and the anointed of the deity. Pagans and Christians alike considered him "emperor by the grace of God," which, strictly speaking, rendered the imperial cult unnecessary. Indeed, he hardly needed the ceremonies and parade of god-awfulness with which Diocletian and his successors were surrounded. Yet imperial authority had actually lost much of its effectiveness due to the growth and nature of late Roman government. Its ranks can be estimated at more than 30,000 men-perhaps an insignificant number compared with that of modern governments but gigantic when set against the total of only a few hundred a century earlier. The problem, however, lay not in numbers but in the assumption, held throughout both bureaucracy and army, that a position of power ex officio entitled the holder to a rake-off of some sort, to be extracted both from the citizenry with whom he came in contact and from fellow members of the service in ranks below his own. This ethos was not new; but during the principate it had been restrained by higher officers and officials, who operated according to a different, essentially aristocratic, code expressed in patron-dependent relations and mutuality. Its currency was not money but favours and services. Such a code was swept away by the rapid increase in the size of government in the later 3rd century and the rise to high civil and military posts by men recruited from the ranks rather than from the upper classes. As they had bought their own promotions or appointments, so they expected to recoup their expenses (and more besides) by such means as selling exemptions and extortion. The more intrusive and demanding the military tax collection or the state's control of the rosters of city senates, the more profit there was for a pervasively corrupt administration. Persons close to the emperor could, for a price, generally screen him from knowledge of what was going on. Constantine, for example, complained quite in

vain—and the complaint was endlessly repeated by his successors—that the city senates were being "emptied of persons obligated to them by birth, who yet are asking for a government post by petition to the emperor, running off to the legions or various civil offices." Such posts could easily be bought. A great deal of imperial planning was thus vitiated by sale. Many of the profiteers started life in the urban upper classes, but, as nouveaux riches, they joined the older landed nobility after a term in the emperor's service.

Mosaic of a fortified Roman villa with lookout towers and an orchard, in the Le Bardo National Museum, Bărdaw, Tunisia

In a few areas where measurement is possible, one can see that a process of consolidation of landownership had been going on for a long time, bringing the rural population increasingly into dependence on the larger property holders. Diocletian's new system of property assessment accelerated this process; it was more thorough and thus exposed the poor and ignorant to exploitation by local officialdom. In response, they sought the protection of some influential man to ward off unfair assessments, selling their land to him and becoming his tenants. In areas disturbed by lawlessness, a large landowner offered them safety as well. The strength of rural magnates in their formidable, even fortified, dwellings, with a dependent peasantry of 100 or even 1,000 around them made much trouble for tax collectors, and landowners thus became the target of many laws. Consolidation of ownership, however, was not apparent in northern Africa, and the reverse process has been established for a carefully researched area of Syria.

Regional differences cannot be disregarded. They were responsible for guiding the development of the later empire along quite varied paths. The archaeological data, which reflect these developments most clearly, register such changes as the degree of wealth in public buildings and the use and elegance of carved sarcophagi or of mosaics in private houses. Broadly speaking, a decline is noticeable throughout the European provinces; it tends to affect the cities earlier than the rural areas and is detectable sometimes by 350, generally by 375. In the Danube provinces. the evidence fits neatly with political history following the Battle of Adrianople in 378, after which their condition was continually disturbed by the Visigothic immigrants. There is, however, no such obvious explanation for areas such as Spain or central Gaul. Italy of the 3rd and 4th centuries was not perceptibly worse off than before, though wealth in the Po region was more concentrated in the cities north of the river. Northern Africa seems to have maintained nearly the same level of prosperity as in earlier centuries, if proper weight is given to ecclesiastical building after Constantine. For Egypt, no clear picture emerges; but all the other Eastern provinces enjoyed in the later empire the same level of economic well-being as before or a still higher one, with more disposable wealth and an increasing population. These conditions continued into the 5th century.

The vast differences between the European and the Eastern provinces are best explained by the shifting focus of imperial energies. It can be traced in the locus of heaviest Consolidation of landowner-

military recruitment, in the lower Danube, as the 3rd century progressed; in the consequent concentration of military expenditure there; and in the siting of the emperors' residence as it was moved from Rome to Milan in the 260s, then to the lower Danube later in the 3rd century (where much fighting occurred), and subsequently to Nicomedia (Diocletian's capital). None of the Tetrarchs chose Rome-its days as the imperial centre were overand when, from among various Eastern cities he considered. Constantine decided on Byzantium as his permanent residence, he simply made permanent a very long-term development. Meanwhile the Rhine frontier and the upper Danube were repeatedly overrun. As can be inferred from the signs of fortification in Pannonia, Gaul, Britain, and Spain, internal policing was neglected. Commercial intercourse, which had been the key to raising the economy and the level of urbanization, became less safe and easy. Villas turned into self-sufficient villages, and the smaller towns also reverted to villages. Only the larger towns, such as Bordeaux, Arles, or Cartagena, maintained their vitality.

Although there was considerable inflation (culminating under Theodosius), in spite of a deflationary fiscal policy, commercial transactions ignored barter and were based instead on currency throughout the empire at the end of the century. The economy was partially under state direction. which was applied to agriculture through bias toward the settler system on imperial estates and to industry through the requisitioning of corporations (artisans, merchants, carriers) and the creation of state workshops (especially for manufacturing military goods). Opinions differ on the intensity of trade, but there was certainly clear progress in

comparison to the 3rd century.

The remnants of pagan culture. The spread of Christianity in no way harmed the flourishing of pagan literature. Instruction in the universities (Rome, Milan, Carthage, Bordeaux, Athens, Constantinople, Antioch, Alexandria) was still based on rhetoric, and literature received the support of senatorial circles, especially in Rome (for example those of the Symmachi and the Nicomachi Flaviani). Latin literature was represented by Symmachus and the poet Ausonius. The last great historian of Rome was Ammianus Marcellinus, a Greek who wrote in Latin for the Roman aristocracy; of his Res gestae, the most completely preserved part describes the period from 353 to 378. The works of Sextus Aurelius Victor and Eutropius. who ably abridged earlier historical works, are fairly accurate and more reliable than the Scriptores historiae Augustae, a collection of imperial biographies of unequal value, undoubtedly composed under Theodosius but for an unknown purpose. Erudition was greatly prized in aristocratic circles, which, enamoured of the past, studied and commented on the classic authors (Virgil) or the ancestral rites (the Saturnalia of Macrobius). Greek literature is represented by the works of philosophers or sophists: Themistius, a political theoretician who advocated absolutism; Himerius of Prusias; and above all Libanius of Antioch, whose correspondence and political discourses from the Theodosian period bear witness to his perspicacity and, often, to his courage.

The Christian church. In the last decade of the 4th century the harsh laws against the perpetuation of the old pieties promulgated by Theodosius gave impetus and justification to waves of icon and temple destruction, especially in the East. It is, nonetheless, likely that a majority of the population was still non-Christian in 400, although less so in the cities and in the East and more so in rural and mountainous areas and the West. Efforts by the church to reach them were intermittent and lacked energy. Bishops generally expected rural magnates to do their job for them; and the church leadership was, in any case, of a social class that viewed the peasantry from a great distance and wanted to keep it that way. Except by such unusual figures as Martin of Tours or Marcellus of Apamea, little effort was made to convert people who were hard to reach. As always in antiquity, it was in the cities where changes occurred-with the exception of monasticism.

Only in the reign of Constantine, and about simultaneously in Egypt and Palestine, had monasticism, a religious movement whose followers lived as hermits and pursued a life of extreme asceticism, become more than the little-regarded choice of rare zealots. Near Gaza and in the desert along the eastern side of Jerusalem a number of tiny clusters of cells had been made from caves and taken as residence by ascetics, from whose fame and example that way of life later spread to many other corners of the Levant. The bishop of Jerusalem, Cyril, by midcentury could speak of "regiments of monks." But it was in the desert on both sides of the Nile that similar ascetic experiments of much greater importance were made, by the hero of the movement, St. Anthony, and others. True monasticism, tempered only by weekly communal worship and organizing, established itself on Anthony's model and under his inspiration in the first decade of the 4th century; it took root above all in the desert of Scete just west of the base of the Nile delta. Coenobitism, joint life in enclosed communities, was the model preferred by St. Pachomius around 330, vigorously directed and diffused by him until mid-century, when both he and Anthony died. Basil of Caesarea was to establish monastic communities in Cappadocia under the influence of what he saw in Egypt on his visit there in the year of Anthony's death: and Athanasius was shortly to write a biography of that saint of enormous influence and to carry word of his life to Italy and Gaul during his own exile there. The biography was soon translated into Latin and inspired a scattering of experiments in asceticism or coenobitism in the West-in Vercellae in Italy, for example, by 330, and at Tours in the 370s under Martin's direction. Tours became the first monastery in the West comparable to those in the East. but development subsequently was slow compared to the 10.000 or more monasteries founded in Egypt by AD 400.

The most distinct and well-reported phenomenon during the century after the conversion of Constantine was the continued religious rioting and harrying in the cities, both in all the major ones and in dozens of minor ones. The death toll exceeded the toll among Christians at the hands of pagans in earlier persecutions. It was rarely of Jews or pagans at the hands of Christians or of Christians at the hands of pagans, but ordinarily of Christians at each others' hands in the course of sectarian strife. For a time. no one sect enjoyed a majority among Homoousians, Arians, Donatists, Meletians, and many others. Bishoprics were fiercely contested and appeals often made to armed coercion. The emperors had assumed the right to interfere and often did so; but under Theodosius, Pope Damasus and St. Ambrose reacted: the state was to restrict itself to furnishing the "secular arm," while the church, in the name of evangelical ethics, claimed the right to judge the emperors, a policy that had grave implications for the future. The "caesaro-papism" of Constantius later gained adherents under the Byzantine emperors. In the meantime, the Goths had been converted to Arianism by Ulfilas during the period of Constantius and Valens, thus presaging conflicts that were to come after the great invasions. Orthodox missionaries had converted Osroëne, Armenia, and even some countries on the Red Sea.

The Christian literature of the 4th century is remarkable. Its first representative is Eusebius of Caesarea, a friend and panegyrist of Constantine and a church historian whose creation of a "political theology" sealed the union between the Christian emperor and the church, St. Athanasius wrote apologetic works and a life of St. Anthony. Also prominent were the great Cappadocians: St. Basil of Caesarea, St. Gregory of Nazianzus, St. Gregory of Nyssa, and St. John Chrysostom of Antioch, the greatest preacher of his time. The Westerners, too, had great scholars and brilliant writers: St. Hilary of Poitiers, enemy of the Arians and of Constantius; St. Ambrose, administrator and pastor, whose excessive authority was imposed on Gratian and even on Theodosius; and St. Jerome, a desert monk and confessor of upper-class Roman ladies, a formidable polemicist who knew Greek and Hebrew and made the first faithful translation of the Old and New Testaments (the Vulgate) as well as of a chronicle of world history, which was a translation and continuation of the work of Eusebius. Finally, St. Augustine, the bishop of Hippo, was a great pastor, a vigorous controversialist, a sensitive and passionate writer (the Confessions), and the powerful

Triumph orthodoxy

Monasticism

Sack of

Rome

by the Visigoths theologian of *The City of God*. The century that developed these great minds cannot be considered decadent.

The eclipse of the Roman Empire in the West (c. 395-500) and the German migrations. Invasions in the early 5th century. After the death of Theodosius the Western empire was governed by young Honorius. Stilicho, an experienced statesman and general, was charged with assisting him and maintaining unity with the East, which had been entrusted to Arcadius. The Eastern leaders soon rejected Stilicho's tutelage. An antibarbarian reaction had developed in Constantinople, which impeded the objectives of the half-Vandal Stilicho. He wanted to intervene on several occasions in the internal affairs at Constantinople but was prevented from doing so by a threat from the Visigoth chieftain Alaric, whom he checked at Pollentia in 402, then by the Ostrogoth Radagaisus' raid in 406, and finally by the great invasion of the Gauls in 407. The following year he hoped to restore unity by installing a new emperor in Constantinople, Theodosius II, the son of Arcadius, who had died prematurely; but he succumbed to a political and military plot in August 408. The division of the two partes imperii was now a permanent one.

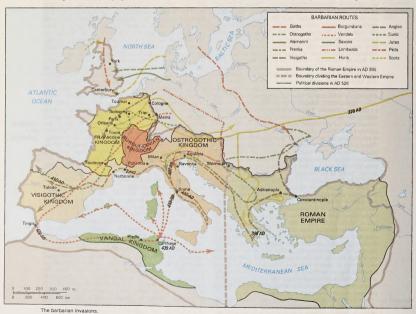

Honorius, seated in Ravenna, a city easier to defend than Milan, had only incompetent courties surrounding him, themselves animated by a violent hatred of the barbarians. Alaric soon reappeared, at the head of his Visigoths, demanding land and money. Tired of the Romans' double-dealing, he descended on Rome itself. The city was taken and pillaged for three days, thus putting an end to an era of Western history (August 410). An Arian, Alaric spared the churches. He died shortly thereafter in the south; his successor, Athaulf, left the peninsula to march against the Gauls.

Fleeing from the terrifying advance of the Huns, on

Dec. 31, 406, the Vandals, Suebi, and Alani, immediately followed by the Burgundians and bands of Alemanni, crossed the frozen Rhine and swept through Gaul, effortlessly throwing back the federated Franks and Alemanni from the frontiers. Between 409 and 415 a great many of these barbarians arrived in Spain and settled in Lusitania (Suebi) and in Baetica (Vandals, whence the name Andalusia). As soon as Gaul had become slightly more peaceful, Athaulf's Visigoths arrived, establishing themselves in Narbonensis and Aquitania. After recognizing them as "federates," Honorius asked them to go to Spain to fight the Vandals. Meanwhile, the Roman general Constantius eliminated several usurpers in Gaul, confined the Goths in Aquitania, and reorganized the administration (the Gallic assembly of 418). But he was unable to expel the Franks, the Alemanni, and the Burgundians, who had occupied the northern part of the country, nor to eliminate the brigandage of the Bagaudae. He was associated with the empire and was proclaimed Augustus in 421, but he died shortly afterward. His son, Valentinian III, succeeded Honorius in 423 and reigned until 455.

The heginning of Germanic hegemony in the West. During the first half of the 5th century the barbarians gradually installed themselves, in spite of the efforts of the Roman general Actius at the head of a small army of mercenaries and of Huns. Actius took back Arles and Narbonne from the Visigoths in 436, either pushed back the Salian and Ripuarian Franks beyond the Rhine or incorporated them as federates, settled the defeated Burgundians in Sapaudia (Savoy), and established the Alani in Orléans. The other provinces were lost: Britain, having been abandoned in 407 and already invaded by the Pitcs and Scots, fell to the Angles, Saxons, and Jutes; a great Suebi kingdom, officially federated but in fact independent, was organized.

Loss of

in Spain after the departure of the Vandals, and it allied itself to the Visigoths of Theodoric I, who were settled in the country around the Garonne.

In 428 the Vandal Gaiseric led his people (80,000 persons, including 15,000 warriors) to Africa. St. Augustine died in 430 in besieged Hippo, Carthage fell in 435, and in 442 a treaty gave Gaiseric the rich provinces of Byzacena and Numidia. From there he was able to starve Rome, threaten Sicily, and close off the western basin of the Mediterranean to the Byzantines.

Shortly afterward, in 450, Attila's Huns invaded the West-first Gaul, where, after having been kept out of Paris, they were defeated by Aetius on the Campus Mauriacus (near Troyes), then Italy, which they evacuated soon after having received tribute from the pope, St. Leo. Attila died shortly afterward; and this invasion, which indeed left more legendary memories than actual ruins, had shown that a solidarity had been created between the Gallo-Romans and their barbarian occupiers, for the Franks, the Alemanni, and even Theodoric's Visigoths had come to Aetius' aid.

After the death of Aetius, in 454, and of Valentinian III. in 455, the West became the stake in the intrigues of the German chiefs Ricimer, Orestes, and Odoacer who maintained real power through puppet emperors. In 457-461 the energetic Majorian reestablished imperial authority in southern Gaul until he was defeated by Gaiseric and assassinated shortly afterward. Finally, in 476, Odoacer deposed the last emperor, Romulus Augustulus, had himself proclaimed king in the barbaric fashion, and governed Italy with moderation, being de jure under the emperor of the East. The end of the Roman Empire of the West passed almost unperceived.

Barbarian kingdoms. Several barbarian kingdoms were then set up: in Africa, Gaiseric's kingdom of the Vandals; in Spain and in Gaul as far as the Loire, the Visigothic kingdom; and farther to the north, the kingdoms of the Salian Franks and the Alemanni. The barbarians were everywhere a small minority. They established themselves on the great estates and divided the land to the benefit of the federates without doing much harm to the lower classes or disturbing the economy. The old inhabitants lived under Roman law, while the barbarians kept their own "personality of laws," of which the best-known is the judicial composition, the Wergild. Romans and barbarians coexisted but uneasily. Among the obstacles to reconciliation were differences in mores; social and political institutions (personal monarchies, fidelity of man to man); language, although Latin was still used in administration; and above all religion: the Arianism of the barbarians permitted the Roman Catholic bishops to retain their hold over their flocks. The only persecution, however, was under the Vandals, whose domination was the harshest.

Two great kingdoms marked the end of the 5th century. In Gaul, Clovis, the king of the Salian Franks (reigned 481/482-511), expelled Syagrius, the last Roman, from Soissons, took Alsace and the Palatinate from the Alemanni (496), and killed Alaric II, king of the Visigoths, at Vouillé (507). His conversion to Catholicism assured him the support of the bishops, and Frankish domination was established in Gaul. At the same time, Theodoric, king of the Ostrogoths, reigned in Italy. He had been charged by the emperor Zeno to take back Italy from Odoacer in 488, and in 494 he had himself proclaimed king at Ravenna. His Goths, few in number, were established in the north; elsewhere he preserved the old imperial administration, with senators as prefects. Externally, he kept Clovis from reaching the Mediterranean and extended his state up to the valley of the Rhône. Theodoric died in 526. Ten years later Justinian charged his general Belisarius with the reconquest of Italy, a costly, devastating, and temporary operation that lasted from 535 to 540.

Analysis of the decline and fall. The causes of the fall of the empire have been sought in a great many directions and with a great deal of interest, even urgency, among historians of the West; for it has been natural for them to see or seek parallels between Rome's fate and that of their own times. In any choice of explanations there is likely to be a hidden sense of priorities determining the definition of "civilization," or specifically the civilization of "Rome" or of "the classical world," If, for example, classical civilization is identified with the literature of the ancients at what one conceives to be its best, then "the end" of this civilization has to be set at some point of decline and explanations for its coming to be sought in the preexisting conditions; or if not on literature but on political domination, then some other point in time must be chosen and explained in terms of what seems to have led up to it. There have been endless variations on this search, and there will continue to be more, no doubt, since it is agreed that literature did, in fact, diminish in quality, as did jurisprudence, although at a different date, and oratory, and vigorous political debate in the capital, and powerfully innovative philosophy, and sculpture, and civic patriotism, and the willingness to die for one's country. "Civilization" turns out to be not one single entity but a web of many strands, each of its own length.

Perhaps the view attracting the most adherents, however. has focused on the ability of the empire to maintain its political and military integrity-that being the strand apparently most central and significant-and the juncture at which that ability is most dramatically challenged and found wanting-the period of "the barbarian invasions." meaning 407 and roughly the ensuing decade. If this juncture in turn is examined and the antecedents of the empire's weakness sought in internal developments, they can only be found in the government. Belief in and obedience to the monarch was not lacking, nor military technology at least matching that of the invaders, nor a population large enough to field a large force, nor the force itself (on paper, at least), nor the economic potential adequate to the arming of it. Particular defeats described by contemporaries in reasonable detail are almost uniformly attributable to the rottenness of government as described above, rendering soldiers undisciplined, untrained, frequently on indefinite leave, and without good morale or proper equipment. Soldiers were unpaid because of various abuses in the collection and delivery of supplies and money from taxpayers, and they were distracted from their proper duties by their own and their officers' extortionate habits in contact with their civilian hosts. For the same basic reason-that is, abuse of power wielded through service in the army or bureaucracy-the administration of the cities no longer enjoyed the efforts of the urban elites, who by 407 had long since fled from active service to some exempt government post or title. For the same reason, finally, corrective measures needed against these systemic weaknesses could not be developed by enlightened men at the centre because they were screened from the truth of things, were at the mercy of incompetent or venal agents. or were unable to maintain themselves in power against the plotters around them. The details of all these charges that can be made against late Roman government are writ large in the great collection of imperial edicts published in 438, the Theodosian Code, as well as in the works of roughly contemporary writers from East and West, such as Synesius, Augustine, Libanius, Themistius, Chrysostom, Symmachus, Bishop Maximus of Turin, and, above all, Ammianus Marcellinus. An empire that could not deliver to a point of need all the defensive force it still possessed could not well stand against the enemy outside.

(P.P./R.MacM.)

BIBLIOGRAPHY

General works on ancient Greek and Roman civilizations. wealth of information on ancient Greek and Roman civilizations is provided by the volumes in The Cambridge Ancient History (1923-), some in newer 2nd and 3rd editions; by N.G.L. HAMMOND and H.H. SCULLARD (eds.), The Oxford Classical Dictionary, 2nd ed. (1970, reprinted 1984); and by JOHN BOARDMAN, JASPER GRIFFIN, and OSWYN MURRAY (eds.), The Oxford History of the Classical World (1986). MICHAEL GRANT and RACHEL KITZINGER (eds.), Civilization of the Ancient Mediterranean: Greece and Rome, 3 vol. (1988), discusses the geography, inhabitants, arts, language, religion, politics, technology, and economy of the area from the early 1st millennium BC to the late 5th century AD. Broad coverage of the physical and cultural settings and of archaeological discoveries is also provided by PETER LEVI, Atlas of the Greek World (1980); TIM CORNELL and JOHN MATTHEWS, Atlas of the Roman World

The end of the Roman Empire of the West

(1982), and NICHOLAS CL. HAMMOND (ed.). Alfas of the Greek and Roman World in Antiquity (1981). Overviews of the his tones of each civilization include, on Greece, NICHOLAS GL. HAMMOND (Ed.) (1986), and the greek of the civilization include, on Greece, NICHOLAS GL. HAMMOND (Ed.) (1986), and the greek of
Appean civilizations. General overviews include EMILY VER-MEULE, Greece in the Bronze Age (1964, reissued 1974), the standard work; HANS-GÜNTHER BUCHHOLZ and VASSOS KARA-GEORGHIS, Prehistoric Greece and Cyprus: An Archaeological Handbook (1973; originally published in German, 1971); SPYRI-DON MARINATOS and MAX HIRMER, Kreta, Thera, und das mykenische Hellas, 3rd ed. (1976), also available in an English translation of an earlier edition, Crete and Mycenae (1960); WILLIAM TAYLOUR, The Mycenaeans, rev. ed. (1983); N.K. SAN-DARS, The Sea Peoples: Warriors of the Ancient Mediterranean. 1250-1150 B.C., rev. ed. (1985); and PETER WARREN, The Aegean Civilizations (1975, reissued 1989). Ancient Crete is discussed in ARTHUR EVANS, The Palace of Minos, 4 vol. (1921-35 reissued 1964), still basic; ARTHUR EVANS, MARK CAMERON, and SINCLAIR HOOD, Knossos Fresco Atlas (1967); SINCLAIR HOOD, The Minoans (1971); and J. WALTER GRAHAM, The Palaces of Crete, rev. ed. (1987). JOHN BOARDMAN, The Cretan Collection in Oxford (1961), describes Cretan antiquities in the Ashmolean Museum. The Cycladic civilizations are examined by JÜRGEN THIMME (ed.), Art and Culture of the Cyclades (also published as Art and Culture of the Cyclades in the Third Millennium B.C., 1977; originally published in German, 1976), an extensive exhibition catalog; CHRISTOS G. DOUMAS, Thera, Pompeii of the Ancient Aegean (1983); and R.L.N. BARBER, The Cyclades in the Bronze Age (1987). Ancient civilization on the Greek mainland is the focus of GEORGE E. MYLONAS, Mycenae and the Mycenaean Age (1966), for the Late Bronze Age and Mycenaean Shaft Grave Circle B: EMILY VERMEULE. The Art of the Shaft Graves of Mycenae (1975); and J.T. HOOKER, Mycenaean Greece (1976). Religion and religious sites are discussed in MARTIN P. NILSSON. The Minoan-Mycenaean Religion and Its Survival in Greek Religion, 2nd rev. ed. (1950, reprinted 1971), still the standard work; and BOGDAN RUTKOWSKI, The Cult Places of the Aegean (1986). Information on ancient pottery and seals may be found in ARNE FURUMARK, The Mycenaean Pottery: Analysis and Classification (1941, reissued 1972); FRIEDRICH MATZ et al., Corpus der Minoischen und Mykenischen Siegel (1964and JOHN BOARDMAN, Greek Gems and Finger Rings (1970). MICHAEL VENTRIS and JOHN CHADWICK, Documents in Mycenaean Greek, 2nd ed. (1973), is essential for information on the writing and decipherment of Linear B, including transcriptions, translations, and commentary on selected tablets. For the Aegean Bronze Age as a background to Homer, see the series Archaeologia Homerica: die Denkmäler und das frühgriechische Epos, ed. by friedrich matz and hans-günter Buchholz (1967-). Sinclair hood, The Arts in Prehistoric Greece (1978, reissued 1988), is the best standard work on this subject. WILLIAM S. SMITH, Interconnections in the Ancient Near-East: A Study of the Relationships Between the Arts of Egypt, the Aegean, and Western Asia (1965).

(M.S.F.H./E.D.T.V.) Ancient Greek civilization. The early Archaic period: JOHN BOARDMAN, The Greeks Overseas: Their Early Colonies and Trade, rev. and enlarged ed. (1980), is a well-illustrated and fully documented account of Greek colonization. Commercial factors are stressed by MARTIN FREDERIKSEN, Campania, ed by NICHOLAS PURCELL (1984). PETER GARNSEY, in Famine and Food Supply in the Graeco-Roman World (1988), is skeptical of the "land-hunger" explanation. See also ROBERT SALLARES, The Ecology of the Ancient Greek World (1991), a discussion of problems of demography and food supply. The importance of rural sanctuaries to the growth of the polis is argued in FRANÇOIS DE POLIGNAC, La Naissance de la cité grecque (1984); and ROBIN OSBORNE, Classical Landscape with Figures (1987), which also discusses the ways in which the Greek countryside was exploited in different regions. "Monumentalization" is stressed in a good general account of the period, ANTHONY SNODGRASS, Archaic Greece: The Age of Experiment (1980). IAN MORRIS, Burial and Ancient Society (1987), discusses burial and the Greek polis. MARTIN BERNAL, Black Athena: The Afroasiatic Roots of Classical Civilization (1987-), is a controversial work about Phoenician influence on Greece.

Explorations of phratry and genos are found in DENIS ROUS-SEL. Tribu et cité (1976); and FÉLIX BOURRIOT, Recherches sur la nature du Genos. 2 vol. (1976), K.J. DOVER. Greek Homosexuality, new ed. (1989), is a good treatment. The significance of the symposium is argued for by OSWYN MURRAY, "The Symposion as Social Organisation," in ROBIN HÄGG (ed.), The Greek Renaissance of the Eighth Century B.C.: Tradition and Innovation (1983), pp. 195-199. Murray's Early Greece (1980) is a readable general history of the period stressing the symposium at a number of points. GABRIEL HERMAN, Ritualised Friendship and the Greek City (1987), examines xenia. A discussion of proxenia may be found in L.H. JEFFERY, Archaic Greece: The City-States, c. 700-500 B.C. (1976), an elegant general history arranged regionally, ROBERT DREWS, Basileus: The Evidence for Kingship in Geometric Greece (1985), argues that the early Greek "kings" (basileis) were really just hereditary aristocrats; but see PIERRE CARLIER, La Royauté en Grèce avant Alexandre (1984), for a differing view.

(1964), for a dimerity view.

Darful monographs on invividual poleis important in the ADarful monographs on invividual poleis important in the Arapole of the City to 338 BC (1984); and THOMAS I, FIGUEIRA, Against
Society and Politics (1981). But see M., IFRILEY, Politics in
the Aracient World (1983), which warns against the dangers of
writing histories of particular poleis.

The later Archaic periods: The classic exposition of the "hop-lite theory" of tyramy is A. ANDERWES, The Greek Tyrants (1956, reissued 1974); it is refined by PAUL CARTLEDGE, "Hop-lites and Heroes: Sparta's Contribution to the Technique of Ancient Warfare," Journal of Hellenic Studies, 97:11–27 (1977). But 0.1. CAWWELL, Philip of Macedon (1978), ch. 10, discusses hoplite fighting as a more individual affair than is sometimes allowed. The ideological implications of hoplite fighting are treated by w.a. CONNON, "Early Greek Land Warfare as Symptems of the Control of the C

W.G. FORREST, A History of Sparta, 950-192 B.C., 2nd ed. (1980), is a provocative brief work, PAUL CARTLEDGE, Sparta and Lakonia: A Regional History, 1300-362 BC (1979), is also useful. "Laconism" is explored in ELIZABETH RAWSON, The Spartan Tradition in European Thought (1969), R.E. WYCHER-LEY, The Stones of Athens (1978), discusses Athens' natural advantages. Attic produce and exports are studied by SIGNE ISAGER and MOGENS HERMAN HANSEN, Aspects of Athenian Society in the Fourth Century B.C. (1975). RUSSELL MEIGGS, Trees and Timber in the Ancient Mediterranean World (1982); and ROBERT GARLAND, The Piraeus: From the Fifth to the First Century B.C. (1987), present naval aspects. Discussion of every aspect of early Athenian political history is contained in P.J. RHODES, Commentary on the Aristotelian Athenaion Politeia (1981). ROBERT PARKER, Miasma: Pollution and Purification in Early Greek Religion (1983), covers Cylon and the religious taint often incurred through some wrongful act or neglect of ritual obligation, M.I. FINLEY, Ancient Slavery and Modern Ideology (1980), investigates the link between Solon and slavery.

A good account of Peisistratid building policy in its competitive aspect is found in T. LESLIE SHEAR, JR., "Tyrants and Buildings in Archaic Athens," in Athens Comes of Age: From Solon to Salamis (1978), pp. 1-15. Peisistratid artistic propaganda is summarized in JOHN BOARDMAN, "Archaic Greek Society: Material Culture," ch. 7c in JOHN BOARDMAN et al. (eds.), The Cambridge Ancient History, vol. 4, 2nd ed. (1988), pp. 414-430. R.M. COOK, "Pots and Pisistratan Propaganda," Journal of Hellenic Studies, 107:167-169 (1987), presents another view. JOHN S. TRAILL, Demos and Trittys: Epigraphical and Topographical Studies in the Organization of Attica (1986), a specialist account of the deme system based on inscriptions, supplements his The Political Organization of Attica: A Study of the Demes, Trittyes, and Phylai, and Their Representation in the Athenian Council (1975). DAVID WHITEHEAD, The Demes of Attica, 508/7-ca. 250 B.C.: A Political and Social Study (1986), is magisterial and reliable. ROBIN OSBORNE, Demos: The Discovery of Classical Attika (1985), is a speculative essay with some interesting suggestions not fully worked out. EMILY KEARNS, "Change and Continuity in Religious Structures after Kleisthenes," in PAUL CARTLEDGE and F.D. HARVEY (eds.), Crux (1985), pp. 189-207, is valuable on the religious aspects of Cleisthenes' reforms. The modern reconstructed Greek trireme is the subject of J.S. MORRISON and J.F. COATES, The Athenian Trireme (1986).

Early Greek philosophy is dealt with generally in EDWARD HUSSEY, The Presocratics (1972); and IONAHTHAN BARNS, The Presocratic Philosophers, rev. ed. (1982), a more difficult work; and on Pherecydes in particular in M.L. West, Early Greek Philosophy and the Orient (1971). More works on Greek philosophy and philosophers can be found in the bibliography of the article THE HISTORY OF WESTERN PHILOSOPHY. ROSALIND

THOMAS, Oral Tradition and Written Record in Classical Athens (1989), supersedes all previous studies on literacy

Classical Greek civilization: Information on the Persian empire and the Ionian revolt can be found in J.M. COOK, The Persian Empire (1983); and a postscript by DAVID M. LEWIS in the book by A.R. BURN, Persia and the Greeks, 2nd ed. (1984). Lewis' Sparta and Persia (1977), analyzes Persian administration, SIMON HORNBLOWER, Mausolus (1982), treats satrapally controlled Anatolia.

General histories of the period 479 BC to Alexander the Great include J.K. DAVIES, Democracy and Classical Greece (1978); and SIMON HORNBLOWER. The Greek World. 479-323 BC, rev. ed. (1991). RUSSELL MEIGGS, The Athenian Empire (1972), offers a full scholarly history and analysis. A very different view, in particular denying that there was a mid-century qualitative change in the character of the Athenian empire, is presented by M.I. FINLEY, "The Fifth-Century Athenian Empire: A Balance-Sheet," in PETER GARNSEY and C.R. WHITTAKER (eds.), Imperialism in the Ancient World (1978), pp. 103-126. More succinct than Meiggs is the very brief work by P.J. RHODES, The Athenian Empire (1985). G.W.M. DE STE. CROIX, The Class Struggle in the Ancient Greek World: From the Archaic Age to the Arab Conquests (1981), contains much relevant material. Athenian foreign policy in the period is explored by E. BADIAN, "The Peace of Callias," Journal of Hellenic Studies, 107:1-39 (1987); and DAVID M. LEWIS, "The Origins of the First Peloponnesian War," in GORDON SPENCER SHRIMPTON and DAVID JOSEPH MCCARGAR (eds.), Classical Contributions (1981), pp. 71-78. Works on Thucydides and his History include w. ROBERT CONNOR, Thucydides (1984); SIMON HORNBLOWER, Thucydides (1987); COLIN MACLEOD, Collected Essays (1981); NICOLE LO-RAUX, The Invention of Athens: The Funeral Oration in the Classical City (1986); and A.W. GOMME, A. ANDREWES, and K.J. DOVER, A Historical Commentary on Thucydides, 5 vol. (1945-81). This last work assumes a good knowledge of Greek, but SIMON HORNBLOWER, A Commentary on Thucydides (1991-), translates all Greek commented on.

P.J. RHODES, The Athenian Boule (1972, reissued 1985), discusses an important aspect of internal Athenian history in the 5th century. A full account of constitutional developments is given in MARTIN OSTWALD, From Popular Sovereignty to the Sovereignty of Law (1986), J.K. DAVIES, Athenian Propertied Families, 600-300 B.C. (1971), is indispensable on individual politicians; it may be supplemented by Davies' Wealth and the Power of Wealth in Classical Athens (1981), A stimulating treatment of demagogues is given in w. ROBERT CONNOR, The New Politicians of Fifth-century Athens (1971); but WESLEY E. THOMPSON, "Athenian Leadership: Expertise or Charisma?" in GORDON SPENCER SHRIMPTON and DAVID JOSEPH MCCAR-GAR (eds.), Classical Contributions (1981), pp. 153-159, argues against all attempts to impute greater professionalism to them. Studies on oligarchic sympathizers include L.B. CARTER, The Quiet Athenian (1986); GLENN RICHARD BUGH, The Horsemen of Athens (1988); and ANDREW LINTOTT, Violence, Civil Strife, and Revolution in the Classical City, 750-330 B.C. (1981).

G.E.M. DE STE. CROIX, The Origins of the Peloponnesian War (1972), argues a controversial thesis, but is excellent on Sparta. A contribution on this topic of the first importance is E. BADIAN, "Thucydides and the Outbreak of the Peloponnesian War," in JUNE W. ALLISON (ed.), Conflict, Antithesis, and the Ancient Historian (1990), pp. 46-91, showing that Thucydides' presentation has suspiciously pro-Athenian features. Athenian strategy in the war itself is discussed in J.B. SALMON, Wealthy Corinth: A History of the City to 338 BC (1984); G.L. CAWK-WELL, "Thucydides' Judgment of Periclean Strategy," Yale Classical Studies, 24:53-70 (1975); and A.J. HOLLADAY, "Athenian Strategy in the Archidamian War," Historia, 27(3):399-426 (1978). Spartan strategy is examined by P.A. BRUNT, "Spartan Policy and Strategy in the Archidamian War," Phoenix, 19 (4):255-280 (1965). The link between speculative thinking and democracy is argued for by G.E.R. LLOYD, Magic, Reason, and Experience: Studies in the Origin and Development of Greek Science (1979); it is qualified in the epilogue to HUGH LLOYD-JONES. The Justice of Zeus, 2nd ed. (1983). See also CYNTHIA FARRAR. The Origins of Democratic Thinking: The Invention of Politics in Classical Athens (1988).

The best handbook on Greek art is MARTIN ROBERTSON, A History of Greek Art, 2 vol. (1975). JOHN BOARDMAN, Greek Art, new rev. ed. (1985), is also worth consulting. Greek tragedy is assessed in BRIAN VICKERS, Towards Greek Tragedy: Drama, Myth, Society (1973); and SIMON GOLDHILL, Reading Greek Tragedy (1986), which attempts to put Greek tragedy in its polis framework, and "The Great Dionysia and Civic Ideology," Journal of Hellenic Studies, 107:58-76 (1987). The standard work on Attic dramatic festivals is ARTHUR PICKARD-CAMBRIDGE, The Dramatic Festivals of Athens, 2nd ed. rev. by JOHN GOULD and DAVID M. LEWIS (1988). Further works may be found in the bibliographies of the articles GREEK DRAMATISTS and GREEK LITERATURE. Fifth-century Athenian building is put in a political context in JOHANNES SIPKO BOERSMA, Athenian Building Policy from 561/0 to 405/4 B.C. (1970); and the brief and provocative work by RHYS CARPENTER, Architects of the Parthenon (1970).

A useful general book about Greek women in classical antiquity is SARAH B. POMEROY, Goddesses, Whores, Wives, and Slaves (1975). The position of Athenian women is discussed in the splendid essay by JOHN GOULD, "Law, Custom, and Myth: Aspects of the Social Position of Women in Classical Athens. Journal of Hellenic Studies, 100:38-59 (1980); and by DAVID M. SCHAPS, Economic Rights of Women in Ancient Greece (1979). A valuable discussion of female religious life in mostly maledominated Attica is CHRISTIANE SOURVINOU-INWOOD, Studies in Girls' Transitions: Aspects of the Arkteia and Age Representation in Attic Iconography (1988), which discusses Brauron and the Artemis cult, celebrated there by women and girls. AVERIL CAMERON and AMÉLIE KUHRT (eds.), Images of Women in Antiquity (1983), is an interesting collection of papers

Slavery is discussed by M.I. FINLEY (ed.), Classical Slavery (1987), and Ancient Slavery and Modern Ideology (1980); and by YVON GARLAN, Slavery in Ancient Greece, rev. and expanded ed. (1988; originally published in French, 1982). The best accounts of ancient Greek military technology are E.W. MARSDEN, Greek and Roman Artillery, 2 vol. (1969-71); A.W. LAWRENCE Greek Aims in Fortification (1979); and JOSIAH OBER, Fortress Attica: Defense of the Athenian Land Frontier, 404-322 B.C. (1985).

The 4th century: M.I. FINLEY, Ancient Sicily, rev. ed. (1979), includes discussion of Dionysius I. The study of 4th-century Athenian democracy has been transformed by MOGENS HERMAN HANSEN, The Athenian Ecclesia, 2 vol. (1983-89), a collection of essays, and The Athenian Assembly in the Age of Demosthenes (1987; originally published in German, 1984). Additional works include R.K. SINCLAIR, Democracy and Participation in Athens (1988), an intelligent synoptic account; and modens HERMAN HANSEN, The Athenian Democracy in the Age of Demosthenes (1991), the best comprehensive treatment. Lysander's role in the causes of the Corinthian war is admirably discussed by A. ANDREWES, "Spartan Imperialism?" in PETER GARNSEY and C.R. WHITTAKER (eds.), Imperialism in the Ancient World (1978). pp. 91-102. The whole period from 404 to 360 BC is discussed from a Spartan point of view by PAUL CARTLEDGE, Agesilaos and the Crisis of Sparta (1987). But G.L. CAWKWELL, "The Decline of Sparta," Classical Quarterly, new series, 33(2):385— 400 (1983), presents a very different perspective denying that there was any serious shortage of manpower at Sparta in this period. The diplomacy of the period is presented in TIMOTHY T.B. RYDER, Koine Eirene (1965).

Contrasting verdicts on the Second Athenian Confederacy are presented by G.T. GRIFFITH, "Athens in the Fourth Century," in PETER GARNSEY and C.R. WHITTAKER (eds.), Imperialism in the Ancient World (1978), pp. 127-144; JACK CARGILL, The Second Athenian League: Empire or Free Alliance? (1981): and G.L. CAWKWELL, "Notes on the Failure of the Second Athenian Confederacy," Journal of Hellenic Studies, 101:40-55 (1981), and "Athenian Naval Power in the Fourth Century," Classical Quarterly, new series, 34(2):334-345 (1984). Mausolus' role in its breakup is addressed by SIMON HORNBLOWER, Mausolus (1982)

Studies on the Theban hegemony include J.A.O. LARSEN, Greek Federal States (1968); G.L. CAWKWELL, "Epaminondas and Thebes," Classical Quarterly, new series, 22:254-278 (1972); and JOHN BUCKLER, The Theban Hegemony, 371-362 BC (1980).

The rise of Macedon is portrayed in N.G.L. HAMMOND, G.T. GRIFFITH, and F.W. WALBANK, A History of Macedonia, 3 vol. (1972-88); and R. MALCOLM ERRINGTON, A History of Macedonia (1990; originally published in German, 1986). Philip and Alexander are placed into historical context by G.L. CAWK-WELL, Philip of Macedon (1978); MILTIADES B. HATZOPOULOS and LOUISA D. LOUKOPOULOS (eds.), Philip of Macedon (1980), which includes good pictures of the Vergina tomb discoveries; A.B. BOSWORTH, Conquest and Empire: The Reign of Alexander the Great (1988), a masterly study, both scholarly and readable; and ROBIN LANE FOX, Alexander the Great (1973, reissued 1986), a lively work.

Fourth-century Greek emigration is discussed well by PAUL MCKECHNIE. Outsiders in the Greek Cities in the Fourth Century B.C. (1989). Greek attitudes to foreigners are explored by ARNOLDO MOMIGLIANO, Alien Wisdom: The Limits of Hellenization (1975), M.J. OSBORNE, Naturalization in Athens, 4 vol. in 3 (1981-83), treats grants of citizenship, "Euergetism" is the subject of PAUL VEYNE, Le Pain et le cirque: Sociologie historique d'un pluralisme politique (1976), also available in an abridged translation, Bread and Circuses (1990). WALTER BURKERT, Greek Religion (1985; originally published in German, 1977), is a full and brilliant study; other works may be found in the bibliography of the article ANCIENT EUROPEAN RELIGIONS.

Hellenism. General historical works include F.W. WALBANK, The Hellenistic World (1981), a useful one-volume account by a leading authority; MICHAEL GRANT, From Alexander to Cleopatra: The Hellenistic World (1982), a well-written, reliable conspectus; PETER GREEN, Alexander to Actium: The Historical Evolution of the Hellenistic Age (1990), on every aspect of Hellenistic cultural and political history; w.w. TARN and G.T. GRIFFITH, Hellenistic Civilisation, 3rd ed. (1952, reissued 1975), a masterly, pioneering, and eminently readable study; JOHN FERGUSON, The Heritage of Hellenism (1973), thematic and well-illustrated; WILLIAM SCOTT FERGUSON, Hellenistic Athens. An Historical Essay (1911, reprinted 1974), still the best book on the subject; M. CARY, A History of the Greek World from 323 to 146 B.C., 2nd ed., rev. (1951, reissued 1972), a useful and clear coverage of the chosen period; and M. ROSTOVTZEFF The Social and Economic History of the Hellenistic World, 3 vol. (1941, reprinted 1986), a comprehensive and authoritative study, though at times controversial.

Particular topics are addressed by the following studies: H. IDRIS BELL, Egypt, from Alexander the Great to the Arab Conquest: A Study in the Diffusion and Decay of Hellenism (1948, reprinted 1977), a standard bistory by a great authority; EDWIN ROBERT BEVAN, The House of Seleucus, 2 vol. (1902, reprinted 2 vol. in 1, 1985), still the best treatment in English; ESTHER V HANSEN, The Attalids of Pergamon, 2nd ed., rev. and expanded (1971), a major original synthesis; w.w. TARN, The Greeks in Bactria & India, 3rd ed. updated by FRANK LEE HOLT (1985), a pioneering and controversial work; A.K. NARAIN, The Indo-Greeks (1957, reissued 1980), critical and sympathetic; and DAVID MAGIE, Roman Rule in Asia Minor: To the End of the Third Century after Christ, 2 vol. (1950, reprinted 1988).

Hellenistic culture and science are described and discussed by T.B.L. WEBSTER, Hellenistic Art (1967), a general work; CHRIS-TINE MITCHELL HAVELOCK, Hellenistic Art, 2nd ed. (1981). detailed studies of individual items; MARGARETE BIEBER, The Sculpture of the Hellenistic Age, 2nd rev. ed. (1981), well-illustrated and reliable; J. CHARBONNEAUX, R. MARTIN, and F. VIL-LARD, Hellenistic Art, 330-50 BC (1973; originally published in French, 1970), magisterial and richly illustrated; ALBIN LESKY, A History of Greek Literature (1966; originally published in German, 2nd ed., 1963), brilliant, but only partly on the period, GEORGE SARTON, A History of Science, vol. 2, Hellenistic Science and Culture in the Last Three Centuries B.C. (1959), an authoritative summary; E.D. PHILLIPS, Greek Medicine (1973, reissued as Aspects of Greek Medicine, 1987), a good overview; A.A. LONG, Hellenistic Philosophy: Stoics, Epicureans, Sceptics, 2nd ed. (1986), an excellent introduction; and MARTIN HENGEL, Judaism and Hellenism: Studies in their Encounter in Palestine During the Early Hellenistic Period (1974, reissued 1981; originally published in German, 1969), a magisterial study. Further studies on Hellenistic philosophy and on Hellenistic religions may be found in the bibliographies of the articles GREEK LIT-ERATURE and EUROPEAN RELIGIONS, ANCIENT, (I Fe)

Ancient Italic peoples. The basic guide is Popoli e civilità dell'Italia antica, 7 vol. (1974-78). Outdated but still useful are JOSHUA WHATMOUGH, The Foundations of Roman Italy (1937. reprinted 1971); and DAVID RANDALL-MacIVER, Italy Before the Romans (1928, reprinted 1972). On the Etruscans there are three essential books in English that guide the reader through the bewildering maze of recent discoveries and research: MAS-SIMO PALLOTTINO, The Etruscans, rev. and enlarged ed. edited by DAVID RIDGWAY (1975; originally published in Italian, 6th ed., rev. and enlarged, 1975); DAVID RIDGWAY and FRANCESCA R. RIDGWAY (eds.), Italy Before the Romans: The Iron Age, Orientalizing, and Etruscan Periods (1979); and LARISSA BONFANTE (ed.), Etruscan Life and Afterlife: A Handbook of Etruscan Studies (1986), which lists the many catalogs of exhibitions and other publications that came out as a result of "The Year of the Etruscans" in Italy in 1985. Among recent interpretations of Etruscan culture and history, the best in English are MAURO CRISTOFANI, The Etruscans: A New Investigation (1979; originally published in Italian, 1978); and MICHAEL GRANT, The Etruscans (1980). GIULIANO BONFANTE and LARISSA BONFANTE, The Etruscan Language (1983), is a helpful introduction. Works on other individual Italic peoples, civilizations, and languages include the Ridgways' book, cited earlier; LUIGI BERNABO BREA, Sicily Before the Greeks, rev. ed. (1966); RENATO PERONI, Archeologia della Puglia preistorica (1967); A. ALFÖLDI, Early Rome and the Latins (1963); GABRIELLA GIACOMELLI, La lingua falisca (1963); GIACOMO DEVOTO, Gli antichi Italici, 3rd ed. rev. (1967); E.T. SALMON, Samnium and the Samnites (1967); G.A. MANSUELLI and R. SCARANI, L'emilia prima dei Romani (1961); G.B. PELLEGRINI and A.L. PROSDOCIMI, La lingua venetica, 2 vol. (1967); and on Italic inscriptions, ORONZO PARLANGELI, Studi messapici (1960); and ALLESSANDRO MORANDI, Epigrafia italica (1982) (N.T. de G.)

Ancient Rome. Rome from its origins to 264: Archaeological evidence on early Rome is discussed and analyzed by RAYMOND BLOCH, The Origins of Rome, rev. ed. (1963; originally published in French, 1946); T.J. CORNELL, "Rome and Inally published in French, 1940); 1.3. CORNELL, "Rome and Latium Vetus," Archaeological Reports, 26:71–88 (1979–80); and ROBERT DREWS, "The Coming of the City to Central Italy," American Journal of Ancient History, 6:133–165 (1981). The archaeology of early Italy in general is covered in DAVID TRUMP. Central and Southern Italy Before Rome (1966), Livy's work on early Rome is carefully annotated and commented on in part by R.M. OGILVIE, A Commentary on Livy, Books 1-5 (1965, reissued 1984). A good survey of Livy's annalistic predecessors is E. BADIAN, "The Early Historians," in T.A. DOREY (ed.), Latin Historians (1966), pp. 1-38. The single best modern treatment of the regal period and the early republic is JACQUES HEURGON, The Rise of Rome to 264 B.C. (1973; originally published in French, 1969). A complete chronological listing of all known magistrates of the Roman Republic with full ancient citations can be found in T. ROBERT S. BROUGHTON, The Magistrates of the Roman Republic, 2 vol. and a supplement (1951-60, reprinted 1984-86). A collection and modern analysis of ancient sources concerning Rome's economic development is TENNEY FRANK (ed.), An Economic Survey of Ancient Rome, 6 vol. (1933-40, reprinted 1975). The legal evidence from early Rome is treated by ALAN WATSON, Rome of the XII Tables: Persons and Property (1975).

The evolution of Rome's foundation myth is discussed by E.J. BICKERMAN, "Origines Gentium," Classical Philology, 47(2):65-81 (April 1952). Bickerman treats a number of important methodological questions on early Rome in "Some Reflections on Early Roman History," Rivista di Filologia e di Istruzione Classica, 97:393-408 (1969), RICHARD I. RIDLEY, "Fastenkritik: A Stocktaking," Athenaeum, 58(3-4):264-298 (1980), surveys various modern views on the reliability of the consular fasti. The single best treatment of the Roman ruling class is MATTHIAS GELZER, The Roman Nobility (1969; originally published in German, 1912). The Roman assemblies and voting procedures are thoroughly examined by GEORGE WILLIS BOTSFORD, The Roman Assemblies from Their Origin to the End of the Republic (1909, reprinted 1968); and LILY ROSS TAYLOR, Roman Voting Assemblies from the Hannibalic War to the Dictatorship of Caesar (1966). Taylor has also carefully studied the origin and development of the 35 urban and rural voting tribes in The Voting Districts of the Roman Republic (1960). E. STUART "Forschungsbericht: The Constitution of the Roman Republic 1940-1954," Historia, 5:74-122 (1956), surveys modern scholarship on a number of important constitutional problems of early Roman history. Staveley has discussed the problem of the distinction between patricians and plebians in "The Nature and Aims of the Patriciate," Historia, 32:24-57 (1983). A collection of essays by different scholars addressing this same problem is KURT A. RAAFLAUB (ed.), Social Struggles in Archaic Rome: New Perspectives on the Conflict of the Orders (1986), which contains an excellent bibliography on early Rome. A detailed and novel approach to the problem of patricians and plebeians is RICHARD E. MITCHELL, Patricians and Plebeians: The Origin of the Roman State (1990). The single best treatment of the military tribunes with consular power and related questions is KURT VON FRITZ, "The Reorganization of the Roman Government in 366 B.C. and the So-called Licinio-Sextian Laws," Historia, 1:3-44 (1950).

The best modern discussion of Roman imperialism is WILLIAM V. HARRIS, War and Imperialism in Republican Rome, 327-70 B.C. (1979). Harris' Rome in Etruria and Umbria (1971). examines Rome's relations with those two regions. Other informative works on Roman expansion include R.M. ERRINGTON, The Dawn of Empire: Rome's Rise to World Power (1971); ERICH S. GRUEN, The Hellenistic World and the Coming of Rome, 2 vol. (1984); and E. BADIAN, Foreign Clientelae, 264-70 B.C. (1958). E.T. SALMON, Roman Colonization Under the Republic (1969), surveys the methods, aims, and consequences of Roman colonization. (G.E.Fo.)

The middle republic (264-133 BC): H.H. SCULLARD, A History of the Roman World: 753-146 BC, 4th ed. (1980), provides a reliable narrative. GAETANO DE SANCTIS, Storia dei Romani, 4 vol. (1907-65), is more detailed. The standard reference work on Polybius is F.W. WALBANK, A Historical Commentary on Polybius, 3 vol. (1957-79). On the wars with Carthage, UL-RICH KAHRSTEDT, Geschichte der Karthager von 218-146 (1913 reprinted 1975), provides source criticism. Military aspects of this period are presented in JOHANNES KROMAYER and GEORG VEITH, Antike Schlachtfelder, vol. 3 in 2 parts (1912): JOHANNES KROMAYER and GEORG VEITH (eds.), Schlachten-Atlas zur an-tiken Kriegsgeschichte, 5 parts (1922–29); J.H. THIEL, A History of Roman Sea-power Before the Second Punic War (1954), and Studies on the History of Roman Sea-power in Republican Times (1946); J.F. LAZENBY, Hannibal's War: A Military History of the Second Punic War (1978); and H.H. SCULLARD, Scipio Africanus. Soldier and Politician (1970). STÉPHANE GSELL, Histoire ancienne de l'Afrique du Nord, 3rd ed., 8 vol. (1928); and B. H. WARMINGTON, Carlbage, rev. ed. (1969), deal with Carlbage. Works on the provinces include DAVID MAGIE, Roman Rule in Asia Minor to the End of the Third Century Affer Christ, 2 vol. (1950, reissued 1988); G.H. STEVENSON, Roman Provincial Administration till life Age of the Antonines (1939, reprinted 1975); and C.H.V. SUTHERLAND, The Romans in Spain, 217 B.C.—AD. 117 (1939, reprinted 1932).

The transformation of Rome and Italy during the middle republic Citizenship, constitution, and politics are discussed in Theodor Momanse, Romisches Steator-General Theodor Momanse, Romisches Steator-General Citizenship, 2nd ed. (1973, reissued 1987); and c. (1974). The World of the Citizen in Republican Rome (1980, originally published in French, 1976). ARNOLD J. TOYNBER, Handla's Legacy The Hannibale War's Effects on Roman Life, (1963); R.A. BRUNT, Italian Manpower, 225 BC-A.D. School, 1987); and SETH HOPKINS, Conquerors and School (1987); and SETH HOPKINS, Conquerors and School (1987); and SETH HOPKINS, Conquerors and General School (1987); and SETH HOPKINS, Conquerors of Rome's victories. P.A. BRUNT, SCHOOL (1987); and SECHIEL (1987); reissued 1986), presents an excellent hreif account. Many important aspects of second-century politics and country are covered in ALAN E. ASTIN, Scipio demilianus (1967).

The late republic (133-31 BC): The best outline in English for the late republic is the first half of H.H. SCULLARD, From the Gracchi to Nero, 5th ed. (1982), with excellent notes and bibliography. The classic reference work is w. DRUMANN, Geschichte Roms in seinem Übergange von der republikanischen zur monarchischen Verfassung, 2nd ed. edited by P. GROEBE, 6 vol. (1899-1929), giving biographies (with full source material) of all prominent figures of the period, arranged by families. Classic interpretations of the fall of the republic are RONALD SYME. The Roman Revolution (1939, reissued 1987); P.A. BRUNT, The Fall of the Roman Republic and Related Essays (1988); LILY ROSS TAYLOR, Party Politics in the Age of Caesar (1949, reissued 1975); ERICH S. GRUEN, The Last Generation of the Roman Republic (1974); and MATTHIAS GELZER, Caesar: Politician and Statesman (1968; originally published in German, 1940). army and expansion are analyzed in EMILIO GABBA, Republican Rome, the Army, and the Allies (1976; originally published in Italian, 1973); and E. BADIAN, Roman Imperialism in the Late Republic, 2nd ed. (1968). Aspects of public and social life are dealt with in T.P. WISEMAN, New Men in the Roman Senate, 139 B.C.-A.D. 14 (1971); ISRAEL SHATZMAN, Senatorial Wealth and Roman Politics (1975); SUSAN TREGGIARI, Roman Freedmen During the Late Republic (1969); A.W. LINTOTT, Violence in Republican Rome (1968); and E. BADIAN, Publicans and Sinners: Private Enterprise in the Service of the Roman Republic (1972. reissued 1983). On cultural development, the standard work is ELIZABETH RAWSON, Intellectual Life in the Late Roman Republic (1985); it may be supplemented by J.H.W.G. LIEBESCHUETZ, Continuity and Change in Roman Religion (1979); BRUCE W. FRIER, The Rise of the Roman Jurists (1985); and GEORGE KENNEDY, The Art of Rhetoric in the Roman World, 300 B.C.-A.D. 300 (1972).

The early Roman Empire (34 BC-40, 193). COLIN WELLS, The Roman Empire (1984), is an intelligent short history up through the Severi. The history is carried further by MICHAEL GENRY, The Climax of Rome: The Final Achievements of the Ancient World, A.D. 161–337 (1968), DONALD EARL, The 4ge of Augustus (1968, reissued 1980), is useful in providing a little more depth. As to governmental institutions, FERGUS MILLAR, The Emperor in the Roman World, 31 BC-40, 337 (1977), of fers a monumentally detailed study of the ruler in his capacity as scivil governor up through Constantine, and RICHARD LA. TALBERT, The Senate of Imperial Rome (1984), describes the role and actions of the ruler's partner. On provincial govern-

ment, as well as much else, FERGUS MILLAR (ed.), The Roman Empire and Its Neighbours, 2nd ed. (1981; originally published in German, 1966), is informative and readable. Commentary on the economy is supplied by KEVIN GREENE, The Archaeology of the Roman Economy (1986). GÉZA ALFÖLDY, The Social History of Rome (1985), on the structure of society; and RAMSAY MACMULLEN, Roman Social Relations, 50 B.C. to A.D. 284 (1974), on the feelings uniting or dividing groups or strata, are complementary works. Provincial history broadly interpreted may be sampled in SHEPPARD FRERE, Britannia: A History of Roman Britain, 3rd ed. rev. (1987); PAUL Mack-ENDRICK, The North African Stones Speak (1980); and A.H.M. JONES, The Greek City from Alexander to Justinian (1940, reissued 1979), still useful, since archaeology has little touched the eastern end of the Mediterranean world. BERNARD ANDREAE, The Art of Rome (1977; originally published in German, 1973), a large, luxuriously illustrated work with an equally rich scholarly text; and NIELS HANNESTAD, Roman Art and Imperial Policy (1986; originally published in Danish, 1976), deal with their material in quite different ways: the former is conventionally art-historical, the latter uses his material to illuminate its context. Architecture is best approached through W.L. MacDONALD, The Architecture of the Roman Empire, rev. ed., 2 vol. (1982-86), a well-written, imaginative account; and through such specialized studies as JOHN PERCIVAL. The Roman Villa: An Historical Introduction (1976, reissued 1988). PHILIPPE ARIÈS and GEORGES DUBY (eds.), A History of Private Life, vol. 1, From Pagan Rome to Byzantium, ed. by PAUL VEYNE (1987; originally published in French, 1985), is a social history in an old-fashioned sense by a master of the most upto-date approaches. The importance of emperor worship is well argued in the detailed work by DUNCAN FISHWICK, The Imperial Cult in the Latin West, vol. 1 in 2 vol. (1987); and, with more interpretation and for the other half of the empire, by S.R.F. PRICE, Rituals and Power: The Roman Imperial Cult in Asia Minor (1984). RAMSAY MACMULLEN, Paganism in the Roman Empire (1981), provides a comprehensive view. Military history is made accessible through G.R. WATSON, The Roman Soldier (1969, reissued 1985). An explication of a major aspect of culture may be found in the latter half of a work by a notable historian, H.I. MARROU, A History of Education in Antiquity (1956, reprinted 1982; originally published in French, 1948).
ALBIN LESKY, A History of Greek Literature (1966; originally published in German, 2nd ed., 1963), may be paired with H.J. ROSE, A Handbook of Latin Literature, from the Earliest Times to the Death of St. Augustine, 3rd ed. (1966); and with the more elegant study by GORDON WILLIAMS, Change and Decline: Roman Literature in the Early Empire (1978). On the church, w.H.C. FREND, The Rise of Christianity (1984), is readable and comprehensive up through the 6th century.

The later Roman Empire: ANDRÉ PIGANIOL, L'Empire chrétien (325-395), 2nd ed. updated by ANDRÉ CHASTAGNOL (1972), offers an exceptionally rich and informative narrative among modern works. DIANA BOWDER, The Age of Constantine and Induern Works, DANA BOWDER, The Tage of Constantine and Julian (1978), is good on those two reigns. A.H.M. Jones, The Later Roman Empire, 284-602: A Social Economic and Admin-istrative Survey, 2 vol. (1964, reprinted 1986), is extraordinarily clear and detailed on these topics. On a major development, monasticism, DERWAS J. CHITTY, The Desert a City: An Introduction to the Study of Egyptian and Palestinian Monasticism Under the Christian Empire (1966, reissued 1977), is highly readable. RAMSAY MACMULLEN, Corruption and the Decline of Rome (1988), includes an up-to-date survey of evidence for decline, and also argues a thesis. HERWIG WOLFRAM, History of the Goths (1988; originally published in German, 2nd ed., 1980), is a superb study of a crucial player in the 4th to 6th centuries. WALTER GOFFART, Barbarians and Romans, A.D. 418-584: The Techniques of Accommodation (1980), carries the account further. (R.MacM.)

The Classical Greek Dramatists: Aeschylus, Sophocles, Euripides, and Aristophanes

f the literature of ancient Greece only a small portion survives. Yet much of it remains important, not only because of its high quality but also because Western literature is partly based on forms that were of Greek invention. Two such literary forms are tragedy (tragōidia; "goat-song") and comedy (komōidia; "revelsong"), both of which presumably originated in ancient Greek rituals of celebration and sacrifice. Both tragedy and comedy were performed at Athens at the spring festival of the god Dionysus (the Great Dionysia). The only extant Greek tragedies are a total of 35 plays written by the Athenian poet-playwrights Aeschylus, Sophocles, and Euripides. In the works of these three men Greek tragedy can be seen both at its creation and at the height of its formal and artistic development. Similarly, the 11 extant complete plays by the Athenian playwright Aristophanes are the only surviving examples of the very first stage in the development of comedy in the Western world, known as Old Comedy. This article treats the lives, works, and achievements of these four classical dramatists. For treatment of the origins, forms, and development of ancient Greek drama and dramatic production, see GREEK LITER-ATURE; THEATRE, THE HISTORY OF WESTERN; THEATRICAL PRODUCTION

Aeschylus

LIFE AND CAREER

Aeschylus was the first of classical Athens' three great writers of tragedy. He grew up in the turbulent period when the Athenian democracy, having thrown off its tyranny (the absolute rule of one man), had to prove itself against both self-seeking politicians at home and invaders from abroad. Aeschylus himself took part in his city's first struggles against the invading Persians. Later Greek chroniclers believed that Aeschylus was 35 years old in 490 BC when he participated in the Battle of Marathon, in which the Athenians first repelled the Persians; if this is true it would place his birth in 525 BC. Aeschylus' father's name was Euphorion, and the family probably lived at Eleusis (west of Athens)

Aeschylus was a notable participant in Athens' major dramatic competition, the Great Dionysia, which was a part of the festival of Dionysus. Every year at this festival, each of three dramatists would produce three tragedies, which either could be unconnected in plot sequence or could have a connecting theme. This trilogy was followed by a satyr play, which was a kind of lighthearted burlesque. Aeschylus is recorded as having participated in this competition, probably for the first time, in 499 BC. He won his first victory in the theatre in the spring of 484 BC. In the meantime, he had fought and possibly been wounded at Marathon, and Aeschylus singled out his participation in this battle years later for mention on the verse epitaph he wrote for himself. Aeschylus' brother was killed in this hattle. In 480 the Persians again invaded Greece, and once again Aeschylus saw service, fighting at the battles of Artemisium and Salamis. His responses to the Persian invasion found expression in his play Persians, the earliest of his works to survive. This play was produced in the competition of the spring of 472 BC and won first prize.

Around this time Aeschylus is said to have visited Sicily to present Persians again at the tyrant Hieron I's court in Syracuse. Aeschylus' later career is a record of sustained dramatic success, though he is said to have suffered one memorable defeat, at the hands of the novice Sophocles, whose entry at the Dionysian festival of 468 BC was victorious over the older poet's entry. Aeschylus recouped the loss with victory in the next year, 467, with his Oedipus trilogy (of which the third play, Seven Against Thebes, survives). After producing his masterpiece, the Oresteia trilogy, in 458. Aeschylus went to Sicily again. The chronographers recorded Aeschylus' death at Gela (on Sicily's south coast) in 456/455, aged 69. A ludicrous story that he was killed when an eagle dropped a tortoise on his bald pate was presumably fabricated by a later comic writer. At Gela he was accorded a public funeral, with sacrifices and dramatic performances held at his grave, which subsequently became a place of pilgrimage for writers.

Aeschylus wrote approximately 90 plays, including satyr plays as well as tragedies; of these, about 80 titles are known. Only seven tragedies have survived entire. One account, perhaps based on the official lists, assigns Aeschylus 13 first prizes, or victories; this would mean that well over half of his plays won, since sets of four plays rather than separate ones were judged. According to the philosopher Flavius Philostratus, Aeschylus was known as the "Father of Tragedy." Aeschylus' two sons also achieved prominence as tragedians. One of them, Euphorion, won first prize in his own right in 431 BC over Sophocles and Euripides.

DRAMATIC AND LITERARY ACHIEVEMENTS

Aeschylus' influence on the development of tragedy was fundamental. Previous to him, Greek drama was limited to one actor and a chorus engaged in a largely static recitation. (The chorus was a group of actors who responded to and commented on the main action of a play with song, dance, and recitation.) The actor could assume different roles by changing masks and costumes, but he was limited to engaging in dialogue only with the chorus. By adding a second actor with whom the first could converse, Aeschylus vastly increased the drama's possibilities for dialogue and dramatic tension and allowed more variety and freedom in plot construction. Although the dominance of the chorus in early tragedy is ultimately only hypothesis, it is probably true that, as Aristotle says in his Poetics, Aeschylus "reduced the chorus' role and made the plot the leading actor." Aeschylus was an innovator in other ways as well. He made good use of stage settings and stage machinery, and some of his works were noted for their spectacular scenic effects. He also designed costumes, trained his choruses in their songs and dances, and probably acted in most of his own plays, this being the usual practice among Greek dramatists.

But Aeschylus' formal innovations account for only part of his achievement. His plays are of lasting literary value

Formal innovations

in their majestic and compelling lyrical language, in the intricate architecture of their plots, and in the universal themes which they explore so honestly. Aeschylus' language in both dialogue and choral lyric is marked by force, majesty, and emotional intensity. He makes bold use of compound epithets, metaphors, and figurative turns of speech, but this rich language is firmly harnessed to the dramatic action rather than used as mere decoration. It is characteristic of Aeschylus to sustain an image or group of images throughout a play; the ship of state in Seven Against Thebes, the birds of prey in Suppliants, the snare in Agamemnon. More generally, Aeschylus deploys throughout a play or trilogy of plays several leading motifs that are often associated with a particular word or group of words. In the Oresteia, for example, such themes as wrath, mastery, persuasion, and the contrasts of light and darkness, of dirge and triumphal song, run throughout the trilogy. This sort of dramatic orchestration as applied to careful plot construction enabled Aeschylus to give Greek drama a more truly artistic and intellectual form.

Aeschylean tragedy deals with the plights, decisions, and fates of individuals with whom the destiny of the community or state is closely bound up; in turn, both individual and community stand in close relation to the gods. Personal, social, and religious issues are thus integrated, as they still were in the Greek civilization of the poet's time. Theodicy (i.e., the justifying of the gods' ways to men) was in some sense the concern of Aeschylus, though it might be truer to say that he aimed through dramatic conflict to throw light on the nature of divine justice. Aeschylus and his Greek contemporaries believed that the gods begrudged human greatness and sent infatuation on a man at the height of his success, thus bringing him to disaster. Man's infatuated act was frequently one of impiety or pride (hubris), for which his downfall could be seen as a just punishment. In this scheme of things, divine jealousy and eternal justice formed the common fabric of a moral order of which Zeus, supreme among the gods, was the guardian.

But the unjust are not always punished in their lifetime; it is upon their descendants that justice may fall. It was this tradition of belief in a just Zeus and in hereditary guilt that Aeschylus received, and which is evinced in many of his plays. The simplest illustration of this is in Persians. in which Xerxes and his invading Persians are punished for their own offenses. But in a play such as Agamemnon, the issues of just punishment and moral responsibility, of human innocence and guilt, of individual freedom versus evil heredity and divine compulsion are more complex and less easily disentangled, thus presenting contradictions which still baffle the human intellect.

Finally, to Aeschylus, divine justice uses human motives to carry out its decrees. Chief among these motives is the desire for vengeance, which was basic to the ancient Greek scheme of values. In the one complete extant trilogy, the Oresteia, this notion of vengeance or retaliation is dominant. Retaliation is a motive of Agamemnon, Clytemnestra, Aegisthus, and Orestes. But significantly, the chain of retaliatory murder that pursues Agamemnon and his family ends not by a perfect balance of blood guilt, not by a further perpetuation of violence, but rather through reconciliation and the rule of law as established by Athena and the Athenian courts of justice.

Aeschylus is almost unequaled in writing tragedy that, for all its power of depicting evil and the fear and consequences of evil, ends, as in the Oresteia, in joy and reconciliation. Living at a time when the Greek people still truly felt themselves surrounded by the gods, Aeschylus nevertheless had a capacity for detached and general thought, which was typically Greek and which enabled him to treat the fundamental problem of evil with singular honesty and success.

THE PLAYS

Theme

iustice

of divine

Persians. One of a trilogy of unconnected tragedies presented in 472 BC, Persians (Greek Persai) is unique among surviving tragedies in that it dramatizes recent history rather than events from the distant age of mythical heroes. The play treats the decisive repulse of the Persians from Greece in 480, in particular their defeat at the Battle of Salamis. The play is set in the Persian capital, where a messenger brings news to the Persian queen of the disaster at Salamis. After attributing the defeat of Persia to both Greek independence and bravery and to the gods' punishment of Persian folly for going outside the bounds of Asia, the play ends with the return of the broken and humiliated Persian king, Xerxes,

Seven Against Thebes. This is the third and only surviving play of a connected trilogy, presented in 467 BC, that dealt with the impious transgressions of Laius and the doom subsequently inflicted upon his descendants. The first play seems to have shown how Laius, king of Thebes, had a son despite the prohibition of the oracle of the god Apollo. In the second play it appears that that son, Oedipus, killed his father and laid a curse on his own two sons, Eteocles and Polyneices. In Seven Against Thebes (Greek Hepta epi Thēbais) Eteocles is shown leading the defense of the city of Thebes against an invading army led by his brother Polyneices and six chieftains from the south of Greece who are bent on placing Polyneices on the Theban throne. Eteocles assigns defenders to each of six of the seven gates of Thebes; but he insists on fighting at the seventh gate, where his opponent will be Polyneices. There the brothers kill each other, and the Theban royal family is thus exterminated, bringing to an end the horrors set in motion by Laius' defiance of the gods.

Suppliants. This is the first and only surviving play of a trilogy probably put on in 463. It was long believed by scholars that Suppliants (Greek Hiketides; Latin Supplices) was one of Aeschylus' earliest plays because of its archaic structure; its chorus, representing the daughters of Danaus (the Danaïds), takes the leading role in the action. But there is now evidence that the trilogy of which Suppliants formed a part was produced in competition with Sophocles, who is first known to have competed in 468. Suppliants thus dates presumably from the middle of Aeschylus' career, not from the beginning.

Born in Egypt, though of Greek descent, the Danaïds have fled with their father to Argos in Greece in order to avoid forced marriage with their cousins, the sons of Aegyptus. Pelasgus, the king of Argos, is torn between charity to the Danaïds and anxiety to appease Aegyptus but nobly agrees in the end to grant them asylum. The trilogy as a whole seems to have favourably stressed the saving power of domestic love as contrasted with both the willful virginity of the Danaïds and the unfeeling, violent lust of their cousins.

Oresteia. The Oresteia trilogy consists of three closely connected plays, all extant, that were presented in 458 BC. In Agamemnon the great Greek king of that name returns triumphant from the siege of Troy, along with his concubine, the Trojan prophetess Cassandra, only to be humiliated and murdered by his fiercely vengeful wife, Clytemnestra. She is driven to this act partly by a desire to avenge the death of her daughter Iphigenia, whom Agamemnon has sacrificed for the sake of the war, partly by her adulterous love for Aegisthus, and partly as agent for the curse brought on Agamemnon's family by the crimes of his father, Atreus. At the play's end Clytemnestra and her lover have taken over the palace and now rule Argos. Many regard this play as one of the greatest Greek tragedies. From its extraordinarily sustained dramatic and poetic power one might single out the fascinating, deceitful richness of Clytemnestra's words and the huge choral songs, which raise in metaphorical and often enigmatic terms the complex of major themes-of theology, politics, and blood relationships-which are elaborated throughout the trilogy.

Libation Bearers (Greek Choephoroi) is the second play in the trilogy and takes its title from the chorus of women servants who come to pour propitiatory offerings at the tomb of the murdered Agamemnon. At the start of this play Orestes, the son of Agamemnon and Clytemnestra, who was sent abroad as a child, returns as a man to take vengeance upon his mother and her lover for their murder of his father. He is reunited with his sister Electra, and together they invoke the aid of the dead Agamemnon in their plans. Orestes then slays Aegisthus, but Orestes'

Orostoin trilogy

subsequent murder of Clytemnestra is committed reluctantly, at the god Apollo's bidding. Orestes' attempts at self-justification then falter and he flees, guilt-wracked, maddened, and pursued by the female incarnations of his mother's curse, the Erinyes (Furies). At this point the chain of vengeance seems interminable.

Eumenides, the title of the third play, means "The Kind Goddesses." The play opens at the shrine of Apollo at Delphi, where Orestes has taken sanctuary from the Furies. At the command of the Delphic oracle, Orestes journeys to Athens to stand trial for his matricide. There the goddess Athena organizes a trial with a jury of citizens. The Furies are his accusers, while Apollo defends him. The jury divides evenly in its vote and Athena casts the tiebreaking vote for Orestes' acquittal. The Furies then turn their vengeful resentment against the city itself, but Athena persuades them, in return for a home and cult, to bless Athens instead and reside there as the "Kind Goddesses" of the play's title. The trilogy thus ends with the cycle of retributive bloodshed ended and supplanted by the rule of law and the justice of the state.

Prometheus Bound. The date of this play (and even its authorship) is disputed, but many scholars regard it as a work of Aeschylus' last years. In Prometheus Bound (Greek Promētheus desmōtēs) the god Prometheus, who in defiance of Zeus has saved mankind and given them fire, is chained to a remote crag as a punishment ordered by the king of the gods. Despite his isolation Prometheus is visited by the ancient god Oceanus, by a chorus of Oceanus' daughters, by the "cow-headed" Io (another victim of Zeus), and finally by the god Hermes, who vainly demands from Prometheus his knowledge of a secret that could threaten Zeus's power. After refusing to reveal his secret, Prometheus is cast into the underworld for further torture. The drama of the play lies in the clash between the irresistible power of Zeus and the immovable will of Prometheus, who has been rendered still more stubborn by Io's misfortunes at the hands of Zeus. The most striking and controversial aspect of the play is its depiction of Zeus as a tyrant. Prometheus himself has proved to be for later ages an archetypal figure of defiance against tyrannical power, a role exemplified in Percy Bysshe Shelley's poem Prometheus Unbound (1820).

(A.J.P./O.T.)

Sophocles

LIFE AND CAREER

The second of classical Athens' three great writers of tragedy, Sophocles was the younger contemporary of Aeschylus and the older contemporary of Euripides, He was born about 496 BC at Colonus, a village outside the walls of Athens. His father, Sophillus, was a wealthy manufacturer of armour, and Sophocles himself received a good education. Because of his beauty of physique, his athletic prowess, and his skill in music, he was chosen in 480, when he was 16, to lead the paean (choral chant to a god) celebrating the decisive Greek sea victory over the Persians at the Battle of Salamis. The relatively meagre information about Sophocles' civic life suggests that he was a popular favourite who participated actively in his community and exercised outstanding artistic talents. In 442 he served as one of the treasurers responsible for receiving and managing tribute money from Athens' subject-allies in the Delian League. In 440 he was elected one of the 10 strategoi (high executive officials who commanded the armed forces) as a junior colleague of Pericles, Sophocles later served as strategos perhaps twice again. In 413, then aged about 83, Sophocles was a proboulos, one of 10 advisory commissioners who were granted special powers and were entrusted with organizing Athens' financial and domestic recovery after its terrible defeat at Syracuse in Sicily. Sophocles' last recorded act was to lead a chorus in public mourning for his deceased rival, Euripides, before the festival of 406. He died that same year.

These few facts are about all that is known of Sophocles' life. They imply steady and distinguished attachment to Athens, its government, religion, and social forms. Sophocles was wealthy from birth, highly educated, noted for his

Sonhocles, bronze bust copied from a Greek original, 340-330 BC. In the Museo Archeologico, Florence.

grace and charm, on easy terms with the leading families, a personal friend of prominent statesmen, and in many ways fortunate to have died before the final surrender of Athens to Sparta in 404. In one of his last plays, Oedipus at Colonus, he still affectionately praises both his own birthplace and the great city itself.

Sophocles won his first victory at the Dionysian dramatic festival in 468, however, defeating the great Aeschylus in the process. This began a career of unparalleled success and longevity. In total, Sophocles wrote 123 dramas for the festivals. Since each author who was chosen to enter the competition usually presented four plays, this means he must have competed about 30 times. Sophocles won perhaps as many as 24 victories, compared to 13 for Aeschylus and four for Euripides, and indeed he may have never received lower than second place in the competitions he entered.

DRAMATIC AND LITERARY ACHIEVEMENTS

Ancient authorities credit Sophocles with several major and minor dramatic innovations. Among the latter is his invention of some type of "scene paintings" or other pictorial prop to establish locale or atmosphere. He also may have increased the size of the chorus from 12 to 15 members. Sophocles' major innovation was his introduction of a third actor into the dramatic performance. It had previously been permissible for two actors to "double" (i.e., assume other roles during a play), but the addition of a third actor onstage enabled the dramatist both to increase the number of his characters and widen the variety of their interactions. The scope of the dramatic conflict was thereby extended, plots could be more fluid, and situations could be more complex.

The typical Sophoclean drama presents a few characters, impressive in their determination and power and possessing a few strongly drawn qualities or faults that combine with a particular set of circumstances to lead them inevitably to a tragic fate. Sophocles develops his characters' rush to tragedy with great economy, concentration, and dramatic effectiveness, creating a coherent, suspenseful situation whose sustained and inexorable onrush came to epitomize the tragic form to the classical world. Sophocles emphasizes that most people lack wisdom, and he presents truth in collision with ignorance, delusion, and folly. Many scenes dramatize flaws or failure in thinking (deceptive reports and rumours, false optimism, hasty judgment,

Typical dramatic framework

Public service

madness). The chief character does something involving grave error; this affects others, each of whom reacts in his own way, thereby causing the chief agent to take another step toward ruin-his own and that of others as well. Equally important, those who are to suffer from the tragic error usually are present at the time or belong to the same generation. It was this more complex type of tragedy that demanded a third actor. Sophocles thus abandoned the spacious Aeschylean framework of the connected trilogy and instead comprised the entire action in a single play. From his time onward, "trilogy" usually meant no more than three separate tragedies written by the same author and presented at the same festival.

Sophocles' language responds flexibly to the dramatic needs of the moment; it can be ponderously weighty or swift-moving, emotionally intense or easygoing, highly decorative or perfectly plain and simple. His mastery of form and diction was highly respected by his contemporaries. Sophocles has also been universally admired for the sympathy and vividness with which he delineates his characters; especially notable are his tragic women, such as Electra and Antigone. Few dramatists have been able to handle situation and plot with more power and certainty; the frequent references in the Poetics to Sophocles' Oedipus the King show that Aristotle regarded this play as a masterpiece of construction, and few later critics have dissented. Sophocles is also unsurpassed in his moments of high dramatic tension and in his revealing use of tragic irony.

The criticism has been made that Sophocles was a superb artist and nothing more; he grappled neither with religious problems as Aeschylus had nor with intellectual ones as Euripides had done. He accepted the gods of Greek religion in a spirit of unreflecting orthodoxy, and he contented himself with presenting human characters and human conflicts. But it should be stressed that to Sophocles "the gods" appear to have represented the natural forces of the universe to which human beings are unwittingly or unwillingly subject. To Sophocles, human beings live for the most part in dark ignorance because they are cut off from these permanent, unchanging forces and structures of reality. Yet it is pain, suffering, and the endurance of tragic crisis that can bring people into valid contact with the universal order of things. In the process, a person can become more genuinely human, more genuinely himself.

THE PLAYS

Conception

of life

Only seven of Sophocles' tragedies survive in their entirety, along with 400 lines of a satyr play, numerous fragments of plays now lost, and 90 titles. All seven of the complete plays are works of Sophocles' maturity, but only two of them, Philoctetes and Oedipus at Colonus, have fairly certain dates. Ajax is generally regarded as the earliest of the extant plays. Some evidence suggests that Antigone was first performed in 442 or 441 BC. Philoctetes was first performed in 409, when Sophocles was 90 years old, and Oedipus at Colonus was said to have been produced after Sophocles' death by his grandson.

Ajax. The entire plot of Ajax (Greek Ajas mastigophoros) is constructed around Ajax, the mighty hero of the Trojan War whose pride drives him to treachery and finally to his own ruin and suicide some two-thirds of the way through the play. Ajax is deeply offended at the award of the prize of valour (the dead Achilles' armour) not to himself but to Odysseus. Ajax thereupon attempts to assassinate Odysseus and the contest's judges, the Greek commanders Agamemnon and Menelaus, but is frustrated by the intervention of the goddess Athena. He cannot bear his humiliation and throws himself on his own sword. Agamemnon and Menelaus order that Ajax' corpse be left unburied as punishment. But the wise Odysseus persuades the commanders to relent and grant Ajax an honourable burial. In the end Odysseus is the only person who seems truly aware of the changeability of human fortune.

Antigone. Antigone is the daughter of Oedipus, the former king of Thebes. She is willing to face the capital punishment that has been decreed by her uncle Creon, the new king, as the penalty for anyone burying her brother Polyneices. (Polyneices has just been killed attacking Thebes, and it is as posthumous punishment for this attack that Creon has forbidden the burial of his corpse.) Obeying all her instincts of love, loyalty, and humanity, Antigone defies Creon and dutifully buries her brother's corpse. Creon, from conviction that reasons of state outweigh family ties, refuses to commute Antigone's death sentence. By the time Creon is finally persuaded by the prophet Tiresias to relent and free Antigone, she has killed herself in her prison cell. Creon's son, Haemon, kills himself out of love and sympathy for the dead Antigone, and Creon's wife, Eurydice, then kills herself out of grief over these tragic events. At the play's end Creon is left desolate and broken in spirit. In his narrow and unduly rigid adherence to his civic duties, Creon has defied the gods through his denial of humanity's common obligations toward the dead. The play thus concerns the conflicting obligations of civic versus personal loyalties and religious mores.

Trachinian Women. This play centres on the efforts of Deianeira to win back the wandering affections of her husband, Heracles, who is away on one of his heroic missions and who has sent back his latest concubine, Tole, to live with his wife at their home in Trachis. The love charm Deianeira uses on Heracles turns out to be poisonous, and she kills herself upon learning of the agony she has caused her husband. Thus, in Trachinian Women (Greek Trachiniai) Heracles' insensitivity (in sending his mistress to share his wife's home) and Deianeira's ignorance result in domestic tragedy.

Oedipus the King. The plot of Oedipus the King (Greek Oidipous Tyrannos: Latin Oedipus Rex) is a structural marvel that marks the summit of classical Greek drama's formal achievements. The play's main character, Oedipus, is the wise, happy, and beloved ruler of Thebes. Though hot-tempered, impatient, and arrogant at times of crisis, he otherwise seems to enjoy every good fortune. But Oedipus mistakenly believes that he is the son of King Polybus of Corinth and his queen. He became the ruler of Thebes because he rescued the city from the Sphinx by answering its riddle correctly, and so was awarded the city's widowed queen, Jocasta. Before overcoming the Sphinx, Oedipus left Corinth forever because the Delphic oracle had prophesied to him that he would kill his father and marry his mother. While journeying to Thebes from Corinth, Oedipus encountered at a crossroads an old man accompanied by five servants. Oedipus got into an argument with him and in a fit of arrogance and bad temper killed the old man and four of his servants.

The play opens with the city of Thebes stricken by a plague and its citizens begging Oedipus to find a remedy. He consults the Delphic oracle, which declares that the plague will cease only when the murderer of Jocasta's first husband, King Laius, has been found and punished for his deed. Oedipus resolves to find Laius' killer, and much of the rest of the play centres upon the investigation he conducts in this regard. In a series of tense, gripping, and ominous scenes Oedipus' investigation turns into an obsessive reconstruction of his own hidden past as he begins to suspect that the old man he killed at the crossroads was none other than Laius. Finally, Oedipus learns that he himself was abandoned to die as a baby by Laius and Jocasta because they feared a prophecy that their infant son would kill his father; that he survived and was adopted by the ruler of Corinth, but in his maturity he has unwittingly fulfilled the Delphic oracle's prophecy of him; that he has indeed killed his true father, married his own mother, and begot children who are also his own siblings.

Jocasta hangs herself when she sees this shameful web of incest, parricide, and attempted child murder, and the guilt-stricken Oedipus then sticks needles into his eyes, blinding himself. Sightless and alone, he is now blind to the world around him but finally cognizant of the terrible truth of his own life.

Electra. As in Aeschylus' Libation Bearers, the action in Electra (Greek Elektra) follows the return of Orestes to kill his mother, Clytemnestra, and her lover Aegisthus in retribution for their murder of Orestes' father, Agamemnon. In this play, however, the main focus is on Orestes' sister Electra and her anguished participation in her brother's plans. To gain admittance to the palace and thus be Plot of Oedinus the King Portrait of Electra able to execute his revenge, Orestes spreads false news of his own death. Believing this report, the despairing Electra unsuccessfully tres to enlist her sister Chrysothemis in an attempt to murder their mother. In a dramatic scene, Orestes then enters in disguise and hands Electra the urn that is supposed to contain his own ashes. Moved by his sister's display of grief, Orestes reveals his true identity to her and then strikes down his mother and her lover. Electra's triumph is thus complete. In the play Electra is seen passing through the whole range of human emotions—from passionate love to cruel hatred, from numb despair to wild joy. There is debate over whether the play depicts virtue triumphant or, rather, portrays a young woman incurably twisted by years of hatred and resentment.

Philoctetes. In Philoctetes (Greek Philoktětěs) the Greeks on their way to Troy have cast away the play's main character. Philoctetes, on the desert island of Lemnos because he has a loathsome and incurable ulcer on his foot. But the Greeks have discovered that they cannot win victory over Troy without Philoctetes and his wonderful bow, which formerly belonged to Heracles. The crafty Odysseus is given the task of fetching Philoctetes by any means possible. Odysseus knows that the resentful Philoctetes will kill him if he can, so he uses the young and impressionable soldier Neoptolemus, son of the dead Achilles, as his agent. Neoptolemus is thus caught between the devious manipulations of Odysseus and the unsuspecting integrity of Philoctetes, who is ready to do anything rather than help the Greeks who abandoned him. For much of the play Neoptolemus sticks to Odysseus' policy of deceit, despite his better nature, but eventually he renounces duplicity to join in friendship with Philoctetes. A supernatural appearance by Heracles then convinces Philoctetes to go to Troy to both win victory and be healed of his disease.

Oedinus at Colonus. In Oedinus at Colonus (Greek Oidipous epi Kolono) the old, blind Oedipus has spent many years wandering in exile after being rejected by his sons and the city of Thebes. Oedipus has been cared for only by his daughters Antigone and Ismene. He arrives at a sacred grove at Colonus, a village close by Athens (and the home of Sophocles himself). There Oedipus is guaranteed protection by Theseus, the noble king of Athens. Theseus does indeed protect Oedipus from the importunate pleadings of his brother-in-law, Creon, for Oedipus to protect Thebes. Oedipus himself rejects the entreaties of his son Polyneices, who is bent on attacking Thebes and whom Oedipus solemnly curses. Finally Oedipus departs to a mysterious death; he is apparently swallowed into the earth of Colonus, where he will become a benevolent power and a mysterious source of defense to the land that has given him final refuge. The play is remarkable for the melancholy, beauty, and power of its lyric odes and for the spiritual and moral authority with which it invests the figure of Oedipus.

Trackers. Four hundred lines of this satyr play survive. The plot of Trackers (Greek Ichneuda) is based on two stones about the miraculous early deeds of the god Hermes: that the infant, growing to maturity in a few days, stole cattle from Apollo, baffling discovery by reversing the animals' hoof marks, and that he invented the lyre by fitting strings to a tortoise shell. In this play the trackers are the chorus of satyrs, who are looking for the cattle; they are amusingly dumbfounded at the sound of the new instrument Hermes has invented. Enough of the play survives to give an impression of its style; it is a genial, uncomplicated travesty of the tragic manner, and the antics of the chorus were apparently the chief source of amusement.

Euripides

Satyr play

LIFE AND CAREER

It is possible to reconstruct only the sketchiest biography of Euripides, the youngest of classical Athens' three great tragedians. Euripides' mother's name was Cleito; his father's name was Mnesarchus or Mnesarchides. One tradition states that his mother was a greengrocer who sold herbs in the marketplace. Aristophanes joked about this in

Euripides, marble herm copied from a Greek original, c. 340–330 BC. In the Museo Archeologico Nazionale, Naples.

By courtesy of the Soprintendenza alle Antichita della

comedy after comedy; but there is better indirect evidence that Euripides came of a well-off family. He was probably born in 484. Euripides first received the honour of being chosen to compete in the dramatic festival in 455, and he won his first victory in 441. Euripides left Athens for good in 408, accepting an invitation from Archelaus, king of Macedonia. He died in Macedonia in 408.

Euripides' only known public activity was his service on a diplomatic mission to Syracuse in Sicily. He was passionately interested in ideas, however, and owned a large library. He is said to have associated with Protagoras, Anaxagoras, and other Sophists and philosopher-scientists. His acquaintance with new ideas brought him restlessness rather than conviction, however, and his questioning attitude toward traditional Greek religion is reflected in some of his plays. Of Euripides' private life, little can be said. Later tradition invented for him a spectacularly disastrous married life. It is known that he had a wife called Melito and produced three sons. One of these was something of a poet and produced the Bachants after his father's death. He may also have completed his father's unfinished play Inhienia at Aulis.

The ancients knew of 92 plays composed by Euripides. Nineteen plays are extant, if one of disputed authorship is included. At only four festivals was Euripides awarded the first prize-the fourth posthumously, for the tetralogy that included Bacchants and Iphigenia at Aulis. As Sophocles won perhaps as many as 24 victories, it is clear that Euripides was comparatively unsuccessful. More to the point is that on more than 20 occasions Euripides was chosen, out of all contestants, to be one of the three laureates of the year. Furthermore, the regularity with which Aristophanes parodied him is proof enough that Euripides' work commanded attention. It is often said that disappointment at his plays' reception in Athens was one of the reasons for his leaving his native city in his old age; but there are other reasons why an old poet might have left Athens in the 23rd year of the Peloponnesian War.

DRAMATIC AND LITERARY ACHIEVEMENTS

Euripides' plays exhibit his iconoclastic, rationalizing attitude toward both religious belief and the ancient legends and myths that formed the traditional subject matter for Greek drama. These legends seem to have been for him a mere collection of stories without any particular authority. He also apparently rejected the gods of Homeric theology, whom he frequently depicts as irrational, petulant, and singularly uninterested in metting out "divine iustice." Uncertain biographical accounts That the gods are so often presented on the stage by Euripides is partly due to their convenience as a source of information that could not otherwise be made available to the audience.

Given this attitude of sophisticated doubt on his part, Euripides invents protagonists who are quite different from the larger-than-life characters drawn with such conviction by Aeschylus and Sophocles. They are, for the most part, commonplace, down-to-earth men and women who have all the flaws and vulnerabilities ordinarily associated with human beings. Furthermore, Euripides makes his characters express the doubts, the problems and controversies, and in general the ideas and feelings of his own time. They sometimes even take time off from the dramatic action to debate each other on matters of current philosophical or social interest.

Euripides differed from Aeschylus and Sophocles in making his characters' tragic fates stem almost entirely from their own flawed natures and uncontrolled passions. Chance, disorder, and human irrationality and immorality frequently result not in an eventual reconciliation or moral resolution but in apparently meaningless suffering that is looked upon with indifference by the gods. The power of this type of drama lies in the frightening and ghastly situations it creates and in the melodramatic, even sensational, emotional effects of its characters' tragic crises.

Given this strong strain of psychological realism, Euripides shows moments of brilliant insight into his characters, especially in scenes of love and madness. His depictions of women deserve particular attention; it is easy to extract from his plays a long list of heroines who are fierce, treacherous, or adulterous, or all three at once. Misogyny is altogether too simple an explanation here, although Euripides' reputation in his own day was that of a woman hater, and a play by Aristophanes, Women at the Thesmophoria, comically depicts the indignation of the Athenian women at their portrayal by Euripides.

The chief structural peculiarities of Euripides' plays are his use of prologues and of the providential appearance of a god (deus ex machina) at the play's end. Almost all of the plays start with a monologue that is in effect a bare chronicle explaining the situation and characters with which the action begins. Similarly, the god's epilogue at the end of the play serves to reveal the future fortunes of the characters. This latter device has been criticized as clumsy or artificial by modern authorities, but it was presumably more palatable to the audiences of Euripides' own time. Another striking feature of his plays is that over time Euripides found less and less use for the chorus; in his successive works it tends to grow detached from the dramatic action.

The word habitually used in antiquity to describe Euripides' ordinary style of dramatic speech is lalia ("chatter"). alluding probably both to its comparatively light weight and to the volubility of his characters of all classes. Notwithstanding this, Euripides' lyrics at times have considerable charm and sweetness. In the works written after 415 BC his lyrics underwent a change, becoming more emotional and luxuriant. At its worst this style is hardly distinguishable from Aristophanes' parody of it in his comedy Frogs, but where frenzied emotion is appropriate, as in the tragedy Bacchants, Euripides' songs are unsurpassed in their power and beauty.

During the last decade of his career Euripides began to write "tragedies" that might actually be called romantic dramas, or tragicomedies with happy endings. These plays have a highly organized structure leading to a recognition scene in which the discovery of a character's true identity produces a complete change in the situation, and in general a happy one. Extant plays in this style include Ion, Iphigenia Among the Taurians, and Helen. Plays of the tragicomedy type seem to anticipate the New Comedy of the 4th century BC.

The fame and popularity of Euripides eclipsed that of Aeschylus and Sophocles in the cosmopolitan Hellenistic period. The austere, lofty, essentially political and "religious" tragedy of Aeschylus and Sophocles had less appeal than that of Euripides, with its more accessible realism and its obviously emotional, even sensational, effects. Euripides thus became the most popular of the three for revivals of his plays in later antiquity; this is probably why at least 18 of his plays have survived compared to seven each for Aeschylus and Sophocles, and why the extant fragmentary quotations from his works are more numerous than those of Aeschylus and Sophocles put together.

THE PLAYS

The dates of production of nine of Euripides' plays are known with some certainty from evidence that goes back to the official Athenian records. Those plays whose dates are prefixed by c. can be dated to within a few years by the internal evidence of Euripides' changing metrical techniques

Alcestis. Though tragic in form, Alcestis (438 BC; Greek Alkēstis) ends happily and took the place of the satyr play that normally followed the three tragedies. King Admetus is doomed to die shortly, but he will be allowed a second life if he can find someone willing to die in his place. His wife, Alcestis, voluntarily dies in place of her husband, who sees too late that the fact and manner of her dying will blight his life. But Admetus' old friend Heracles shows up and rescues Alcestis from the clutches of Death. restoring her to her happy and relieved husband.

Medea. One of Euripides' most powerful and best known plays, Medea (431 BC; Greek Mēdeia) is a remarkable study of the mistreatment of a woman and of her ruthless revenge. The Colchian princess Medea has been taken by the hero Jason to be his wife. They have lived happily for some years at Corinth and have two sons. But then Jason casts Medea off and decides to marry the Princess of Corinth. Medea is determined on revenge, and after a dreadful mental struggle between her passionate sense of injury and her love for her children, she decides to punish her husband by murdering both the Corinthian princess and their own sons, thereby leaving her husband to grow old with neither wife nor child. She steels herself to commit these deeds and then escapes in the chariot of her grandfather, the sun-god Helios, leaving Jason without even the satisfaction of punishing her for her crimes. Euripides succeeds in evoking sympathy for the figure of Medea, who becomes to some extent a representative of women's oppression in general.

Children of Heracles. The plot of Children of Heracles (430 BC; Greek Hērakleidai) concerns the Athenians' defense of the young children of the dead Heracles from the murderous intentions of King Eurystheus of Argos. The play is basically a simple glorification of Athens.

Hippolytus. In Hippolytus (428 BC; Greek Hippolytos) Aphrodite, the goddess of love and sexual desire, destroys Hippolytus, a lover of outdoor sports who is repelled by sexual passion and who is instead devoted to the virgin huntress Artemis. Aphrodite makes Phaedra, wife of Theseus, the king of Athens, fall violently in love with her stepson Hippolytus. Phaedra is deeply ashamed of her illicit passion, but when Hippolytus angrily rejects her love she is so mortified by his denunciation that she cannot forbear from falsely accusing him of rape before she kills herself. Her accusation provokes Theseus into pronouncing a curse on his son that eventually leads to Hippolytus' death. But Artemis reveals Hippolytus' innocence before he dies, and the young man is able to forgive his father, thus freeing Theseus from the dreadful stain of bloodguilt. Given the nature of its plot, the play is remarkable for its propriety.

Andromache. This play is set in the aftermath of the Trojan War. After an exciting beginning marked by strong anti-Spartan feeling, most of the original characters in Andromache (c. 426 Bc) disappear and the interest is dissipated.

Hecuba. Also set in the aftermath of the Trojan War, Miseries Hecuba (c. 425 BC; Greek Hekabē) shows the double disaster that reduces the aged Trojan queen Hecuba, now a widowed slave, by sheer weight of hatred and misery to a mere animal ferocity. Hecuba first loses her daughter Polyxena, who is taken off to be sacrificed to the ghost of Achilles. Hecuba then discovers the corpse of her last son, Polydorus, who has been murdered by his Thracian host, Polymestor. Hecuba eventually persuades the Greek

The tragicomedies

Psychologi-

cal realism

commander Agamemnon to allow her to take vengeance; she and her women then blind Polymestor and murder his two young sons. Such is the power of misery to deprave, and the play's closing prophecy of Hecuba's future transformation into a bitch seems appropriate.

Suppliants. The title figures of Suppliants (c. 423 BC; Greek Hiketides; Latin Supplices) are the mothers of the Argive leaders who have been killed while attacking Thebes. The bodies of their sons have been left unburied by the Thebans, and they eventually persuade the Athenians to recover them. It is disputed whether the play is a straightforward eulogy of Athens and its democracy, or whether its sentiments are being expressed ironically.

Electra. The title character of Electra (c. 418 BC; Greek Elektra) and her brother Orestes murder their mother, Clytemnestra, in retribution for her murder of their father, Agamemnon. Electra herself is portrayed as a frustrated and resentful woman who finally lures her mother to her death by appealing to her maternal instincts. After the horrible murder both Electra and her reluctant accomplice Orestes are consumed by remorse. This is a bitterly realistic and antiheroic play that draws a disturbingly convincing portrait of both Electra's sufferings and her unattractive personality.

Madness of Heracles. The title character of Madness of Heracles (c. 416 BC: Greek Hēraklēs mainomenos; Latin Hercules furens) is temporarily driven mad by the goddess Hera and kills his wife and children. Subsequently Heracles recovers his reason and, after recovering from suicidal despair, is taken to spend an honourable retire-

ment at Athens.

Plays with

scenes

recognition

Trojan Women. The setting of Trojan Women (415 BC; Greek Trōades) is the time immediately after the taking of Troy, and the play treats the sufferings of the wives and children of the city's defeated leaders, in particular the old Trojan queen Hecuba and her children. Hecuba's daughter Cassandra is taken off to be the concubine of Agamemnon, and then her daughter-in-law Andromache is led off to be the slave of Neoptolemus. Andromache's son Astyanax is taken from her to be hurled to his death from the walls of Troy. Finally, as Troy goes up in flames, Hecuba and the other Trojan women are taken off to the ships to face slavery in Greece. This play is a famous and powerful indictment of the barbarous cruelties of war. It was first produced only months after the Athenians captured the city-state of Melos, butchering its men and reducing its women to slavery, and the Trojan Women's mood may well have been influenced by the Athenians' atrocities and the Melians' fate, which are both mirrored

This tragicomedy's sombre action is reversed by a recognition scene. In Ion (c. 413 BC), Creusa, the queen of Athens, is married to an immigrant king, Xuthus, but the couple do not have any children. Years before, the Queen was raped by the god Apollo but abandoned the subsequent child. The boy Ion has grown up as a temple slave at Delphi, where the play is set. When they meet, mother and son feel a strong affinity, but when the Delphic oracle says the boy is the son of Xuthus, the Oueen in her despairing childlessness plots to kill the young stranger who threatens to take over her inheritance. At the last minute they recognize each other by means of the cradle Creusa had long ago left with her baby. The play has a superficially satisfactory ending, but its portraval of human suffering and of divine carelessness and mendacity is tinged with darker feelings.

Iphigenia Among the Taurians. This is another tragicomedy, composed chiefly of a recognition scene followed by a clever escape. The title character of Iphigenia Among the Taurians (c. 413 BC; Greek Iphigeneia en Taurois: Latin Iphigenia in Tauris) has been saved by the goddess Artemis from sacrifice by her father and now serves the goddess' temple at Tauris in Thrace. Iphigenia's brother Orestes is captured by the local tyrant and is delivered to her for sacrifice. She recognizes him, however, and after some exciting mishaps they manage to escape from Tauris with the help of Athena.

Helen. In this frankly light play, Euripides deflates one of the best known "facts" of Greek mythology, that Helen

ran off adulterously with Paris to Troy. In Helen (412 BC: Greek Helene) only a phantom went with Paris to Troy, and the real Helen pines faithfully in Egypt. When Menelaus on his way home from Troy is shipwrecked in Fount he is haffled by the duplicate Helen until the evaporation of the phantom allows his reunion with the real one. The pair then escape from the King of Egypt, who is keen to marry Helen, by an amusing artifice.

Phoenician Women. This is a diverse, many-charactered play whose original version has been tampered with. Phoenician Women (c. 409 BC; Greek Phoinissai) is set at Thebes and concerns the mutual slaughter of the two sons

of Oedipus, Eteocles and Polyneices.

Orestes In this play Euripides makes nonsense of the old story of Orestes' murder of his mother, Clytemnestra, by setting the play in a world where courts of law already exist. In Orestes (408 BC), the main character, his sister Electra, and his cousin and friend Pylades are condemned to death by the men of Argos for the murder. Their uncle Menelaus is too spineless to defend them, and they are finally reduced to plotting to kill Menelaus' wife, Helen, and abduct her innocent daughter. This chaos of violence and attempted murder is only resolved by the deus ex machina Apollo, who appears and restores harmony at the end of the play.

The Greek fleet is becalmed at Aulis Iphigenia at Aulis. and is thus unable to convey the expeditionary force against Troy. Agamemnon learns that he must sacrifice his daughter Iphigenia as a means of appeasing the goddess Artemis, who has caused the unfavourable weather. Agamemnon lures his daughter into coming to Aulis to be sacrificed by pretending that she will marry Achilles. Once the truth is out, Iphigenia, after begging pathetically for her life, goes willingly to her death. Though incomplete and corrupted by later adapters, Iphigenia at Aulis (c. 406) BC; Greek Iphigeneia en Aulidi) is a fine tragedy whose realistic atmosphere is heightened by several subtle and poignant scenes between its main characters.

Bacchants. This play is regarded by many as Euripides' masterniece. In Bacchants (c. 406 BC: Greek Bakchai: Latin Bacchae) the god Dionysus arrives in Greece from Asia intending to introduce his orgiastic worship there. He is disguised as a charismatic young Asian holy man and is accompanied by his women votaries, who make up the play's chorus. He expects to be accepted first in Thebes, but the Thebans reject his divinity and refuse to worship him, and the city's young king, Pentheus, tries to arrest him. In the end Dionysus drives Pentheus insane and leads him to the mountains, where Pentheus' own mother, Agave, and the women of Thebes in a bacchic frenzy tear him to pieces. Agave returns to Thebes triumphant carrying Pentheus' head, and her father, Cadmus, has to lead her back to sanity and recognition. The play shows how the liberating and ecstatic side of the Dionysiac religion must be balanced against the dangerous irresponsibility that goes with the Dionysiac loss of reason and selfconsciousness.

Cyclops. Cyclops (Greek Kyklöps) is the only complete surviving satyr play. The play's cowardly, lazy satyrs with their disgraceful old father Silenus are slaves of the maneating one-eyed Cyclops Polyphemus in Sicily. Odysseus arrives, driven to Sicily by adverse weather, and eventually succeeds (as in Homer's Odyssey) in blinding the Cyclops. He thus enables the Cyclops' victims to escape.

(H.D.F.K./O.T.)

Aristophanes

The most famous of all comic dramatists of ancient Greece, Aristophanes is also the one whose works have been preserved in the greatest quantity. He is the only extant representative of the Old Comedy, that is, of the phase of comic dramaturgy in which chorus, mime, and burlesque still played a considerable part and which was characterized by bold fantasy, merciless invective and outrageous satire, unabashedly licentious humour, and a marked freedom of political criticism. But Aristophanes belongs to the end of this phase, and, indeed, his last extant play, which has no choric element at all, may well

I ate mas-

be regarded as the only extant specimen of the short-lived Middle Comedy, which, before the end of the 4th century BC, was to be superseded in turn by the milder and more realistic social satire of the New Comedy.

LIFE AND CARFER

Impor-

tance of

Pelopon-

War on his

nesian

work

Little is known about the life of Aristophanes, and most of the known facts are derived from references in his own plays. Born c. 450 BC, he was an Athenian citizen belonging to the deme, or clan, named Pandionis, but his actual birthplace is uncertain. (The fact that he or his father, Philippus, owned property on the island of Aegina may have been the cause of an accusation by his fellow citizens that he was not of Athenian birth.) He began his dramatic career in 427 BC with a play, the Daitaleis (The Banqueters), which appears, from surviving fragments, to have been a satire on his contemporaries' educational and moral theories. He is thought to have written about 40 plays in all. A large part of his work is concerned with the social, literary, and philosophical life of Athens itself and with themes provoked by the great Peloponnesian War (431-404 BC). This war was essentially a conflict between imperialist Athens and conservative Sparta and so was long the dominant issue in Athenian politics. Aristophanes was naturally an opponent of the more or less bellicose statesmen who controlled the government of Athens throughout the better part of his maturity. Aristophanes lived to see the revival of Athens after its defeat by Sparta. He died in about 388 BC.

DRAMATIC AND LITERARY ACHIEVEMENTS

Aristophanes' reputation has stood the test of time; his plays have been frequently produced on the 20th-century stage in numerous translations, which manage with varying degrees of success to convey the flavour of Aristophanes' puns, witticisms, and topical allusions. But it is not easy to say why his comedies still appeal to an audience almost 2,500 years after they were written. In the matter of plot construction Aristophanes' comedies are often loosely put together, are full of strangely inconsequential episodes, and often degenerate at their end into a series of disconnected and boisterous episodes. Aristophanes' greatness lies in the wittiness of his dialogue; in his generally good-humoured though occasionally malevolent satire; in the brilliance of his parody, especially when he mocks the controversial tragedian Euripides; in the ingenuity and inventiveness, not to say the laughable absurdity, of his comic scenes born of imaginative fantasy; in the peculiar charm of his choric songs, whose freshness can still be conveyed in languages other than Greek; and, at least for audiences of a permissive age, in the licentious frankness of many scenes and allusions in his comedies.

THE PLAYS

Babylonians. This comedy, which is extant only in fragments, was produced at the festival of the Great Dionysia. The festival was attended by delegates of the city-states, which were theoretically "allies" but were in practice satellites of Athens. Because Babylonians (426 BC; Greek Babylonioi) not only virulently attacked Cleon, the demagogue then in power in Athens, but also showed the "allies" as the slaves of the Athenian Demos (a personification of the Athenian citizen electorate), Aristophanes was impeached by Cleon. Though the details are not known, he seems to have been let off lightly.

Acharnians. This is the earliest of the 11 comedies of Aristophanes that have survived intact. Acharnians (425 BC; Greek Acharneis) is a forthright attack on the folly of the war. Its farmer-hero, Dicaeopolis, is tired of the Pelobonnesian War and therefore secures a private peace treaty with the Spartans for himself in spite of the violent opposition of a chorus of embittered and bellicose old charcoal burners of Acharnae. Dicaeopolis takes advantage of his private treaty to trade with the allies of the Spartans. The Athenian commander Lamachus tries to stop him, but by the end of the play Lamachus slumps wounded and dejected while Dicaeopolis enjoys a peacetime life of food, wine, and sex.

Knights: This play shows how little Aristophanes was

affected by the prosecution he had incurred for Babylonians. Knights (424 BC; Greek Hippeis) consists of a violent attack on the same demagogue, Cleon, who is depicted as the favourite slave of the stupid and irascible Demos until he is, at last, ousted from his position of influence and authority by Agoracritus, a sausage seller who is even more scoundrelly and impudent than Cleon.

Clouds. This play (423 BC; Greek Nephelai) is an attack on "modern" education and morals as imparted and taught by the radical intellectuals known as the Sophists. The main victim of the play is the leading Athenian thinker and teacher Socrates, who is purposely (and unfairly) given many of the standard characteristics of the Sophists. In the play Socrates is consulted by an old rogue, Strepsiades ("Twisterson"), who wants to evade his debts. The instruction at Socrates' academy, the Phrontisterion ("Thinking Shop"), which consists of making a wrong argument sound right, enables Strepsiades' son to defend the beating of his own father. At the play's end the Phron-

tisterion is burned to the ground,

Wasps. This comedy satirized the litigiousness of the Athenians in the person of the mean and waspish old man Philocleon ("Love-Cleon"), who has a passion for serving on juries. In Wasps (422 BC; Greek Sphēkes) Philocleon's son, Bdelycleon ("Loathe-Cleon"), arranges for his father to hold a "court" at home; but, since the first "case" to be heard is that of the house dog accused of the theft of a cheese, Philocleon is finally cured of his passion for the law courts and instead becomes a boastful and uproarious drunkard. The play's main political target is the exploitation by Cleon of the Athenian system of large subsidized juries.

Peace. This play was staged seven months or so after both Cleon and Brasidas, the two main champions of the war policy on the Athenian and Spartan sides respectively, had been killed in battle and, indeed, only a few weeks before the ratification of the Peace of Nicias (? March 421 BC), which suspended hostilities between Athens and Sparta for six uneasy years. In Peace (421 BC; Greek Eirēnē) the war-weary farmer Trygaeus ("Vintager") flies to heaven on a monstrous dung beetle to find the lost goddess Peace, only to discover that the God of War has buried Peace in a pit. With the help of a chorus of farmers Trygaeus rescues her, and the play ends with a joyful celebration of marriage and fertility.

Birds. This play can be regarded merely as a "comedy of fantasy," but some scholars see Birds (414 BC; Greek Ornithes) as a political satire on the imperialistic dreams that had led the Athenians to undertake their ill-fated expedition of 415 BC to conquer Syracuse in Sicily. Peisthetaerus ("Trusty") is so disgusted with his city's bureaucracy that he persuades the birds to join him in building a new city that will be suspended in between heaven and earth; it is named Nephelokokkygia and is the original Cloudcuckooland. The city is built, and Peisthetaerus and his bird comrades must then fend off the undesirable humans who want to join them in their new Utopia. He and the birds finally even starve the Olympian gods into cooperating with them. Birds is Aristophanes' most fantastical play, but its escapist mood possibly echoes the dramatist's sense of Athens' impending decline.

Lysistrata. This comedy was written not long after the catastrophic defeat of the Athenian expedition to Sicily (413 BC) and not long before the revolt of the Four Hundred in Athens, whereby an oligarchic regime ready to make peace with Sparta was set up (411 BC). Lysistrata (411 BC; Greek Lysistratë) depicts the seizure of the Acropolis and of the treasury of Athens by the city's women who, at Lysistrata's instigation, have, together with all the women of Greece, declared a sex strike until such time as the men will make peace. The women defy their menfolk until the peace is arranged, after which both the Athenian and Spartan wives are reunited with their husbands. The play is a strange mixture of humour, indecency, gravity, and farce.

Women at the Thesmophoria. In Women at the Thesmophoria (411 BC; Greek Thesmophoriazousai) Euripides has discovered that the women of Athens, angered by his constant attacks upon them in his tragedies, mean to Attack on Sophists

Plot of Lysistrata discuss during their coming festival (the Thesmophoria) the question of contriving his death. Euripides tries to persuade the effeminate Agathon, a tragic poet, to plead his cause. Agathon refuses, and Euripides persuades his brother-in-law Mnesilochus to undertake the assignment. Mnesilochus is disguised with great thoroughness as a woman and sent on his mission, but his true sex is discovered and he is at once seized by the women. There follow three scenes in which he tries unsuccessfully to escape; all three involve brilliant parodies of Euripides' tragedies, and all three attempts fail. Finally, Euripides himself arrives and succeeds in rescuing his advocate by promising never again to revile women.

Frogs. This is a literary comedy. In Frogs (405 BC; Greek Batrachoi) Dionysus, the god of drama, is concerned about the poor quality of present-day tragedy in Athens now that his recent favourite, Euripides, is dead. Dionysus disguises himself as the hero Heracles and goes down to Hades to bring Euripides back to the land of the living. As the result, however, of a competition arranged between Euripides and his great predecessor, Aeschylus, Dionysus is won over to the latter's cause and returns to earth with Aeschylus, instead, as the one more likely to

help Athens in its troubles.

Women at the Ecclesia. In Women at the Ecclesia (c. 392 BC; Greek Ekklēsiazousai) the women of Athens dress up as men, take over the Ecclesia (the Athenian democratic assembly), and introduce a communistic system of wealth, sex, and property. It is not one of Aristophanes' more appealing plays.

Wealth. The last of the author's plays to be performed in his lifetime. Wealth (388 BC; Greek Ploutos) is a somewhat moralizing work and does not enhance his reputation-though, as suggested, it may have inaugurated the

Middle Comedy.

Shortly after producing his Wealth, Aristophanes died, leaving two plays (now lost), the Aiolosikon and the Kokolos, which his son staged c. 387 BC; both of them are generally assumed to have been mythological burlesques. (M.Pl./O.T.)

MAJOR WORKS

Aeschylus WORKS: Persai (472 BC; Persians); Hepta epi Thēbais (467 BC; Seven Against Thebes); Hiketides (c. 463 BC; Latin trans., Supplices; Eng. trans., Suppliants); the trilogy known as the Oresteia (458 BC), comprising Agamemnon, Choephoroi (Libation Bearers), and Eumenides, Prometheus desmôtes (date

uncertain, probably late; Prometheus Bound).

TEXTS: The Greek text is available in Denys Page (ed.), Aeschyli septem quae supersunt tragoedias (1972, reprinted 1975), in the Oxford Classical Text series. Herbert Weir Smyth (trans.), Aeschylus, 2 vol. (1922-26, reprinted 1973-83), in the Loeb Classical Library series, presents the original text with an English translation.

RECOMMENDED EDITIONS: Aeschylus, 2 vol. (1953-56, reissued 1967), contains English translations of all the plays and is part of The Complete Greek Tragedies series, ed. by Richmond Lattimore and David Grene. Recent editions of the trilogy are Oresteia, trans. by Hugh Lloyd-Jones, 3 vol. (1979, reissued in 1 vol., 1982); and The Oresteia, trans. by Robert Fagles (1975, reissued 1984).

Sophocles

WORKS: Aias mastigophoros (probably before 441 BC; Ajax); Antigone (c. 442-441 BC); Oidipous Tyrannos (soon after 430 BC; Latin trans., Oedipus Rex; Eng. trans., Oedipus the King); Trachiniai (possibly after 430 BC; Trachinian Women); Elektra (between 418 and 410 BC; Electra); Philoktētēs (409 BC; Philoctetes); Oidipous epi Kolōnō (produced posthumously in 401 BC; Oedipus at Colonus); Ichneutai (sizable fragments; date uncertain; Trackers).

TEXTS: The Greek text is available in A.C. Pearson (ed.). Sophoclis fabulae (1924, reprinted 1975), in the Oxford Classical Text series; and R.D. Dawe (ed.), Sophoclis tragoediae, vol. 1 and 2 (1975-79), part of the Teubner series. Greek text with English translation is presented in R.C. Jebb (ed. and trans.), Sophocles, 7 vol. (1883-96, reprinted from various editions, 1976).

RECOMMENDED EDITIONS: Sophocles, 2 vol. (1954-69), contains translations of all the plays and is part of The Complete Greek Tragedies series, ed. by Richmond Lattimore and David Grene. See also Robert Fagles (trans.), The Three Theban Plays (1982, reissued 1984), which includes Antigone, Oedipus the King, and Oedipus at Colonus.

Alkēstis (438 BC; Alcestis); Mēdeia (431 BC; Medea); WORKS. Hērakleidai (c. 430 BC; Children of Heracles); Hippolytos (428 Herakteladi (c. 45) BC; Chilaren of Herakes, Improvis (426 BC; Hippolytus); Andromachê (c. 426 BC); Hekabê (c. 425 BC; Hecuba); Hiketides (c. 423 BC; Latin trans., Supplices; Eng. trans., Suppliants); Élektra (c. 418 BC; Electra); Hêraklês mainomenos (c. 416 BC; Latin trans., Hercules furens; Eng. trans., Madness of Heracles); Troades (415 BC; Trojan Women); Ion (c. 413 BC); Iphigeneia en Taurois (c. 413 BC; Latin trans., Iphigenia in Tauris; Eng. trans., Iphigenia Among the Taurians); Helenē (412 BC; Helen); Phoinissai (c. 409 BC; Phoenician Women); Orestes (408 BC); Iphigeneia en Aulidi (c. 406 BC; Iphigenia at Aulis); Bakchai (c. 406 BC; Latin trans., Bacchae; Eng. trans., Bacchants); Kyklöps (date unknown; Cyclops); Rhēsos (authorship disputed: date unknown: Rhesus); Hypsipyle (sizable fragments; date uncertain)

TEXTS: The Greek text is available in Euripidis fabulae. ed. by J. Diggle (1981-), a new Oxford Classical Text replacing the 3-vol. text ed. by Gilbert Murray, 1902-09; 2 vol. of the

Diggle work have appeared to 1986.

Diggie work have appeared to 1900.

RECOMMENDED EDITIONS: Euripides, 5 vol. (1955–59), contains English translations of all the plays and is part of The Complete Greek Tragedies series, ed. by Richmond Lattimore and David Grene. All the complete plays excluding Cyclops and Rhesus are found in the Penguin Classics series, trans. by Philip Vellacott, Three Plays (1953, reissued 1974), Medea, and Other Plays (1963), Orestes, and Other Plays (1972), and The Bacchae, and Other Plays, rev. ed. (1972). See also Geoffrey S. Kirk (trans.), The Bacchae (1970, reprinted 1979 as The Bacchae of Euripides).

Aristophane.

WORKS: Babylonioi (426 BC; Babylonians); Acharneis (425 BC; Acharnians); Hippeis (424 BC; Knights); Nephelai (423 BC; BC; Acharmans, Trippes (422 BC; Wasps); Refriet (423 BC; Clouds); Spikkes (422 BC; Wasps); Eirône (421 BC; Peace); Ornithes (414 BC; Birds); Lysistratē (411 BC; Lysistrata; Thes-mophoriazousai (411 BC; Women at the Thesmophoria); Batra-choi (405 BC; Frogs); Ekklesiazousai (c. 392 BC; Women at the

Ecclesia); Ploutos (388 BC; Wealth).

The Greek text is available in Victor Coulon (ed.) TEXTS. and Hilaire Van Daele (trans.), Aristophane, 5 vol. (1923-30), part of the Budé series. Greek text with English translation is presented in Benjamin Bickley Rogers (ed. and trans.), Aristophanous komodiai: The Comedies of Aristophanes, 6 vol. in 7 (1902-16: reissued as part of the Loeb Classical Library series. 3 vol., 1924, reissued 1979-82); and in Alan H. Sommerstein (ed. and trans.), The Comedies of Aristophanes (1980-), five plays in single volumes having appeared to 1986.

RECOMMENDED EDITIONS: All the plays appear in English translation in three separate volumes in the Penguin Classics series, trans. respectively by David Barrett (1964, reprinted

1976), by Alan H. Sommerstein (1973, reprinted 1977), and by David Barrett and Alan H. Sommerstein (1978).

Greek Literature

reek literature has a continuous history extending from the 1st millennium BC to the present day.
From the beginning its writers were Greeks living not only in Greece proper but also in Asia Minor, the Aegean Islands, and Magna Graecia (Sicily and southern Italy). Later, after the conquests of Alexander the Great, Greek became the common language of the eastern Mediterranean lands and then of the Byzantine Empire. Literature in Greek was produced not only over a much wider area but also by those whose mother tongue was not Greek. Even before the Turkish conquest (1453) the area had begun to shrink again, and now it is chiefly confined to the territory of the republic of Greece.

Ancient Greek literature

Of the literature of ancient Greece only a relatively small proportion survives. Yet it remains important, not only because much of it is of supreme quality but also because until the mid-19th century the greater part of the literature of the Western world was produced by writers who were familiar with the Greek tradition, either directly or through the medium of Latin, who were conscious that the forms they used were mostly of Greek invention, and who took for granted in their readers some familiarity with classical literature.

STYLISTIC PERIODS

The history of ancient Greek literature may be divided into three periods: preclassical (to the end of the 6th century BC); classical (5th and 4th centuries BC); and Hellenistic and Greco-Roman (3rd century BC onward).

Preclassical period, to the end of the 6th century BC. The Greeks created poetry before they made use of writing for literary purposes, and from the beginning their poetry was intended to be sung or recited. (The art of writing was little known before the 7th century BC. The script used in Crete and Mycenae [Linear B] is not known to have been employed for other than administrative purposes, and after

the destruction of the Mycenaean cities it was forgotten.) Its subject was myth-part legend, based sometimes on the dim memory of historical events; part folktale; and part primitive religious speculation. But since the myths were not associated with any religious dogma, even though they often treated of gods and heroic mortals, they were not authoritative and could be varied by a poet to express new concents

Thus, at an early stage Greek thought was advanced as poets refashioned their materials; and to this stage of preclassical literature belonged the epics ascribed to Homer. the Iliad and the Odyssey, retelling intermingled history and myth of the Mycenaean Age. These two great poems, standing at the beginning of Greek literature, established most of the literary conventions of the epic poem. The didactic poetry of Hesiod (c. 700 BC) was probably later in composition than Homer's epics and, though different in theme and treatment, continued the epic tradition.

The several types of Greek lyric poetry originated in the preclassical period among the poets of the Aegean Islands and of Ionia on the coast of Asia Minor. Archilochus of Paros, of the 7th century BC, was the earliest Greek poet to employ the forms of elegy (in which the epic verse line alternated with a shorter line) and of personal lyric poetry. His work was very highly rated by the ancient Greeks but survives only in fragments; its forms and metrical patterns-the elegiac couplet and a variety of lyric metres-were taken up by a succession of Ionian poets. At the beginning of the 6th century Alcaeus and Sappho, composing in the Aeolic dialect of Lesbos, produced lyric poetry mostly in the metres named after them (the alcaic and the sapphic), which Horace was later to adapt to Latin poetry. No other poets of ancient Greece entered into so close a personal relationship with the reader as Alcaeus, Sappho, and Archilochus do. They were succeeded by Anacreon of Teos, in Ionia, who, like Archilochus, composed his lyrics in the Ionic dialect. Choral lyric, with musical accompaniment, belonged to the Dorian tradition and its dialect, and its representative poets in the period were Aleman in Sparta and Stesichorus in Sicily.

Both tragedy and comedy had their origins in Greece. "Tragic" choruses are said to have existed in Dorian Greece around 600 BC, and in a rudimentary dramatic form tragedy became part of the most famous of the Dionysian festivals, the Great, or City, Dionysia at Athens, about 534. Comedy, too, originated partly in Dorian Greece and developed in Attica, where it was officially recognized rather later than tragedy. Both were connected with the worship of Dionysus, god of fruitfulness and of wine and ecstasy.

Written codes of law were the earliest form of prose and were appearing by the end of the 7th century, when knowledge of reading and writing was becoming more widespread. No prose writer is known earlier than Pherecydes (c. 550 BC) of Syros, who wrote about the beginnings of the world; but the earliest considerable author was Hecataeus of Miletus, who wrote about both the mythical past and the geography of the Mediterranean and surrounding lands. To Aesop, a semi-historical, semi-mythological character of the mid-6th century, have been attributed the moralizing beast fables copied by later writers.

Classical period, 5th and 4th centuries BC. True tragedy was created by Aeschylus and reached its culmination with Sophocles and Euripides in the second half of the 5th century. Aristophanes, the greatest of the comedic poets. lived on into the 4th century, but the Old Comedy did not survive the fall of Athens in 404. (These four dramatists and their works are treated in detail in GREEK DRAMA-TISTS, THE CLASSICAL.)

The sublime themes of Aeschylean tragedy, in which man stands answerable to the gods and receives awe-inspiring Types of early Greek poetry

insight into their purposes, are exemplified in the three plays of the Oresteia. The tragedy of Sophoeles made a progress toward both dramatic complexity and naturalness while remaining orthodox in its treatment in its treatment in the plane of skeptical enlightenment and doubted the trional picture of the gods. Corresponding development of dramatic realization accompanied the shift of vision: the number of individual actors was raised to three, each capable of

The three stages of dramatic comedy

Importance

of the Museum at

Alexandria

The Old Comedy of Aristophanes was established later than tragedy but preserved more obvious traces of its origin in ritual; for the vigour, wit, and indecency with which it keenly satirized public issues and prominent persons clearly derived from the primitive ribaldry of the Dionysian festival. Aristophanes last comedies show a transition, indicated by the dwindling importance of the chorus, toward the Middle Comedy, of which no plays are extant. This phase was followed toward the beginning of the 3rd century by the New Comedy, introduced by Menander, which turned for its subjects to the private fictional world of ordinary people. Later adaptations of New Comedy in Latin by Plautus and Terence carried the influence of his work on to medieval and modern times.

In the 5th century, Pindar, the greatest of the Greek choral lyrists, stood outside the main lonic-Attic stream and embodied in his splendid odes a vision of the world seen in terms of aristocratic values that were already growing obsolete. Greek prose came to maturity in this period. Earlier writers such as Anaxagoras the philosopher and Protagoras the Sophist used the traditional lonic dialect, as did Herodotus the historian. His successors in history,

Thucydides and Xenophon, wrote in Attic.

The works of Plato and Aristotle, of the 4th century, are the most important of all the products of Greek culture in the intellectual history of the West. They were pre-occupied with ethics, metaphysics, and politics as man's highest study and, in the case of Aristotle, extended the range to include physics, natural history, psychology, and literary criticism. They have formed the basis of Western philosophy and, indeed, they determined, for centuries to come, the development of European thought. (For detailed treatment see ARISTOTELIANISM, ARISTOTLE AND and PLATONISM, PLATO AND.)

This was also a golden age for rhetoric and oratory, first stught by Corax of Syracuse in the 5th century. The study of rhetoric and oratory raised questions of truth and morality in argument, and thus it was of concern to the philosopher as well as to the advocate and the politician and was expounded by teachers, among whom Isocrates was outstanding. The orations of Demosthenes, a statesman of 4th-century Athens and the most famous of Greek orators, are preeminent for force and power.

Hellenistic and Greco-Roman periods. In the huge empire of Alexander the Great, Macedonians and Greeks composed the new governing class; and Greek became the language of administration, a new composite dialect based to some extent on Attic and called the Koine, or common language. Everywhere the traditional city-state was in decline, and the individual was becoming aware of his isolation and seeking consolidation and satisfaction outside corporate society. Artistic creation now came under private patronage, and, except for Athenian comedy, compositions were intended for a small, select audience that admired polish, erudition, and subletty.

An event of great importance for the development of new tendencies was the founding of the Museum, the shrine of the Muses with its enormous library, at Alexandria. The chief librarian was sometimes a poet as well as tutor of the heir apparent. The task of accumulating and preserving knowledge begun by the Sophists and continued by Aristotle and his adherents was for the first time properly endowed. Through the researches of the Alexandrian scholars, texts of ancient authors were preserved.

The Hellenistic period lasted from the end of the 4th to the end of the 1st century Bc. For the next three centuries, until Constantinople became the capital of the Byzantine Empire, Greek writers were conscious of belonging to a world of which Rome was the centre. THE GENRES

Epic narrative. At the beginning of Greek literature stand the two great epics, the *Iliad* and the *Odyssey*. Some features of the poems reach far into the Mycenaen age, perhaps to 1500 sc, but the written works are traditionally ascribed to Home; in something like their present form they probably date to the 8th century. (Homer and the works attributed to him are treated in detail in Homerical Home

The Iliad and the Odyssev

EPICS, THE.) The Iliad and the Odyssey are primary examples of the epic narrative, which in antiquity was a long narrative poem, in an elevated style, celebrating heroic achievement. The Iliad is the tragic story of the wrath of Achilles, son of a goddess and richly endowed with all the qualities that make men admirable. With his readiness to sacrifice all to honour, Achilles embodies the Greek heroic ideal; and the contrast between his superb qualities and his short and troubled life reflects the sense of tragedy always prevalent in Greek thought. Whereas the Iliad is tragedy, the Odyssey is tragicomedy. It is an enriched version of the old folktale of the wanderer's return and of his triumph over those who were usurping his rights and importuning his wife at home. Odysseus too represents a Greek ideal. Though by no means inadequate in battle, he works mainly by craft and guile; and it is by mental superiority that he survives and prevails.

Both poems were based on plots that grip the reader, and the story is told in language that is simple and direct, yet eloquent. The Iliad and the Odyssey, though they are the oldest European poetry, are by no means primitive. They marked the fulfillment rather than the beginning of the literary form to which they belong. They were essentially oral poems, handed down, developed, and added to over a vast period of time, a theme upon which successive nameless poets freely improvised. The world they reflect is full of inconsistencies; weapons belong to both the Bronze and Iron Ages, and objects of the Mycenaean period jostle others from a time five centuries later. Certain mysteries remain: the date of the great poet or poets who gave structure and shape to the two epics; the social function of poems that take several days to recite; and the manner in which these poems came to be recorded in writing probably in the course of the 6th century BC.

In the ancient world the *Iliad* and the *Odyssey* stood in a class apart among epic poems. Of these, there were a large number known later as the epic cycle. They covered the whole story of the wars of Thebes and Troy as well as other famous myths. A number of shorter poems in epic

style, the Homeric Hymns, are of considerable beauty. Didactic poetry was not regarded by the Greeks as a form distinct from epic. Yet the poet Hesiod belonged to an altogether different world from Homer. He lived in Boeotia in central Greece about 700 BC. In his Works and Days he described the ways of peasant life and incidentally described the dreary Boeotian plain afflicted by heat, cold, and the oppression of a "gift-devouring" aristocracy. He believed passionately in a Zeus who cared about right and wrong and in Justice as Zeus's daughter. Hesiod's other surviving poem, the Theogony, attempts a systematic genealogy of the gods and recounts many myths associated with their part in the creation of the universe. Middle Eastern influence is clearly to be seen, especially in some of the cruder speculation about the origin of the universe. By the end of the 6th century the epic tradition was a spent force until its revival in the Hellenistic period, and the few composers of epic narrative left little but their names.

Lyric poetry. Hesiod, unlike Homer, told something of himself, and the same is true of the lync poets. Except for Pindar and Bacchylides at the end of the classical period, only fragments of the works of these poets survive. There had always been lyric poetry in Greece. All the great events of life as well as many occupations had their proper songs, and here too the way was open to advance from the anonymous to the individual poet.

The word "lyric" covers many sorts of poem. On the one hand, poems sung by individuals or chorus to the lyre, or sometimes to the flute, were called melic; elegiacs, in which the epic hexameter, or verse line of six metriDidactic poetry Elegiac

poets

If Archilochus of Paros in fact was writing as early as 700 BC, he was the first of the post-epic poets. The fragments reflect the turbulent life of an embittered adventurer. Scorn both of men and of convention is the emotion that seems uppermost, and Archilochus was possessed of tremendous powers of invective. Of lesser stature than Archilochus were his successors, Semonides (often mistakenly identified with Simonides) of Amorgos and

Hipponax of Ephesus.

Like the iambic writers, the elegiac poets came mostly from the islands and the Ionian regions of Asia Minor. Chief among them were Callinus of Ephesus and Mimnermus of Colophon. On the mainland of Greece, Tyrtaeus roused the spirit of the Spartans in their desperate struggle with the Messenian rebels in the years after 650. His martial poems are perhaps of more historical than literary interest. The same is to some extent true of the poems in elegiac, iambic, and trochaic (the latter a metre basically of four alternately long and short syllables) metres by Solon, an Athenian statesman, who used his poetry as a vehicle for propaganda. Xenophanes (born about 560 BC) rather in the same way used his poems to propagate his revolutionary religious and ethical ideas. The elegiacs attributed to Theognis seem to be poems of various dates suitable for use at drinking parties. Many of them were actually by Theognis himself (about 540 BC). Some give uninhibited expression to his hatred of the lower class rulers who had ousted the aristocracy of Megara; others are love poems to the boy Cyrnus; still others are gnomic commonplaces of Greek wisdom and morality.

About the beginning of the 6th century a new kind of poetry made its appearance in the island of Lesbos. It was composed in the local Aeolic dialect by members of the turbulent and factious aristocracy. Alcaeus (born about 620 BC), absorbed in political feuds and in civil war, expressed with striking directness searing hate and blind exultation. With the same directness and infinite grace, Sappho, a younger contemporary who seems to have enjoyed a freedom unknown to the women of mainland Greece, told of her loves and hates, though little is known of her relations with the girls named in her poems. The surviving works by their successor in personal lyric, Anacreon of Teos, suggest a more convivial amorousness.

Choral lyric was associated with the Dorian parts of the Greek mainland and the settlements in Sicily and south Italy, whereas poetry for solo performance was a product of the Ionian coast and the Aegean Islands. Thus choral song came to be conventionally written in a Doric dialect.

Choral lyric, which had lyre and flute accompaniments. was highly complicated in structure. It did not use traditional lines or stanzas; but the metre was formed afresh for each poem and never used again in exactly the same form, though the metrical units from which the stanzas, or strophes, were built up were drawn from a common stock and the form of the strophe was usually related to the accompanying dance. This elaborate art form was connected mainly with the cult of the gods or, as in the case of Pindar, the celebration of the victors in the great Hellenic games.

The earliest poet of choral lyrics of whose work anything has survived was Alcman of Sparta (about 620 BC). Somewhat later Stesichorus worked in Sicily, and his lyric versions of the great myths marked an important stage in the development of these stories. Simonides of Ceos, in Ionia, was among the most versatile of Greek poets. He was famed for his pathos, but today he is best known for his elegiac epitaphs, especially those on the Greek soldiers who fell in the struggle against Persia.

The supreme poet of choral lyric was Pindar from Thebes in Boeotia (born 518 or possibly 522-died after 446 BC), who is known mainly by his odes in honour of the victors at the great games held at Olympia, Delphi, the Isthmus of Corinth, and Nemea. The last of the lyric poets was Bacchylides (flourished 5th century BC), whose work, though often exquisite, is empty, reflecting the declining significance of myth.

Tragedy. Tragedy may have developed from the dithyramb, the choral cult song of the god Dionysus. Arion of Lesbos, who is said to have worked at Corinth in about 600, is credited with being the first to write serious poetry in this medium. Thespis (6th century BC), possibly combining with dithyrambs something of the Attic ritual of Dionysus of Eleutherae, is credited with having invented tragedy by introducing an actor who conversed with the leader of the chorus. These performances became a regular feature of the great festival of Dionysus at Athens about 534 BC. Aeschylus introduced a second actor, though his drama was still centred in the chorus, to whom, rather than to each other, his actors directed themselves

At the tragic contests at the Dionysia each of three competing poets produced three tragedies and a satyr play, or burlesque, in which there was a chorus of satyrs. Aeschylus, unlike later poets, usually made of his three tragedies a dramatic whole, treating a single story, as in the Oresteia. the only complete trilogy that has survived. His main concern was not dramatic excitement and the portraval of character but rather the presentation of human action in

relation to the overriding purpose of the gods.

His successor was Sophocles, who abandoned for the most part the practice of writing in trilogies, reduced the importance of the chorus, and introduced a third actor. His work too was based on myth, but whereas Aeschylus tried to make more intelligible the working of the divine purpose in its effects on man's life, Sophocles was readier to accept the gods as given and to reveal the values of life as it can be lived within the traditional framework of moral standards. Sophocles' skill in control of dramatic movement and his mastery of speech were devoted to the presentation of the decisive, usually tragic, hours in the lives of men and women at once "heroic" and human. such as Oedipus.

Euripides, last of the three great tragic poets, belonged to a different world. When he came to manhood, traditional beliefs were scrutinized in the light of what was claimed by Sophist philosophers, not always unjustifiably, to be reason; and this was a test to which much of Greek religion was highly vulnerable. The whole structure of society and its values was called into question. This movement of largely destructive criticism was clearly not uncongenial to Euripides. But as a dramatic poet he was bound to draw his material from myths, which, for him, had to a great extent lost their meaning. He adapted them to make room for contemporary problems, which were his real interest. Many of his plays suffer from a certain internal disharmony, yet his sensibilities and his moments of psychological insight bring him far closer than most Greek writers to modern taste. There are studies, wonderfully sympathetic, of wholly unsympathetic actions in the Medea and Hippolytus; a vivid presentation of the beauty and horror of religious ecstasy in the Bacchants; in the Electra, a reduction to absurdity of the values of a myth that justifies matricide; in Helen and Iphigenia Among the Taurians, melodrama with a faint flavour of romance.

Comedy. Like tragedy, comedy arose from a ritual in honour of Dionysus, in this case full of abuse and obscenity connected with averting evil and encouraging fertility. The parabasis, the part of the play in which the chorus broke off the action and commented on topical events and characters, was probably a direct descendant of such revels. The dramatic element may have been derived from the secular Dorian comedy without chorus, said to have arisen at Megara, which was developed at Syracuse by Epicharmus (c. 530-c. 440). Akin to this kind of comedy seems to have been the mime, a short realistic sketch of scenes from everyday life. These were written rather later by Sophron of Syracuse; only fragments have survived but they were important for their influence on Plato's dialogue form and on Hellenistic mime. At Athens, comedy became an official part of the celebrations of Dionysus in 486 BC. The first great comic poet was Cratinus. About 50 years

The tragedies of Aeschylus, Sophocles, and Euripides

odes

Pindar's

later Aristophanes and Eupolis refined somewhat the wild robustness of the older poet. But even so, for boldness of fantasy, for merciless invective, for unabashed indecency, and for freedom of political criticism, there is nothing like the Old Comedy of Aristophanes, whose work alone has survived. Cleon the politician, Socrates the philosopher, Euripides the poet were alike the victims of his masterly unfairness, the first in Knights; the second in Clouds; and the third in Women at the Thesmophoria and Frogs; whereas in Birds the Athenian democracy itself was held up to a kindlier ridicule. Aristophanes survived the fall of Athens in 404, but the Old Comedy had no place in the revived democracy.

The gradual change from Old to Middle Comedy took place in the early years of the 4th century. Of Middle Comedy, no fully developed specimen has survived. It seems to have been distinguished by the disappearance of the chorus and of outspoken political criticism and by the growth of social satire and of parody; Antiphanes and Alexis were the two most distinguished writers. The complicated plots in some of their plays led to the development of the New Comedy at the end of the century, which is best represented by Menander. One complete play, the Dyscolus, and appreciable fragments of others are extant on papyrus. New Comedy was derived in part from Euripidean tragedy; its characteristic plot was a translation into terms of city life of the story of the maiden-wronged by a god-who bears her child in secret, exposes it, and recognizes it years after by means of the trinkets she had put into its cradle.

History. The first great writer of history was Herodotus of Halicarnassus, who was also a geographer and anthropologist. The theme of his history, written in large part for Athenian readers, is the clash between Europe and Asia culminating in the Persian War. The account of the war itself, which occupies roughly the second half of the work, must have been composed by means of laborious inquiry from those whose memories were long enough to recall events that happened when Herodotus was a child or earlier. The whole history, though in places badly put together, is magnificent in its compass and unified by the consciousness of an overriding power keeping the universe and mankind in check.

Thucydides (c. 460-c. 400) was perhaps the first person to apply a first-class mind to a prolonged examination of the nature of political power and the factors by which policies of states are determined. As a member of the board of generals he acquired inside knowledge of the way policy is shaped. After his failure to save Amphipolis in 424, he spent 20 years in exile, which he used as an opportunity for getting at the truth from both sides. The result was a history of the war narrowly military and political but of the most penetrating quality. Thucydides investigated the effect on individuals and nations both of psychological characteristics and of chance. His findings were interpreted through the many speeches given to his characters.

The

and

histories of

Thucydides

Xenophon

Just as Thucydides had linked his work to the point at which Herodotus had stopped, so Xenophon (431-died before 350) began his Hellenica where Thucydides' unfinished history breaks off in 411. He carried his history down to 362. His work was superficial by comparison with that of Thucydides, but he wrote with authority of military affairs and appears at his best in the Anabasis, an account of his participation in the enterprise of the Greek mercenary army, with which the Persian prince Cyrus tried to expel his brother from the throne, and of the adventurous march of the Greeks, after the murder of their leaders by the Persians, from near Babylon to the Black Sea coast. Xenophon also wrote works in praise of Socrates, of whom his understanding was superficial.

No other historical writing of the 4th century has survived except for a substantial papyrus fragment containing a record of events of the years 396-395. Later, history declined to being merely a province of rhetoric.

Rhetoric and oratory. In few societies has the power of

fluent and persuasive speech been more highly valued than it was in Greece, and even in Homer there are speeches that are pieces of finished rhetoric. But it was the rise of democratic forms of government that provided a great incentive to study and instruction in the arts of persuasion. which were equally necessary for political debate in the assembly and for attack and defense in the law courts.

The formal study of rhetoric seems to have originated in Syracuse c. 460 BC with Corax and his pupils Tisias and Gorgias (died c. 376); Gorgias was influential also in Athens. Corax is reputed to have been the first to write a handbook on the art of rhetoric, dealing with such topics as arguments from probability and the parts into which speeches should be divided. Most of the Sophists had pretensions as teachers of the art of speaking, especially Protagoras, who postulated that the weaker of two arguments could by skill be made to prevail over the stronger. and Prodicus of Ceos

Antiphon (c. 480-411), the first professional speech writer, was an influential opponent of democracy. Three speeches of his, all dealing with homicide cases, have been preserved, as have three "tetralogies," sets of two pairs of speeches containing the arguments to be used on both sides in imaginary cases of homicide. In them primitive ideas are expressed concerning bloodguilt and the duty of vengeance. Antiphon's style is bare and rather crudely antithetical. Gorgias from Sicily, who visited Athens in 427, introduced an elaborate balance and symmetry emphasized by rhyme and assonance. Thrasymachus of Chalcedon made a more solid contribution to the evolution of

a periodic and rhythmical style.

Andocides (c. 440-died after 391), an orator who spent much of his life in exile from Athens, wrote three speeches containing vivid narrative; but as an orator he was admittedly amateurish. Lysias (c. 455-died after 380) lived at Athens for many years as a resident alien and supported himself by writing speeches when he lost his wealth. His speeches, some of them written for litigants of humble station, show dexterous adaptation to the character of the speaker, though the most interesting of all is his own attack on Eratosthenes, one of the Thirty Tyrants imposed on Athens by the Spartans in 404 BC.

The 12 extant speeches of Isaeus, who was active in the first half of the 4th century BC, throw light on aspects of of the 4th Athenian law. Isocrates, who was influential in Athens for half a century before his death in 338, perfected a periodic prose style that, through the medium of Latin, was widely accepted as a pattern; and he helped give rhetoric its predominance in the educational system of the ancient world. In his writings, which took the form of speeches but were more like pamphlets, Isocrates shows some insight into the political troubles besetting Greece, with its

endless bickering between cities incapable of cooperation. The greatest of the orators was Demosthenes (384-322), supreme in vehemence and power, though lacking in some of the more delicate shadings of rhetorical skill. His speeches were mainly political, and he is best remembered for his energetic opposition to the rise of Macedonia under its king Philip II, embodied in the three "Philippics." After Demosthenes, oratory faded, together with the political setting to which it owed its preeminence. Two more 4thcentury-BC writers need only be mentioned, Hyperides (c.

390-322) and Lycurgus (c. 390-324). Philosophical prose. Prose as a medium of philosophy was written as early as the 6th century. Practitioners include Thales, Anaximander, Democritus, and Heracleitus. Philosophical prose was the greatest literary achievement of the 4th century. It was influenced by Socrates (who himself wrote nothing) and his characteristic method of teaching by question and answer, which led naturally to the dialogue. Alexamenus of Teos and Antisthenes, both disciples of Socrates, were the first to use it; but the greatest exponent of Socratic dialogue was the Athenian Plato (428/427-348/347). Shortly after Socrates' death in 399 Plato wrote some dialogues, mostly short; to this group of work belong the Apology, Protagoras, and Gorgias. In the decade after 385 he wrote a series of brilliant works. Phaedo, Phaedrus, Symposium, and the Republic. His Socrates is the most carefully drawn character in Greek literature. Subsequent dialogues became more austerely philosophical; Socrates tended increasingly to be a mere spokesman for Plato's thought; and in the last of his works, the Laws, he was replaced by a colourless "stranger."

Origin of the study of rhetoric

Orators century BC

Aristotle

The Aitia

limachus

of Cal-

they had invented, found it too poetical. Plato's pupil Aristotle (384–322) was admired in antiquity for his style; but his surriving works are all of the "esotteric" sort, intended for use in connection with his philosophical and scientific school, the Lyceum. They are without literary grace, and at times they approximate lecture notes. His works on literary subjects, the Rhetoric, and above all, the Poetics, had an immense effect on literary theory after the Renaissance. In the ancient world, Aristotelian doctrine was known mainly through the works of his successor Theophrastus (c. 372–288/287), now lost except for two books on plants and a famous collection of 30 Characters, sketches of human types much imitated by English writers of the 17th century.

With Theophrastus, Attic prose died out for a time. Technical prose in this period was produced in abundance; and rhetoric, a mere literary exercise divorced from political influence, became ornate and flowery in manner.

Late forms of poetry. The creative period of the Hellenistic Age was practically contained within the span of the 3rd century BC. To this period belonged three outstanding poets: Theocritus, Callimachus, and Apollonius of Rhodes. Theocritus (c. 310-250), born at Syracuse, is best known as the inventor of bucolic mime, or pastoral poetry, in which he presented scenes from the lives of shepherds and goatherds in Sicily and southern Italy. He also dramatized scenes from middle-class life; and in his second idyll the character Simaetha, who tries by incantations to recover the love of the man who has deserted her, touches the fringe of tragedy. He also used another Hellenistic form, the epyllion, a short scene of heroic narrative poetry in which heroic stature is often reduced by playful realism and delicate psychology. In his hands the hexameter attained a lyric purity and sweetness unrivaled elsewhere. He was the first of the nature poets, succeeded by Moschus and Bion.

Callimachus (flourished about 260) was a scholar as well as a poet. His most famous work, of which substantial fragments survive, was the Attita, an elegiac poem describing the origins of various rites and customs. It was heavy with learning but diversified by passages of entertaining narrative. His six hymns show immense poetic expertise but no religious feeling, for the gods of Olympus had long since become obsolete. Callimachus also wrote epigrams, and fragments survive of lambi ("lambs"). The form was widely used throughout the 3rd century to denounce the vanities of the world. Sometimes, in a mixture of prose and verse, these pieces had links with satire; and their chief exponents were Bion the Borysthenite, Menippus of Gadara, Cercidas of Megalopolis, and Phoenis of Colophon.

Callimachus avoided epic in favour of the greater intensity possible in shorter works. The last surviving classical Greek epic was written by his successor at Alexandria, Apollonius of Rhodes (born about 295). Apollonius 'account of the voyage of the Argonauts is so full of local legend that the coherence of the poem is lost; but the story of Medea's wild passion for Jason, the leader of the Argonauts, is marked by a new sort of romantic awareness that is fully realized in the episode of Dido's passion for Aeneas in Virgil's Aeneid.

The desire to combine learning with poetry led to the revival of didactic verse. The Phaenomena of Aratus of Soli (c. 315-c. 245) is a versification of a treatise on the stars by Eudoxus of Cnidus (c. 390-c. 340). Chance has preserved the poems of Nicader (probably 2nd century) on the unlikely subjects of cures for bites and antidotes to posions.

The mimes of Herodas (3rd century), short realistic sketches of low life in iambic verse, have affinities with the non-pastoral mimes of Theocritus. They perhaps give a hint as to the character of the literature of popular entertainment, now largely lost. Mime, especially pantomime, was the main entertainment throughout the early Roman Empire.

After the middle of the 3rd century, poetic activity largely died away, though the great period of scholarship at Alexandria and at Pergamum was still to come. The names of a few poets are known: Euphorion (born about 275) of Chalcis and Parthenius (flourished 1st century Bc), the teacher of Virgil. Thereafter Greek poetry practically ceased, apart from a sporadic revival in the 4th century AD. An exception exists in the case of epigrammatic poetry in elegiac couplets, surviving mainly in two compilations, the Planudean and Palatine anthologies.

Late forms of prose. Almost all of the great mass of Hellenistic prose-and later prose, historical, scholarly, and scientific-has perished. Among historians Polybius (c. 200-c. 118 BC), the most outstanding, has survived in a fragmentary condition. Present at Rome when it was succumbing to the first influences of Greek literature, he wrote mainly of events of which he had direct experience. often with great insight; his work covered the period from 264 to 146. Diodorus Siculus' universal history (1st century BC) is important for the sources quoted there. The most considerable of lost historians was Timaeus (c. 356c. 260), whose history of the Greeks in the west down to 264 provided Polybius with his starting point, Later historians were Dionysius of Halicarnassus (flourished about 20 BC); Appian of Alexandria (2nd century AD), who wrote on Rome and its conquests; and Arrian (c. AD 96c. 180) from Bithynia, who is the most valuable source on Alexander the Great.

The most important works of criticism, of which little has survived, were by Dionysius of Halicarnassus and the obscure Longinus. Longinus' treatise On the Sublime (c. AD 40) is exceptional in its penetrating analysis of creative literature. The Bibliotheea attributed to Apollodorus (c. 180 sc) is a handy compendium of mythology.

Scientific work such as the astronomy and geography of Eratosthenes (c. 276-c. 194) of Alexandria is known mainly from later summaries; but much that was written by the mathematicians, especially Euclid (flourished c. 300 Bc) and Archimedes (c. 287-212), has been preserved.

Much survives of the writings of the physician Galen (AD 129-199). His contemporary Sextus Empiricus is an important source for the history of Greek philosophy. The survey of the Mediterranean by Strabo in the time of Augustus preserved much valuable information; and so, in a more limited field, did the description of Greece by Pausanias (2nd century AD). Greek achievement in astronomy and geography was summed up in the work of Ptolemy of Alexandria in the 2nd century AD.

Greek became the language of the large settlement of Jews at Alexandria, and the Septuagint, the Greek version of the Old Testament, was completed by about the end of the 2nd century BC. Much of the Apocrypha was composed in Greek, and the New Testament was written in popular Greek (Koine). Of the early Christian writers in Greek the most notable were Clement of Alexandria (c. An 150-c. 215) and Origen (c. AD 185-c. 254), together with Clement of Rome and Ignatius of Antioch.

The Parallel Lives of famous Greeks and Romans by Plutarch (c. AD 46-c. 119) of Chaeronea in Boeotia was for centuries one of the formative books for educated Europeans. Great figures from an idealized past are presented for the edification of the lesser men of his own day; and the anecdotes with which the Lives abound are of various degrees of credibility. They belong to biography rather than to history, though they are an important source for historians. A number of shorter works on a wide variety of subjects have come down under the Latin title Moralia (Greek Ethica), which show the intellectual tide of Greece on the ebb.

There was much concern over a question that had been argued ever since the days when Athens had ceased to be a free city: to what extent was Attie prose a norm that writers and especially orators were bound to follow? Many had shunned it in favour of a more ornamental Asiatic style. But at the end of the lst century An there was a revival of the Attic dialect. Speeches and essays were written for wide circulation. This revival is known as the Second Sophistic movement, and chief among its writers were Dion Chrysostom (1st century An), Aelius Aristides (2nd century), and Philostratus (early 3rd century). The only writer of consequence, however, was Lucian (c. 120-c. 190). His works are mainly slight and satirical; but

Plutarch's

his gift of humour, even though repetitive, cannot be denied. Lives and Opinions of Eminent Philosophers was a valuable work of the 3rd century by Diogenes Laërtius, a

writer otherwise unknown.

Erotic

romances

Philosophical activity in the early empire was mainly confined to moralizings based on Stoicism, a philosophy advocating a life in harmony with nature and indifference to pleasure and pain. Epictetus (born about AD 55) influenced especially the philosophic Roman emperor Marcus Aurelius (121-180), whose Meditations have taken their place beside works of Christian devotion. Many of Plutarch's Moralia were Platonic, with vaguely mystical tendencies; but Plotinus (c. 205-260/270) was the last major thinker in the classical world, giving new direction to Platonic and Pythagorean mysticism.

The latest creation of the Greek genius was the novel. or erotic romance. It may have originated as early as the 1st century BC; but its roots reach back to such plays of triumphant love as the lost Andromeda of Euripides, to the New Comedy, to Xenophon's daydreams about the education of Cyrus, and to the largely fictitious narratives that were one extreme of what passed for history from the 3rd century BC onward. Of these last, the best known examples are the Alexander romances, a wildly distorted and embroidered version of the exploits of Alexander the Great, which supplied some of the favourite reading of the Middle Ages. Erotic elegy and epigram may have contributed something and so may the lost Milesian Tales of Aristides of Miletus (c. 100 BC), though these last appear to have depended on a pornographic interest that is almost completely absent from the Greek romances. Only fragments survive of the Ninus romance (dealing with the love of Ninus, legendary founder of Nineveh), which was probably of the 1st century BC; but full-length works survive by Chariton (2nd century AD), Heliodorus (3rd century AD), Xenophon (2nd or 3rd century AD) of Ephesus, and Achilles Tatius (2nd century AD). All deal with true lovers separated by innumerable obstacles of human wickedness and natural catastrophe and then finally united. Danhnis and Chloe by Longus (between 2nd and 3rd century AD) stands apart from the others because of its pastoral, rather than quasi-historical, setting. The works of Dictys Cretensis and Dares Phrygius belong to the same period. They claim to give a pre-Homeric account of the Trojan War. The Greek originals are almost wholly lost, but the Latin version was for the Middle Ages the main source for the story of Troy. (D.W.L./Ed.)

Byzantine literature

GENERAL CHARACTERISTICS

Byzantine literature may be broadly defined as the Greek literature of the Middle Ages, whether written in the territory of the Byzantine Empire or outside its borders. By late antiquity many of the classical Greek genres, such as drama and choral lyric poetry, had long been obsolete, and all Greek literature affected to some degree an archaizing language and style, perpetuated by a long-established system of education in which rhetoric was a leading subject. The Greek Church Fathers were the products of this education and shared the literary values of their pagan contemporaries. Consequently the vast and imposing Christian literature of the 3rd to 6th centuries, which established a synthesis of Hellenic and Christian thought, was largely written in a language already far removed from that spoken by all classes in everyday life, and indeed from that of the New Testament. This diglossy-the use of two very different forms of the same language for different purposes-marked Byzantine culture for 1,000 years; but the relations between the high and low forms changed with the centuries. The prestige of the classicizing literary language remained undiminished until the end of the 6th century; only some popular saints' lives and world chronicles escaped its influence. In the ensuing two and a half centuries, when the very existence of the Byzantine Empire was threatened, city life and education declined, and with them the use of classicizing language and style. With the political recovery of the 9th and 10th centuries began a literary revival, in which a conscious attempt

was made to recreate the Hellenic-Christian culture of late antiquity. Simple or popular language was despised; many of the early saints' lives were rewritten in inflated and archaizing language and style. By the 12th century the cultural self-assurance of the Byzantines enabled them to develop new literary genres, including romantic fiction. in which adventure and love are the main motifs, and satire, which occasionally made use of imitations of spoken Greek. The period from the Fourth Crusade (1204) to the capture of Constantinople by the Ottoman Turks (1453) saw both a vigorous revival of narrowly imitative, classicizing literature, as the Byzantines sought to assert their cultural superiority over the militarily and economically more powerful West, and at the same time the beginning of a flourishing literature in an approximation to vernacular Greek. But this vernacular literature was limited to poetic romances, popular devotional writing, and the like. All serious writing continued to make use of the prestigious archaizing language of learned tradition.

Byzantine literature's two sources, classical and Christian, each provided a series of models and references for the Byzantine writer and reader. Often both were referred to side by side: for example, the emperor Alexius Compenus defended his seizure of church property to pay his soldiers by referring to the precedents of Pericles and the biblical king David. Much of Byzantine literature was didactic in tone, and often in content too. And much of it was written for a limited group of educated readers, who could be counted upon to understand every classical or biblical allusion and to appreciate every figure of rhetoric. Some Byzantine genres would not be considered of literary interest today, but instead seem to belong to the domain of technical writing. This is true in particular of the voluminous writings of the Church Fathers, such as Athanasius. Gregory of Nazianzus, Basil, John Chrysostom, Cyril of

Alexandria, and Maximus the Confessor.

PRINCIPAL FORMS OF WRITING

Nonliturgical poetry. Poetry continued to be written in classical metres and style. But the sense of appropriateness of form to content was lost. An example is the transitional work of Nonnus, a 5th-century Egyptianborn Greek who eventually converted to Christianity. His long poem Dionysiaca was composed in Homeric language and metre, but it reads as an extended panegyric on Dionysus rather than as an epic, Nonnus is plausibly credited with a paraphrase, in similar metre and style, of the Gospel According to St. John, thereby fusing classical and Christian traditions. Several short narrative poems in Homeric verse, of mythological content, were composed by contemporaries of Nonnus. Paul the Silentiary in the mid-6th century used the same Homeric form for a long descriptive poem on the Church of the Divine Wisdom (Hagia Sophia) in Constantinople. Many brief occasional poems were written in hexameters or elegiac couplets until the late 6th century. But changes in the phonology of Greek, and perhaps declining educational standards. made these metres difficult to handle. A cleric, George the Pisidian, wrote long narrative poems on the wars of the emperor Heraclius (610-641), as well as a poem on the six days of the creation, in jambic trimeters (12-syllable lines, consisting in principle of three pairs of iambic feet, each of a short syllable followed by a long). His example was followed by Theodosius the Deacon in his epic on the recapture of Crete from the Arabs in the 10th century. This 12-syllable line became the all-purpose metre in the middle and later Byzantine periods and was the vehicle for narrative, epigram, romance, satire, and moral and religious edification. From the 11th century it found a rival in a 15-syllable stressed line, which was used by the monk Symeon the New Theologian in many of his mystical hymns and which became a vehicle for court poetry in the 12th century. It was also used by the metropolitan Constantine Manasses for his world chronicle and by the anonymous redactor of the epic romance of Digenis Akritas. It was in this metre, which followed no classical models, that the early vernacular poems were written, such as the romances of Callimachus and Chrysorrhoe, Belthandros and Chrysantza, the Byzantine Achilleid (the

Relation to classical and Christian literatures

Developments Byzantine hero of which has nothing in common with Homer's Achilles but his name), and the Romance of Belisarius. These are the most significant works of genuine fiction in Byzantine literature. Many of these poems were adaptations or imitations of medieval Western models: examples are Phlorios and Platziaphlora (the Old French Floire et Blancheflor), Imberios and Margarona, and Apollonius of Tyre, each a romantic narrative. The epic genre is represented by a long unpublished poem on the Trojan War, adapted from the Roman de Troie of the 12th-century French poet Benoît de Sainte-Maure. This openness to the Latin West was new. But even when they were based on Western models, Byzantine poems differed in tone and expression from their exemplars. Most of this vernacular poetry cannot be dated more precisely than to the 13th or 14th century.

Much Byzantine poetry is rather unimaginative, longwinded, and tedious. But some poets show a genuine vein of inspiration, for instance, John Geometres (10th century) or John Mauropous (11th century), or remarkable technical brilliance, such as Theodore Prodromus (12th century), or Manuel Philes (14th century). The ability to write passable verse was widespread in literate Byzantine society, and poetry-or versification-was greatly appreciated.

Liturgical poetry. From the earliest times song-and short rhythmic stanzas (troparia) in particular-had formed part of the liturgy of the church. Poems in classical metre and style were composed by Christian writers from Clement of Alexandria and Gregory of Nazianzus to Sophronius of Jerusalem. But the pagan associations of the genre, as well as the difficulties of the metre, made them unacceptable for general liturgical use. In the 6th century elaborate rhythmical poems (kontakia) replaced the simpler troparia. They owed much to Syriac liturgical poetry. In form the kontakion was a series of up to 22 rhythmical stanzas, all constructed on the same accentual pattern and ending with the same short refrain. In content it was a narrative homily on an event of biblical history or an episode in the life of a saint. There was often a marked dramatic element. Rich in imagery, complex in structure, and infinitely variable in rhythm, the new liturgical poetry can be compared with the choral lyric of ancient Greece. The greatest composer of kontakia was Romanos Melodos (Romanos the Melode; early 6th century), a Syrian probably of Jewish origin. In the late 7th century the kontakion was replaced by a longer liturgical poem, the kanon, consisting of eight or nine odes, each of many stanzas and each having a different rhythmic and melodic form. The kanon was a hymn of praise rather than a homily. Its great length encouraged repetition and inflation, and a more ornamental style of singing enhanced the importance of the music at the expense of the words. The most noteworthy composers of kanones were Andrew of Crete, John of Damascus, Theodore Studites, Joseph the Hymnographer, and John Mauropous. No new hymns were added to the liturgy after the 11th century, but kanones continued to be composed as a literary exercise. The original music of kontakia and kanones alike is lost,

Historical works. Conscious as they were of their classical and biblical past, the Byzantines wrote much history. Until the early 7th century a series of historians recounted the events of their own time in classicizing style, with fictitious speeches and set descriptive pieces, in a genre that owed much to the classical Greek historians Thucydides and Polybius. Procopius, Agathias, Peter the Patrician. Menander Protector, and Theophylactus Simocattes each took up where a predecessor left off. Thereafter this vein virtually ran dry for 250 years. The revival of cultural confidence and political power in the late 9th century saw a revival of classicizing history, with an interest in human character-Plutarch was often the model-and the causes of events. Joseph Genesius in the 10th century and the group of historical writers known collectively as the Continuators of Theophanes recorded, not without partiality, the origin and early days of the Macedonian dynasty. From then until the later 14th century there was never a generation without its historian. The most noteworthy historians were Symeon the Logothete and Leo the Deacon in the 10th century; Michael Psellus, Michael Attaleiates, and John Scylitzes in the 11th century; Anna Compena, John Cinnamus, and Nicetas Choniates in the 12th century; George Acropolites and George Pachymeres in the 13th century; and Nicephorus Gregoras and the emperor John Cantacuzenus in the 14th century. The last days of the Byzantine Empire were recounted from very different points of view by George Sphrantzes, the writer known simply as Ducas (who was a member of the former Byzantine imperial house of that name), Laonicus Chalcocondyles, and Michael Critobulus in the second half of the 15th century

World

chronicles

Another kind of interest in the past was satisfied by world chronicles, beginning with the creation or some early biblical event. Often naively theological in their explanation of causes, black-and-white in their depiction of character, and popular in language, they helped the ordinary Byzantine to locate himself in a scheme of world history that was also a history of salvation. The Chronographia of John Malalas in the 6th century and the Paschal Chronicle (Chronicon Paschale) in the 7th century were succeeded by those of Patriarch Nicephorus at the end of the 8th century, Theophanes the Confessor in the early 9th century, and George the Monk in the late 9th century. Such chronicles continued to be written in later centuries, sometimes with critical and literary pretensions, as in the case of John Zonaras, or in vaguely romanticized form in verse, as in the case of Constantine Manasses.

The importance that Byzantine rulers attached to history is attested by the vast historical encyclopaedia compiled on the orders of Constantine VII (913-959) in 53 volumes,

of which only meagre fragments remain. Rhetoric. Though there was no opportunity for political or forensic oratory in the Byzantine world, the taste for rhetoric and the appreciation of well-structured language, choice figures of speech and thought, and skillful delivery remained undiminished in Byzantine society. From the 10th century onward survives a vast body of encomiums, funeral orations, memorial speeches, inaugural lectures, addresses of welcome, celebrations of victory, and miscellaneous panegyrics. This outpouring of polished rhetoric played an important role in the formation and control of public opinion in the limited circles where opinions mattered and occasionally served as a vehicle of genuine political controversy. To this same domain belong the myriad Byzantine letters, often collected and edited by their author or a friend. These letters were not intended to be either private or informative-real information was conveyed orally by the bearer-but they were important in maintaining networks of contact among the elite as well as in providing refined aesthetic pleasure.

Modern Greek literature (after 1453)

POST-BYZANTINE PERIOD

After the Turkish capture of Constantinople in 1453, Greek literary activity continued almost exclusively in those areas of the Greek world under Venetian rule. Thus Cyprus, until its capture by the Turks in 1571, produced a body of literature in the local dialect, including the 15th-century prose chronicle Recital Concerning the Sweet Land of Cyprus by Leóntios Machairás and a collection of translations and imitations in elaborate verse forms of Italian poems by Petrarch and others. Crete, which remained in Venetian hands until 1669, became the centre of the greatest flowering of Greek literature between the fall of Constantinople and the foundation of the modern Greek state. There a number of authors developed the Cretan dialect into a rich and subtle medium of expression. In it were written a number of tragedies and comedies, a single pastoral tragicomedy, and a single, anonymous religious drama, The Sacrifice of Abraham, mostly based on Italian models. The leading playwright was Geórgios Chortátsis. In the first half of the 17th century Vitséntsos Kornáros composed his romance, Erotókritos. These Cretan authors composed their works almost entirely in the 15-syllable iambic verse of the Greek folk song, whose modes of expression influenced them deeply.

In the Ottoman-ruled areas of Greece the folk song, which concisely and unsentimentally conveyed the aspira-

The kontakion

The kanön tions of the Greek people of the time, became practically the sole form of literary expression.

Toward the end of the 18th century, however, a number of intellectuals emerged who, under the influence of European ideas, set about raising the level of Greek education and culture and laying the foundations of an independence movement. The participants in this "Greek Enlightenment" also brought to the fore the language problem, each promoting a different form of the Greek language for use in education. The leading Greek intellectual of the early 19th century was the classical scholar Adamántios Koraïs, who in voluminous writings on Greek language and education, argued for a form of Modern Greek "corrected" according to the ancient rules.

INDEPENDENCE AND AFTER

The Greek

language

problem

Old Athenian School. The Greek state established as a result of the Greek War of Independence (1821-29) consisted only of a small section of the present-day Greek mainland and a few islands. Athens, which became the capital of Greece in 1834, soon came to be the chief cultural centre, gathering together writers from various areas, particularly Constantinople. The Soutsos brothers, Aléxandros and Panayótis, introduced the novel into Greece, but they are best known for their Romantic poetry, which as time went by moved gradually away from the Demotic ("popular"), or commonly spoken, language toward the Katharevusa ("purist") form institutionalized by Koraïs. The work of these writers, which relied greatly on French models, looks back to the War of Independence and the glorious ancient past. Their melancholy sentimentality was not shared by Aléxandros Rízos Rangavis, a verbose but versatile and not inconsiderable craftsman of Katharevusa in lyric and narrative poetry, drama, and the novel. By the 1860s and '70s, however, Athenian poetry was generally of poor quality and was dominated by a sense of despair and longing for death. Prose throughout the period was monopolized by the historical novel. Emmanuel Roidis' novel called I Pápissa Ioánna (1866: Pope Joan) is a hilarious satire on medieval and modern religious practices as well as a pastiche of the historical novel. Pávlos Kalligás, in Thános Vlékas (1855), treated contemporary problems such as brigandage. In Loukis Láras (1879; Eng. trans., Loukis Laras) Dimítrios Vikélas presented a less heroic view of the War of Independence.

Heptanesian School. Meanwhile more interesting developments had been taking place in the Ionian Islands (Heptanesos). During the 1820s two poets from the island of Zacynthus made their name with patriotic poems celebrating the War of Independence. One of these, Andréas Kálvos, who composed his odes in neoclassical form and archaic language, never wrote poetry afterward, while the other, Dhionísios Solomós, went on to become one of the greatest of modern Greek poets. Dealing with the themes of liberty, love, and death, Solomós embodied a profoundly Romantic sensibility in extraordinary fragments of lyrical intensity, which gave a new prestige to the Demotic language. Solomós' followers continued to cultivate the Demotic, particularly Antónios Mátesis, whose historical social drama, O vasilikós (1859; "The Basil Plant"), was the first prose work of any length to be written in the Demotic. Aristotélis Valaoritis continued the Heptanesian tradition with long patriotic poems inspired by the Greek national struggles.

Demoticism and folklorism, 1880-1922. From the 1880s onward the New Athenian School, inspired by the revived interest in folklore as a survival of ancient Greek culture, began to react against the sterile bombast of the Katharevusa versifiers, producing instead a more intimate poetry based on the language, customs, and beliefs of the Greek peasantry, and in particular on Greek folk songs.

The leading ideologist of this "demoticist" movement, which aimed to promote traditional popular culture at the expense of the pseudo-archaic pedantry fashionable in Athens, was Yánnis Psicháris (Jean Psichari), whose book My Journey (1888) was partly a fictionalized account of a journey around the Greek world and partly a belligerent manifesto arguing that the Demotic language should be officially adopted as a matter of national urgency. The demoticist movement inspired poets to enrich the Greek popular tradition with influences from abroad. Chief among these was Kostis Palamás, who dominated the literary scene for several decades with a large output of essays and articles and whose best poetry appeared between 1900 and 1910. In his lyric and epic poems he attempted to synthesize ancient Greek history and mythology with the Byzantine Christian tradition and modern Greek folklore in order to demonstrate the essential unity of Greek culture. Angelos Sikelianós continued this enterprise in effusive and powerful lyric poetry of a profoundly mystical nature.

In prose, the folklore cult fostered development of the short story, written initially in Katharevusa, with Demotic gradually taking over in the 1890s. These stories, and the novels that accompanied them, depicted scenes of traditional rural life, sometimes idealized and sometimes viewed critically by their authors. The pioneer of the Greek short story, Geórgios Vizyenós, combined autobiography with an effective use of psychological analysis and suspense. The most famous and prolific short-story writer, Aléxandros Papadiamándis, produced a wealth of evocations of his native island of Skiáthos imbued with a profound sense of Christian tradition and a compassion for country folk; his novel I fónissa (1903: The Murderess) is a fine study in psychological abnormality. The novel O zitiános (1896; The Beggar), by Andréas Karkavitsas, satirically depicts the economic and cultural deprivation of the rural population. From about 1910 this critical attitude is further reflected in the prose writing of Konstantinos Chatzópoulos and Konstantinos Theotókis Meanwhile Grigórios Xenópoulos wrote novels with an urban setting and devoted considerable effort to drama a medium that received a substantial boost from the demoticist movement.

One major figure defies categorization for it was outside Greece, in Alexandria, that Constantine Cavafy lived and wrote. His finely wrought, epigrammatic poems, with their tragically ironic views of Hellenistic and Byzantine history. contain daring, sensuous glimpses of homosexual love.

Literature from 1922. The Asia Minor Disaster of 1922, in which Greece's expansionist designs on the Ottoman Empire were finally thwarted, brought about a radical change in the orientation of Greek literature. Before committing suicide, Kóstas Kariotákis wrote some bitterly sarcastic poetry conveying the gap between the old ideals and the new reality.

The reaction against the defeatism of 1922 came with the Generation of 1930, a group of writers who began publishing around that date. They reinvigorated Greek literature by discarding the old verse forms in poetry and by producing ambitious novels that were intended to embody the spirit of the times. Both poets and novelists sought to combine European influences with the best of what was Greek. The restrained poetry of George Seferis skillfully married references to ancient mythology with pensive meditation on man's modern situation, while his finely written essays recast the Greek tradition according to his own priorities. Odvsseus Elvtis celebrated the Aegean scenery as an ideal world of sensual enjoyment and moral purity. Each of these poets won the Nobel Prize for Literature, Seferis in 1963 and Elýtis in 1979. Yánnis Ritsos adopted various new modes of writing in his celebration of the Greek partisans in World War II, in long dramatic monologues spoken by characters from Greek mythology, and in laconic poems depicting everyday, but often ironically presented, scenes.

The Generation of 1930 produced some remarkable novels, among them Strátis Myrivílis' I zoí en tafo (1930; Life in the Tomb), a journal of life in the trenches in World War I; Argo (2 vol., 1933 and 1936) by Yórgas Theotokás, about a group of students attempting to find their way through life in the turbulent 1920s; and Eroica (1937) by Kosmás Polítis, about the first encounter of a group of well-to-do schoolboys with love and death.

After World War II prose writing was dominated by novels reflecting the experiences of the Greeks during eight War II and years of war (1941-49). Iánnis Berátis recounted his experiences of 1941 in an unemotional manner in To Platy

Potami (1946; "The Broad River"). In a trilogy of novels entitled Aksyvérnites polities (1960–65; Drifting Cities), Stratis Tsrkas masterfully recreated the atmosphere of the Middle East in World War II. In the short story, Dimitris Chatzis painted rionic portraits of real and fictional characters in his native Ioánnina in the period before and during World War II, exposing their self-interested machinations.

Nevertheless, the most famous novelist of the period, the Cretan Níkos Kazantzákis, was a survivor from an earlier generation. In a series of novels, beginning with Vios ke politía tou Aléxi Zorbá (1946; Zorba the Greek) and continuing with his masterpiece O Christos xanastavronete (1954; Christ Recrucified), he embodied a synthesis of ideas from various philosophies and religions in largerthan-life characters who wrestle with great problems, such as the existence of God and the purpose of human life. Kazantzákis had earlier published his 33,333-line Odísia (1938; Odyssey), an epic poem taking up the story of Odysseus where Homer had left off. Pandelis Prevelákis published a number of philosophical novels set in his native Crete, the most successful being O ilios tou thanátou (1959; The Sun of Death), which shows a boy learning to come to terms with death.

During the 1960s Greek prose writers attempted to explore the historical factors underlying the contemporary social and political situation. In the novel To trio steffici (1962; The Third Wedding) by Köstas Tachtiss, the female narrator tells the story of her life with venomous verve, unwittingly exposing the oppressive nature of the Greek family. Yórgos Ioánnou's part-fictional, part-auto-biographical short prose pieces present a vivid picture of life in Thessaloniki (Salonika) and Athens from the 1930s

No individual poets of the postwar generations tower above the rest; but Tákis Sinópoulos, Miltos Sachodins, and Manólis Anagnostákis, all marked by their wartime experiences of the 1940s, are among those with the greatest reputations.

Biological Growth and Development

lthough the essence of growth is an increase in the size or the amount of an entity, it is useful to distinguish between growth of living things and that of inanimate objects. The growth of inanimate objects, such as the process that occurs during the formation of crystals, is limited in an important way. The crystals can increase in size but are unable to reproduce themselves; living things, on the other hand, not only increase in size but also reproduce themselves. Growth of living things always occurs by an increase in the number or size of the basic units of organisms, cells, and always eventually includes reproduction. To appreciate fully the way in which living things grow and the ways this growth is regulated requires a consideration of the way in which cells increase in size and number.

The word growth is often used synonymously with development, and, indeed, increase in size is a striking feature of development. But development, in this context, may also include changes in the types of cell specialization (differentiation) and extensive movements of cells. Movements of cells and tissues during embryonic development are partially responsible for the form of the body and

This article is concerned with the processes of growth and development of living organisms from the moment that fertilization takes place through the processes of maturation and senescence. (Death in the biological sense and its other aspects are treated in detail in the article DEATH.) This article is divided into the following sections and subsections:

GROWTH

The process of growth

The increases in cell size and number that take place during the life history of an organism are seldom random; rather, they occur according to a plan that eventually determines the size and shape of the individual. Growth may be restricted to special regions of the organism, such as the layers of cells that divide and increase in size near the tip of the plant shoot. Or the cells engaged in growth may be widely distributed throughout the body of the organism, as in the human embryo. In the latter case, the rates of cell division and of the increase in cell size differ in different parts. That the pattern of growth is predetermined and regular in plants and animals can be seen in the forms of adults. In some organisms, however, notably the slime molds (see PROTOPHYTES: Slime molds), no regular pattern of growth occurs, and a formless cytoplasmic mass is the result.

The rate of growth of various components of an organism may have important consequences in its ability to adapt to the environment and hence may play a role in evolution. For instance, an increase in the rate of growth of fleshy parts of the fish fin would provide an opportunity for the fish to adapt more easily to terrestrial locomotory life than could a fish without this modified fin. Without disproportionate growth of the fin-ultimately resulting from random changes in the genetic material (mutations)-the evolution of limbs through natural selection might have been impossible.

TYPES OF GROWTH

In cells. The increase in size and changes in shape of a developing organism depend on the increase in the number and size of cells that make up the individual. Increase in cell number occurs by a precise cellular reproductive mechanism called mitosis. During mitosis the chromosomes bearing the genetic material are reproduced in the nucleus, and then the doubled chromosomes are precisely distributed to the two daughter cells, one of each chromosomal type going to each daughter cell. Each end of the dividing cell receives a complete set of chromosomes before the ends separate. In animal cells this is a pinching off (cytokinesis) of the cell membrane; in plant cells a new cellulose wall forms between the new cells.

During the period of cell life preceding the actual distribution of chromosomes, the mother cell often grows to twice its original size. Hence, a cycle consisting of cell growth and cell division is established. Cell growth-an increase in cytoplasmic mass, chromosome number, and cell surface-is followed by cell division, in which the cytoplasmic mass and chromosomes are distributed to the daughter cells. An increase in cytoplasmic mass does not always occur during cell-division cycles, however. During the early development of an embryo, for example, the original egg cell, usually a very large cell, undergoes repeated series of cell divisions without any intervening growth periods; as a result, the original egg cell divides into thousands of small cells. Only after the embryo can obtain food from its environment does the usual pattern of growth and mitosis occur.

In plants. The fact that most plant cells undergo extensive size increase unaccompanied by cell division is an important distinction between growth in plants and in animals. Daughter cells arising from cell division behind the tip of the plant root or shoot may undergo great increases in volume. This is accomplished through uptake of water by the cells; the water is stored in a central cavity called a vacuole. The intake of water produces a pressure that, in combination with other factors, pushes on the cellulose walls of the plant cells and is responsible for the increase in length and girth of the cells and of the plant. In plants, much of the size increase occurs after cell division and results primarily from an increase in water content of the cells without much increase in dry weight.

The very young developing plant embryo has many cells

distributed throughout its mass that undergo the cycle of growth and cell division. As soon as the positions of the root tip, shoot tip, and embryonic leaves become established, however, the potential for cell division becomes restricted to cells in certain regions called meristems. One meristematic centre lies just below the surface of the growing root; all increases in the number of cells of the primary root occur at this point. Some of the daughter cells remain at the elongating tip and continue to divide. Other daughter cells, which are left behind in the root, undergo the increase in length that enables the new root to push deeper into the soil. The same general plan is evident in the growing shoot of higher plants, in which a restricted meristematic region at the tip is responsible for the formation of the cells of the leaves and stem; cell elongation occurs behind this meristematic centre. The young seedling secondarily develops cells associated with the vascular strands of phloem and xylem-tissues that carry water to the leaves from the soil and sugar from the leaves to the rest of the plant. These cells can divide again, providing new cell material for development of a woody covering and for more elaborate vascular strands. Hence, the growth of higher plants-i.e., those aspects involving both the pattern of stems, leaves, and roots and the increase in bulk-results primarily from cell division at the meristem followed by a secondary increase in size because of water uptake. These activities occur throughout the period of plant growth.

In animals. The growth of animals is more restricted in time than is that of plants, but cell division is more generally distributed throughout the body of the organism. Although the rate of cell division differs in different regions, the capacity for cell division is widely distributed in the developing embryo. Increase in size is rapid during the embryonic period, continues at a reduced rate in juveniles. and thereafter is absent. Cell division and size increase continue, however, even after increase in total body size no longer occurs. Because these events are balanced by cell death, post-juvenile increase in cell number is primarily a replacement phenomenon. Height increase in mammals is limited by cessation of cell division and bone deposition in the long bones. The long juvenile period of growth in humans is unusual, most higher animals attaining mature size soon after the end of embryonic development. Some organ systems undergo little cell division and growth after birth; for instance, all of the germ cells (precursors of egg cells) of the female are formed by the time of birth. Similarly, all of the nerve cells of the brain are formed by the end of the embryonic period. Further increase in the size of the nervous system occurs by outgrowth of nerve fibres and deposition of a fatty insulation material along them. Although the greatest increase in size of nerve cells occurs, as in plant cells, after the cessation of cell division, the nerve fibre outgrowth in animals represents a true increase in the amount of cytoplasm and cell surface and not just an uptake of water.

Some organs retain the potential for growth and cell division throughout the life-span of the animal. The liver, for example, continues to form new cells to replace senescent and dving ones. Although cell division and growth occur throughout the liver, other organs have a special population of cells, called stem cells, that retain the capacity for cell division. The cells that produce the circulating red cells of mammalian blood are found only in the marrow of the long bones. They form a permanent population of dividing cells, replacing the red cells that continuously die and disappear from the circulation.

The rates of both growth and cell division can vary widely in different body parts. This differential increase in size is a prime factor in defining the shape of an organism.

NORMAL AND ABNORMAL GROWTH

Tumours. When growth is not properly regulated, anomalies and tumours may result. If the increase in the number of liver cells is abnormal, for example, tumours

The role of water in plant-cell growth

Features associated with tumour growth

Compen-

the kidney

satory growth in of the liver, or hepatomas, may result. In fact, one feature of malignant tumours, or cancers, is the absence of the usual growth patterns and rates. The cells of malignant tumours, in addition to having abnormal growth rates, have altered adhesive properties, which enable them to detach easily from the tumour; in this way the cells may spread to other parts of the body (metastasize) and grow in unusual locations. It is the growth of tumours in places other than the organ of origin that usually causes the death of an organism. Tumours may vary widely in their growth rates. They may grow very rapidly or so slowly that the rate approaches that of normal cell division in adult tissues. Tumours are not only characterized by an increase in the rate of cell division but also by abnormal patterns of growth. The new cells formed in the tumour are not organized and incorporated into the structure of the organ and may form large nodules. These abnormal growths may present no medical problems (e.g., moles) or may cause disastrous effects, as is the case of the pressure on the brain caused by a tumorous mass of the meningeal covering of the brain. (For additional information about abnormal growth, see below Aberrations of growth: biological information.)

Regeneration. Not all abnormal growths are tumours. If a tree is partially burned, cells below the bark produce a new covering for the exposed vascular strands. Growth may not be normal, and an obvious scar or growth of the new bark is apparent. Similarly, if the skin of a mammal is severely injured, the repair, although abnormal and imperfect, causes the organism no physiological difficulty. Many organisms possess the ability to regrow, or regenerate, with varying degrees of perfection, parts of the body that are lost or injured. Salamanders possess remarkable powers of regeneration, being able to form new eyes or a new limb if the original is lost. Lizards can regenerate a new tail; even humans can regenerate parts of the liver. The reasons for the differences in regenerative powers in different animals remain a fascinating mystery of great practical importance. When regeneration does occur, some specialized cells usually lose their specialized characteristics and enter a period of an increased rate of cell division; subsequently, the new cells respecialize into the tissues of the original body part. Plants whose tops are lost as in pruning can also sometimes form new meristematic centres from dormant tissues and produce new shoots, (For additional information see below Biological regeneration.) Compensatory growth. Many organs of animals occur

in pairs, and if one is lost the remaining member increases in size, as if responding to the demands of increased use. If one of the two kidneys of a human is removed, for example, the other increases in size. This is called a compensatory reaction and may occur either by some increase in cell size (hypertrophy), by an increase in the rate of cell division (hyperplasia), or both. Although an increase in cell number is primarily responsible for the compensatory reaction of the kidney, the number of individual filtration units (glomeruli) does not increase. Hence, cell division increases the size of glomeruli but not the total number. Some of the most striking examples of increases in cell size in animals take place during stimulation of endocrine organs, which secrete regulatory substances called hormones; when the thyroid gland is stimulated, for example, the individual cells of the gland may increase dramatically in size

Factors that regulate growth

ENVIRONMENTAL FACTORS

Temperature. The environment in which an organism lives plays an important role in modifying the rate and extent of growth. Environmental factors may be either physical (e.g., temperature, radiant energy, and atmospheric pressure) or chemical. Organisms and the cells of which they are composed are extremely sensitive to temperature changes; as the temperature decreases, the biochemical reactions necessary for life occur more slowly. A lowering of the temperature by 10° C (18° F) slows metabolism at least twofold and often more.

The width of trees increases partly by cell division and

enlargement of secondary meristematic tissue below the bark. During the cold of winter, cell division and enlargement may cease completely; but during the spring renewed growth occurs. This intermittent growth is influenced by temperature, light, and water. The amount of growth may decrease considerably if the spring is cold, if day length is changed by obstructions blocking the sunlight, or if a drought occurs. In fact, the width of the growth rings visible on the surface of the cut tree trunk provides a partial history of climatic conditions, the spacing of the growth rings of different size having been correlated with known periods of drought and cold to provide reliable archaeological dating of various structures, as in the timbers used in Indian pueblos in the southwestern United States.

Temperature also affects both warm- and cold-blooded animals. Many warm-blooded (e.g., bears) and coldblooded (e.g., frogs) vertebrates cease growing during the Dormancy cold winter and simply enter an inactive or dormant state. which is characterized by a very low rate of metabolism. In animals that do not become dormant, increased demands for food consumption occur during celd periods to provide energy to maintain body temperature: this utilization of food energy may limit the energy available for size

increase if food is in short supply. Pressure. Because atmospheric pressure is relatively constant except in the mountains, it probably is of little importance in growth regulation. Increases in pressure in the ocean's depths may be significant, however, since it is known that increases in hydrostatic pressure interfere with cell division. Tissues of deep-sea fishes must have become adapted to such pressure effects, which have been little studied thus far. Movements of the terrestrial atmosphere-winds-may affect growth patterns in trees and shrubs, as is evident in the exotic shapes of certain conifers that grow along coastlines exposed to strong pre-

vailing winds

Light. Of all the physical factors, light plays the best understood and most dramatic role. Many of the effects of light on plant growth are obvious and direct. Light energy is the driving force for photosynthesis, the series of chemical reactions in green plants in which carbon dioxide and water form carbohydrates and upon which all life ultimately depends. Insufficient light causes death or retardation of growth in green plants. But light also has indirect effects of great importance. Green plants possess small amounts of a pigment called phytochrome that can exist in two forms. One form absorbs red light (660 millimicrons, or mu; 1 mu = 3.937×10^{-8} inch). When plants containing this pigment absorb red light, the pigment is converted to another form, which absorbs far-red light (730 mµ); the latter form can be converted back again to the original red absorbing form. These conversions have dramatic consequences; for example, red light inhibits stem elongation and lateral root formation but stimulates leaf expansion, chloroplast development, red flower coloration, and spore germination. Cycles of red and far-red

light also can affect flower formation. The effects of light on animals, although less obvious, may be important, as, for example, the effect of light on growth of the reproductive system of some animals. Increase in day length, hence in the amount of light, seems to initiate growth and development of the sex organs (gonads) in some birds during the spring. Curiously, the eyes are not the receptors for the light signal that activates the endocrine system to initiate growth of gonads; rather, cells deep in the brain are sensitive to the small amounts of light that pass directly through the thin skull of the bird. Most animals show cyclic activity, or rhythms, in various important physical (e.g., movement) and chemical (e.g., respiration) events that are essential to the individual. These rhythms are often regulated by short exposure to

Chemical factors. Chemical factors of importance in the environment include the gases in the atmosphere and the water, mineral, and nutritional content of food. Plants require carbon dioxide, water, and sunlight for photosynthesis: drought slows plant growth and may even kill the plant. The effects of atmospheric contaminants-e.g., oxides of nitrogen, hydrocarbons, and carbon monoxide-

Indirect effects of light on plants

are known to have deleterious effects on the growth and reproduction of both plants and animals.

Plants and animals require minerals and small amounts of elements such as zine, magnesium, and boron. Nitrogen and phosphorus are provided to plants as nitrates and phosphates in the soil. Inadequate quantities of any nutritional factor in the soil of result in poor plant growth and poor crop yields. Animals require oxygen, water, and elements from the environment. Because they are unable to synthesize sugars from carbon dioxide, animals must acquire these nutrients through the diet, either directly, by the consumption of other animals that in turn have utilized plants as food. If the quality or quantity of this food is poor, either growth is retarded or death occurs (see NURRIDIS).

Vitamins in diet Vitamins, a class of compounds with a variety of chemical structures, are needed by animals in small amounts. Animals cannot synthesize all vitamins they require; those that cannot be synthesized must therefore be acquired in the diet, either from plants or from other animals that can synthesize the vitamin. Because certain vitamins are necessary in certain important metabolic reactions, vitamin deficiency during growth may have a variety of effects—stunting, malformation, disease, or death (see BIOCHEMI-CAL COMPONENTS or PORGANISM: Yitamins).

INTERNAL FACTORS

The organism is dependent on the environment for the raw materials for growth, but growth is also regulated internally. Because the size and form of plants and animals are under genetic control, events such as the rate and site of cell division and the extent of cell enlargement can be affected by mutations. It is not yet known, however, precisely how these factors, which are the ultimate determinants of growth, are controlled in individual cells.

One very important class of intrinsic growth regulators is that of the hormones. The principal plant hormone, auxin, is produced in the leaves: it moves by precise mechanisms, as yet poorly understood, to the other parts of the plant, controlling such processes as elongation of plant cells. Auxin somehow changes the characteristics of the rigid cell wall of the plant cell so that it becomes more flexible; the internal pressure within the cell then forces it to become larger. Other plant hormones may also play a role in the process; hormones such as cytokinins and gibberellins influence the rate of cell division in the meristems. Some dwarf plants can be stimulated to grow to normal size simply by applying gibberellin.

Hormones also play a decisive role in animal growth. One hormone from the pituitary gland at the base of the brain is called growth hormone because of its extensive and widespread effects on growth. A deficiency of growth hormone in pre-adolescents results in dwarfsm, and over-supply of the hormone foften caused by a tumour) results in gigantism. If an excess of growth hormone is produced after the long bones can no longer grow—i.e., post-adolescence—a disease called acromegally, which is characterized by increases in the size of the hands and feet and broadening of facial features, results. A deficiency of thyroid hormone in children also causes growth retardation.

The sex hormones secreted from the pituitary gland interact in a complex way to regulate the growth of the gonads. The gonads in turn produce estrogen and progesterone in females and testosterone in males; these hormones control the development of human secondary sexual characteristics—body hair, enlargement of mammary glands in females, and gowth of the vocal cords in males. Although the growth hormones and sex hormones play a vital role in growth, the exact mechanism by which they function has not been established with certainty (see BIOCHEMICAL COMPONENTS OF ORGANISMS; Hormones).

In addition to having the ability to synthesize the factors that regulate growth, plants and animals evidently possess exquisite mechanisms for integrating and regulating the production of hormones; i.e., the appropriate amounts of the right hormones are produced at the right time and the right place for normal growth.

Although many plants, including trees, grow throughout their lives, growth of parts of the organism is not perpetual; e.g., leaves of a given species attain a specific size and can grow no larger. In animals, growth stops entirely, except for replacement, after the juvenile period. The limits for both total body size and organ size are probably established by genetic mechanisms. The factors involved in limiting the growth of an organism are not yet definitely known, but evidence indicates that the liver releases into the bloodstream protein molecules that can limit growth of the organ. Thus, one theoretical view is that an organ may produce substances that serve to limit its own growth, thereby establishing a feedback mechanism, A protein called nerve-growth factor is important for the growth of some parts of the mammalian nervous system. If too much of the nerve-growth factor is present, growth of sympathetic nerve fibres is extensive and aberrant. If the nerve-growth factor is eliminated from the body-by injection of an antibody against the factor-the sympathetic nerves wither and disappear. Other subtle growth regulatory substances specific for various organ systems may eventually be discovered.

The dynamics of growth

MEASUREMENT OF GROWTH

The mathematical analysis of the rate of growth has been a subject of interest for many years. It is based on the rule of cell division: one cell gives rise to two daughter cells. Hence, the theoretical increase in cell number would be a geometric series, in which one cell produces two cells, then four, eight, 16, and so on. In reality, however, the rate of growth is not constant but declines after a period of time, usually because of influences in the environment or because of inherent genetic limitations. Thus the curve showing the growth of cell populations and of organisms is usually S-shaped, or sigmoid, when growth is plotted against time on a graph (see Figure 1). The increase in

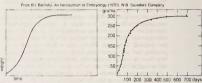

Figure 1: Sigmoid growth curves.
(Left) Ideal sigmoid growth curve. (Right) An actual postnatal growth curve of the white rat.

cell number resulting from cell division accounts for the rising part of the curve; the rate of cell division decreases at the plateau in the curve. The S-shaped growth curve is generally applicable to the growth of organisms. If growth is plotted against time on a logarithmic scale, the early intense growth (called log growth) in the rising phase of the growth curve falls on a straight line.

The rate of growth may be defined by the differential equation $v = \partial W/\partial t (I/W)$, in which v is the growth rate and W is the weight at any given time, t. The solution of this equation provides a value for relative increase—the increase in weight related to the initial mass of the growing substance. The animal that most closely approaches a constant rate of growth is an insect larva. In most animals the rate of growth is an insect larva. In most animals the rate of growth declines as the organism becomes larger and older.

ation of se—the e grow-

Rate of

Although the S-shaped growth curve describes with fair accuracy the growth of populations of single cells, such as bacteria or cells of higher organisms in tissue culture—the growth in a sterile nutrient environment of cells of tissues from organisms—the growth rates of different parts of whole organisms vary. The relationship of the growth of one part of an organism to that in another part is called allometry. An equation expressing the fundamental relationship of allometric growth is $y = bx^{\epsilon}$ in which y is the size of one organ: x is the size of another; b is a constant; and k is known as the growth ratio. Although such mathematical tools have allowed a very thorough

Limits of

description of the differential growth of different parts of an organism, they have unfortunately not provided insight into the physical and chemical control of the growth rate.

inhibition

of growth

Even though the chemical, physical, and genetic bases of growth are elusive, much has been learned about the process by growing tissues in a sterile nutrient environment. Even if the source of the tissue is an organ that has completely stopped growing, such as the nervous system of an animal or the phloem of a plant, the cells will begin to grow again in culture, often at a logarithmic rate of increase. It may therefore be concluded that the organism as a whole places constraints upon the ability of individual cells to reproduce and that, when these constraints are removed, the growth potential of the cells is no longer restrained. Even in tissue culture, however, the rate of cell growth eventually slows, hence the sigmoid-shaped growth curve. During the rapid growth phase of cells in tissue culture, they usually lose the ability to carry out the specialized function characteristic of their organ of origin; for example, if cartilage cells divide rapidly, they no longer synthesize cartilaginous matrix. This phenomenon of apparent despecialization has been a topic of great theoretical interest: are rapid growth and specialization mutually exclusive activities? Evidence shows that some types of specialized cells may be maintained in tissue culture for very long periods of time and still retain the ability to carry out specialized biosyntheses, so that the apparent loss of specialized function in tissue culture cells may not fundamentally result from a mutual exclusivity of growth and differentiation.

When the growth of tissue-culture cells begins to slow. one factor responsible is exhaustion of critical components from the medium. But even if the medium is frequently replaced, when the bottom of the culture dish becomes densely packed with a layer of cells, the growth rate drops-a phenomenon called contact inhibition of growth. It is believed that cells so close that they are always touching provide a signal that retards the rate of cell division. Apparently identical cells in tissue culture also show great variation in growth rate. Some cells from the skin, for instance, when placed in culture, may divide every eight hours; other similar cells may divide only every 36 hours. The growth of cells in a controlled environment such as tissue culture offers many possibilities for studying the fundamental mechanisms controlling cell growth and, consequently, the growth of organisms and populations.

Aberrations of growth: biological malformation

The processes of development are regulated in such a way that few malformed organisms are found. Those that do appear may, when properly studied, shed light on normal development. The science of teratology-a branch of morphology or embryology-is concerned with the study of these structural deviations from the normal, whether in animals or plants.

In general, abnormalities can be traced to deviations from the normal course of development, often in very early embryonic stages. Such deviations may be caused by abnormal (mutant) genes, by environmental conditions, by infection, by drugs, and, perhaps most frequently, by interactions between these sets of causes. A general interpretation has been that one factor in many cases is reduction of the rate of development, the kind and degree of deformity depending upon the stage at which the retardation occurs. This interpretation is supported by the results of descriptive studies of anomalies, and especially (L.C.D.) by evidence from experimental teratology.

PLANT MALFORMATIONS

Monstrosities, freaks, and other malformations have interested botanists for many years. There are numerous categories of such growth abnormalities in plants, and these are often related only loosely or not at all to one another.

Exaggerated growth. Sometimes divergence from the normal represents merely a quantitative change, which is

evidenced by a harmonious but exaggerated manifestation of the normal developmental processes. This is well illustrated in the so-called bakanae, or foolish seedling disease, of rice. The bakanae disease is caused by the fungus Gibberella fujikuroi. Diseased plants are often conspicuous in a field because of their extreme height and pale spindly appearance. This exaggerated growth response was found to be due to specific substances, known as gibberellins which were produced by the fungus. Evidence is now available to indicate that gibberellins, also produced by higher plant species, participate directly as an essential growth-regulating system in all higher plant species. The gibberellins of either fungal or higher plant origin stimulate the normal development of certain genetic dwarfs of maize and peas, which cannot themselves produce the gibberellins in amounts sufficient for their normal

development. A common deformity of tobacco, called frenching, occurs in most tobacco-growing regions of the world. The advanced state of this condition is characterized by a cessation of terminal bud and stem growth. When dominance of the stem tips is lost, the buds in the axils of the leaves develop, and unusually large numbers of leaves (as many as 300) appear on a plant. The leaves are characteristically sword- or string-shaped because of the failure of the leafblades to develop. Such plants have the apperance of a rosette. Although the cause of frenching has not yet been unequivocally established, it is thought to be due to a toxic substance produced by the nonpathogenic soil bacterium Bacillus cereus.

Alteration of floral parts. Under the stimulus of pathogenic organisms of the most diverse kinds, the senals. petals, stamens, or pistils of a flower may be transformed into structures that are very different in appearance from those found normally. Certain viruses can cause enlargement of the leaflike flower parts (sepals) surrounding the base of a blossom in plants of the nightshade family. The tomato big-bud virus appears to affect the sepals of the tomato flower rather specifically. These structures enlarge greatly under the influence of the virus and fuse to form huge bladderlike structures that may be 10 times or more the normal size. In the Madagascar periwinkle (Vinca rosea), however, viruses of this type bring about a green colouring in the petals, stamens, and styles; normally the petals are pink and the stamens and styles whitish. There is in this instance a retrograde development of floral parts into foliage leaves. (Findings such as these are of interest to the morphologist because they support the contention that the flower should be regarded as a modified leafy branch.)

Translocation of organs. Plant organs may arise in unusual places as a result of the infection by certain types of pathogenic agents. The carrot-yellows virus, for example, stimulates production of aerial tubers in the axils of the leaves of potato plants. Large numbers of adventitious roots (arising in abnormal places) appear on the stems of tomato plants infected with the bacteria Pseudomonas solanacearum and Agrobacterium tumefaciens as well as the Fusarium wilt fungus and the cranberry false blossom

An extreme example of adventitious shoot formation is found in Begonia phyllomaniaca after shock. In this instance, small plantlets develop spontaneously in incredible numbers from the superficial cell layers of the leaf blades, petioles, and stems. The adventitious shoots do not arise from preformed buds but develop from cells at the base of hairs and especially from certain glands present in great numbers in young stems and leaves of this species. Although these plantlets develop a vascular system of their own, the vast majority never succeed in connecting that system with the vascular system of the host. They must therefore be regarded not as branches but rather as independent organisms.

Witches'-brooms. Witches'-brooms, or hexenbesens, are closely grouped, many-branched structures commonly found on a number of species of trees and shrubs and caused by certain fungi. Witches'-brooms live a more or less independent existence, despite the fact that they are derived from the tissues of the host. In accordance with their independence, the witches'-brooms tend to break

Effect gibberellins

independence of abnormal growths

away from the normal correlations of the parent plant. Instead of branching out horizontally, the brooms stand as more or less erect clusters of branches. Witches'-brooms do not as a rule flower, and the vegetative buds may open several weeks earlier in the spring than do those present on healthy branches, indicating further the independence of these structures from normal controls.

Similar structures occur in certain plant species after virus infection. These appear to result from the excessive stimulation and development of secondary shoots. The witches'-broom virus in potatoes, for example, causes the infected plant to produce numerous buds on the aboveground stems of potato plants. Long, slender stolons resembling aerial roots that are covered with hairs develop

from these adventitious buds. Fasciation. This condition is best placed in that category of teratological abnormalities known as monstrosities. Fasciation is a term that has been used to describe a series of abnormal growth phenomena resulting from many different causes, all of which result in flattening of the main axis of the plant. Although a ribbonlike expansion of the stem is often the most striking feature of this condition, all parts of the plant may be affected. As fasciation develops, the growing point of the plant becomes broader; the unregulated tissue growth results in significant increases in the weight and volume of the plant. The apical growing point becomes linear and comblike in some instances or develops numerous growing points, producing a witches'broom effect. In still other instances, the growing points may be coiled and resemble a ram's horn, or they may be fused and highly distorted into a grotesque tangle of coils. Fasciations found in plants such as the common cockscomb (Celosia argentea cristata) and in cacti are highly prized by gardeners.

There seems little doubt that nutritional changes due to disturbances in the growth-hormone relationships in a plant play an important role in fasciation. It has been suggested that maldistribution of growth hormones in the plant is also a cause of these abnormalities. (ACBr)

ANIMAL MALFORMATIONS

Among the newborn young and embryos of man and most other species of animals are found occasional individuals who are malformed in whole or in part. The most grossly abnormal of these have been referred to from ancient times as monsters, probably because the birth of one was thought to signify something monstrous or portentous; the less severely malformed are usually known as abnormali-

ties or anomalies.

The origin

of malfor-

mations

Monsters have been regarded by primitive peoples as of supernatural origin. The birth of a malformed individual was often attributed, before the rise of modern science, to intercourse between human beings and devils or animals. The mythical beings that appear in the folklore of many peoples-races of dwarfs and giants, of sirens, mermaids, and men with a single median eye (cyclops) or leg (skiapods)-were probably suggested by observations of malformed humans. Giants and dwarfs were often classed as monsters, probably because of the prominent places they occupied in mythology.

The objective study of malformations began with the English physiologist William Harvey (1651), who correctly attributed them to deviations from the normal course of embryonic development. Systematic scientific study, however, had to await the pioneer work of the French anatomists Étienne and Isidore Geoffroy Saint-Hilaire. Their Traité de Teratologie (1836), which laid the basis for the science of teratology, still remains a valuable source of information. Recent improvements in understanding have come from the application of experimental analytical methods and from increased knowledge of the mechanisms of inheritance-e.g., from genetics.

In man certain gross defects in babies at birth have been shown to be associated with effects acting through the mother in early pregnancy: gross defects of eyes and ears caused by infection of the mother with rubella (German measles); and microcephalic idiocy with diagnostic use of X ray on the mother. The latter observations have been confirmed by animal experimentation. It has been established that higher rates of congenital malformations occur in areas of higher natural radioactivity. The effect may be induced by fallout from atomic explosions.

The teratogenic action of many drugs has been tragically dramatized. The appearance of an alarming number of deformed, basically limbless infants, especially in Germany, in the late 1950s and early 1960s, was traced to the ingestion by pregnant women of the sedative thalidomide (known under many trade names). This drug adversely influences the developing fetus; it appears to interfere with development only in the first seven weeks of pregnancy. Hallucinogenic drugs, such as LSD (lysergic acid diethylamide), are suspected of damaging chromosomes, and their use could result in defective offspring.

According to form, two main classes of malformations may be recognized: those with defective or excessive growth in a single body, and those with partial or complete doubling of the body on one of its axes.

Repetition or deficiency of parts. Somatic characters. Repetition or deficiency of single parts, such as fingers or toes (polydactyly, hypodactyly [ectrodactyly], brachydactyly), is a frequent anomaly in man and other mammals. In many analyzed cases it has been shown to result from the inheritance of an abnormal gene that produces a localized disturbance of a growth process in the embryo. In the rabbit a recessive gene for brachydactyly (short digits) causes a localized breakdown of circulation in the developing limb bud of the embryo, followed by necrosis (tissue death) and healing,

Absence or abnormality of whole limbs is less common and includes, besides clubfoot, the so-called congenital amputations once thought to be caused by the strangulation of a limb by a fold of embryonic membrane (amnion). It is probable that internal abnormalities of the bone are more frequent causes of such amputations than are strangulations. Cases are recorded of human identical twins in which both members have the same type of limb abnormality, suggesting a hereditary predisposition to this type of malformation. Besides malformed individuals with rudimentary limbs (phocomelus; having "seallike limbs"), others have incomplete or underdeveloped extremities (hemimelus, micromelus, ectromelus).

A rare type of malformation, but one that has always attracted special interest, occurs when the lower extremities are more or less united, as in the mythical figures of sirens or mermaids. Such sirenoid individuals may have a single foot (uromelus), or limbs fused throughout their length with no separate feet (sirenomelus or symmelus).

Absence of the brain at birth (anencephaly); an abnormally small brain and head (microcephaly); and enlargement of the brain and head, sometimes to prodigious dimensions due to dilation of the ventricles by fluid (hydrocephaly), are frequent congenital defects in man. In some cases they have been traced to defective genes, although they may also arise from accidental or traumatic processes during embryonic development. Occasionally, malformed persons are found in which a part of the brain protrudes through the cranium as an encephalocoele. An extreme variant of this type is pseudencephaly, in which the whole brain is everted and rests upon the top of the cranium like a wig.

Cyclopian malformations with a single median eye occur rarely in man and other animals. More frequent anomalies are anophthalmia (absence of eves) and microphthalmia (abnormally small eyes), both occasionally the result of abnormal heredity. Defective closure of lines of junction in the embryo produces malformations such as cleft palate, in which the ventral laminae of the palate have failed to fuse, and harelip, in which the median nasal and maxillary processes fail to unite. A frequent abnormality in human infants is spina bifida, in which the spine fails to close over and a gap is left in the vertebral column. These conditions are inherited, albeit somewhat irregularly, in man.

Sexual anomalies. In man and other vertebrates, male and female individuals usually have distinctive characters in addition to the primary one of producing either sperm or eggs. Individuals with both male and female functions are known as hermaphrodites. While this is the normal condition in some lower animals and in many flowering Defects of the brain and head of man

plants, it is so rare in mammals as to be regarded as anomalous. Individuals with mixtures of male and female characters (usually sterile) are known as intersexes. In man there occur two rare conditions that, according to recent evidence, represent partial sex reversal. Individuals with Klinefelter's syndrome are apparent males who produce no sperm. Many cases have been shown to have two X-chromosomes (the usual state determining femaleness) with an additional Y-chromosome (which carries genetic factors for maleness). Individuals with Turner's syndrome are apparent females without functional ovaries. The cases analyzed have only one X-chromosome (like the normal male with one X- and one Y-chromosome). These anomalies are clearly caused by disturbances in the mechanism for sex determination.

Complex syndromes. A remarkable feature of malformations in vertebrates including man is the association of multiple abnormalities in complex syndromes. Thus, in man harelip, spina bifida, hydrocephalus, and polydactyly may be found in the same individual; acrocephalosyndactyly (an egg- or dome-shaped skull and partial or complete fusion of digits in both hands and feet) often occurs with harelip, contractures, spina bifida, and mental

In man, individuals afflicted with mongolism, also known as Down's syndrome, have facial and bodily characters that permit diagnosis at or even before birth. Mongols have 47 instead of the normal 46 chromosomes. The extra chromosome is apparently responsible for the abnormal

Doubling of parts. Individuals partially or wholly double, but joined together, are represented by the rare occurrence in man of Siamese twins, so-called from a famous Siamese pair exhibited for many years in the 19th century. The condition consists of identical twins joined by a bridge of tissue through which the circulatory systems communicate. Such twins probably arise by the incomplete separation of a single fertilized egg into two parts; the experimental production of such double individuals in newts has been accomplished by constricting the egg in the two-cell stage.

In man, partially double symmetrical malformations are found. They vary from those with a single head but with neck, trunk, and limbs doubled, through those with two heads and a single trunk, to others with head, shoulders, and arms doubled, but with one trunk and one pair of legs. Such double malformations probably arise following the less complete separation of the halves of the early embryo or partial separation at later stages. A rare type is one in which there is a Janus head, two faces on a single head and body. Janus malformations have been produced experimentally in amphibian embryos by a variety of treatments in early stages. A group of cases in which the hinder end of the body was doubled from the sacrum back has been found in one strain of mice and appears to be due to abnormal heredity. Doubling of whole limbs in amphibia has been produced experimentally by injuring the limb rudiment at an early, sensitive stage. (For additional information on abnormal human development, see below Human growth and development: (L.C.D.) abnormal development.)

Biological regeneration

Siamese

twins

Organisms differ markedly in their ability to replace lost or amputated body parts. Some grow a new structure on the stump of the old one. By such regeneration whole organisms may dramatically replace substantial portions of themselves when they have been cut in two, or may grow organs or appendages that have been lost. Not all living things regenerate parts in this manner, however. The stump of an amputated structure may simply heal over without replacement. This wound healing is itself a kind of regeneration at the tissue level of organization: a cut surface heals over, a bone fracture knits, and cells replace themselves as the need arises.

Regeneration, as one aspect of the general process of growth, is a primary attribute of all living systems. Without it there could be no life, for the very maintenance of an organism depends upon the incessant turnover by which all tissues and organs constantly renew themselves In some cases rather substantial quantities of tissues are replaced from time to time, as in the successive production of follicles in the ovary or the molting and replacement of hairs and feathers. More commonly, the turnover is expressed at the cellular level. In mammalian skin the epidermal cells produced in the hasal layer may take several weeks to reach the outer surface and be sloughed off. In the lining of the intestines, the life span of an individual

epithelial cell may be only a few days. The motile, hairlike cilia and flagella of single-celled organisms are capable of regenerating themselves within an hour or two after amputation. Even in nerve cells, which cannot divide, there is an endless flow of cytoplasm from the cell body out into the nerve fibres themselves. New molecules are continuously being generated and degraded with turnover times measured in minutes or hours in the case of some enzymes, or several weeks as in the case of muscle proteins. (Evidently, the only molecule exempt from this inexorable turnover is deoxyribon-cleic acid

[DNA] which ultimately governs all life processes.)

There is a close correlation between regeneration and generation. The methods by which organisms reproduce themselves have much in common with regenerative processes. Vegetative reproduction, which occurs commonly in plants and occasionally in lower animals, is a process by which whole new organisms may be produced from fractions of parent organisms; e.g., when a new plant develops from a cut portion of another plant, or when certain worms reproduce by splitting in two, each half then growing what was left behind. More commonly, of course, reproduction is achieved sexually by the union of an egg and sperm. Here is a case in which an entire organism develops from a single cell, the fertilized egg, or zygote. This remarkable event, which occurs in all organisms that reproduce sexually, testifies to the universality of regenerative processes. During the course of evolution the regenerative potential has not changed, but only the levels of organization at which it is expressed. If regeneration is an adaptive trait, it would be expected to occur more commonly among organisms that appear to have the greatest need of such a capability, either because the hazard of injury is great or the benefit to be gained is great. The actual distribution of regeneration among living things, however, seems at first glance to be a rather fortuitous one. It is difficult indeed to understand why some flatworms are able to regenerate heads and tails from any level of amputation, while other species can regenerate in only one direction or are unable to regenerate at all. Why do leeches fail to regenerate, while their close relatives, the earthworms, are so facile at replacing lost parts? Certain species of insects regularly grow back missing legs, but many others are totally lacking in this capacity. Virtually all modern bony fishes can regenerate amputated fins, but the cartilaginous fishes (including the sharks and rays) are unable to do so. Among the amphibians, salamanders regularly regenerate their legs, which are not very useful for movement in their aquatic environment, while frogs and toads, which are so much more dependent on their legs, are nevertheless unable to replace them. If natural selection operates on the principle of efficiency, then it is difficult to explain these many inconsistencies.

Some cases are so clearly adaptive that there have evolved not only mechanisms for regeneration, but mechanisms for self-amputation, as if to exploit the regenerative capability. The process of losing a body part spontaneously is called autotomy. The division of a protozoan into two cells and the splitting of a worm into two halves may be regarded as cases of autotomy. Some colonial marine animals called hydroids shed their upper portions periodically. Many insects and crustaceans will spontaneously drop a leg or claw if it is pinched or injured. Lizards are famous for their ability to release their tails. Even the shedding of antlers by deer may be classified as an example of autotomy. In all these cases autotomy occurs at a predetermined point of breakage. It would seem that wherever nature contrives to lose a part voluntarily, it provides the capacity for replacement.

Cellular

Whether regeneration is adaptive

Sometimes, when part of a given tissue or organ is removed, no attempt is made to regenerate the lost structures. Instead, that which remains behind grows larger. Like regeneration, this phenomenon—known as compensatory hypertrophy—can take place only if some portion of the original structure is left to react to the loss. If three-quarters of the human liver is removed, for example, the remaining fraction enlarges to a mass equivalent to the original organ. The missing lobes of the liver are not themselves replaced, but the residual ones grow as large as necessary in order to restore the original function of the organ. Other mammalian organs exhibit similar reactions. The kidney, pancreas, thyroid, adrenal glands, gonads, and lungs compensate in varying degrees for reductions in mass by enlargement of the remaining parts.

It is not invariably necessary for the regenerating tissue to be derived from a remnant of the original tissue. Through a process called metaplasia, one tissue can be converted to another. In the case of lens regeneration in certain amphibians, in response to the loss of the original lens from the eye, a new lens develops from the tissues at the edge of the iris on the upper margin of the pupil. These cells of the iris, which normally contain pigment granules, lose their colour, proliferate rapidly, and collect into a sherical mass which differentiates into a new lens.

MODES OF REGENERATION

Basic patterns. Not all organisms regenerate in the same way. In plants and in coelenterates such as the hydra and jellyfishes, missing parts are replaced by reorganization of preexisting ones. The wound is healed, and the neighbouring tissues reorganize themselves into whatever parts may have been cut off. This process of reorganization, called morphallaxis, is the most efficient way for simple organisms to regenerate. Higher animals, with more complex bodies, regenerate parts differently, usually by the production of a specialized bud, or blastema, at the site of amputation. The blastema, made up of cells that look very much alike despite their often diverse origins, made its first appearance evolutionarily in flatworms and is encountered in the regenerative processes of all higher animals. It provides the tissue that will form the regenerated part.

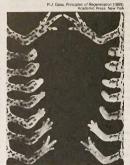

Atypical regeneration. Sometimes the part that grows back is not the same as that which was lost, and, occasionally, regeneration may be induced without having lost anything at all. It is not uncommon for a regenerated part to be incomplete. Earthworms, for example, usually regenerate only five segments in the anterior direction even if more than that number have been amputated. Many insects regenerate abnormally small legs from which some segments may be missing. Tadople tails when amputated grow back to about only half their original length. These and other cases testify to the fact that a little regeneration is often good enough—that it is not necessary in every case to reproduce a flawless copy of the original.

Sometimes that which is regenerated is very different from the original. Among the arthropods there are cases in which the stump of an antenna grows a leg, while a cut eyestalk regenerates an antenna. More commonly, the regenerated part may be a reasonable facsimile of the original but will differ in details. A regenerated lizard tail contains an unsegmented cartilaginous tube instead of a series of vertebrae as did the original tail. The spinal cord lacks segmented ganglia, and the scales in the skin differ in character from the original ones. A regenerated tail, therefore, is easily distinguished from an original one yet appears sufficient to serve the purpose. Another interesting case is that of jaw regeneration in salamanders. If the lower jaw is amputated a new one will grow back, but it is often smaller than the original. It contains teeth and a mandible, but lacks a new tongue. Furthermore, the new mandible is a cartilaginous model of the original, and is not known to convert into bone.

Sometimes more of a part grows back than has been removed by amputation. A limb stump, for example, can occasionally give rise to hands with extra digits. Lobsters have been known to regenerate double structures, in which case the new parts are mirror images of each other.

THE REGENERATION PROCESS

Origin of regeneration material. Following amputation, an appendage capable of regeneration develops a blastema from tissues in the stump just behind the level of amputation (see photograph). These tissues undergo drastic changes. Their cells, once specialized as muscle, bone, or cartilage, lose the characteristics by which they are normally identified (dedifferentiation); they then begin to migrate toward, and accumulate beneath, the wound epidermis, forming a rounded bud (blastema) that bulges out from the stump. Cells nearest the tip of the bud continue

Successive stages in the regeneration of opposite limbs in a newt following amputation through (left) lower and (right) upper arms. At the top are the original limbs. From top to bottom are the successive stages of regeneration at 7, 21, 25, 28, 32, 42, and 70 days after amputation. The (right) more proximal stump elongates faster but differentiates more slowly than does the (left) more distal stump.

to multiply, while those situated closest to the old tissues of the stump differentiate into muscle or cartilage, depending upon their location. Development continues until the final structures at the tip of the regenerated appendage are differentiated, and all the proliferating cells are used up in the process.

The blasterna cells seem to differentiate into the same kind of cells they were before, or into closely related types. Cells may perhaps change their roles under certain conditions, but apparently rarely do so. If a limb blastema is transplanted to the back of the same animal, it may continue its development into a limb. Similarly, a tail blastema transplanted elsewhere on the body will become a tail. Thus, the cells of a blastema seem to bear the indelible stamp of the appendage from which they were produced and into which they are destined to develop. If a tail blastema is transplanted to the stump of a limb, however, the structure that regenerates will be a composite of the two anoendages.

Polarity and gradient theory. Each living thing exhibits polarity, one example of which is the differentiation of an organism into a head, or forward part, and a tail, or hind part. Regenerating parts are no exception; they exhibit polarity by always growing in a distal direction (away from the main part of the body). Among the lower invertebrates, however, the distinction between proximal (near, or toward the body) and distal is not always clear cut. It is not difficult, for example, to reverse the polarity of "stems" in colonial hydroids. Normally a piece of the stem will grow a head end, or hydranth, at its free, or distal, end; if that is tied off, however, it regenerates a hydranth at the end that was originally proximal. The polarity in this system is apparently determined by an activity gradient in such a way that a hydranth regenerates wherever the metabolic rate is highest. Once a hydranth

Differences between whole organisms and appendages has begun to develop, it inhibits the production of others proximal to it by the diffusion of an inhibitory substance downward along the stem.

When planarian flatworms are cut in half, each piece grows back the end that is missing. Cells in essentially identical regions of the body where the cut was made form blastemas, which, in one case gives rise to a head and in the other becomes a tail. What each blastema regenerates depends entirely on whether it is on a front piece or a hind piece of flatworm: the real difference between the two pieces may be established by metabolic differentials. If a transverse piece of a flatworm is cut very thin-too narrow for an effective metabolic gradient to be set upit may regenerate two heads, one at either end. If the metabolic activity at the anterior end of a flatworm is artificially reduced by exposure to certain drugs, then the former posterior end of the worm may develop a head.

Appendage regeneration poses a different problem from that of whole organisms. The fin of a fish and the limb of a salamander have proximal and distal ends. By various manipulations, it is possible to make them regenerate in a proximal direction, however. If a square hole is cut in the fin of a fish, regeneration takes place as expected from the inner margin, but may also occur from the distal edge. In the latter case, the regenerating fin is actually a distal structure except that it happens to be growing in a proximal direction.

Amphibian limbs react in a similar manner. It is possible to graft the hand of a newt to the nearby body wall, and once a sufficient blood flow has been established, to sever the arm between the shoulder and elbow. This creates two stumps, a short one consisting of part of the upper arm, and a longer one made up of the rest of the arm protruding in the wrong direction from the side of the animal. Both stumps regenerate the same thing, namely, everything normally lying distal to the level of amputation, regardless of which way the stump was facing. The

reversed arm therefore regenerates a mirror image of itself. Clearly, when a structure regenerates it can only produce parts that normally lie distal to the level of amputation. The participating cells contain information needed to develop everything "downstream," but can never become more proximal structures. Regeneration, like embryonic development, occurs in a definite sequence.

Regulation of regeneration. There are certain prerequisites without which regeneration cannot occur. First and foremost, there must be a wound, although the original appendage need not have been lost in the process. Second, there must be a source of blastema cells derived from remnants of the original structure or an associated one. Finally, regeneration must be stimulated by some external force. The stimuli often involve the nervous system. An adequate nerve supply is required for the regeneration of fish fins, taste barbels, and amphibian limbs. In the case of many tail regenerations, the spinal cord provides the necessary stimulus. Lens regeneration in salamander eves depends upon the presence of a retina. Arthropod appendages regenerate in the presence of molting hormones. Protozoan regeneration requires the presence of a nucleus. In case after case, regeneration depends on more than a healed wound and a source of blastema cells. It is often triggered by some physiological stimulus originating elsewhere in the body, a stimulus invariably associated with the very function of the structure to be regenerated. The conclusion is inescapable that regeneration is primarily the recovery of deficient functions rather than simply the replacement of lost structures.

The imperative of need is of further importance in suppressing excess regeneration. To be able to regenerate is to run the risk of regenerating too much or too often. If regeneration did not depend upon a physiological stimulus, such as those mediated by nerves or hormones, there would be no reason why simple wounds should not sprout

whole new appendages. It is not known why regeneration fails to occur in many cases, as in the legs of frogs or the limbs and tails of mammals. The nerve supply might be inadequate, for when the number of nerves is artificially increased, regeneration is sometimes induced. This cannot be the whole answer, however, because not all appendages depend on nerves for their regeneration; newt jaws, salamander gills, and deer antlers do not require nerves to regenerate.

Possibly the failure to regenerate relates to the ways in which wounds heal. In higher vertebrates there is a tendency to form thick scar tissue in healing wounds, which may act as a barrier between the epidermis and the underlying tissues of the stump. In the absence of direct contact between these two tissues, the stump may not be able to give rise to the blastema cells required for regeneration.

THE RANGE OF REGENERATIVE CAPABILITY

Virtually no group of organisms lacks the ability to regenerate something. This process, however is developed to a remarkable degree in lower organisms, such as protists and plants, and even in many invertebrate animals such as earthworms and starfishes. Regeneration is much more restricted in higher organisms such as mammals. in which it is probably incompatible with the evolution of other body features of greater survival value to these complex animals.

Protists and plants. Algae. One of the most outstanding feats of regeneration occurs in the single-celled green alga-Acetabularia. This plant-like protist of shallow tropical water consists of a group of short rootlike appendages; a long thin "stem," up to several centimetres in length; and an umbrella-like cap at the top. The entire organism is one cell, with its single nucleus situated at the base in one of the "roots." If the cap is cut off, a new one regenerates from the healed over stump of the amputated stem. The nucleus is necessary for this kind of regeneration, presumably because it provides the information needed to direct the development of the new cap. Once this information has been produced by the nucleus, however, the nucleus can be removed and regeneration continues unabated.

If the nucleus from one species of Acetabularia is added to a cell-body of another species, and the cap of the recipient cell is amputated, the new cap that regenerates will be a hybrid because each nucleus exerts its own morphogenetic influences. On the other hand, if the nucleus from one species is substituted for that in another, regeneration reflects the properties of the new nucleus.

Protozoans. Most single-celled, animal-like protists regenerate very well. If part of the cell fluid, or cytoplasm, is removed from Amoeba, it is readily replaced. A similar process occurs in other protozoans, such as flagellates and ciliates. In each case, however, regeneration occurs only from that fragment of the cell containing the nucleus. Amputated parts that lack a nucleus cannot survive. In some ciliates, such as Blepharisma or Stentor, the nucleus may be elongated or shaped like a string of beads. If either of these organisms is cut in two so that each fragment retains part of the elongated nucleus, each half proceeds to grow back what it lacks, giving rise to a complete organism in less than six hours. The way in which such a bisected protozoan regenerates is almost identical with the way it reproduces by ordinary division. Even a very tiny fragment of the whole organism can regenerate itself, provided it contains some nuclear material to determine what is supposed to be regenerated.

Green plants. The mechanisms by which vascular plants grow have much in common with regeneration. Their roots and shoots elongate by virtue of the cells in their meristems, the conical growth buds at the tip of each branch. These meristems are capable of indefinite growth, especially in perennial plants. If they are amputated they are not replaced, but other meristems along the stem, normally held in abeyance, begin to sprout into new branches that more than compensate for the loss of the original one. Such a process is called restitution.

Plants are also capable of producing callus tissue wher- Callus ever they may be injured. This callus is proliferated from cambial cells, which lie beneath the surface of branches and are responsible for their increase in width. When a callus forms, some of its cells may organize into growing points, some of which in turn give rise to roots while

others produce stems and leaves. Invertebrates. Coelenterates. The vast majority of research on coelenterates has been focussed on hydras and Nuclear material

Failure of regenerative processes Planarian

regenera-

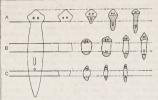

tion

some of the colonial hydroids. If a hydra is cut in half, the head end reconstitutes a new foot, while the basal portion regenerates a new hydranth with mouth and tentacles. This seemingly straightforward process is deceptively simple. From tiny fragments of the organism whole animals can be reconstituted. Even if a hydra is minced and the pieces scrambled, the fragments grow together and reorganize themselves into a complete whole. The indestructibility of the hydra may well be attributed to the fact that even the intact animal is constantly regenerating itself. Just below the mouth is a growth zone from which cells migrate into the tentacles and to the foot where they eventually die. Hence, the hydra is in a ceaseless state of turnover, with the loss of cells at the foot and at the tips of the tentacles being balanced by the production of new ones in the growth zone. If such an animal is X-rayed, the proliferation of new cells is inhibited and the hydra gradually shrinks and eventually dies owing to the inexorable demise of cells and the inability to replace them.

In colonial hydroids, such as Tubularia, there is a series of branching stems, each of which bears a hydranth on its end. If these hydranths are amputated they grow back within a few days. In fact, the organism normally sheds its hydranths from time to time and regenerates new ones naturally.

Flatworms. Planarian flatworms are well-known for their ability to regenerate heads and tails from cut ends (see Figure 2). In the case of head regeneration, some

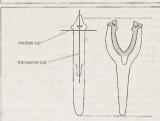

Figure 2: (Top) Regeneration in the planarian flatworm Dugesia. The three rows show regeneration from (A) anterior section, (B) midsection, and (C) posterior section of the animal at the left. (Bottom) Regeneration of a double head in a planarian. Regenerated tissue is shaded.

blastema cells become brain tissues, others develop into the eyes, and still others differentiate as muscle or intestine. In a week or so, the new head functions almost as well as the original.

The blastema that normally gives rise to a single head is, under certain circumstances, even capable of becoming two heads if the stump of a decapitated flatworm is divided in two by a longitudinal cut. Each of the two halves then gives rise to a complete head. Thus, each blastema develops into an entire structure regardless of its size or position in relation to the rest of the animal.

In the case of flatworms there is still considerable disagreement concerning the origins of the blastema. Some investigators contend that it is derived from neoblasts, undifferentiated reserve cells scattered throughout the body. Others claim that there are no such reserve cells and that the blastema develops from formerly specialized cells near the wound that dedifferentiate to give rise to the blastema cells. Whatever their source, the cells of the blastema are capable of becoming many different things depending upon their location

Regeneration in flatworms occurs in a stepwise fashion. The first tissue to differentiate is the brain, which induces the development of eyes. Once the head has formed, it in turn stimulates the production of the pharynx. The latter then induces the development of reproductive organs farther back. Thus, each part is necessary for the successful development of those to come after it; conversely, each part inhibits the production of more of itself. If decapitated flatworms are exposed to extracts of heads, the regeneration of their own heads is prevented. Such a complex interplay of stimulators and inhibitors is responsible for the successful regeneration of an integrated morphological structure.

Annelids. The segmented worms exhibit variable degrees of regeneration. The leeches, as already noted, are wholly lacking in the ability to replace lost segments, whereas the earthworms and various marine annelids (polychaetes) can often regenerate forward and backward. The expression of such regenerative capacities depends very much on the level of amputation. Anteriorly directed regeneration usually occurs best from cuts made through the front end of the worm, with little or no growth taking place from progressively more posterior bisections. Posteriorly directed regeneration is generally more common and extensive. Some species of worms replace the same number of segments as were lost. Hypomeric regeneration, in which fewer segments are produced than were removed, is more common, however.

Anterior regeneration depends upon the presence of the central nerve cord. If this is cut or deflected from the wound surface, little or no forward regeneration may take place. Posterior regeneration requires the presence of the intestine, removal of which precludes the formation of hind segments. Thus, it would seem that no head will regenerate without a central nervous system, nor a tail without an opening.

Arthropods. Many insects and crustaceans regenerate legs, claws, or antennas with apparent ease. When insect legs regenerate, the new growth is not visible externally because it develops within the next proximal segment in the stump. Not until the following molt is it released from its confinement to unfold as a fully developed leg only slightly smaller than the original. In the case of crabs, regenerating legs bulge outward from the amputation stump. They are curled up within a cuticular sheath, not to be extended until the sheath is molted. Lobsters and crayfish regenerate claws and legs in a straightforward manner as direct outgrowths from the stumps. As in other crustaceans, however, these regenerates lie immobile within an enveloping cuticle and do not become functional until their sheath is shed at the next molt.

In all arthropods regeneration is associated with molting, Molting and therefore takes place only during larval or young stages. Most insects do not initiate leg regeneration unless there remains ample time prior to the next scheduled molt for the new leg to complete its development. If amoutation is performed too late in the intermolt period, the onset of regeneration is delayed until after shedding; the regenerate then does not appear until the second molt. Metamorphosis into the adult stage marks the end of molting in insects, and adults accordingly do not regenerate amputated appendages.

Crustaceans often tend to molt and grow throughout life. They therefore never lose the ability to grow back missing appendages. When a leg is lost, a new outgrowth appears even if the animal is not destined to molt for many months. Following a period of basal growth, during which a diminutive limb is produced, the regenerated part eventually ceases to elongate. Not until a few weeks before the

Fin reдепегаtion

Farly

ment

theories of

develop-

next molt does it resume growth and complete its development, triggered by the hormones that induce molting.

Vertebrates. Fishes. Many different parts of the fish's body will grow back. Plucked scales are promptly replaced by new ones, and amputated gill filaments can regenerate easily. The "whiskers," or taste barbels, of the catfish grow back as perfect replicas of the originals. The most conspicuous regenerating structures in fishes, however, are the fins. When any of these are amputated, new fins grow out from the stumps and soon restore everything that was missing. Even the coloured stripes or spots that adorn some fins are reconstituted by new pigment cells that repopulate the regenerated part. Fin regeneration depends on an adequate nerve supply. If the nerves are cut leading into the fin, regeneration of neither the amoutated fin nor excised pieces of the bony fin rays can take place

Amphibians. Salamanders are remarkable for their ability to regenerate limbs. Larval frogs, or tadpoles, also possess this ability, but usually lose it when they become frogs. It is not known why frog legs do not regenerate, and under appropriate stimuli they can be induced to do so.

Tadpoles and salamanders can replace amputated tails. Tadpole tails have a stiff rod called the notochord for support, whereas salamanders possess a backbone, composed of vertebrae. Both tails contain a spinal cord. When the salamander regenerates its tail, the spinal cord grows back and segmental nerve-cell clusters (ganglia) differentiate. Tadpoles also regenerate their spinal cords, but not the associated ganglia. If the spinal cord is removed or destroyed in the salamander, no tail regeneration occurs; if it is removed from the tadpole tail, however, regeneration can proceed without it.

Reptiles. Lizards also regenerate their tails, especially in those species that have evolved a mechanism for breaking off the original tail when it is grasped by an enemy. When the lizard tail regenerates, however, it does not replace the segmented vertebrae. Instead, there develops a long tapering cartilaginous tube within which the spinal cord is located and outside of which are segmented muscles. The spinal cord of the lizard tail is necessary for regeneration, but the regenerated tail does not reproduce the ganglia that are normally associated with it. Occasionally, a side tail may be produced if the original tail is broken but not lost

Birds. Regeneration of amoutated appendages in birds is not known to occur; however, they do replace their feathers as a matter of course. While most species shed and regenerate feathers one at a time so as not to be grounded, flightless birds, such as penguins, may molt them all at once. Male puffins cast off their colorful beaks after the mating season, but grow new ones the following year. In like manner, the dorsal keel on the upper beaks of male pelicans is shed and replaced annually

Mammals. Although mammals are incapable of regenerating limbs and tails, there are a few exceptional cases in which lost tissues are in fact regenerated. Not the least of these cases is the annual replacement of antiers in deer. These remarkable structures, which normally grow on the heads of male deer, consist of an inner core of bone enveloped by a layer of skin and nourished by a copious blood supply. During the growing season the antlers elongate by the proliferation of tissues at their growing tips. The rate of growth in some of the larger species may surpass one centimetre (0.39 inch) per day; the maximum rate of growth recorded for the elk is 2.75 centimetres (1.05 inches) per day. When the antlers have reached their full extent, the blood supply is constricted, and the skin, or velvet, peels off, thus revealing the hard, dead, bony antlers produced by the male deer in time for the autumn mating season. The regeneration of elk antlers spans about seven months (see Figure 3). The following spring, the old antlers are shed and new ones grow to replace them.

replacement

I March I April I May I June I Figure 3: Regeneration of antiers in the elk (see text).

Still another example of mammalian regeneration occurs in the case of the rabbit's ear. When a hole is punched through the external ear of the rabbit, tissue grows in from around the edges until the original opening is reduced or obliterated altogether. This regeneration is achieved by the production of new skin and cartilage from the margins of the original hole. A similar phenomenon occurs in the case of the bat's wing membrane. (R.J.G.)

GENERAL FEATURES OF BIOLOGICAL DEVELOPMENT

Development in its most general meaning refers to any process of progressive change. In this sense, most modern philosophical outlooks would consider that development of some kind or other characterizes all things, in both the physical and biological worlds. Such points of view go back to the very earliest days of philosophy.

Among the pre-Socratic philosophers of Greek Ionia, half a millennium before Christ, some, like Heracleitus, believed that all natural things are constantly changing. In contrast, others, of whom Democritus is perhaps the prime example, suggested that the world is made up by the changing combinations of atoms, which themselves remain unaltered, not subject to change or development. The early period of post-Renaissance European science may be regarded as dominated by this latter atomistic view, which reached its fullest development in the period between Newton's laws of physics and Dalton's atomic theory of chemistry in the early 19th century. This outlook was never easily reconciled with the observations of biologists, and in the last hundred years a series of discoveries in the physical sciences have combined to swing opinion back toward the Heracleitan emphasis on the importance of process and development. The atom, which seemed so

unalterable to Dalton, has proved to be divisible after all, and to maintain its identity only by processes of interaction between a number of component subatomic particles, which themselves must in certain aspects be regarded as processes rather than matter. Albert Einstein's theory of relativity showed that time and space are united in continuum, which implies that all things are involved in time; that is to say, in development.

The philosophers who charted the transition from the nondevelopmental view, for which time was an accidental and inessential element, were Henri Bergson and, in particular, Alfred North Whitehead. Karl Marx and Friedrich Engels, with their insistence on the difference between dialectical and mechanical materialism, may be regarded as other important innovators of this trend, although the generality of their philosophy was somewhat compromised by the political context in which it was placed and the rigidity with which their later followers have interpreted it.

Philosophies of the Heracleitan type, which emphasize process and development, provide much more appropriate frameworks for biology than do philosophies of the atomistic kind. Living organisms confront biologists with changes of various kinds, all of which could be regarded as in some sense developmental; however, biologists have found it convenient to distinguish the changes and to use the word development for only one of them. Biological development can be defined as the series of progressive, nonrepetitive changes that occur during the life history of an organism. The kernel of this definition is to contrast development with, on the one hand, the essentially repetitive chemical changes involved in the maintenance of the body, which constitute "metabolism," and on the other hand, with the longer term changes, which, while nonrepetitive, involve the sequence of several or many life histories, and which constitute evolution.

blurring of distinctions in nature

Genotype

phenotype

versus

As with most formal definitions, these distinctions cannot always be applied strictly to the real world. In the viruses, for instance, and even in bacteria, it is difficult to make a distinction between metabolism and development, since the metabolic activity of a virus particle consists of little more than the development of new virus particles. In certain other cases, the distinction between development and evolution becomes blurred: the concept of an individual organism with a definite life history may be very difficult to apply in plants that reproduce by vegetative division, the breaking off of a part that can grow into another complete plant. The possibilities for debate that arise in these special cases, however, do not in any way invalidate the general usefulness of the distinctions as conventionally made in biology.

The scope of development

All organisms, including the very simplest, consist of two components, distinguished by a German biologist, August Weismann, at the end of the 19th century, as the "germ plasm" and the "soma." The germ plasm consists of the essential elements, or genes, passed on from one generation to the next, and the soma consists of the body that may be produced as the organism develops (Figure 4). In more modern terms, Weismann's germ plasm is identified with DNA (deoxyribonucleic acid), which carries, encoded in the complex structure of its molecule, the instructions necessary for the synthesis of the other compounds of the organism and their assembly into the appropriate structures. It is this whole collection of other compounds (proteins, fats, carbohydrates, and others) and their arrangement as a metabolically functioning organism that constitutes the soma. Biological development encompasses, therefore, all the processes concerned with implementing the instructions contained in the DNA. Those instructions can only be carried out by an appropriate executive machinery, the first phase of which is provided by the cell that carries the DNA into the next generation: in animals and plants by the fertilized egg cell; in viruses by the cell infected. In life histories that have more than a minimal degree of complexity, the executive machinery itself becomes modified as the genetic instructions are gradually put into operation, and new mechanisms of protein synthesis are brought into functional condition. The fundamental problem of developmental biology is to understand the interplay between the genetic instructions and the mechanisms by which those instructions are carried out.

In the language of genetics the word genotype is used to indicate the hereditary instructions passed on from one generation to another in the genes, while phenotype is the term given to the functioning organisms produced by those instructions. Biological development, therefore, consists of the production of phenotypes. The point made in the last paragraph is that the formation of the phenotype of one generation depends on the functioning of part of the phenotype of the previous generation (e.g., egg cell), as the mechanism that begins the interpretation of the instructions contained in the new organism's genotype.

TYPES OF DEVELOPMENT

In the entire realm of organisms, many different modes of development are found, the most important categories of which can be discussed as pairs of contrasting types.

Quantitative and qualitative development. Development may amount to no more than a quantitative change (usually an increase) in a system that remains essentially

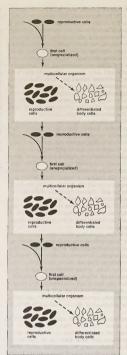

Figure 4: Weismann's concept of the continuity of the germ plasm.

Biological Sciences Curriculum Study Green Version High of Biology, 2nd ed. (1968); Rand McNally & Company

unaltered. Qualitative development involves an alteration in the nature of the system. Pure examples of the first type are difficult to find. Approximations to it occur when an animal or plant has attained a structure with the full complement of organs; it then appears to increase only in size, that is to say, quantitatively. This would be a period of simple growth. A closer examination nearly always shows that the system is also undergoing some qualitative change, however. A human infant at birth, for example, already has its full complement of organs, but the ensuing developmental period up to adulthood involves not only growth but also processes of maturation that involve qualitative as well as quantitative changes. Perhaps the most uncomplicated examples of quantitative development occur in certain simple plants and animals. Flatworms, for example, may become reduced in size when starved but increase in size again when provided with suitable nutrition; they thus undergo quantitative changes. Even in these cases, however, it is found that the constituent organs do not always merely become reduced in size but may actually suffer the loss of certain parts.

Progressive and regressive development. The normal processes of development in the majority of plants and animals may be considered progressive since they lead to increases in size and complexity and to the addition of

The adaptability of regression

Alterna-

tion of

genera-

tions

new elements to the system. As already indicated, some organisms, when placed in adverse conditions, may undergo regressive changes, both in size and complexity. Such regressive changes are a part of the normal life history of certain organisms. Characteristically, these are species in which the organism at an early stage develops a relatively complex structure that enables it to be motile, and later adopts a form of life for which motility is no longer a necessity. A good example is that of the barnacles, a group of marine crustaceans in which the egg at first develops into a motile larva that soon settles down and becomes firmly attached to a solid underwater surface. The barnacle then loses many of the organs characteristic of the motile phase and develops into its familiar stationary form

There are a number of other examples, particularly in groups in which the adults adopt a parasitic form of life. especially within the digestive system or other tissues of a host animal, from which they have only to absorb their nutriment without having to move or to possess suitable organs for capturing prey. In such cases the early developmental period is characterized by progression toward more complex forms followed by a period of regression in which many of these organs may be lost. During this regressive period certain components of the organism (i.e., those concerned with functioning as a sessile or parasitic form) may undergo progressive development at the same

time as the other organs are regressing.

Single-phase and multiphase development. The most familiar organisms, including man, undergo a single-phase development; the organs that appear at early stages persist throughout the whole of life. There are many kinds of animals that develop one or more larval stages adapted to a life different from that of the adult. Perhaps the best known of these is the common frog. The egg first develops into a tadpole, which is provided with a large muscular tail by which it swims. The tadpole eventually undergoes a change of form, or metamorphosis. This involves the regression and resorption of the tail and the growth of the limbs. During this time the rest of the body of the tadpole undergoes less profound changes; the organs persist but undergo relatively far-reaching progressive changes. In other animals, the alteration between the larval and the adult forms may be much more drastic. The egg of a sea urchin, for instance, at first develops to a small larva (the pluteus), which is completely unlike that of the adult. During metamorphosis nearly all the structures of the pluteus disappear; the five-rayed adult develops from a very small rudiment within the larva. In other groups of marine invertebrates, there may be successive larval stages before the adult form appears.

Plants in general appear to exhibit a type of development related in a general way to the multiphased development just discussed in animals, although rather different from it in essence. This is called the "alternation of generations" (Figure 5). The majority of higher plants possess two sets of similar chromosomes in each of their cells, that is to say they are diploid (2n), as are most higher animals. But in sexual reproduction, diploid cells undergo a reduction division so as to form precursors of the sex cells, which are

Figure 5: Generalized life cycle showing alternation of generations.

haploid-i.e., they contain only one set of chromosomes. In animals these cells develop directly into the sex cellsegg and sperm-which unite in fertilization. In plants the haploid cells undergo some developmental processes before the functioning sex cells are produced. The products of this development are spoken of as the "haploid generation." In most higher plants the haploid development is quite reduced, so that the hanloid individuals contain only a few nuclei-those associated with the pollen tube on the male side and a few associated with the egg on the female side. In some lower plants, however, such as mosses and ferns, the haploid development may be much more extensive and give rise to quite sizable separate plants. In such cases a species contains two kinds of individuals, produced by different types of developmental processes controlled. however, by the same genotype. This may be compared with the multiphasing development of larval forms in animals. The situation in plants, however, is characterized by the two forms of the organism having different chromosomal constitutions-haploid and diploid-whereas the larval forms and the adult of an animal species have the same chromosomal constitution.

Structural and functional development. These two categories cannot be regarded as a pair of opposites as were the previous pairs in this list; rather, they are two aspects of all processes of biological development and can be separated only conceptually, and for purposes of convenience of description. Function is the capacity of the biological system to carry out operations. At the level of the organism, these operations include walking, swimming, eating, digesting, etc.; at the cell level, typical functions are respiring, contracting, conducting nervous impulses, secreting hormones, etc.; and at the molecular level, all functions depend on the production of enzymes, coded by particular genes. Structure encompasses all parts of the organism capable of carrying out functions localized within the body of the organism and arranged in some particular spatial pattern. Contractile cells, for example, are grouped together to form muscle, and other cells are grouped together to form elements of the skeleton; both the muscles and the skeletal elements have definite spatial

relations to each other. These two aspects of development-function and structure-are not opposed to each other in any way. On the contrary, it is obvious that the higher level functions are clearly dependent on the proper structural relations and functions of cell systems. Even at the basic cellular or molecular levels, secretion or nervous conduction essentially depends upon the proper structural relation of the subcellular elements. It is, however, often convenient to focus discussion on one or other of these two aspects of development; for instance, a study may be made into the developmental processes that bring about the production of hemoglobin or insulin by a certain kind of cell, without at the moment being concerned with structural problems. Or again, the focus may be on the results of a certain process by which a mass of cells develops into a typical hand with five digits. In such an inquiry the structural aspects are paramount.

Normal and abnormal development. If a number of fertilized eggs of a given species are provided with conditions that enable them to develop at all, they will, with extraordinary regularity, develop into exceedingly similar adult organisms. The range of conditions they can tolerate is rather wide, and the similarity of the end products surprisingly complete. There are, indeed, good grounds for recognizing what must be considered normal development. The situation is perhaps more marked in animals than in plants, since the plants produced from a given batch of seed under a variety of environmental conditions often present considerably greater variation than is commonly found among animals. Even among plants, however, the differences produced by different conditions of cultivation are usually no more than quantitative differences in size and number of such organs as leaves and flowers, so that an individual can be described as well or poorly developed rather than as normally or abnormally developed. It is only in relatively few cases that a plant develops in quite different ways under two different conditions, neither of

Form and function

latitude of normal developCancerous

growth as

progressive

which can be considered abnormal or normal. In certain aquatic plants, for instance, the shape of the emergent leaves is different from the leaves that develop underwater. In such cases the plant actually has two normal forms of development.

It is possible, of course, to produce abnormal organisms by submitting a developing system to stimuli not usually encountered in a normal environment, such as certain chemicals. The presence of unusual genes also may result in deviations from the normal processes of development. In the vast majority of cases such abnormalities can be regarded as resulting from failure to carry out fully the normal processes of development. Functional abnormality in the adult consists in the failure of the system to produce a certain enzyme or functional cell type; a structural abnormality consists in the unusual appearance of certain component elements or in their arrangement in incompletely realized patterns. It is extremely rare to find examples in which the abnormality consists in the addition of a new enzyme not produced in normal development, or the formation of a new structural pattern of the elements.

One very important type of development that, from some points of view, can be considered as an exception to the rule that abnormal development is nearly always retrogressive, is carcinogenesis, the production of tumours. Carcinogenesis involves a change in the developmental behaviour of a group of cells. Initially, it often involves a loss of some of the functional and structural characteristics that previously appeared in the cells. It is commonly followed, however, by the assumption of new properties, which however untoward they may be for the host animal. must be considered as a progressive type: the cells often grow faster and multiply sooner than the noncancerous cells, for example. Furthermore, the cells may undergo a sequence of changes in character and in their arrangement within the tumour. All these features can be regarded in a developmental sense as progressive.

In view of the great rarity of cases of abnormal development that lead to progressive changes, it seems to follow that the organs produced during the normal development of any given species actually exhaust all the potentialities of its genotype for the production of orderly functional structures. It appears that the only abnormal developments that can be produced are either displacements of normal organs, or inadequacies in carrying out normal processes, or the initiation of progressive but quite disorderly processes, as in the production of tumours (see above Aberrations of growth: biological malformation).

GENERAL SYSTEMS OF DEVELOPMENT

Development of single-celled organisms. In viruses, activities consist in the production, aided by the machinery of a host cell, of units for building new virus or phage particles: development is simply the assemblage of these constituent units

In the next higher grade of biological organization, the organism consists of a single cell. Many single-celled algae produce special forms of cells that correspond to the sex cells, or gametes; these cells may unite in fertilization, the resulting fertilized egg, or zygote, undergoing a short period of development. In many other single-celled organisms, however, reproduction takes place by the simple division of an original cell into two daughter cells. In such forms, development normally is part of the process of subdivision. It involves the remodelling of the parent cell into two smaller cells, which are then separated by the division. Something similar must, of course, be involved in the division of cells of higher organisms also. In many single-celled organisms, however, the cell contains a number of defined parts, which are arranged in very definite ways, so that the process of remodelling is very striking and easily observed. This is so, for instance, with ciliated protozoans, in which the cortex is provided with a large number of hairlike cilia or other appendages, arranged in precise patterns, and often with such other structures as a mouth or a gullet. These structures are reproduced in two identical but smaller copies during cell division. This does not necessarily imply that no other developmental processes are possible. The process of regeneration of parts removed occurs quite independently of cell division, for example.

Open and closed systems of development. There is a marked difference between the general system of development in multicellular plants and multicellular animals. In a plant, certain groups of cells retain throughout the whole life of the plant an embryonic capability to give rise to many types of cells. These regions, known as meristems, occur at the growing tips of branches and roots and as a cylindrical sheath around the stem. They consist of rapidly dividing cells capable of assembling into groups that form buds from which may arise new stems, leaves, flowers, or roots.

By contrast, most animals have no special regions that retain an embryonic character. In most forms, the whole egg, and the whole collection of cells immediately derived from it, take part in the developmental processes and form parts of the developing embryo. In some forms that go through a number of larval stages, the development of certain cells is interrupted at an early stage, and they are set aside and resume their development to form a later type of larva, or to form the adult after the larval stages are completed. An example would be the imaginal buds of some insects. The cells of these buds cannot be regarded as retaining a fully embryonic character comparable to that of the plant meristems, since they cannot perform all the developmental processes but only those involved in the production of the particular late-larval or adult structure for which they have been set aside. In general, then, plants remain embryonic in character, capable as it were of starting again from the beginning to carry out the entire developmental process. Their development is, in this sense, "open." Most animals, on the other hand, lack persistently embryonic cells of this kind, and their development may be characterized as "closed." (There may be certain exceptions to this in very simple forms. such as flatworms, in which certain cells called neoblasts seem able to participate in any type of development; these cells are usually scattered throughout the body, and the major developmental processes that bring into being the general form of the organism cannot be attributed to them, as the development of the plant can be attributed to the meristems.)

Blastogenesis versus embryogenesis. Some animals possess a second system of development, in contrast to the "closed" embryonic system emphasized in the last section. In its most fully developed form, this system consists in remodelling a portion of the parental body into a new organism without any involvement of eggs or sperm. In an adult hydra, a microscopic aquatic animal, a portion of the body may begin to grow exceptionally fast; its cells differentiate into the various cell types and become molded into the constituent organs to build up a new individual identical to the parent. The group of cells responsible for this behaviour is, in its early stages, referred to as a bud. or blastema. Before they become activated these cells may appear quite indistinguishable from the other cells of the body and betray no embryonic capability comparable to the meristems of plants.

In some higher organisms, including certain insects, reptiles, and amphibians, incomplete but still fairly extensive new developments of a similar kind may take place. They require the stimulus of an injury, however, which may involve the removal of part of the normal body. The usual result is a new development to regenerate, or replace, the missing part. The first stage in such regenerative processes consists in the formation of a blastema, that is, a group of rapidly dividing cells that shows little sign of cellular specialization. The evidence indicates that they may not arise, as was once thought, from persisting embryonic cells scattered within the adult body, but instead are formed of cells near the position of the injury. These cells lose their normal adult character and become capable of developing into most of the tissues required to replace the parts removed by the injury (see above Biological regeneration).

Development from a blastema, or blastogenesis, presents many contrasts to embryogenesis, the normal form of development from a fertilized egg. In blastogenesis, tissues that, during embryonic development, appear in se-

Protozoan development

The developmental aspect of regeneraquence one after another, may be formed simultaneously and without any obvious sequential relations. Very little. however, is as yet understood about the mechanisms by which the various tissues within the blastema become differentiated from one another. It may well be that these mechanisms are more similar to those found in embryonic development than appears at first sight

CONSTITUENT PROCESSES OF DEVELOPMENT

Size and

number

Growth. As was pointed out earlier, developing systems normally increase in size, at least during part of their development. "Growth" is a general term used to cover this phenomenon. It comprises two main aspects: (1) increase in cell numbers by cell division and (2) increase in cell size. These two processes may in some examples occur quite separately from each other; for instance, cells in certain rapidly growing tissues (e.g., the connective tissue or blood-forming systems in vertebrates) may increase greatly in number, while the cells remain approximately the same size. Alternatively, in some organs (e.g., the salivary glands of insects) the cells may increase greatly while remaining the same in number, each cell becoming enlarged, or hypertrophied. In such greatly enlarged cells there is often duplication of the genes, involving an increase in the DNA content of the nucleus, although no cell division takes place, and the nucleus continues as a single body, although with a multiplied, or "polyploid," set of chromosomes.

In very many cases, however, the growth of an organ depends on increases both in cell number and in cell size, The relative importance of these two processes has yet to be properly investigated. One case that has been well studied is the size of the wings of the fruit fly Drosophila. The number of cells in the wing can be easily determined, since each bears a single hair that can be seen and counted in simple microscopic preparations. It has been found that there is an accommodation of factors: if there is an unusually large number of cells, these may be somewhat smaller than usual, so that the total size of the wing re-

mains relatively unchanged

Perhaps the major theoretical difficulty in the concept of growth is that it is a quantitative notion attached to an illdefined entity. Growth is an increase in size; but size of what? If a cell or organ increases in volume merely by the absorption of water, or by the laying down of a mineral substance such as calcium carbonate, is this to be regarded as growth or not?

Morphogenesis. As was pointed out earlier, morphogenesis refers to all those processes by which parts of a developing system come to have a definite shape or to occupy particular relative positions in space. It may be regarded as the architecture of development. Morphogenetic processes involve the movement of parts of the developing system from one place to another in space, and therefore involve the action of physical forces, in contrast to processes of differentiation (see below), which require only chemical operations. Although in practice the physical and chemical processes of development normally proceed in close connection, for purposes of discussion it is often convenient to make an artificial separation between them.

There is an enormous variety of different kinds of structures within living organisms. They occur at all levels of size, from an elephant's trunk to organelles within a cell, visible only with the electron microscope. There is still no satisfactory classification of the great range of processes by which these structures are brought into being. The following paragraphs constitute a tentative categorization that seems appropriate for the present state of biological

thought on this topic.

"Morphogenesis by differential growth. After their initiation, the various organs and regions of an organism may increase in size at different rates. Such processes of differential growth will change the overall shape of the body in which they occur. Processes of this kind take place very commonly in animals, particularly in the later stages of development. They are of major importance in the morphogenesis of plants, where the overall shape of the plant, the shape of individual leaves, and so on, depends primarily on the rates of growth of such component

elements as the stems, the lateral shoots, and the vein and intervein material in leaves. In both animals and plants. such growth processes are greatly influenced by a variety of hormones. It is probable that factors internal to individual cells also always play a role.

Although differential growth may produce striking alterations in the general shape of organisms, these effects should probably be considered as somewhat superficial, since they only modify a basic pattern laid down by other processes. In a plant, for instance, the fundamental pattern is determined by the arrangement of the lateral buds around the central growing stem; whether these buds then grow fast or slowly relative to the stem is a secondary matter, however striking its results may be.

Morphogenetic fields. Many fundamental processes of pattern formation (e.g., the arrangement of lateral buds in growing plants) occur within areas or three-dimensional masses of tissue that show no obvious indications of where the various elements in the pattern will arise until they actually appear. Such masses of tissue, in which a pattern appears, have been spoken of as "fields." This word was originally used in the early years of the 20th century by German authors who suggested an analogy between biological morphogenetic fields and such physical entities as magnetic or electromagnetic fields. The biological field is a description, but not an explanation, of the way in which the developing system behaves. The system develops as though each cell or subunit within it possessed "positional information" that specifies its location within the field and a set of instructions that lays down the developmental

behaviour appropriate to each position.

There have been several attempts to account for the nature of the positional information and of the corresponding instructions. The oldest and best known of these is the gradient hypothesis. In many fields there is some region that is in some way "dominant," so that the field appears as though organized around it. It is suggested that this region has a high concentration of some substance or activity, which falls off in a graded way throughout the rest of the field. The main deficiency of the hypothesis is that no one has yet succeeded in identifying satisfactorily the variables distributed in the gradients. Attempts to suppose that they are gradients of metabolic activity have, on investigation, always run into difficulties that can only be solved by defining metabolic activity in terms that reduce the hypothesis to a circular one in which metabolic activity is defined as that which is distributed in the gradient.

Recently, a new suggestion has been advanced concerning position information. Most processes within cells normally involve negative feedback control systems. These systems have a tendency to oscillate, or fluctuate regularly. In fact, any aspect of cell metabolism may be basically oscillatory in character; the cycle of cell growth and division may be only one example of a much more widespread phenomenon. The substances involved in these oscillations are likely to include diffusible molecules capable of influencing the behaviour of nearby cells. It is easy to envisage the possibility that there might be localized regions with oscillations of higher frequency or greater amplitude that act as centres from which trains of waves are radiated in all directions. It has been suggested that positional information is specified in terms of differences in phase between two or more such trains of transmitted oscillations.

Certain types of field phenomenon may involve an amplification of stochastic (random) variations. In systems containing a number of substances, with certain suitable rates of reaction and diffusion, chance variation on either side of an initial condition of equilibrium may become amplified both in amplitude and in the area involved. In this way, the processes may give rise to a pattern of differentiated areas, distributed in arrangements that depend on the boundary conditions.

Morphogenesis by the self-assembly of units. Complex structures may arise from the interaction between units that have characteristics such that they can fit together in a certain way. This is particularly appropriate for morphogenesis at the simple level of molecules or cells. Units such as the atoms of carbon, hydrogen, oxygen, nitrogen, and so on, can assemble themselves into orderly molecular struc-

pearance of nattern

Molecular assembly

tures, and larger molecules, such as those of tropocollagen, or protein subunits in general, can assemble themselves into complexes whose structure is dependent on localized and directional intermolecular forces. It seems that such comparatively large entities as the units that come together to form the head structures of bacteriophages or bacterial flagella are capable of orderly self-assembly, but the chemical forces that give rise to the interunit bonds are still little understood.

Processes that fall into the same general category as selfassembly may occur within aggregates of cells. The units that self-assemble are the cells themselves. Interaction and aggregation may be allowed to occur in assemblages of cells of one or more different kinds. In such cases it is commonly found that the originally isolated cells tend to adhere to one another, at first more or less at random and independently of their character, but later they become rearranged into a number of regions consisting of cells of a single kind. When the cells in the initial collection differ in two different characteristics, for instance in species and organ of origin, the assortment in some cases brings together cells from the same organ, in other cases cells from the same species. Mixtures of chick and mouse cells, for instance, reassort themselves into groups derived from the same organ, whereas cells from two different species of amphibia sort out into groups from the same species more or less independently of organ type.

This morphogenetic process probably has only a restricted application to the formation of structures in normal development, in which only in a few tissues (e.g., the connective system) do cells ever pass through a free stage in which they are not in intimate contact with other cells, and cells of different origin do not normally become intermingled so as to call for processes of reassortment. To explain normal morphogenetic processes of plants and animals one must look to the results that can be produced by the differential behaviour of cells that remain in constant close contact with one another. Several authors have shown how striking morphogenetic changes could be produced within a mass of cells that remain in contact, but that undergo changes in the intensity of adhesion between neighbouring cells, in the area of surface in the proportion

to cell volume, and so on.

Differentiation. Differentiation is simply the process of becoming different. If, in connection with biological development, morphogenesis is set aside as a component for separate consideration, there are two distinct types of differentiation. In the first type, a part of a developing system will change in character as time passes; for instance, a part of the mesoderm, starting as embryonic cells with little internal features, gradually develops striated myofilaments, and with a lapse of time develops into a fully formed muscle fibre. In the second type, space rather than time is involved; for instance, other cells within the same mass of embryonic mesoderm may start to lay down an external matrix around them and eventually develop into cartilage. In development, differentiation in time involves the production of the characteristic features of the adult tissues, and is referred to as histogenesis. Differentiation in space involves an initially similar (homogeneous) mass of tissue becoming separated into different regions and is referred to as regionalization.

Histogenesis involves the synthesis of a number of new protein species according to an appropriate timetable. The most easily characterized are those proteins formed in a relatively late stage of histogenesis, such as myosin and actin in muscle cells. The synthesis of proteins is under the control of genes, and the problem of histogenesis essentially reduces to that of the genetic mechanisms that direct protein synthesis.

Regionalization is concerned with the appearance of differences between various parts of what is at first a homogeneous, or nearly homogeneous, mass. It is a prelude to histogenesis, which then proceeds in various directions in the different regions so demarcated. The processes by which the different regions acquire distinct contrasting characteristics must be related to some of the processes discussed under morphogenesis. Unlike morphogenesis, regionalization need not involve any change in the overall snatial shape of the tissues undergoing it. Regionalization falls rather into the type of process for which field theories have been invoked.

Control and integration of development

PHENOMENOLOGICAL ASPECTS

One of the most striking characteristics of all developmental systems is a tendency to produce a normal end result in spite of injuries or abnormalities that may have affected the system in earlier stages. In many cases, perhaps in most, only injuries inflicted during a certain restricted period of development can be fully compensated for. During such periods the system is said to be capable of regulation or the restoration of normality.

Developmental regulation is often discussed in terms of homeostasis, or regulatory mechanisms. Many systems, including biological ones, exhibit a tendency to return to initial equilibrium once they are diverted from it. A developing system is, by definition, always changing in time, moving along some defined time trajectory, from an initial stage, such as a fertilized egg, through various larval stages to adulthood, and finally to senescence. The regulation that occurs in such systems is a regulation not back to an initial stable equilibrium, as in homeostasis, but to some future stretch of the time trajectory. The appropriate word to describe this process is homeorhesis. which means the restoration of a flow.

A second major phenomenological characteristic of development is that the end state attained is not unitary but can be analyzed into a number of different organs and tissues. The overall time trajectory of this system can, therefore, also be analyzed into a number of component trajectories, each leading to one or another of the end products that can be distinguished in the later stages. A major discovery of the early experiments on developing systems was that, in many cases at least, the different time trajectories diverge from one another relatively suddenly during some short period of development, which usually occurs well before any visible signs of divergence can be seen microscopically or by any other available means of analysis. The most dramatic and influential example of this was provided by studies on the development of the amphibian egg at the time of gastrulation, or formation of a hollow ball of cells. At this time the lower hemisphere of the embryo will be pushed inward (invaginated) to develop into the mesoderm and endoderm, and the upper hemisphere will remain on the surface, expanding in area to cover the whole embryo. Approximately one-third of the upper hemisphere will develop into the nervous system and the remainder into the skin. During the period when these morphogenetic movements of invagination and expansion are occurring, a process takes place by which a portion of the upper hemisphere enters a trajectory toward neural tissue and another part enters a trajectory leading to epidermal development. This process of determination of developmental pathways happens relatively quickly. during a period when the cells of the two different regions appear superficially alike. The occurrence of the determination can in fact be demonstrated only experimentally. Before it occurs, any part of the hemisphere can develop either into neural tissure or into skin. After it has happened, each part can develop only into one or the other of these alternatives.

It is clear that an adequate theory of development has to account not only for the processes by which a developing system moves along its appropriate time trajectory. but also for the nature of the processes by which the trajectories diverge from one another and become fixed or determined in the developing cells.

The determined state can be transmitted through many cell generations. An example of this transmission can be seen in Drosophila flies. The imaginal buds of Drosophila are small packets of cells that become separated from the main body of the embryo in the early stages of development. They persist throughout larval life and then enter into the differentiation of adult characteristics when stimulated to do so by the hormones secreted at the time of pupation. These pupation hormones disappear from the

Tissues and regions

> Determination

body of the adult insect, and imaginal buds transplanted into the body cavity of an adult undergo many cell generations, but they do not show any signs of differentiating into the specific tissues of the corresponding adult organ, After many generations of proliferation, however, the cells can be transplanted back into a larva ready to pupate; they thus submit to the pupation hormones and differentiation occurs. Through many generations of proliferation the cells have retained the determination as to which adult organ they will develop into when the pupation hormones become available.

Attempts to identify the determining agent have not yet been successful. Experiments on amphibian eggs, however, have given rise to one important general conclusion; namely, that the process of determination can take place only during a certain period of development, in which the cells of the upper half of the amphibian egg are poised between the two alternatives of development into neural tissue or into skin. They are said at this time to be "competent" for one or the other of these types of development. While they are in this state, and only while they are in it, a variety of external agents can switch them into one or the other of the possible pathways. Such a situation may be contrasted with one in which the cells were neutral, or featureless, and required then an external agent to transmit to them the quality of becoming nervous tissue or of becoming skin. This would mean that the reacting cells required information or instructions to be added to them from outside. Such a situation is not characteristic of biological development. Both in highly developed organisms such as amphibians and in simpler ones such as bacteria, the external agents act only as a releaser that switches on one or another process for which all of the necessary information is already incorporated in the cells concerned.

ANALYTICAL ASPECTS

The existence of these developmental phenomena was realized in the first third of this century. During this period, biologists had no clear notion of the fundamental concepts needed to explain development. Developmental biologists, or embryologists, attempted to account for their observations by means of ill-defined notions, such as "potencies" or "organ-forming substances," or by referring to cellular properties that are real enough but obviously in themselves complex and essentially secondary in nature, such as cellular adhesiveness, the capacity of cell surfaces to differentially absorb certain substances, and so on. It was only gradually that developmental biologists came to realize the importance of the demonstration by genetics that nearly all the instructions required for the building of a new organism are contained in the genes that come together during fertilization, and that the small additional amount of information, contained primarily in the ovum, is itself a product of genetic instructions provided in the body of the mother in which the ovum is produced. The fundamental problems of the theory of development are. therefore, to understand how these units interact with one another to form more complex mechanisms that bring about the cellular or tissue behaviours of the different types of developing systems.

In the development of the neural system of vertebrates, for example, a great many genes must be active in controlling the synthesis of particular proteins. In the formation of the wing of a Drosophila, the activity of some 20 or 30 genes has been definitely demonstrated, and certainly many more are involved. The action of all these genes, however, must be considered to form a network involving many types of feedback and other interactive loops, the overall result of which is a product in which many compohents are present in precisely defined concentrations; and further, the developmental process leading to this end result must be buffered or stabilized, in the sense that if the process is diverted from its normal course at an early stage, it returns to some later stage of the normal trajectory. The realization that the basic units of development are genes indicates that a stabilized time trajectory involves the action of tens, if not hundreds, of genes. The realization that biological development is fundamentally an expression of the controlled activities of genes has finally resolved one of the old philosophical controversies about the nature of development, between preformation and epigenesis. The former supposed that, at the initiation of development, for instance in the fertilized egg, the system already contained some representative of every organ that would eventually put in an appearance. The vindicated theory of epigenesis, on the other hand, supposed that later appearing entities were produced during the course of development.

The modern interpretation of epigenesis is that the initial stage of development does contain certain entities with well-defined properties, namely the genes. These do not, however, represent directly the later formed organs, which arise by the gradual interaction and progressive unfolding

of the properties of groups of genes. One of the major problems confronting modern developmental biology-namely, the nature of "determination"requires an understanding of how genes are "primed" to enter into activity when an appropriate stimulus is given. The state of priming presumably has to apply to quite a large number of genes, though perhaps not to all that will be involved in the stabilized, or buffered, time trajectory. since some may be brought into activity by the operation of the earlier active ones. The priming, moreover, has to be able to persist through cell division and be capable of transmission through many generations of cell proliferation. Few concrete suggestions as to the mechanism have vet been made. One is that the primed genes are already producing the ribonucleic acid molecules, called messenger RNA's, which direct protein synthesis in the cell, but that these messengers are in some way inactivated or prevented from activating the protein-synthesizing machinery; this is known as the "masked messenger" hypothesis. Arguments in favour of this hypothesis are, however, circumstantial rather than direct. In some cases, for instance that of the Drosophila imaginal buds, there is direct evidence against it. Another hypothesis, perhaps more attractive, but much vaguer, is that the determination or priming involves the intervention of some of the large amounts of reiterated DNA known to be present in the cells of higher organisms. At the present time, however, biology lacks any convincing theory of determination in terms of gene action.

It appears at first sight that more is known about actual differentiation than initial determination. Actual differentiation must involve the controlled synthesis of particular proteins, coded for by specific genes, Certainly, a great deal is known about the mechanisms that control the action of genes in directing the synthesis of proteins in simple organisms such as viruses and bacteria. It is tempting to suppose that similar systems operate in controlling the synthetic activities of genes in higher organisms. Unfortunately, no single case of an exactly similar controlling system has ever been discovered in higher organisms, in spite of an intense search for it. It may in fact be suggested that until there is a fuller understanding of the mechanism of "priming" genes at the time of determination, there can scarcely be an adequate account of the way in which the activity of these genes is controlled at later stages.

Development and evolution

Evolution is carried out by a process dependent on mutation and natural selection. Expositions of this thesis, however, tend to overlook the fact that mutation occurs in the genotype, whereas natural selection acts only on the phenotype, the organism produced. It follows from this that the theory of evolution requires as one of its essential parts a consideration of the developmental or epigenetic processes by which the genotype becomes translated into the phenotype. The consequences of such considerations are discussed in the following sections.

EFFECT ON LIFE HISTORIES

Length and timing of the reproductive phase. Natural selection results in the production by one generation of offspring that are able to survive and reproduce themselves to form a further generation. The time unit appropriate to natural selection is therefore the generation interval. There will always be some natural selective pressure for the shortening of the generation interval, simply out of "masked messenger" hypothesis

as repositories of developmental instructions

The genes

The evolu-

tionary

significance of

death

a natural economy, and for an increase of the number of offspring produced by any reproducing individual. One of the ways in which such an increase could be assured would be the lengthening of the reproductive phase in the life history; another would be an increase in the number

of offspring produced.

These are, of course, not the only natural selective pressures that operate. It is clear enough that, in evolution, they have often been overcome by other pressures. There is another natural selective pressure of more general importance. This is the pressure to restrict the length of the reproductive period, and indeed to remove reproductive individuals, in order to make room for the maturation of a new generation in which new genetic combinations can he tried out for their fitness. A species whose individuals were immortal would exhaust its possibilities for future evolution as soon as its numbers saturated all the ecological niches suitable for its way of life. Death is a necessary condition for the trying out of new genetic combinations in later generations. It is usually brought about, in great part at least, by combinations of two processes: restriction of the period of effective reproduction to a certain portion of a life history, and as a necessary consequence of this, the absence of natural selection for genetic mutations that would be effective in preserving life after reproduction has ceased. In some organisms-for instance, long-lived trees-there may be no restriction of reproduction to a particular period in the life history, but their development involves the gradual accumulation of larger and larger quantities of nonliving materials, such as dead wood, which presents a growing handicap, in the face of which the organism cannot indefinitely maintain itself against the inevitable hazards of existence. It is still something of a question whether these natural selective forces are sufficient in themselves to account for the phenomena of senescence, aging, and eventual death, which are found in various forms throughout nearly the whole biological kingdom (see below Aging and senescence).

As was mentioned above, evolution has produced a number of the types of multiphasic development, in which the life history involves a succession of larval stages. Such types of development offer the possibility of changing the relative importance of the various stages in relation to the exploitation of resources and reproduction by the species. There are, for instance, many types of animals (particularly insects) in which nearly the whole life history is passed in a larval stage in which most of the feeding and growth of the organism is carried out, the final adult stage being short and used almost entirely for reproduction. Another evolutionary strategy has been to transfer the reproductive phase from the final stage of the life history to some earlier larval stage. This again has occurred in certain insects. If such a process is carried to its logical evolutionary conclusion, the final previously adult stage of the life history may totally disappear, the larval stage of the earlier evolutionary form becoming the adult stage of the later derivative of it. An example in which this process is at least partially accomplished is in the axolotl, a salamander that reproduces in a larval stage and in nature rarely if ever metamorphoses into the adult, but can be persuaded to do so if injected with extra supplies of the hormone thyroxin. It has been suggested that such processes of neoteny (the retention of some juvenile characteristics in adulthood) have played a decisive role in certain earlier phases of evolution, evidence of which is now lost. It has been argued that the whole vertebrate phylum may have originated from modifications of one of the larval stages of an invertebrate group.

Recapitulation of ancestral stages. The modifications of life histories just mentioned are aspects of a more general situation; namely, that the only variations that can become available for natural selection to operate on are those that can be produced by alterations of the developmental or epigenetic system of an existing organism. Any new mutant gene can cause a change only in a precessiting set of developmental interactions; the phenotypes to which it can give rise are limited by the nature of the system that it will modify. One immediate result of this situation is that the development of a later evolved form will re-

tain many features from the development of its ancestors; most evolutionary developments are likely to be additions to the previous organization. Since there is evolutionary pressure to reduce the length of time between generations, the addition of a new feature to development is likely to be accompanied by a speeding up of the older stages, and probably omission of certain of them.

To repeat, the development of a late-evolved form retains those aspects of earlier life histories that are essential for the building up of later developmental stages that may be important for natural selection. In the vertebrates, for instance, highly evolved types such as mammals and birds produce during their early development remnants of the primitive kidneys (pronephros and mesonephros) that functioned as excretory organs in their evolutionary ancestors. Although these organs no longer perform their physiological functions in later organisms, they play an essential role during the formative processes of embryonic development. Some structures characteristic of evolutionary ancestors may be retained for relatively short evolutionary periods after they have lost their original function simply because there is not sufficient natural selective pressure to bring about their elimination when they no longer have any obvious function, either physiologically or epigenetically; the human appendix is an example

Adaptability and the canalization of development. A developing organism is subjected to natural selection by its particular environment. The environment is not the same for all individuals of a population, nor does it necessarily remain the same throughout evolutionary periods of time. An organism can be regarded as having to meet environmental changes that are unpredictable. There are basically two different types of strategy employed, in various proportions in different organisms, to meet this situation. One, perhaps the more obvious, is to evolve a high capacity for modification by environmental circumstances in ways that increase fitness in the environment in question: this is the strategy of increasing adaptability. It is probably true to say that all organisms show some canacity for adaptation, either short-term (physiological) or longer term (developmental), to their environments. In most organisms, however, particularly in most higher organisms, there is considerable development of the alternative strategy, which is to build up well-buffered or channelled developmental processes, which lead to the production of a relatively predictable invariant end result in the face of very diverse environments. The second strategy is likely to be followed in situations in which the environment is likely to change markedly during the course of the organism's life.

Whether or not this is the main reason for the evolution of channelled, or canalized, developmental systems, a considerable degree of canalization is very common. It is relatively rare to find instances in which the form of an animal is highly dependent on the early environment, although such dependence is common enough among plants. Much more frequently, situations such as that typified by the house mouse are encountered: the mouse develops into an almost identical form whether it lives in the tropics or in a cold-storage depot.

This canalization of development severely restricts the phenotypic effects that can be produced by mutations. In particular, many new mutations occurring in a single dose in a diploid organism are found to be recessive, or ineffective in causing any alteration in the phenotype. As this discussion makes clear, canalization should not be considered as a relation involving only the normal and mutated forms of a particular gene, but rather the result of the interaction of many genes.

GENETIC ASSIMILATION

A long-standing controversy in biology has been concerned with whether phenotypic modifications produced by abnormal environments are heritable in the sense that they can be produced by later generations in the absence of the original environmental stress. The hypothesis that they are heritable was advanced by the French evolutionist Lamarck in the 18th century and is generally known as the "inheritance of acquired characters." It found some The tendency to channel development

The role of neoteny in evolution

Conveying

the genes

through

alternate

generations

supporters among biologists, some of whom used it as an argument against the Darwinian theory of evolution. In a broad sense, all characters are to some extent inherited, in that they depend on the genotype of the organism, and to some extent acquired, since development is also affected by the environment. In a stricter sense, however, Lamarck's hypothesis suggests that there is some inherent biological property that enables organisms to pass on physical modifications to their descendants, independently of a Darwinian mechanism of selection.

The combination of adaptability and canalization in development can explain such phenomena in strictly Darwinian rather than Lamarckian terms. The abnormal environment acting during development may succeed in modifying even a well-canalized development system. If the modification is of an adaptive kind and increases the finess of the individuals in the unusual environment, it will be favoured by natural selection. The development of the selected individuals will, however, also show some properties of canalization, that it so say, resistance to

further environmental changes. This invariance may be sufficient to prevent offspring of the selected individuals from reverting completely to the original phenotype even if they are removed from the abnormal environment. After selection for an adaptive modification in an abnormal environment has proceeded for many generations, a form may be produced whose canalization is strong enough to maintain the new phenotype almost unaltered when the environment reverts to what it was before the abnormality occurred. This process, which has been demonstrated in a number of laboratory experiments, is known as genetic assimilation. It produces exactly the same results as those emphasized by advocates of the Lamarckian inheritance of acquired characters, but it produces them by an orthodox Darwinian mechanism operating on developmental systems that have the common properties of canalization and adaptability. It provides the most convincing explanation for the evolution of organisms that are physiologically or functionally adapted to the demands their way of life will make.

PLANT DEVELOPMENT

Although both plants and animals share the chemical basis of inheritance and of translation of the genetic code into structural units called proteins, plant development differs from that of animals in several important ways. Higher plants sustain growth throughout life and, in this sense, are perpetually embryonic; animals, on the other hand, generally have a determinate period of growth, after which they are considered mature. Furthermore, both growth and organ formation in plants are influenced by their possession of a rigid cell wall and a fluid-filled space called the vacuole, two features unique to the plant cell. Conversely, certain features of animal cells are absent in plants. Notable is the lack of cellular movements and fusions that play an important part in tissue and organ development in higher animals.

General features

LIFE CYCLES

The life cycle of all tracheophytes (vascular plants), byophytes (moses and liverworts), and many algae and fungi is based on an alternation of generations, or different life phases: the gametophyte, which produces gametes, or sex cells, alternating with the sporophyte, which produces spores. Gametophytes develop from the spores and, like them, are normally haploid; i.e., each cell has one set of chromosomes. Sporophytes develop from a fertilized egg, or zygote, that results from the fusion of gametes (fertilization) formed by the gametophytes; they are accordingly diploid; i.e., each cell has two sets of chromosomes. Although the two generations are phases of one life cycle, they have independent developmental histories; each begins as a single cell, passes through a juvenile period, matures, and gives rise to the alternate phase.

In various algae and fungi the two generations are alike in form (i.e., are isomorphic), and, despite the difference in chromosome number, their development follows essentially identical pathways. More commonly, however, the alternating generations have different forms (i.e. are heteromorphic); this is true for the bryophytes and for all vascular plants, both angiosperms (flowering plants) and gymnosperms (conifers and allies). General rules for vascular plants are that the sporophyte generation is physically the larger, has a more complex developmental history, produces a greater range of cell types, and expresses a more diverse biochemistry; the gametophyte is often diminutive, reduced in the case of the angiosperms to a mere few cells. In the bryophyte, is the more conspicuous.

Although the gametophyte generation in vascular plants is small and has limited physiological capabilities, its cells must convey genes capable of directing the sporophytic developmental pattern, because the pattern is transmitted through the gametes to the zygote (Figure 6). The expres-

sion of "sporophytic" genes must therefore be repressed in the gametophyte, probably from the time of spore formation (sporogenesis). Correspondingly, events associated with gamete formation (gametogenesis) or fertilization must somehow free the sporophytic genes and thus permit the zygote to enter the sporophytic developmental pattern. Although it might be supposed that the "switch" is associated with the difference in chromosome number between the haploid spore (a single set) and the diploid zygote (a double set), this has been shown not to be the determining factor.

The alternation of generations illustrates an important principle, namely that cell lineages arising from single parental cells containing the same genetic potentiality may pursue mutually exclusive developmental patterns. Channelling, or canalizing, events of this nature occur repeatedly in the course of development of an individual plant, beginning with the pattern of cell division from the very first cleavage of the zwoto cell.

BODY PLANS

Collectively plants manifest a wide range of body plans, ranging from the single cell (or unicell), with a single nucleus, through various types of colonial and filamentous forms to massive multicellular structures. (Algae, including the single-celled forms, have a great deal in common in structure and biochemistry with vascular plants. Bacteria and fungi generally are not considered plants, but because of their various plantlike qualities they are taken as plants for the purposes of this section.)

For the unicell, development is the same as cell differentiation. Although many unicellular fungi and algae show little differentiation other than that connected with reproduction, others undergo elaborate structural changes that illustrate many principles basic to development in multicellular plants. An important example is the green alga Acetabularia. This alga first produces a rootlike system and stalk and then, later, a flattened umbrella-like cap. The developmental potentialities of this unicell, with its single nucleus, are, however, limited; in order for there to be any advance beyond the state seen in Acetabularia, with the development of greater body mass and a division of labour among different parts, an increase in the number of participating nuclei seems obligatory

One method of providing more nuclei is by nuclear division without a corresponding cell division; the result is a coenocytic structure. Plants with this type of multinucleate organization show considerable diversity; examples are found in both algae and fungi. Growth occurs by the extension of the cell wall in certain zones, usually at the tips of filaments, and structural differentiation results from branching and the specialization of parts for particular functions. The aggregation of coenocytic filaments can lead to the development of a three-dimensional body, or thallus, but plants with this type of organization have not achieved great size.

A more significant type of body plan, one based on the multicellular filament, is found in its most simple form in certain algae known as diatoms, in which chains of cells of indefinite length arise, although the cells show no evidence of interaction. More advanced is the condition of many other algae, in which there occur branches that may either be identical with the original filament or show structural or physiological specialization. This condition occurs in certain green algae, in which the main branches creep and the lateral branches grow erect; such diversification represents an important developmental innovation and, possibly, the evolutionary beginnings of organ specialization in plants

Three-dimensional body forms may evolve from the association of cells in colonies. Cells among the colonial green algae are of definite number; each component cell resembles a free-living unicell, but all are united by cellular connections, or plasmodesmata, which may be important in coordinating the development of the colony. Colonies are often of precise geometric shape, forming either a circular plate or a sphere. In elaborate ones, certain cells are specialized for reproduction, and others are concerned

primarily with movement.

Another developmental pathway resulting in more massive body structure is by the association of filaments. The reproductive structures of many fungi are composed of large numbers of closely interwoven filaments, which, although not physically connected, do interact in some way to produce structures such as the mushroom cap. Several filamentous body plans are found among the red algae. In one, a single main (axial) filament grows at one end, but, just behind its tip, cells divide to produce a number of lateral filaments that grow parallel with the axial filament. The older parts of the thallus, therefore, seem to be an aggregate of filaments. More massive structures are produced when there are several axial filaments; and, by branching, particularly when accompanied by fusion, dense tissues resembling the basic undifferentiated tissue (parenchyma) of higher plants are formed. In these algae, cellular connections occur between daughter cells of a filament, and others may develop secondarily between cells of neighbouring filaments.

The transition from a filamentous to a three-dimensional

form appears most notably in the brown algae. In certain brown algae, growth is by an axial filament, but, behind the tipmost cell, divisions produce a denser tissue lacking evidence of filamentous organization. In the sporophytes of kelp, one of the largest and most complex of the algae, cell division often is restricted to areas comparable to the growing tips of vascular plants, and, although a filamentous organization may be evident in the centre of the thallus, the surrounding cortical regions are composed of a tissue that is essentially undifferentiated. (The gametophytes of kelp, however, have a simple filamentous

Three-di-

mensional

body form

organization.) Among nonvascular plants, true parenchyma is found in the bryophytes, in both the gametophyte and sporophyte phases. The development of the moss gametophyte illustrates the transition from a filamentous to a highly organized three-dimensional growth form. The moss spore germinates into a filamentous plant, the protonema, which later produces a leafy shoot. This type of transition from simple to more complex growth form is accompanied by the synthesis of new kinds of ribonucleic acids (RNA's), presumably through the activation of genes that were not expressed during the early growth of the gametophyte.

Much of the remainder of this section is concerned with the development of the complex body forms of vascularplant sporophytes, which do not normally pass through any filamentous stages. It may be noted, however, that, in the course of evolution, the capacity for this type of growth has not been lost, since it may be adopted by cells

grown in tissue cultures in the laboratory.

PREPARATORY EVENTS

The sporophytes of all vascular plants produce cells called spore mother cells-since they will give rise to sporesin spore cases (sporangia). Spore mother cells are usually surrounded, during development, by a special nutritive tissue. In the more primitive groups each sporangium holds many mother cells. This is true also in the pollenproducing sporangia of gymnosperms and angiosperms but not in the egg-producing sporangia (ovules), which usually have only one mother cell.

In certain lower vascular plants, typified by the club moss Selaginella, the gametophyte is formed entirelyor almost entirely-within the spore wall. Two kinds of gametophytes develop from the two kinds of spores produced by the sporophyte in different sporangia; the larger spore (megaspore) gives rise to the female gametophyte, the smaller spore (microspore) to the male. This condition is referred to as heterospory. The gametophytes, or prothalli, of other club mosses and most horsetails and ferns are sexually undifferentiated and arise from one kind of

spore, a condition termed homospory.

In these groups the gametophytes develop as free-living and independent plants that ultimately produce the gametes. In general, the male gametes (antherozoids) are produced in globose structures (antheridia) that are either stalked or sunken in the gametophyte. The antherozoids, always many in number, develop from mother cells enclosed in the jacket of the antheridium. Each antherozoid can move by using its whiplike hairs, or flagella, two or three (in the lycopods) or many (in the horsetails and ferns). The female gametes are formed singly in flaskshaped structures (archegonia) that also are either stalked or sunken in the gametophyte. The neck of the flask is closed by neck canal cells, which later break down to permit the entry of the male gamete. The egg itself lies in the basal part, or venter, of the flask, with a ventral canal cell above it. When the male gametes, or antherozoids, are released by the rupture of the antheridium, they swim in a water film to the archegonia and effect fertilization.

Among the gymnosperms the male gametophyte is much reduced and is a parasite on the sporophyte for only a short time. Cell cleavages within the spore wall cut off a prothallial cell, which will give rise to the vegetative (i.e., nonreproductive) part of the plant, and an antheridial cell, which divides into a tube cell and a generative cell. The male gametophyte so formed and contained within the spore wall is the pollen grain. After transfer to the ovule by wind, the pollen grain germinates to form a tube, and

Multicellularity: an advance in development

the generative cell divides into two cells, one of which forms the male gametes by further division. The gametes bear numerous spirally arranged flagella. The female gametophyte meanwhile develops entirely within the parent sporangium in the ovule. The size of the single functional spore increases greatly as the spore nucleus divides repeatedly to produce numerous free nuclei. Cell-wall formation then begins at the periphery, extending inward until the whole area is divided into cells. Up to four archegonia are formed, sunken in the tissue of the gametophyte, each with a female gamete, or egg.

The end of the gametophyte phase and the beginning of the sporophyte phase occur at fertilization, when one of the male gametes fuses with the female gamete to form the zygote, which will then develop as the sporophyte. (Development of the sporophyte can, in some cases, be triggered by means other than fertilization, in which case generations the organism is said to arise parthenogenetically.)

Fertiliza-

change of

tion: a

The male gametophyte of angiosperms is reduced to three cells, one so-called vegetative cell and two male gametes. The division producing the gametes may occur either before dispersal of the pollen grain or later, during the growth of the pollen tube. The female sporangium has one or two coats, or integuments, except for an opening (micropyle) at one end; the sporangium with an integument is called the ovule. The female gametophyte, known in this group as the embryo sac, develops from the parent spore while it is still retained in the sporangium. Three cell divisions result in eight nuclei, which arrange themselves so that three lie at each end and two lie in the centre. The cytoplasm then cleaves and three cells are formed at each pole, leaving two nuclei in a large central cell. The three cells at the micropylar pole (end toward the micropyle) form the egg apparatus. Two of these cells, called synergids, correspond to the neck cells of an archegonium; the third is the egg cell. The three cells at the opposite pole, the antipodals, play a part in embryo nutrition in certain genera. The two polar nuclei in the central cell ultimately unite, becoming the fusion nucleus. The pollen grain is transferred by various agencies (wind, water, animals) to the stigma of the female flower, and, as in the gymnosperms, it germinates to produce a tube. This tube grows through intervening tissues, through an opening (micropyle) of the egg, and enters a cell near the micropyle (synergid), in which the two male gametes are discharged. The unique feature of this phase of angiosperm development is that two fertilizations occur. One male gamete fuses with the egg to give the diploid zygote; the other makes its way to the fusion nucleus in the central cell, already diploid, and by a second fusion gives a triploid primary endosperm nucleus, which is later concerned in the formation of the nutritive tissue, or endosperm.

Early development: from zygote to seedling

EMBRYO FORMATION

Cleavage of the zygote. In vascular plants embryo formation, or embryogenesis, usually occurs within a few hours after fertilization, with the first cell division that cleaves the zygote, or fertilized egg, into two daughter cells. Thereafter, rapid cell division provides the building blocks of the primary organs of the embryo sporophyte: the first root, first leaves, and the shoot apex. Temporary structures concerned with embryo nutrition-suspensor and foot-may also be produced. These organs originate in a polarization established at the time of zygote cleavage, but the details of their development vary widely among the different groups

In the club mosses the zygote divides in a plane at right angles to the axis of the archegonium. The daughter cell toward the neck forms a short filament of cells, the suspensor; the inner cell gives rise to the other organs of the embryo, the shoot, root, and foot. The axis of the embryo is inclined to that of the archegonium and may be almost at right angles. This is in contrast to the behaviour of the true mosses, in which the embryo is oriented along the length of the archegonium, with the foot directed inward and the structures that are equivalent to the shoot, namely the spore capsule and its stalk, directed toward the neck.

A polarity like that of the mosses appears in the horsetails in which the zygote divides by transverse and longitudinal walls to form a group of four cells. Of these, the two cells toward the neck give rise to the shoot system; the inner two produce the foot and root.

The details of early embryogenesis in gymnosperms vary consider-ably. In the cycads and ginkgos, the initial cleavage establishes a polarity opposite to that in the horsetails. the inner cell giving rise to the shoot and the outer producing the root. Many conifers are unique in that the zygote undergoes a period of free-nuclear division without cell formation, producing usually four or eight nuclei, which move to the end of the zygote, away from the neck cells, where cleavage begins. In the pines a further division gives four tiers of four cells. The intermediate tiers extend greatly to form a suspensor; each of the four cells at the lower pole may act as the parent cell of an embryo, a

condition sometimes referred to as polyembryony. In contrast, there is no free-nuclear stage in angiosperm embryogenesis. The zygote cleaves by a wall more or less at right angles to the axis of the embryo sac. The daughter cell next to the micropyle (basal cell) produces a suspensor and contributes to the root; the inner (terminal) cell gives rise to the shoot system. (Angiosperm embryogenesis is more fully described in the following section dealing with

the origin of primary organs.) Notwithstanding the variation in the different groups, the pattern of development established in the early cell cleavages is consistent. The primary polarization of the zygote must necessarily be imposed by the adjacent tissues of the sporophyte, but thereafter the fate of daughter cells depends on control established within the young sporophyte itself.

Although it is often possible to specify the origin of the cell lineages contributing to the various organs and tissue layers, a geometric regularity in cell division is generally maintained through only the first few division cycles in the embryo. The final form of the embryo is thus determined not through the specification of a precise scheme of cell division, as in the development of colonial algae, but through an overall control in which cell and tissue interactions play an important part.

Origin of the primary organs. Angiosperm embryogenesis can be described in terms of a much studied flowering plant called shepherd's purse (Capsella bursa-pastoris). The zygote divides into two cells, the terminal cell and the basal cell. The terminal cell divides by a wall formed at right angles to the first cleavage wall and then again by a wall formed at right angles to this; a quadrant of cells is thus formed (Figure 7A-D). The partition of the quadrant cells in a transverse plane then produces an octant stage (Figure 7E). By transverse divisions, the basal cell forms a filament, the suspensor, of up to ten cells, the end cell of which swells to form an absorbing organ. The attachment cell, or hypophysis, adjoins the octants derived from the terminal cell (Figure 7F).

At this time, the prospective future of each of the zones of the embryo can be specified. Four cells of the octant group will ultimately produce the seed leaves (cotyledons) and the shoot apex; the other four will form the hypocotyl, the part of the embryo between the cotyledons and the primary root (radicle). The hypophysis will give rise to the radicle and the root cap; the cells of the suspensor will degenerate as the embryo matures.

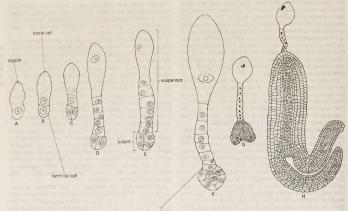

The zones of the embryo destined to form the principal organs are established by this first sequence of divisions, and tissue layers are defined during the ensuing divisions. The octant cells divide by curved walls parallel to the surface; in this way the outer layer responsible for producing the epidermis of the shoot system is defined. Divisions of a more irregular nature in the inner zone ultimately define the tissues from which the central cylinder and vascular core of the main axis of the shoot will develop. Simultaneously, the hypophysis forms a group of eight cells by three successive divisions, the planes of which are mutually at right angles. Of these eight cells, the outer four produce the root cap and epidermis; the inner four contribute to the radicle.

The embryo is at first globular (Figure 7F), but it soon

becomes heart-shaped by a combination of numerous cell divisions and enlargement in two zones of the outer hemisphere (Figure 7G). In this manner two cotyledons form. The volume of tissue between the cotyledons is the prospective shoot apex. The characteristic form of the apex is not established until after germination.

As the cotyledons become extended, the embryo bends, because of physical restraints, to conform with the cavity of the embryo sac (Figure 7H). From the heart-shaped phase onward, the core of the hypocotyl and the radicle appears as a cylinder of narrow and elongated cells. This is the parent tissue of the vascular system of the seedling. The surrounding tissue contributes the cortex layer of the

The embryogenesis of Capsella illustrates only one of several patterns found among flowering plants. Among dicotyledons, the planes of division of the terminal cell, the form of the suspensor, and the contribution made by the basal cell to the embryo all provide evidence used in determining the embryogenetic plan.

Monocotyledons, flowering plants the seeds of which contain only one cotyledon, share with dicotyledons such as Capsella the main features of early embryogenesis, including the possession of a suspensor and, in most cases, a fairly regular progression of cell divisions to the octant stage. Thereafter the symmetrical growth pattern is lost through the development of the single cotyledon. In the lily family (Liliaceae), generally accepted as a primitive family of monocotyledons, the cotyledon is derived from an octad of cells arising from the terminal cell. The hypocotyl and stem apex are derived from the proximal cell of a short filament formed by the basal cell, and the root comes from the pair of cells next to it. The suspensor forms from the distal cell or cells of the filament. In the more advanced families of monocotyledons, including the grasses (Gramineae) and orchids (Orchidaceae), embryogenesis is much less regular. The grass embryo possesses structures that do not occur in any other flowering plants, namely, the scutellum, an organ concerned with the nutrition of the seedling, and the coleoptile and coleorhiza, protective sheaths of the young shoot and the radicle. The scutellum arises from octant cells, which also contribute to the cotyledon. The basal cell forms part of the coleoptile and also gives rise to the shoot apex and the tissues of the root and coleorhiza. The embryo is asymmetrical, with the shoot apex lying on one side in a notch, ensheathed by the coleoptile.

In marked contrast, embryogenesis of the orchids is more simple. Except when a suspensor is formed, early cleavages follow no well-defined plan, and the product is an ovoid mass of tissue called the proembryo. No cotyledon, stem apex, or root apex is organized in this early period; these

organs do not appear until after germination has occurred. Nutritional dependence of the embryo. During their early growth, the embryos of all vascular plants exist as virtual parasites depending for nutrition on either the gametophyte or the previous sporophyte generation through the agency of the gametophyte or, in the special case of the angiosperms, upon an initially triploid tissue, the endosperm, which is itself nourished by the parent sporophyte.

The early nutrition of the sporophyte in ferns, horsetails, and club mosses such as Lycopodium is clearly provided by the gametophyte. In these groups the young sporophyte produces a multicellular structure, the foot, which remains embedded in the tissues of the gametophyte throughout early development withdrawing nutrients. Ultimately, both shoot and root of the sporophyte grow out from the gametophyte, but, even after the first leaf has begun to photosynthesize and thus to produce its own food, the gametophyte may persist.

In Selaginella, the gametophytes are sexually distinct. The female gametophyte develops within the wall of the megaspore. The archegonia are exposed after the megaspore wall splits, but the gametophyte never escapes completely. After fertilization, the zygote cleaves, and the outer cell produces a long suspensor that pushes the embryo deeply into the tissues of the gametophyte. A foot is then formed, as in Lycopodium, and further development of the embryo continues at the expense of reserves transferred to the megaspore from the preceding sporophyte generation.

There are superficial similarities between the nutritional history of the embryo in gymnosperms and in Selaginella, for, in each, the female gametophyte, dependent upon reserves derived from the sporophyte, acts as an intermediary between one sporophyte generation and the next.

In the pines, the female gametophyte develops within the tissues of the nucellus and acquires abundant food reserves. The proembryo forms after a period of free-nuclear division in the zygote, and the tier of cells above the basal as parasites

four then elongates to form a suspensor, which pushes the embryonic group deep into the gametophyte (Figure 8). Secondary suspensor cells may form from the basal tier to continue the process. During embryogenesis, the gametophyte continues to grow and to accumulate food materials, which are transferred to the embryo or remain as reserves in the seed.

as reserves in the seed.
From Companion Marphology of Variable Plane by Advance 3 Feater and Company Copyright 5 to 10 feater and Company Copyright 5 feater and Copyright 5 feater and Copyright 5 feater and

Figure 8: Fertilization and early embryogenesis in Pinus.

The female gametophyte of angiosperms never acquires copious reserves, although starch is frequently present in the central cell and sometimes in the egg itself. The unique feature, here, is that the embryo is nutritionally dependent upon the endosperm, a tissue that, in the genetical sense, constitutes a third organism-neither gametophyte nor sporophyte. Furthermore, as a tissue the endosperm manifests several other special characteristics. The nuclei have three chromosome sets and, therefore, three times the deoxyribonucleic acid (DNA) of haploid cells. As nuclear division ends, the amount of DNA per nucleus increases still further, a condition comparable with that in various plant- and animal-gland nuclei, presumably connected with the nutritional function of the endosperm. Nuclear division takes place at first without cell-wall formation so that a coenocyte is produced; later, partitioning of the cytoplasm results in a cellular tissue.

The reserves accumulated in the endosperm include carbohydrates (especially starch), lipids, and proteins. As reserves accumulate, the nuclei of the endosperm cells may undergo deformation and degeneration. In many plants the growing embryo consumes the endosperm before seed maturation; in others, the tissue persists in the seed, providing a reserve for the developing seedling after germition. Endosperm is not formed in certain angiosperms. In such cases the embryo depends on the transfer of nutrients directly from the sporophyte.

Tissues other than the endosperm may become specialized for the early nutrition of the embryo. The antipodal cells of the female gametophyte sometimes acquire glandular properties, as may cells of the nucellus surrounding the embryo sac. In some species the embryo itself develops a suspensor that penetrates the tissues of the parent sporophyte and acts as an absorbing organ.

Dormancy of the embryo. Among the lower pteropsids (club moses, horstails, and ferns), the principal agent of dispersal is the haploid spore and not, as in gymnosperms and angiosperms, the seed, the ripened ovule containing a dormant embryo. Since the embryo of lower pteropsids is not involved in dispersal, it does not usually undergo any marked period of dormancy after the differentiation of the primary organs. Development inistead proceeds continuously through dependence upon the gametophyte until the young sporophyte is established as a physiologically independent plant. The embryos of gymnosperms and angiosperms pass into a state of dormancy soon after the differentiation of the primary organs and the sporophyte is dispersed in a seed.

In the period leading up to dormancy, several changes occur in the embryo. The accumulation of reserves in the cotyledons or elsewhere ceases, respiratory rate declines rapidly, and cell division, with associated protein and nucleic-acid synthesis, stops. Correlated with these events are cellular changes typical of tissues with low metabolic activity. Especially obvious is the general dehydration of the cells that constitute the seed and the thickening of the cell walls of the ovule to form the seed coat (testa). The product is a structure in which the embryo is protected from temperature extremes by its state of desiccation and is often guarded from further drying and from mechanical or biological degradation by the seed coats. The seed coat often contributes to the maintenance of dormancy by physically impeding the passage of water and gases to and from the embryo, by chemically inhibiting germination, and by mechanically restricting the growth of the embryo.

Role of the seed coat in dormancy

GERMINATION AND EARLY GROWTH

Dormancy is brief for some seeds, for example those of certain short-lived annual plants. After dispersal and under appropriate environmental conditions, such as suitable temperature and access to water and oxygen, the seed germinates, and the embryo resumes growth.

The "breaking" of dormancy. The seeds of many species do not germinate immediately after exposure to conditions generally favourable for plant growth but require a "breaking" of dormancy, which may be associated with change in the seed coats or with the state of the embryo itself. Commonly the embryo has no innate dormancy and will develop after the seed coat is removed or sufficiently damaged to allow water to enter. Germination in such cases depends upon rotting or abrasion of the seed coat in the soil. Inhibitors of germination must be either leached away by water or the tissues containing them destroyed before germination can occur. Mechanical restriction of the growth of the embryo is common only in species that have thick, tough seed coats. Germination then depends upon weakening of the coat by abrasion or decomposition.

In many seeds the embryo cannot germinate even under suitable conditions until a certain period of time has lapsed. The time may be required for continued embryonic development in the seed or for some necessary finishing process—"after ripening"—the nature of which remains obscure.

The seeds of many plants that endure cold winters will not germinate unless they experience a period of low temperature, usually somewhat above freezing. Otherwise germination fails or is much delayed, with the early growth of the seedling often abnormal. (This response of seeds to chilling has a parallel in the temperature control of dormancy in buds.) In some species, germination is promoted by exposure to light of appropriate wavelengths, in others, light inhibits germination. For the seeds of certain plants, germination is promoted by red light and inhibited by light of longer wavelength, in the "far red" range of the

Low temperatures and seed germination

The food reserves

Orienta-

seedling

tion of the

spectrum. The precise significance of this response is as yet unknown, but it may be a means of adjusting germination time to the season of the year, or of detecting the depth of the seed in the soil. Light sensitivity and temperature requirements often interact, the light requirement being entirely lost at certain temperatures.

In the process of germination, water is absorbed by the embryo, which results in the rehydration and expansion of the cells. Shortly after the beginning of water uptake, or imbibition, the rate of respiration increases, and various metabolic processes, suspended or much reduced during dormancy, resume. These events are associated with structural changes in the organelles (membranous bodies concerned with metabolism), in the cells of the embryo.

The emergence of the seedling. Active growth in the embryo, other than swelling resulting from imbibition, usually begins with the emergence of the primary root from the seed, although in some species (e.g., the coconut) the shoot emerges first. Early growth is dependent mainly upon cell expansion, but, within a short time, cell division begins in the radicle and young shoot; thereafter, growth and further organ formation (organogenesis) are based upon the usual combination of increase in cell number and enlargement of individual cells.

Until it becomes nutritionally self-supporting, the seedling depends upon reserves provided by the parent sporophyte. In angiosperms these reserves are found in the endosperm, residual tissues of the ovule, or in the body of the embryo, usually in the cotyledons. In gymnosperms, food materials are contained mainly in the female gametophyte. Since reserve materials are partly in insoluble form-as starch grains, protein granules, lipid droplets, and the like-much of the early metabolism of the seedling is concerned with mobilizing these materials and delivering, or translocating, the products to active areas. Reserves outside the embryo are digested by enzymes secreted by the embryo and, in some instances, also by special cells of the endosperm.

In some seeds (e.g., castor beans) absorption of nutrients from reserves is through the cotyledons, which later expand in the light to become the first organs active in photosynthesis. When the reserves are stored in the cotyledons themselves, these organs may shrink after germination and die or develop chlorophyll and become photosynthetic.

Environmental factors play an important part not only in determining the orientation of the seedling during its establishment as a rooted plant but also in controlling some aspects of its development. The response of the seedling to gravity is important. The radicle, which normally grows downward into the soil, is said to be positively geotropic. The young shoot, or plumule, is said to be negatively geotropic, because it moves away from the soil; it rises by the extension of either the hypocotyl, the region between the radicle and the cotyledons, or the epicotyl, the segment above the level of the cotyledons. If the hypocotyl is extended, the cotyledons are carried out of the soil, but, if the epicotyl elongates, the cotyledons remain in the soil. Light affects both the orientation of the seedling and its form. When a seed germinates below the soil surface, the plumule may emerge bent over, thus protecting its delicate tip, only to straighten out when exposed to light (the curvature is retained if the shoot emerges into darkness). Correspondingly, the young leaves of the plumule in such plants as the bean do not expand and become green except after exposure to light. These adaptative responses are known to be governed by reactions in which the light-sensitive pigment phytochrome plays a part. In most seedlings, the shoot shows a strong attraction to light, or a positive phototropism, which is most evident when the source of light is from one direction. Combined with the response to gravity, this positive phototropism maximizes the likelihood that the aerial parts of the plant will reach the environment most favourable for photosynthesis.

Later development: the sporophyte plant body

CONTINUATION OF ORGAN FORMATION

Although it is convenient to refer to the early development of the plant sporophyte from the fertilized egg as embryogenesis, the process is never actually concluded as it is in the higher animals. In vascular plants, organ formation (organogenesis) is not confined to early life, and the processes of shoot, root, and leaf formation that occur first in the embryo are repeated, albeit in modified form, throughout the life of the plant. The life-span may be short and determinate, as in annual plants such as the cereals, or long, lasting for many years-indeed potentially indefinitely, except for limitations imposed by the environment and accidents-as in trees. The protracted growth of perennials, or plants that resume growth each growing season, tends to lead to increase in size, but bulk is not necessarily directly correlated with age, because individual leaves, flowers, and even whole limbs continuously die and are shed. Some long-lived plants, however, do reach a point at which losses of body mass balance the increase resulting from continued growth and organ formation.

The activity of meristems. Characteristically, vascular plants grow and develop through the activity of organforming regions, the growing points. The mechanical support and additional conductive pathways needed by increased bulk are provided by the enlargement of the older parts of the shoot and root axes. New cells are added through the activity of special tissues called meristems, the cells of which are small, intensely active metabolically, and densely packed with organelles and membranes, but usually lacking the fluid-filled sacs called vacuoles. Meristems may be classified according to their location in the plant and their special functions. One important distinction is between persistent meristems, typified by those of the growing points, and meristems with a limited life, those associated with organs, such as the leaf, of determinate growth. The regions of rapid cell division at the tips (apices) of the stem and the root are terminal meristems. In the stem apex, the uppermost part is the promeristem, below which is a zone of transversely oriented early cell walls, the file, or rib, meristem. The procambium is a meristematic tissue concerned with providing the primary tissues of the vascular system; the cambium proper is the continuous cylinder of meristematic cells responsible for producing the new vascular tissues in mature stems and roots. The cork cambium, or phellogen, produces the protective outer layers of the bark.

Among meristems of limited existence is the marginal, or plate, meristem responsible for the increase in surface area of a leaf; it contributes new cells mainly in one plane. Another type of meristem of limited life is called intercalary; it is responsible for the extension of some stems (as in the grasses) by the addition of new tissues remote from the growing points.

The number of dividing cells in persistent meristems remains roughly constant, with one of the daughter cells of each division remaining meristematic and the other differentiating as a component of a developing organ. The geometrical arrangements in the particular organ determine the way in which this occurs, but in general the consequence is that the meristem is continuously moving away from the maturing tissue as growth continues. It remains, therefore, a localized zone of specialized tissue. never becoming diluted by the interposition of expanding or differentiating cells. In organs such as leaves, flowers, and fruits, in which the growth is determinate, the divisions of meristematic cells become more widely scattered, and the frequency progressively falls as the proportion of the daughter cells that differentiate increases. Ultimately, at maturity, no localized meristem remains.

The contribution of cells and tissues. The two major factors determining the forms of plant tissues and organs are the orientation of the planes of cell division and the shapes assumed by the cells as they enlarge. Clearly, if the division planes in a cell mass are randomly oriented and individual cells expand uniformly, the tissue will enlarge as a sphere. On the other hand, if cell division planes are oriented regularly or the expansion of individual cells is directional, the tissue can assume any of a number of shapes. In a stem, for example, the cell division planes of the promeristem are oriented at various angles to the stem axis, so that new cells produced contribute to both width and length. Below this region, in the rib meristem, the proportion of divisions with the cell plate at right angles to

Classification of meristems the axis increases, so that the cells tend to be oriented in files. The cells in these files expand vertically more than they do horizontally, and, accordingly, the stem develops as a cylinder.

The factors that control the orientation of cell division planes in meristems are largely unknown. Cell interactions, however, are presumed to coordinate the distribution and orientation of the divisions. In each cell microtubules in the cytoplasm help to orient the nucleus before it divides. Then, at the time of the division, other microtubules arranged in a spindle-shaped figure (the mitotic spindle) are involved in separating the daughter chromosomes and moving them to opposite ends of the parent cell. Thereafter, the residual part of the spindle helps to locate the plate that separates the two daughter cells. Microtubules are also concerned in determining the direction of growth in expanding cells, since they appear to influence the construction of the cell wall by controlling the way cellulose is laid down in it.

Although change in shape is a form of cell differentiation, the term in the more general sense refers to a change in function, usually accompanied by specialization and the loss of the capacity for further division. Biochemical differentiation often involves a change in the character of the cell organelles-as when a generalized potential pigment body (proplastid) matures as a chloroplast, a chlorophyll-containing plastid. But it may also involve structural changes at a subcellular level, as when organelles change their character in cells engaged in intense

metabolic activity.

Influence

of the mitotic

spindle

Plant cell

walls

The differentiation of plant cells for the movement of materials and the provision of mechanical support or protection invariably depends upon modification of the walls. This usually entails the accretion of new kinds of wall materials, such as lignin in woody tissue and cutin and suberin in epidermal tissues and cork. The accompanying structural changes must be controlled, for the wall materials are not applied at random but according to a pattern appropriate to the particular cell or tissue. The development of patterns during cell-wall growth depends not only on the cytoplasmic microtubules, as in the construction of the cells that will give rise to the water-conducting vessels (xylem elements), but also on cytoplasmic membranes, as in the formation of sievelike end walls (sieve plates) in the cells that will give rise to food-conducting vessels (phloem elements).

The differentiation of xylem culminates in the death of the participating cells, and the vessels are formed of chains of empty walls. This is an example of "programmed death," not an uncommon phenomenon in plant and animal development.

THE SHOOT SYSTEM AND ITS DERIVATIVES

The shoot tip. The gametophytes of mosses and liverworts and the sporophytes of many higher plants have a shoot, or early stem, with a single cell at its tip, or apex, from which all the tissues of the stem arise. This apical cell is usually four-sided (tetrahedral), with three faces directed downward, and the fourth capping the apex. Daughter cells are continually cut off sequentially from the three inner faces, the apical cell preserving its tetrahedral shape. In cell lineages derived from the daughter cells, the division planes may remain oriented in a more or less regular manner, so that, for some distance below the apex, the three sectors can be recognized in the stem. This basic pattern occurs in the arrangement of the "leaves" of some mosses, which lie in three ranks. In many plants, however, division planes in the lower part of the apex show no particular correlation with the planes of cleavage of the apical cell, and the lateral appendages do not reflect any three-part arrangement.

Gymnosperm and angiosperm apices do not possess apical cells. The generative role is discharged by an ill-defined zone of tissue called the promeristem. Regularities may appear in the distribution of division planes only in the extreme tip region. Over the outer part of the apex, the cells often appear to lie in one to three layers, which constitute the tunica (Figure 9). Enclosed by the tunica lies a core of cells that exhibits no distinct layering; this zone is

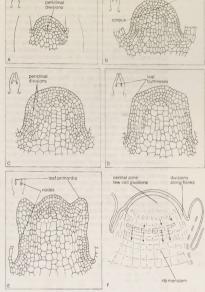

Figure 9: Leaf initiation in shoot tip of Hypericum uralum

the corpus. The layers of the tunica normally contribute to the surface layers of the plant, and the corpus provides the deeper lying tissues.

The tunica-corpus analysis emphasizes the orientation of division planes, but apices can be examined from other points of view-the sizes of cells, the degree of vacuolation, and the concentration of various cell constituents, especially ribonucleic acid (RNA), vary through the apex and this sometimes results in more or less distinctive zones. Both gymnosperm and angiosperm apices have been classified on the bases of such zonal patterns, but the validity of this approach, as well as its usefulness for understanding the function of the apex as a morphogenetic centre, has been questioned.

Since 1950, a theory of angiosperm apical zonation de-

veloped by French and Belgian botanists has been gaining support. This theory proposes that the central region of the apical dome constitutes a mass of cells with relatively low division rates, the méristème d'attente, or "waiting meristem." Surrounding this region is an annular zone of cells

with higher division rates, the anneau initial, or "initiating ring." Features other than division rates characterize these zones: RNA and protein content are lower in the méristème d'attente than in the anneau initial, and the nucleoli are smaller. In longitudinal section, the differences contribute to the patterns distinguishable in apices, some of which have been used as bases for structural classification. The main contention of the Franco-Belgian school, however, is that the zonation represents a functional difference. The méristème d'attente is regarded as a region mainly concerned with controlling the geometry of the apex. The

cells have a restricted metabolism concerned primarily in

generative role of promeristem tissue

maintaining a low rate of increase in cell number, and they themselves, as well as their immediate derivatives, take no part in organogenesis or associated differentiation. The anneau initial, by contrast, is that part of the apex that produces the beginnings, or primordia, of lateral organs. Not only is the division rate higher, but the tissue as a whole is involved in metabolic syntheses that precede morphogenesis.

One difficulty in investigating the stem apex arises from the uncertainty about which aspects are important for the overall function: division planes, division frequency, metabolic patterns, or some combination of these. Still another complication results because the apex is in a state of constant change during the growth of the plant. A longterm developmental trend begins after the definition of the growing point in early embryogenesis and continues thereafter through juvenility and the period of vegetative growth into the reproductive phase. Superimposed on this trend is a cyclical change reflecting the periodic generation of the primordia of leaves and lateral shoots in the region immediately under the apex.

The production of leaves. Leaves originate on the flanks of the shoot apex. A local concentration of cell divisions marks the very beginning of a leaf; these cells then enlarge so as to form a nipple-shaped structure called the leaf buttress. The cells of the leaf buttress may be derived from the tunica alone or from both the tunica and the corpus.

In the early growth of the leaf primordium, new cells are contributed mainly by meristematic activity at the pole directed away from the stem, so that the buttress extends in length. The subsequent distribution of growth varies among the different groups of vascular plants according to the shape of the mature leaf. In considering the angiosperms, a broad-leaved dicotyledon (tobacco; Figure 10) and a narrow-leaved monocotyledon (maize [corn])

will serve as examples.

Figure 10: Longitudinal and transverse sections of tobacco foliage leaf primordia in successive stages of development. (A,B) The primordium in early development. (C) The small lateral ridges appearing about midway on the primordium are forerunners of thelamina. (D) Development of the lamina started. (E) Further expansion of the lamina and the beginning of development of the main lateral veins. (F) Primordium five millimetres in length showing development, toward the base, of the network of provascular strands. (G) Primordium with the development of the lamina and system of venation well started. Dotted lines in C-E represent external boundaries of midrib and lateral veins and not the provascular portion

The tobacco leaf as an example

Apical growth dominates in the tobacco-leaf primordium until a height of about 0.5 millimetre (0.02 inch) is reached. Thereafter, the buttress becomes more and more flattened in the transverse plane by laterally oriented cell divisions and further expansion growth on either side. The dividing zones are the marginal meristems, through the activity of which the leaf gains its laminate form. In each meristem the outer file of cells, or marginal initials, contributes the epidermal layers by continued division. The cells below, the submarginal initials, provide the tissue of the inner part of the leaf. Usually a certain number of cell layers is defined in the mesophyll (the parenchyma between the epidermal layers of a foliage leaf). Cell division is not limited to the region of the marginal meristems but continues throughout the leaf in each of the layers, always in the same plane, until the final cell number is approached. The rate then declines, ceasing in the different layers at different times. Divisions usually end first in the epidermis. then in the lower mesophyll layers of a leaf such as that of tobacco, and last in the main photosynthetic tissue, the palisade laver, just beneath the upper epidermis.

The vascular pattern in a tobacco leaf is determined early in the development of the vessel primordium. A procambial strand is formed by the elongation of narrow axial cells, and this extends both toward the base and toward the apex, eventually linking with the procambium of the stem. When the marginal meristems become active, the lateral veins of the leaf are initiated first, followed by the third and later order branchings that give the characteristic network of veins in the mature leaf.

Although the differentiation of the cells of the vascular system begins at the base, the epidermal and mesophyll cells mature from the tip inward toward the stem. The palisade cells elongate in a plane at right angles to the epidermis; those of the lower mesophyll expand irregularly to give lobed forms. The cells of the epidermis, shaped like irregular paving stones, continue to expand in the plane of the leaf after growth ceases in the mesophyll, so that the cells of the internal tissues are pulled apart to form the system of air spaces found in the mature leaf.

Dicotyledonous leaves are folded in various ways in the bud. the patterns being determined by differential growth in the tissues of the upper and lower surfaces (laminae) of the young leaves. Differential growth may cause the lamina either to roll or fold toward the leaf midrib or to fold near lateral veins, thus pleating the lamina. The folds in the bud are, of course, eliminated during the final phase of leaf expansion.

In the development of the maize leaf, the primordium arises first as a prominence some distance below the apical dome. The zone of division and growth extends laterally around the apex so that a complete collar forms; then the margins overlap. Meanwhile the original tip zone continues to elongate, eventually surpassing the stem apex. Tip growth declines thereafter, and further increase in cell number results from meristematic activity at the base. The early development of the vascular system is unlike that in dicotyledons, for several parallel procambial strands, rather than a single midrib, are initiated. The first of these grow toward the apex, but, as tip growth ceases, procambial strands form above and extend toward the base, passing through the node, or point of insertion of the leaf primordium, and into the stem below. As the leaf extends in length, the tissues begin to mature first at the tip, and a wave of differentiation passes down toward the base, where cell division and extension growth may continue long after the tip of the leaf is mature. Protection for this immature and succulent tissue of the leaf base is afforded by the sheaths of older leaves surrounding it.

These examples illustrate the principles involved in leaf development, but there are many deviations associated with variations in leaf form. Lobing and toothing result from the persistence of cell division and growth in particular stretches of the margin after growth ceases in between. Carried to the extreme, this localized growth gives the feather-like pinnate leaf. Many monocotyledons form cylindrical leaves as a result of a fusion of the margins of the primordium after it has encircled the stem.

Branching of the shoot. The shoots of most vascular plants branch according to a consistent plan, with each new axis arising in the angle between a leaf and a stemthat is, in a leaf axil. In some plants, buds may also form from the older parts of shoot or root remote from the main apices; these buds, termed adventitious, do not conform to the general plan.

A lateral shoot apex is initiated on the flanks of the main apex but at some distance below the point of emergence of the youngest leaf primordium. As in the origin of a leaf, generally the outer cell layers contribute to the surface tissues of the new apex by maintaining a consistent pattern of divisions. In some species a tunica of more than one cell layer quickly forms, so that the new apex appears as a miniature version of the main one; alternatively, the differentiation may not become apparent until the new

Variations in leaves

histogen

theory of

origin

root-tissue

primordium has attained considerable bulk. In all cases, the new apex must reach a minimal volume before it in turn can begin to form its own lateral primordia and to organize true axillary buds. As this volume is attained, méristème d'attente-anneau initial zonation appears. As in the main apex, the formation of new primordia is associated with the annular zone.

From this point on, the development of the lateral shoot is the same as that of the main shoot, except that growth may not be as rapid because the main apex, or leading bud, dominates and absorbs much of the available nutrient. The early growth of the axillary bud proceeds quite vigorously until a certain number of leaf primordia has been formed; then apical activity slows. Cell division gradually stops, and with it the associated syntheses; thus there is no increase in the DNA of the nuclei of the meristem after the last division. The bud, in effect, passes into a state of dormancy, even though the external conditions for growth are propitious. This phenomenon is known as correlative bud inhibition, since it is determined by the activity of the leading bud of the shoot. If the leading bud is removed, the inhibited lateral buds resume growth, and with it the associated syntheses

Vascular development. Cell division planes in the zone just below the apex of the shoot tend to be oriented so that vertical files of cells are formed. This is more evident in the central core than in the surrounding cortical region, for the pattern is not disturbed by the insertion of lateral members. The first signs of the differentiation of the vascular system appear some distance below the apex. in a zone of tissue distinguishable by the smaller crosssectional area of individual cells. These cells, forming the procambium zone, arise by divisions oriented at right angles to the axis and may form a complete cylinder; generally, however, interruptions occur, the segments being related to the uppermost leaf primordia. In a dicotyledon such as tobacco, the cylinder at its highest level consists of strands running upward toward the points of insertion of the primordia. Thus, as the site of each primordium is determined, a strand forming in the adjacent region of the stem will contribute to the cylinder, but at a higher level than the preceding strand. The link with the earlier formed procambium is not simple, however. The strand passing upward toward a leaf primordium usually is composed of branches arising from strands that enter the two nearest older leaves below it. Because it in turn will contribute a branch for the next leaf, the cylinder is really a hollow network, the "gaps," or leaf traces, marking the points of departure of the leaf veins.

During subsequent development, the strands, or vascular bundles, increase in thickness by further cell divisions, and connections form with the vascular systems of axillary buds. The cells differentiate to give the characteristic tissues of the vascular system: phloem vessels (conducting tissue), phloem parenchyma (packing tissue), and phloem fibres (supporting tissue) toward the outside and xylem vessels (woody conducting tissue) toward the inside. The differentiation occurs in an upward direction, so that the maturation of the vascular tissues follows at a more or less constant distance behind the apex.

Although details differ, the above account of the origin of the primary vascular system is broadly applicable to gymnosperms and many ferns. Vascular development differs somewhat in certain flowering plants. In many monocotyledons, such as maize, the several vascular strands that pass down from each leaf primordium into the stem do not contribute to a single cylinder but are scattered in the ground tissue, or parenchyma, of the stem. Lateral interconnections form principally at the nodes.

*Increase in stem diameter is accomplished in the older stems of dicotyledons by the activity of the cambium, which produces secondary vascular tissue. This meristem, a relic of the procambium, is composed of thin-walled cells, is flattened in the radial plane, and persists between primary vascular tissue, the differentiated outer phloem, and the inner xylem. When secondary thickening begins, the parenchymatous cells between the vascular bundles also resume division, ultimately forming a cambium cylinder. The cells of the cambium divide, producing initial phloem cells toward the outside and initial xylem cells within. Files of cells are also cut off among the initial phloem and xylem cells that remain parenchymatous and are called phloem and xylem rays.

As in the apical meristem, the number of dividing cells in the cambium remains constant, except that more cells occasionally are added by divisions in the radial plane so that the girth of the cambial cylinder expands in pace with the growth of the xylem within. The addition of new phloem toward the outside compresses the primary phloem and the cortical tissues in a radial direction while stretching them tangentially. These primary tissues do not persist, however. As the girth of the stem increases, the epidermis is disrupted, and the outer layers of the cortex become meristematic, giving rise to the cork cambium, which generates cork cells on the outside. The cork layer, or bark, then takes over the protective function of the epidermis.

THE ROOT SYSTEM AND ITS DERIVATIVES

The root tip. Plants that have a single apical ceil in the shoot also have a single apical cell in the root. The cell is again tetrahedral, but sometimes daughter cells are cut off from all four faces, with the face directed away from the axis producing the cells of the root cap. The cells derived from the other faces continue to divide mostly by forming transverse walls, but occasionally also in the longitudinal plane. In this way vertical columns of cells form-tending, because of their mode of origin, to be disposed in three sectors.

In the roots of gymnosperms, angiosperms, and some lower plants, there is no single apical cell. Again, as with the shoot, such root apices can be analyzed in different ways. Perhaps the most useful approach is based upon tracing the sources of the main tissues in the apical region. Such an analysis has led to the histogen theory, which proposes that the three principal tissues of the root-vascular cylinder, cortex, and epidermis-originate from three groups of initial cells, or histogens, in the apical meristem-plerome, periblem, and dermatogen respectively. A fourth histogen, the calyptrogen, produces the root cap. The histogens have been thought to lie in linear order in the apex, with the initial cells of the vascular system toward the older part of the root, and those of the cap toward the tip.

The histogen theory is difficult to apply to some types of roots, and there has been uncertainty about the numbers of histogens. The discovery of the "quiescent centre" in the root apex has clarified many features, however. The quiescent centre is a group of cells, up to 1,000 in number, in the form of a hemisphere, with the flat face toward the root tip; it lies at the centre of the meristem, in much the same position, in fact, as the tetrahedral apical cell in certain lower plants (Figure 11). The cells of the quiescent centre are unusual in that their division rate is lower than that in the surrounding meristem. The cells of the centre have other distinctive features as well, notably a lower rate of protein synthesis than that of neighbouring cells.

The quiescent centre is surrounded by actively dividing cells of the promeristem that are the initial cells of the various tissues of the root. Those abutting the flat, tipdirected face contribute to the root cap; those above the quiescent centre are distributed in a cup shape. The cells in the centre of the cup produce the procambium and so. ultimately, give rise to the vascular cylinder. The annular zone of cells surrounding this central group forms the initials of the cortex; surrounding this, in turn, a ring of initial cells forms the protoderm, the layer corresponding to the epidermis at this level of the root.

The quiescent centre, a constant feature of the root tip, is apparently generally present in angiosperm and probably also in gymnosperms. The quiescent centre probably plays a role comparable with that of the apical cell in some lower plant roots, maintaining the geometry of the system. It has also been suggested that it may be concerned with the synthesis of growth hormones, although no direct evidence exists. When roots are damaged mechanically or by radiation, the cells of the centre can resume a rapid division rate, and they then participate in regeneration.

"cylinder" of vessels

Cambium activity

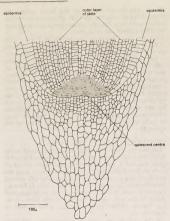

Figure 11: Median section of root apex of Zea mays.

Adapted from Biological Reviews of the Cambridge Philosophical Society (1959)

The zone of cell division extends some distance along the length of the root above the tip region. Although the girth may increase by longitudinal divisions and the widening of the daughter cells, most divisions occur in the transverse plane resulting in the formation of longitudinal files of cells.

In longitudinal section, the tissue zones become progressively better defined away from the tip. An internal protective band, the endodermis, becomes conspicuous as a single sheath of cells surrounding the procambium. The phloem procambium, recognizable by its narrow cells, begins to differentiate in the lower part of the region of elongation. The xylem also becomes distinct, the thickenings appearing first in the upper part of the extension zone. Differentiation keeps pace with the advance of the root tip as new cells are added in the promeristem. When xylem occupies the core, there is no pith as in the shoot, but the cells of the outermost layers of the vascular cylinder remain undifferentiated, forming the pericycle, a tissue important in the formation of lateral roots. Within the bounds of the pericycle, the xylem is star-shaped in section, with the first-formed xylem elements (protoxylem) occupying the ridges. The phloem lies in the intervening grooves. Outside of the endodermis, the cortical cells elongate but remain thin-walled. Above the level of the rootcap sheath, the epidermis forms the outer layer of the root, and, beyond the extension zone, its cells begin to develop root hairs.

A more complete account can be given for the mechanics of development of the root apex than for that of the stem, mainly because of its greater simplicity. An important difference lies in the absence of a mechanism for the cyclical production of lateral organs at the apex itself.

Branching of the root. The branching of the root takes place in the older parts and does not directly involve the apical meristem. The tissues concerned are the endodermis and the layer immediately beneath it, the pericycle. The endodermis participates in root branching in certain lower plants with apical cells. A cell of this layer enlarges and forms a tertahedral cell, which becomes the new apical cell; by further divisions a hemispherical volume of tissue forms around it—the whole constituting a new apex.

In many other plants, including gymnosperms and angiosperms, the lateral roots develop from the pericycle. Cells in this layer enlarge and begin to divide until a dome of tissue develops. Called the incipient apex, the dome

pushes out the surrounding endodermis, which may itself resume divisions, its daughter cells enlarging to create a sheath around the new root tip. During further growth. the dome assumes an organization like that of the primary root apex. At first, all cells are meristematic; then, while the primordium is still small, cells in the central zone cease DNA synthesis, and this zone becomes the new quiescent centre. Beyond it, the root cap is produced, and, at the base, initial cells begin to develop the cell files that become the vascular cylinder, cortex, and epidermis, The vascular tissues differentiate from the base outward. and link eventually with xylem and phloem of the parent root. All this development occurs before the tip of the new root emerges from the tissues of the parent root. The growth of the new tip into the cortex first pushes out the endodermal sheath, if one is present, and then bursts it. The cortical cells are themselves crushed and probably resorbed as the root grows on, until finally the tip breaks through the epidermis.

In most roots, new laterals are initiated in the pericycle opposite to the protoxylem ridges. They tend accordingly to form vertical ranks along the length of the root, reflecting the number of bands of protoxylem. Although lateral roots arise in quite a different way from leaves and axillary shoots at the stem apex, there are certain common features. Pericyclic cells about to produce a root primordium synthesize ribonucleic acid, in anticipation of the period of growth and morphogenesis that will result in a new apex. The same behaviour is seen in the cells of the annular zone, from which leaf primordia arise at the stem apex, and also in the axillary zones at a slightly lower level, from which new stem apices develop.

Later growth. In the secondary growth of the root, cell division in the primary xylem produces a cambium, which abuts the pericycle over the protoxylem ridges and passes between the phloem strands and the xylem in the grooves. Activity of the root cambium is comparable with that of the stem cambium; phloem elements are cut off outward, and xylem elements are cut off within. With continued growth in thickness, the star-shaped figure of the primary xylem is lost, and the cambium eventually forms a cylindical sheath. Again, as in the stem, the protective function of the epidermis is ultimately taken over by cork layers produced by a cork cambium in the outer cortex.

Correlations in plant development

COORDINATION OF SHOOT AND ROOT DEVELOPMENT

Although the structural organization of the vascular plant is comparatively loose, development of the various parts is well coordinated. Control is dependent upon the movement of chemical substances, including both nutrients and hormones.

An example of correlation is the growth of shoot and root. The enlargement of aerial parts is accompanied by increased demands for water, minerals, and mechanical support that are met by coordinated growth of the root system. Several factors apparently are concerned with control, because shoot and root affect each other reciprocally. The root depends on the shoot for organic nutrients, just as the shoot depends on the root for water and inorganic nutrients and the flow of ordinary nutrients must, therefore, play some part. More specific control, however, may be provided by the supply of nutrients required in very small amounts. The root depends on the shoot for certain vitamins, and variation in the supply, reflecting the metabolic state of the aerial parts, may also influence root growth. In addition, hormonal factors affecting cell division pass upward from the root into the stem; although the exact role of the hormones has not yet been established with certainty, they may provide one way by which the root system can influence the activity of the shoot apex.

The control of secondary thickening is another important example of growth correlation. As the size of the shoot system increases, the need for both greater mechanical support and increased transport of water, minerals, and manufactured food is met by an increase in stem girth through the activity of the vascular cambium. Generally, the cambium of trees in temperate zones is most active in

Meeting demands for food and support

Generation of lateral roots the spring, when buds open and shoots extend, creating a demand for nutrients. Cell division begins near the bud in each shoot and then spreads away from it. The terminal bud stimulates the cambium to divide rapidly through the action of two groups of plant hormones: auxins and gibberellins

The inhibition of lateral buds, another example of correlated growth response, illustrates a reaction opposite to that occurring in the control of cambial activity. Lateral buds are inhibited in general because axillary shoots grow more slowly or not at all, while the terminal bud is active. This so-called apical dominance is responsible for the characteristic single trunk growth seen in many conifers and in herbaceous plants such as the hollyhock. Weaker dominance results in a bushy growth form with repeated branching. The fact that lateral, or axillary, buds become more active when the terminal bud is removed suggests that hormonal control is involved.

The flow of auxin from the shoot tip is, in part, responsible for inhibiting axillary buds. The nutritional status of the plant also plays a role, apical dominance being strongest when mineral supply and light are inadequate. Because axillary buds are released from inhibition when treated with cell-division promoting substances (cytokinins), it has been suggested that these substances are also concerned in regulating axillary-bud activity.

DETERMINATION OF MATURE FORM

After its establishment as an independent plant, the sporophyte passes through a juvenile period before reaching maturity and becoming reproductive. Juvenility may be brief or, as in the case of trees, may extend over several years. The duration is determined partly by internal factors and partly by environmental controls related to the seasons.

In some ways juvenility is a continuation of developmental trends initiated in the embryo. In many plants, new organs are produced sequentially through early life, each of progressively more mature form. The first leaf of the young fern sporophyte, for example, is small and relatively simple, and the vascular system consists of a few forked strands. As growth proceeds, succeeding new leaves are of increasing complexity, and the shape begins to resemble that typical of the reproductive frond; in addition, vasculation shifts to the mature pattern, often one with a network of veins. Comparable trends occur in flowering plants, in which leaves at successive levels of plant maturity often show a progressive increase in the complexity of lobing

Some of the changes associated with the juvenile period can be attributed to the gradual enlargement of the growing point, necessarily small in the embryo; its volume increases progressively with development. This increase in cell number is usually associated with the emergence of a "mature" zonation pattern. The typical internal structure of the shoot apex does not develop until a specific number of leaves form

Gradual structural change in the growing point, however, does not adequately account for all aspects of juvenility. Sometimes, the transition from juvenile to adult leaf form is not graded but sudden. The juvenile leaves of species of the gymnosperm Chamaecyparis, for example, are needlelike and spreading; the adult leaves are scalelike and lie close to the stem. Among flowering plants, various species of Eucalyptus have juvenile leaves that are ovate and mature leaves that are sickle-shaped.

Such sudden transitions from juvenile to adult form, referred to as phase change, seem to depend not on slow shifts in the apex but on some determinative event or correlated group of events. The two forms are relatively stable and tend to resist change; for example, cultured tissues taken from the juvenile (ivy-leaved) parts of ivy plants maintain a higher rate of cell division, and portions, or cuttings, taken from these parts tend to form roots more readily than those from the adult (simple-leaved) parts.

The establishment of these relatively stable but not wholly irreversible states is comparable with the determination of shoot and root poles during embryogenesis and, indeed, with the alternation of generations itself. The transmission of differentiated states through cell lineages presumably

reflects the action of "switching" devices controlling the expression of different parts of the genetic complement. In this sense, phase change and related phenomena do not differ essentially from those of differentiation and organogenesis in general.

The transition in plants to the reproductive state is an example of a developmental event with some of the characteristics of phase change. Among seed plants, the reproductive structures are transformed shoots-strobili (including cones) of various kinds in the gymnosperms and flowers in angiosperms.

From a developmental point of view, the flower can be Flower regarded as a shoot axis of determinate growth, with the developlateral members occupying the sites of leaves differentiat- ment ing as floral organs-sepals, petals, stamens, and pistils. In the transition to flowering, the stem apex undergoes distinctive changes, the most conspicuous of which is in the shape of the apical region, which is related to the kind of structure to be formed, whether a single flower, as in the tulip, or a cluster of flowers (an infloresence), as in the lilac. The region of cell division extends over the entire apex, and the ribonucleic acid content of terminal cells increases. When a single flower forms, lateral primordia emerge at higher and higher levels on the flanks of the apical dome, and the entire apex is absorbed in the process, after which apical growth ceases. When an inflorescence forms, early changes are generally comparable to that for the single flower with one major difference-axillary primordia emerge that either become floral meristems or develop as secondary inflorescence branches. These primordia appear closer to the apex than do those of axillary buds on a vegetative shoot. In grasses, the activation of axillary meristems is the most notable early indication of

the passage into flowering. The rate of maturation and the timing of the transition to the reproductive phase are sometimes governed by internal controls and thus are relatively insensitive to the environment, provided conditions are generally favourable for growth. Frequently, however, the developmental rate is affected profoundly by recurring cycles in the environment, particularly those of temperature and of day length. In effect, these cycles provide a timetable for the plant, thus adjusting flowering, fruiting, and seed dispersal to the season and increasing the chances for successful propagation.

The control of the developmental rate by temperature is especially evident in many herbaceous plants of temperate climates. These plants, as indicated earlier, often must experience cold, either as seeds or as young plants, before they can begin flower production; otherwise they undergo an excessively long period of leafy, or vegetative, growth, After the cold experience, which can be given artificially, the plant is said to have been vernalized, or brought to the spring condition. Again the response is akin to a determination, because the condition attained is transmitted through subsequent cell divisions. Furthermore, there are indications that vernalization induces a persistent modification in the metabolism of apical cells and their derivatives. Ingenious theoretical schemes, offered to explain the apparent paradox that low temperature should actually accelerate a developmental process, are based mostly upon the proposition that a special vernalization hormone (vernalin) is involved. Although little direct evidence for the existence of vernalin exists, a class of hormones found in certain plant species, the gibberellins, does participate. The cold requirements of some species, such as the carrot, can be eliminated by the application of gibberellin, although

the amounts needed are substantial. The annual cycle of changing day length obviously provides the best of all "clocks" for the regulation of plant development. The effect of day length (or rather length of continuous darkness) on the transition to flowering is part of the general phenomenon of photoperiodism. Certain plants, called short-day plants, grow vegetatively when the nights are shorter than a critical minimum period (days long); exposure to longer nights (days short), however, accelerates development and brings on early flowering. Conversely, long-day plants develop very slowly toward flowering during daily cycles with longer than a minimum

Vernalization of the

Phase change

The

phase

duration of

a iuvenile

Photoperiod as a trigger flowering of darkness (days short), and are accelerated by exposure to short nights (days long). Other plants either require days of intermediate length for flowering or respond to a sequence of different photoperiods.

The leaf, rather than the stem apex, is the light-receiving organ in the photoperiodic reaction, although it is at the apex that subsequent developmental changes occur. One commonly accepted view is that, as a consequence of the photoperiodic experience, a specific flower-inducing hormone (as yet not isolated but referred to as "florigen") is synthesized in the leaf and translocated to the apex.

As in the case of vernalization, photoperiod undoubtedly affects the metabolism of the known plant hormones, and so influences many other developmental responses apart from flowering. The effect of the duration of illumination on the carbohydrate balance of the plant may also be important. Nutritional effects on flowering are well known in many species-certain fruit trees, for example.

Whether or not environmental factors influence the passage into a reproductive state of a plant, the transition must be viewed as part of the general development from juvenility to maturity: in this sense, flowering is not a radical alternative to vegetative growth but its culmination. Yet, entirely new organ types are produced at the flowering apex, presumably under the influence of genes inactive during vegetative growth.

SEASONAL ADAPTATIONS

Certain plants are perennial and survive from year to year by matching their growth to the progression of the seasons or by suspending growth altogether during unfavourable times, such as winter or a dry season.

In the temperate zone, some time before winter begins, growth ceases in the shoots of woody plants, resting buds are formed, and deciduous trees lose their leaves. The resting bud consists of a short axis, with the stem apex surrounded by modified unexpanded leaves, which protect the stem, especially from drying. The cells show marked frost resistance, similar to that of the embryo of the seed. Corresponding changes occur in herbaceous plants, in which the preparation for winter may involve the dying back of aerial parts altogether, leaving protected organs at or below the soil surface.

Growth sometimes ceases, even under favourable conditions, as a result of internal changes in the plant, This is true for some trees, which cease growth in midsummer. The passage into winter dormancy, however, is often controlled by the shortening of day length at the end of the growing season; in some plants decreasing night temperature also plays a part. Most temperate zone trees cease growth and form resting buds when the day length falls below a critical minimum.

Photoperiodic control seems to involve the formation of inhibitor compounds. In birches, for example, the leaf perceives the day length "signal" and transmits inhibitory materials to the apex, thus bringing growth to a stop and inducing the formation of a resting bud. The dormancy hormone, abscisic acid, may be concerned in this response and also in leaf abscission.

Budbreak in certain trees is controlled by photoperiod, growth resuming in the lengthening days of spring; lightperceptive organs are probably the young leaves inside the bud scales. Sometimes budbreak depends only on temperature increases that occur in spring, as in certain plants of Mediterranean climates.

The resumption of development in buds may result from a change in the balance of growth-inhibiting substances, such as abscisic acid, and growth promoters, notably the gibberellins. Buds can be caused to open prematurely by gibberellin treatment, which, as in the case of vernalization, can sometimes replace a cold experience; moreover, the gibberellin content in the buds of certain woody plants increases during chilling. Other hormones are probably also involved, however, for budbreak in plants such as the grapevine can be promoted by cytokinins, the plant celldivision factors

An important general feature of adaptive periodicities is that the developmental changes anticipate the conditions for which they will ultimately provide the appropriate physiological or morphological adjustment. The ability of plants to utilize environmental indicators such as temperature and day-length changes is vital for the survival of plants. The production of such adaptive devices is made possible by the state of continuous embryogeny, already stressed as one of the most important characteristics of plant growth. (J.H.-H.)

ANIMAL DEVELOPMENT

General features

Development, in the context of this section, includes the processes that lead eventually to the formation of a new animal starting from cells derived from one or more parent individuals. Development thus occurs following the process by which a new generation of organisms is produced by the parent generation.

REPRODUCTION AND DEVELOPMENT

Metazoan гергоduction

Response

to an ap-

proaching

unfavour-

able season

In multicellular animals (Metazoa), reproduction takes one of two essentially different forms; sexual and asexual. In asexual reproduction the new individual is derived from a blastema, a group of cells from the parent body, sometimes, as in Hydra and other coelenterates, in the form of a "bud" on the body surface. In sponges and bryozoans, the cell groups from which new individuals develop are formed internally and may be surrounded by protective shells; these bodies, which may serve as resistant forms capable of withstanding unfavourable environmental conditions, are released after the death of the parent. In certain animals the parent may split in half, as in some worms, in which an individual worm breaks into two fairly equal parts (except that the anterior half receives the mouth, "brain," and sense organs if they are present).

Obviously, in such a case it is impossible to say which of the two resulting individuals is the parent and which the offspring. Some brittle stars (starfish relatives) may reproduce by breaking across the middle of the body disk, with each of the halves subsequently growing its missing half and the corresponding arms.

A common feature of all forms of asexual reproduction is that the cells-always a substantial number of cells, never only one cell-taking part in the formation of the new individual are not essentially different from other body, or somatic, cells. The number of chromosomes (bodies carrying the hereditary material) in the cells participating in the formation of a blastema is the same as in the other somatic cells of the parent, constituting a normal, double, or diploid (2n), set.

In sexual reproduction, a new individual is produced not by somatic cells of the parent but by sex cells, or gametes, which differ essentially from somatic cells in having undergone meiosis, a process in which the number of chromosomes is reduced to one-half of the diploid (2n) number found in somatic cells; cells containing one set of chromosomes are said to be haploid (n). The resulting sex cells thus receive only half the number of chromosomes present in the somatic cell. Furthermore, the sex cells are generally capable of developing into a new individual only after two have united in a process called fertilization (see REPRODUCTION AND REPRODUCTIVE SYSTEMS: The process of fertilization).

Each type of reproduction-asexual and sexual-has advantages for the species. Asexual reproduction is, at least in some cases, the faster process, leading most rapidly to the development of large numbers of individuals. Males and females are independently capable of producing offspring. The large size of the original mass of living matter and its high degree of organization-the new individual inherits parts of the body of the parent; a part of the alimentary canal, for instance-make subsequent development more

Advantages of sexual and asexual reproduction

break

simple, and the attainment of a stage capable of selfsupport easier. New individuals produced by asexual reproduction have the same genetic constitution (genotype) as their parent and constitute what is called a clone. Though asexual reproduction is advantageous in that, if the parent animal is well adapted to its environment and the latter is stable, then all offspring will benefit, it is disadvantageous in that the fixed genotype not only makes any change in offspring impossible, should the environment change. but also prevents the acquisition of new characteristics, as part of an evolutionary process. Sexual reproduction, on the other hand, provides possibilities for variation among offspring and thus assists evolution by allowing new pairs of genes to combine in offspring. Since all body cells are derived from the fertilized egg cell, a mutation, or change, occurring in the sex cells of the parents immediately provides a new genotype in each cell of the offspring. In the course of evolution, sexual reproduction has been selected for, and established in, all main lines of organisms; asexual reproduction is found only in special cases and restricted groups of organisms.

PREPARATORY EVENTS

In the case of multicellular animals we find there are two kinds of sex cells: the female sex cell (ovum, or egg), derived from an oocyte (immature egg), and the male sex cell (spermatozoon or sperm), derived from a spermatocyte. Eggs are produced in ovaries; sperm, in testes. Both the egg and the sperm contribute to the development of the new individual; each providing one set of genes, thereby restoring the diploid number of chromosomes in the fertilized egg. The sperm possesses a whiplike tail (flagellum) that enables it to swim to the egg to fertilize it. In most cases the egg, a stationary, spherical cell, provides the potential offspring with a store of food materials, or yolk, for its early development (Figure 12). The term yolk does not

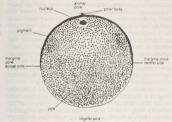

Figure 12: Amphibian egg, vertical section, showing distribution of volk and pigment in interior

refer to any particular substance but in fact includes proteins, phosphoproteins, lipids, cholesterol, and fats, all of which substances occur in various proportions in the eggs of different animals. In addition to yolk, eggs accumulate other components and acquire the structure necessary for the development of the new individual. In particular the egg acquires polarity-that is, the two ends, or poles, of the egg become distinctive from each other. At one pole, known as the animal pole, the cytoplasm appears to be more active and contains the nucleus (meiotic divisions occur in this region); at the other, called the vegetal pole, the cytoplasm is less active and contains most of the yolk. The general organization of the future animal is closely related to the polarity of the egg.

When the amount of food reserve is comparatively small, as it is in many marine invertebrates and mammals (in the latter the embryo is nourished by materials in the mother's blood), the egg may be barely visible to the unaided eve. The egg of the sea urchin is about 75 microns (0.003 inch) in diameter; that of a human being is slightly more than 0.1 millimetre. Eggs are classified according to the amount of yolk present. An egg with a small quantity of evenly

distributed yolk is called an oligolecithal egg. One with more yolk that is unevenly distributed (i.e., concentrated towards the vegetal pole) is telolecithal; and one with still greater amounts of yolk in granules or in a compact mass is megalecithal

The egg is surrounded by protective membranes, which may be soft and jellylike or hard and calcified, like shells. Egg membranes are produced while the egg is either in the ovary or being carried away from the ovary in a tube called an oviduct. The eggs of many animals have both kinds of membranes. In insects, a hard shell (chorion) forms around the eggs in the ovaries. In frogs, a very thin vitelline membrane forms around the eggs in the ovary; subsequently a layer of jelly is deposited around the eggs while they pass through the oviducts. In birds, a very thin vitelline membrane is produced around the egg in the ovary; then several layers of secondary membranes are formed in the oviduct before the egg is laid. The outermost of these secondary membranes is the calcareous shell. In mammals the egg is surrounded by the so-called pellucid zone, which is equivalent to the vitelline membrane of other animals; follicle cells form an area called the corona radiata around this zone.

After fertilization the egg, now called a zygote, is endowed with genes from two parents and has begun actual development. (Activation of the egg may be brought about by an agent other than sperm in certain animals, but such cases of parthenogenesis are exceptional. (See REPRODUC-TION AND REPRODUCTIVE SYSTEMS.)

After fertilization, the zygote undergoes a series of transformations that bring it closer to the essential organization of the parents. These transformations, initiated at a physiological, perhaps even at a molecular, level, eventually result in the appearance of certain structures. The whole process is called morphogenesis (Greek morphē, "shape" or "form"; genesis, "origin" or "production"). The process of development is more easily understood if, at every step. the changes necessary to bring the system nearer the goal are considered. Depending on the achievements necessary at any step, development can be subdivided into a number of discrete phases, the first of which, cleavage, immediately follows fertilization.

Early development

EMBRYO FORMATION

Cleavage. Since the goal of development is the production of a multicellular organism, many cells must be produced from the single-celled zygote. This task is accomplished by cleavage, a series of consecutive cell divisions. Cells produced during cleavage are called blastomeres. The divisions are mitotic-i.e., each chromosome in the nucleus splits into two daughter chromosomes, so that the two daughter blastomeres retain the diploid number of chromosomes. During cleavage, almost no growth occurs between consecutive divisions, and the total volume of living matter does not change substantially; as a consequence, the size of the cells is reduced by almost half at each division. At the beginning of cleavage, cell divisions tend to occur at the same time in all blastomeres, and the number of cells is doubled at each division. As cleavage progresses, the cells no longer divide at the same time.

Cleavage in most animals follows an orderly pattern, with the first division being in the plane of the main axis of the egg (Figure 13). This cleavage plane is arbitrarily called vertical, on the assumption that the main axis of the egg is vertical. The second cleavage plane is again vertical but at right angles to the first, giving rise to four equal cells arranged around the main axis of the egg (Figure 13). The third cleavage plane is at right angles to both the first and second cleavage planes and is horizontal, or equatorial. Subsequent divisions may alternate between vertical and horizontal cleavage planes, but later cleavage divisions become randomly oriented. This pattern is typical of many animal groups; however, more complicated patterns of cleavage are found in such animals as annelids, mollusks. and nematodes

As the amount of volk in the egg increases, it influences cleavage by hindering the cytoplasmic movements mem.

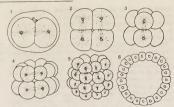

Figure 13: Cleavage of an oligolecithal egg (sea cucumber) in progressive stages 1 through 6 (see text)

Influence of yolk on cleavage

involved in mitosis. If there is only little yolk (oligolecithal eggs), the yolk granules follow the movements of the cytoplasm and are distributed in the resulting blastomeres. But if the amount of yolk is larger (megalecithal eggs), cleavages occur nearer the animal pole, where there is less yolk; as a result, the blastomeres nearer the animal pole are smaller than those nearer the vegetal pole. The presence of yolk masses may retard the onset of cleavage in a part of the egg or even suppress it altogether; in this case cleavage is partial, or meroblastic. Only a part of the egg material then is subdivided into cells, the rest remaining as a mass that serves as nourishment for the developing embryo.

Cleavage is complete, or holoblastic, in many invertebrates including coelenterates, annelids, echinoderms, tunicates, and cephalochordates. The blastomeres may be either about equal or only slightly different in size. Cleavage in amphibians is holoblastic, but the size of the blastomeres is very uneven. Blastomeres are smallest at the animal pole and largest (and yolky) at the vegetal pole. Somewhat similar conditions prevail in many mollusks. In most fishes, birds, reptiles, and egg-laying mammals (monotremes), cleavage is discoidal-i.e., restricted to a disk of cytoplasm at the animal pole of the egg, most of the yolky egg material remaining uncleaved (Figure 14). Cleavage in insects and many other arthropods is

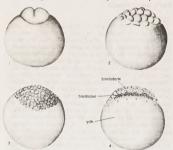

Figure 14: Discoidal cleavage of an egg of a bony fish.

superficial-i.e., the entire surface layer of egg cytoplasm subdivides into cells, and the egg contains a central mass of uncleaved yolk. The conditions of cleavage in placental mammals, including man, are peculiar.

During cleavage, development involves only an increase of cell numbers; the shape of the embryo does not change, and chemical transformations within the embryo are restricted to those necessary for cell division. Chemical and structural transformations are concerned with accumulating chromosomal material in the nuclei of the blastomeres. Before each division the chromosomes carrying the genes double in number; this means that the chromosomal material, deoxyribonucleic acid (DNA), has to be synthesized. This synthesis proceeds possibly at the expense of cytoplasmic ribonucleic acid (RNA) but certainly also from simpler organic compounds. A certain amount of protein synthesis is also necessary for cleavage to proceed: if developing eggs are treated with puromycin, a substance which is known to suppress protein synthesis, cleavage stops immediately. The proteins concerned have not vet been identified. No proteins are synthesized, however, that would foreshadow the future differentiation of parts of the embryo. It is believed that the genes in the chromosomes remain largely inactive during cleavage. The rhythm (speed) of cleavage is wholly dependent on the cytoplasm of the egg.

Although the shape and volume of the embryo do not change during cleavage, one important change in gross organization does take place. As the blastomeres are produced, they move outward, leaving a centrally located fluid-filled cavity. In cases of holoblastic cleavage, the blastomeres become arranged in a layer from one to several cells thick surrounding the cavity. The embryo at this stage may be likened to a hollow ball and is known as a blastula (Figure 15:1). The outer layer of cells is called the blastoderm, and the fluid-filled cavity the blastocoel. In discoidal cleavage the cells, which do not surround the whole embryo, lie only on the animal pole; nevertheless. a blastocoel may be formed by a crevice appearing between the blastomeres and the mass of volk (Figure 14). The blastomeres then may be arranged as a saucer-shaped blastodisk covering the blastocoel.

The formation of the blastula signifies the end of the period of cleavage. The next stage of development is concerned not with an increase in cell number, though cell divisions continue at a slower pace, but with rearrangement of the available cell masses to conform with the gross features of the future animal.

Gastrulation. The embryo in the blastula stage must go through profound transformations before it can approach adult organization. An adult multicellular animal typically possesses a concentric arrangement of tissues of the body; this feature is common to all animal groups above the level of the sponges. Adult tissues are derived from three embryonic cell layers called germinal layers: the outer layer is the ectoderm, the middle layer is the mesoderm, and the innermost layer is the endoderm (entoderm). The ectoderm gives rise to the skin covering, to the nervous system, and to the sense organs. The mesoderm produces the muscles, excretory organs, circulatory organs, sex organs (gonads), and internal skeleton. The endoderm lines the alimentary canal and gives rise to the organs associated with digestion and, in chordates, with breathing,

The blastula, which consists of only one cell layer, undergoes a dramatic reshuffling of blastomeres preparatory to the development of the various organ systems of the animal's body. This is achieved by the process of gastrulation, which is essentially a shifting or moving of the cell material of the embryo so that the three germinal layers

are aligned in their correct positions. The rearrangement of the blastula to form the germinal layers is seen clearly in certain marine animals with oligolecithal eggs. The hollow blastula consists of a simple epithelial layer (the blastoderm), the transformation of which can be likened to the pushing in of one side of a rubber ball (Figure 15). As a result of such inpushing (or invagination), the spherical embryo is converted into a double-walled cup, the opening of which represents the position of the former vegetal pole. The involuted part of the blastoderm, lining the inside of the double-walled cup, gives rise to the endoderm and mesoderm, and the blastomeres remaining on the exterior become the ectoderm. As a consequence of the infolding at the vegetal pole, the blastocoel is reduced or obliterated, and a new cavity is created, the primitive gut cavity, or archenteron, which eventually gives rise to the hollow core (lumen) of the alimentary canal. At this stage the embryo has a primitive gut with an opening to the exterior and is known as a gastrula. The opening of the gastrula is the blastopore, or primitive mouth; both terms are somewhat misleading. It would seem that the term blastopore should be applied more appropriately to an opening in a blastula, in which, of course, no opening exists. As to the term primitive

trula stage

Germinal

lavers

Chromosome doubling

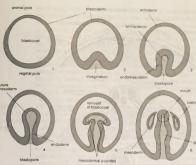

Figure 15: Gastrulation and mesoderm formation in the embryo of a starfish.

mouth, it must be pointed out that the blastopore does not always give rise to the adult mouth. In certain animal groups it becomes the anus, and a mouth forms as a completely new opening.

In some coelenterates, cells at the vegetal pole do not form an invaginating pocket, but individual cells slide inward, losing connection with other cells of the blastoderm, Eventually these cells fill the blastocoel and form a compact mass of endoderm. The cavity (archenteron) within this mass and the opening (blastopore) to the exterior are

then produced secondarily by the separation of these cells. Amphioxus, echinoderms, and amphibians. Gastrulation does not always proceed exactly as described above. In the course of evolution, certain animal groups have modified this critical stage of embryonic development, and these modifications have undoubtedly contributed to the successful continuation of species. In the primitive fishlike chordate amphioxus, for example, the invaginating blastoderm eventually comes into close contact with the inner surface of the ectoderm, thus practically squeezing the blastocoel out of existence or at least reducing it to a narrow crevice between the ectoderm and the endomesoderm. In echinoderms, on the other hand, a smaller portion of the blastoderm invaginates, and the blastocoel remains as a spacious internal cavity between the ectoderm and the endomesoderm. It persists as the primary body cavity and is the only body cavity (apart from the cavity of the alimentary canal) in such invertebrates as nematodes and rotifers.

In the double-walled-cup stage, the two internal germinal layers-endoderm and mesoderm-may not yet be distinct. Their separation may occur later, in the second phase of gastrulation, by one of two methods. One is the development of outpocketings from the wall of the archenteron. In starfishes and other echinoderms, the deep part of the endomesodermal invagination forms two thin-walled sacs, one on each side of the gastrula (Figure 15). These are the rudiments of the mesoderm; the remaining part of the archenteron becomes the endoderm and produces the lining of the gut. The cavities within the mesodermal sacs expand to become the coelom, the secondary body cavity of the animal. A somewhat similar process of mesoderm and coelom development occurs in amphioxus among the chordates, except that a series of mesodermal sacs forms on either side of the embryo, foreshadowing the segmented (metameric) structure common to chordates. Only the most anterior pairs of the mesodermal sacs actually contain a cavity at the time of their formation; the more posterior ones are solid masses of cells separating from the archenteric wall and from one another and developing coelomic cavities later.

A second method of mesoderm formation is by the splitting off of mesodermal cells from the original common mass of endomesoderm. This may take the form of single cells detaching themselves from the archenteron or of whole sheets of cells splitting off from the endoderm. An example of the latter type is seen in the gastrulation of amphibians. The development of specific regions of the early amphibian embryo-by the use of natural pigmentation or artificially introduced dyes-can be followed and their location in the adult recorded in diagrams called fate maps. The fate map of a frog blastula just prior to gastrulation demonstrates that the materials for the various organs of the embryo are not yet in the position corresponding to that in which the organs will lie in a fully developed animal. The endodermal material for the foregut, for example, lies not far from the vegetal pole; the ectodermal component of the mouth region (stomodeum) is situated close to the animal pole. Extensive rearrangement of the embryo is necessary to bring all the parts into their correct relationships.

Because of the large amount of yolk and resulting uneven cleavage, gastrulation in amphibians cannot proceed by a simple infolding of the vegetal hemisphere. A certain amount of invagination does take place, assisted by an active spreading of the animal hemisphere of the embryo; as a result, the ectoderm covers the endodermal and mesodermal areas. The spreading is sometimes described as an "overgrowth"-an inappropriate term, since no growth or increase of mass is involved. The future ectoderm simply thins out, expands, and covers a greater surface of the embryo in a movement known as epiboly.

Gastrulation in amphibians, in lungfishes, and in the cyclostomes (hagfishes and lampreys) begins with the formation of a pit on what will become the back (dorsal) side of the embryo (Figure 16). The pit represents the active

From B.I. Balinsky, An Introduction to Embryology, 3rd ed

Figure 16: Gastrulation in the frog embryo. Embryos. in four progressive stages, are represented as cut in the

shifting inward of the cells of the blastoderm. As these cells undergo a change in shape, there occurs also a contraction at the external surface, with adjacent cells being drawn toward the centre of the contraction even before an actual depression is formed. The cells most concerned in this process will become part of the future foregut. Further movement of the cells inward results in the formation of a distinct pit, which rapidly develops into a pocketlike archenteron with its opening, the blastopore. Once the archenteron is formed, more and more of the exterior cells roll over the edge of the blastopore and disappear into the interior. In the course of gastrulation the shape of the blastopore changes from a simple pit to a transverse slit and finally into a groove encircling the yolky material at the vegetal pole. As a result of epiboly of the animal hemisphere, the upper edge of the groove is gradually pushed down until the yolky cells of the vegetal pole are covered completely. The edges of the blastopore then converge toward the vegetal pole, the slit between them

tion of archenteron in amphibians

Gastrulation in starfishes being eventually reduced to a narrow canal, which lies at the posterior end of the embryo and, in some species, becomes the anal opening. (In other cases the canal closes, and a new anal opening breaks through nearby, slightly more ventrally.)

The cavity of the archenteron increases as more material from the outside is transferred inward, and the blastocoel becomes almost completely obliterated. Both mesoderm and endoderm are shifted into the interior, and only the ectoderm remains on the embryo surface. The mesoderm splits from the endoderm: the endoderm lines the archenteric cavity (and eventually becomes the lining of the alimentary canal), as the mesoderm surrounds the endoderm to form the chordamesodermal mantle. By the time the blastopore closes, the three germ layers are in their correct spatial relationship to each other.

Reptiles, birds, and mammals. Although amphibian gastrulation is considerably modified in comparison with that in animals with oligolecithal eggs (e.g., amphioxus and starfishes), an archenteron forms by a process of invagination. Such is not the case, however, in the higher vertebrates that possess eggs with enormous amounts of yolk, as do the reptiles, birds, and egg-laying mammals. Cleavage in these animals is partial (meroblastic), and, at its conclusion, the embryo consists of a disk-shaped group of cells lying on top of a mass of yolk. This cell group often splits into an upper layer, the epiblast, and a lower layer, the hypoblast. These layers do not represent ectoderm and endoderm, respectively, since almost all the cells that form the embryo are contained in the epiblast. Future mesodermal and endodermal cells sink down into the interior, leaving only the ectodermal material at the surface. In reptiles, egg-laving mammals, and some birds, a pocket-like depression occurs in the epiblast but encompasses only chordamesoderm or even only the notochord. Individual cells of the remainder of the mesoderm and endoderm migrate into the interior and there arrange themselves into a sheet of chordamesoderm and of endoderm, the latter of which mingles with cells of the hypoblast if such a layer is present. The migration of the cells destined to form mesoderm and endoderm does not take place over the whole surface of the disk-shaped embryo but is restricted to a specific area along the midline. This area is more or less oval in reptiles and lower mammals; distinctly elongated in higher mammals and birds, it is called the primitive streak (Figure 17), a thickened and slightly depressed part of the epiblast that is thickest at the anterior end, called the Hensen's node.

In animals having discoidal cleavage, the three germinal layers at the end of gastrulation are stacked flat; ectoderm on top, mesoderm in the middle, and endoderm at the bottom. The embryo is produced from the flattened layers by a process of folding to form a system of concentric tubes (Figure 18). The edges of the germ layers, which are not involved in the folding process, remain attached to the yolk and become the extra-embryonic parts; they are not directly involved in supplying cells for the embryo but break down yolk and transport it to the developing embryo.

Higher mammals-apart from the egg-laving mammalsdo not have yolk in their eggs but, having passed through an evolutionary stage of animals with yolky eggs, retain,

Figure 17: Anterior half of blastoderm of a bird embryo cut transversely to show migration of mesodermal and endodermal cells from the primitive streak

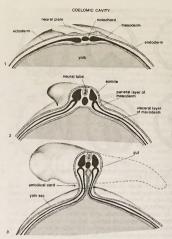

Figure 18: Vertebrate body formation from three germinal layers showing separation from volk sac after discoidal cleavage.

particularly in gastrulation, features common to reptiles (and birds, which also had reptilian ancestors). As a result, at the end of cleavage the formative cells of the embryothe cells that will actually build the body of the animalare arranged in the form of a disk over a cavity that takes the place of the volk of the reptilian ancestors of mammals. Within the disk of cells a primitive streak develops, and the three germinal layers are formed much as in many reptiles and birds

Gastrulation and the formation of the three germinal layers is the beginning of the subdivision of the mass of embryonic cells produced by cleavage. The cells then begin to change and diversify under the direction of the genes. The genes brought in by the sperm exert control for the first time; during cleavage all processes seem to be under control of the maternal genes. In cases of hybridization, in which individuals from different species produce offspring, the influence of the sperm is first apparent at gastrulation: paternal characteristics may appear at this stage; or the embryo may stop developing and die if the paternal genes are incompatible with the egg (as is the case in hybridization between species distantly related).

The diversification of cells in the embryo progresses rapidly during and after gastrulation. The visible effect is that the germinal layers become further subdivided into aggregations of cells that assume the rudimentary form of various organs and organ systems of the embryo. Thus the period of gastrulation is followed by the period of organ

formation, or organogenesis.

EMBRYONIC ADAPTATIONS

Throughout its development the embryo requires a steady supply of nourishment and oxygen and a means for disposal of wastes. These needs are met in various ways, depending in particular on (1) whether the eggs develop externally (oviparity), are retained in the maternal body until ready to hatch (ovoviviparity), or are carried in the maternal body to a later stage (viviparity); and (2) the length of embryonic development.

Adaptations in animals other than mammals. Eggs of many marine invertebrates are discharged directly into water, and the period of development before the larva emerges is relatively brief. Oxygen diffuses easily into the Gastrulation in higher mammals small eggs, and nourishment is provided by a moderate amount of yolk. During cleavage the yolk is distributed to all the blastomeres. Much of the nourishment in the egg is stored as animal starch, or glycogen, which is almost completely used by the time the larva emerges from the egg. A small amount of water and inorganic salts are taken in by the embryo from surrounding seawater. Eggs developing in freshwater carry their own supply of necessary amounts of certain salts that are not present in sufficient quantities in the environment. Products of metabolismespecially carbon dioxide and nitrogenous wastes in the form of ammonia-diffuse out from small embryos developing in water.

Mecha.

drving

nisms to

overcome

The eggs of terrestrial animals must overcome the hazard of drying. In certain species this danger is avoided because the animal returns to water to breed, such as frogs and salamanders. Some groups of insects (e.g., dragonflies, mayflies, and mosquitoes) also lay eggs in water, and the larvae are aquatic. Eggs of other animals (e.g., snails, earthworms) are laid in moist earth and thus are protected from drying up. In terms of evolution, however, a decisive solution to the problem of development on land was arrived at by most insects and by reptiles and birds, which developed eggs with a shell impermeable to water or, at least, resistant to rapid evaporation. The shells of bird and insect eggs, while restricting evaporation of water, allow oxygen to diffuse into the egg and carbon dioxide to diffuse out. Apart from gas exchange, the eggs constitute closed systems, which give nothing to the outside and require nothing from it. Such eggs are called cleidoic. Because the products of nitrogen metabolism in cleidoic eggs cannot pass through the eggshell, animals (birds and insects) have had to evolve a method of storing wastes in the form of uric acid, which, since it is insoluble, is nontoxic to the embryo.

After a short period of development in the egg, the emerging young animal has to fend for itself, unless there is some form of parental care. Exposure to the external environment at a tender age results frequently in loss of life, a hazard met by many animals through an increase in the supply of nourishment within the egg, thus allowing the young to attain a greater size and development. This tendency to produce large yolky eggs has been achieved independently in different evolutionary lines: in octopuses and squids among the mollusks, in sharks among the fishes, and in reptiles and birds among the terrestrial vertebrates.

As has been indicated, cleavage is incomplete in eggs with large amounts of yolk. Although some yolk platelets may be enclosed in the formative cells of the embryo, the bulk of the yolk remains an uncleaved mass, overgrown and surrounded by the cellular part of the embryo. In such cases a membranous bag, or yolk sac, is formed (Figure 19) and remains connected to the embryo by a narrow stalk (the evolutionary precursor of the umbilical cord of mammals). The cellular layers surrounding the yolk sac and forming its walls may consist of all three germinal layers (in reptiles and birds), so that the yolk virtually

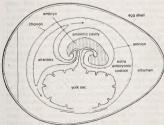

Figure 19: Position of a bird embryo in the egg and the relation of the allantois to the amniotic cavity and the yolk sac.

comes to lie inside an extension of the gut of the embryo: or (in bony fishes) the yolk sac may be enclosed in layers of ectoderm and mesoderm. In either case a network of blood vessels develops in the walls of the yolk sac and transports the yolk products to the embryo. As the yolk is broken down and utilized, the volk sac shrinks and is eventually drawn into the body of the embryo. In addition to the yolk sac, extra-embryonic parts are also encountered in the form of embryonic membranes, which are found in higher vertebrates and in insects. Vertebrates have three embryonic membranes: the amnion, the chorion, and

In reptiles, birds, and mammals, folds develop on the surface of the yolk sac just outside and around the body of the embryo proper. These folds, consisting of extraembryonic ectoderm and extra-embryonic mesoderm, rise up and fuse dorsally, enclosing the embryo in a doublelined, fluid-filled chamber known as the amniotic cavity. The inner lining of the fold becomes the amnion, and the outer becomes the chorion, which ultimately surrounds the entire embryo. The amniotic fluid protects the embryo from drying, prevents the adhesion of the embryo to the inner surface of the shell, and provides the embryo with efficient shock absorption against possible damaging jolts. (The aminion and chorion develop in the same way in insect embryos.) The third membrane, or allantois, is originally nothing more than the urinary bladder of the embryo. It is a saclike growth of the floor of the gut, into which nitrogenous wastes of the embryo are voided. It enlarges greatly during the course of development, eventually expanding between the amnion and chorion and also between the chorion and the yolk sac, to become the third embryonic membrane. In addition to providing storage space for the nitrogenous wastes of the embryo, the allantois takes up oxygen, which penetrates into the egg from the exterior, and delivers it, by way of a network

of blood vessels, to the embryo. Adaptations in mammals. At some early stage during the evolution of viviparous mammals, eggs came to be retained in the oviducts of the mother. The embryo then was provided with nourishment from fluids in the oviduct: the yolk, which became redundant, gradually ceased to be provided, and the eggs became oligolecithal. The eggshell, present in reptiles, was no longer needed and eventually disappeared, as did the white of the egg. The chorion, however, remained as the most external coat of the developing embryo through which nourishment reaches the embryo. It acquired the ability to adhere closely to the walls of the uterus (which was what that part of the oviduct holding the embryo had become) and became the so-called trophoblast. The blood-vessel network of the underlying allantois conveys nutrients that diffuse through the trophoblast to the body of the embryo proper. These modifications gave rise to a new organ, the placenta, formed from tissues of both the mother and the embryo: the uterine wall with its blood vessels provided by the mother; the trophoblast and allantois-and in some mammals also the yolk sac-with their blood vessels provided

by the embryo The overall development of placental mammals as a result of these changes is profoundly different from that of their ancestors, the reptiles, and proceeds in the following way: the tiny yolkless egg is fertilized in the upper portion of the oviduct by sperm received from the male in the process of coupling (coitus); cleavage starts as the egg is propelled slowly down the oviduct by action of cilia in the oviduct lining. At the end of cleavage a solid ball of cells called a morula is produced. The surface cells of the morula become the trophoblast and the inner cell mass gives rise to the embryo (the formative cells) and also its yolk sac, amnion, and allantois. A cavity appears within the morula, converting it into a hollow embryo, called the blastocyst. This cavity resembles the blastocoel but, in fact, is analogous to the yolk sac of meroblastic eggs, except that there is no yolk and the cavity is filled with fluid. At the blastocyst stage, the embryo enters the uterus and attaches itself to the uterine wall. This attachment, or implantation, a crucial step in the development of a mammal, is attained through the action of the trophoblast, tion

allantois

which forms extensions, known as villi, that penetrate the uterine wall (Figure 20). In higher placental mammals, the lining of the uterine wall and, in varying degrees, the underlying tissues as well are partially destroyed, resulting in a closer relationship between the blood supplies of the mother and the embryo. Indeed, in man and in some rodents, the blastocyst sinks completely into the uterine wall and becomes surrounded by uterine tissue.

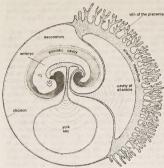

Figure 20: Embryo of placental mammal surrounded by embryonic membranes.

While implantation takes place, the formative cells arrange themselves in the form of a disk under the trophoblast. In the disk, the germinal layers develop much as in birds, with the formation of a primitive streak and migration of the chordamesoderm into a deeper layer. A layer of endoderm is formed adjoining the cavity of the blastocyst, and an amniotic cavity develops, enclosing the embryo; in lower placental mammals, the allantois also develops. The embryo proper, lying in the amniotic cavity, is connected to the extra-embryonic parts by the umbilical cord. The umbilical cord lengthens greatly during later development. In higher mammals, the cavity of the allantois is reduced, but the allantoic blood vessels become well developed and extend through the umbilical cord, connecting the embryo to the placenta. The blood that circulates in the placenta brings oxygen and nutrients from the maternal blood to the embryo and carries away carbon dioxide and other waste products from the embryo to the maternal blood for disposal by the maternal body.

Although tissues of maternal and embryonic origin are closely apposed in the placenta, there is little actual mingling of the tissues. Despite an occasional penetration of an embryo cell into the mother and vice versa, there is a placental barrier between the two tissues. The blood circulation of the mother is at all times completely separated from that of the embryo and its extra-embryonic parts. The placental barrier, however, does allow molecules of various substances to pass through; such differential permeability is indeed necessary if the embryo is to obtain nourishment. The permeability of the placental barrier differs in different animals; thus antibodies, which are protein molecules, may penetrate the placental barrier in man but not in cattle

The maintenance of the fetus-as the more advanced embryo of a mammal is called-in the uterus is under hormonal control. In the initial stages of pregnancy, the continued existence of the embryo in the uterus depends on the hormone progesterone, which is secreted by the corpora lutea, "yellow bodies," that develop in the ovary after an egg has been released.

At birth the fetal parts of the placenta separate from the maternal parts. Contraction of the uterine wall first releases the fetus from the uterus; the fetal parts of the placenta (the afterbirth) follow. In certain cases of intimate connection between fetal and maternal tissues, the maternal tissues are torn, and birth is accompanied by profuse bleeding.

Organ formation

PRIMARY ORGAN RUDIMENTS

Immediately after gastrulation-and sometimes even while gastrulation is underway-the germinal layers begin subdividing into regions that will give rise to various parts of the body. Subdivision proceeds in stages; initially a mass of cells is set aside for an organ system (for the alimentary canal, for instance) and subsequently further subdivided into the rudiments of various parts of the organ system, such as the liver, stomach, and intestines. The initially formed larger units are referred to as primary organ rudiments; those they later give rise to, as secondary organ rudiments.

The type of organ rudiment produced depends on the organization of the body in any particular group in the animal kingdom. In the vertebrates the earliest subdivision within a germinal layer is the segregation within the Developchordamesodermal mantle of the rudiment of the notochord from the rest of the mesoderm (Figure 18). During gastrulation the material of the notochord comes to lie middorsally in the roof of the archenteron. It separates by longitudinal crevices from the chordamesodermal mantle lying to the left and right. The material of the notochord then rounds off and becomes a rod-shaped strand of cells immediately under the dorsal ectoderm, stretching from the blastopore toward the anterior end of the embryo, to the midbrain level. In front of the tip of the notochord, there remains a thin sheet of prechordal mesoderm

The mesodermal layer adjoining the notochord becomes thickened and, by transverse crevices, subdivided into sections called somites (Figure 21). The somites, which later give rise to the segmented body muscles and the vertebral column, are the basis of the segmented organization typical of vertebrates (seen especially in the lower fishlike forms but also in the embryos of higher vertebrates). The lateral and ventral mesoderm, which remains unsegmented, is called the lateral plate. The somites remain connected to the lateral plate by stalks of somites that play a particular role in the development of the excretory (nephric) system in vertebrates; for this reason they are called nephrotomes. Rather early the mesodermal mantle splits into two layers, the outer parietal (somatic) layer and the inner visceral (splanchnic) layer, separated by a narrow cavity (Figure 22) that will expand later to form the coelomic, or secondary, body cavity. The coelomic cavity extends initially through the nephrotomes into the somites; in the somites it is eventually obliterated. Endoderm completely surrounds the lumen of the archenteron (when present) and produces the cavity of the alimentary canal. If no archenteric cavity is formed during gastrulation, the cavity of the alimentary canal is formed by the separation of cells in the middle of the mass of endoderm (as in bony fishes) or by folding of the sheet of endoderm (Figure 18). The endodermal gut sooner or later acquires an extended anterior part called the foregut and a narrower and more elongated posterior part, the hindgut. Characteristic of chordates is the development of the nervous system from a part of ectoderm lying originally on the dorsal side of the embryo, above the notochord and the somites. This part of the ectodermal layer thickens and becomes the neural plate (Figure 18:1), whose edges rise as neural folds that converge toward the midline, fuse together, and form the neural tube. In vertebrates the neural tube lies immediately above the notochord and extends beyond its anterior tip. The neural tube is the rudiment of the brain and spinal cord; its lumen gives rise to the cavities, or ventricles, of the brain and to the central canal of the spinal cord. The remainder of the ectoderm closes over the neural tube and becomes, in the main, the covering layer (epithelium) of the animal's skin (epidermis). As the neural tube detaches itself from the overlying ectoderm, groups of cells pinch off and form the neural crest, which plays an important role in the development of, among other things, the segmental nerves of the brain and spinal cord.

ment of notochord

Formation of the neural crest

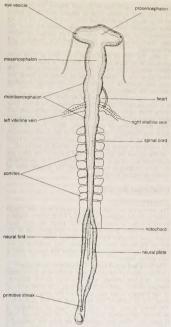

Figure 21: Early chick embryo, showing development of the brain vesicles and of some of the mesodermal structures From B.I. Balinsky, An Introduction to Embryology, 3rd ed. (1970); W.B. Saunders

In developing the primary organ rudiments mentioned above, the embryo acquires a definite organization clearly recognizable as that of a chordate animal. Similar processes, which occur in the development of other animals, establish the basic organization of an annelid, a mollusk, or an arthropod.

The organization of the embryo as a whole appears to be determined to a large extent during gastrulation, by which process different regions of the blastoderm are displaced and brought into new spatial relationships to each

other. Groups of cells that were distant from each other in the blastula come into close contact, which increases possibilities for interaction between materials of different origin. In the development of vertebrates in particular, the sliding of cells (presumptive mesoderm) into the interior and their placement on the dorsal side of the archenteron (in the archenteric "roof"), in immediate contact with the overlying ectoderm, is of major importance in development and subsequent differentiation. Experiments have shown that, at the start of gastrulation, ectoderm is incapable of progressive development of any kind; that only after invagination, with chordamesoderm lying directly underneath it, does ectoderm acquire the ability for progressive development. The dorsal mesoderm, which later differentiates into notochord, prechordal mesoderm, and somites, causes the overlying ectoderm to differentiate as neural plate. Lateral mesoderm causes overlying ectoderin to differentiate as skin. The influence exercised by parts of the embryo, which causes groups of cells to proceed along a particular path of development, is called embryonic induction. Though induction requires that the interacting parts come into close proximity, actual contact is not necessary. The inducing influence-whatever it might beis a diffusible substance emitted by the activating cells (the inductor). The inducing substance of the mesoderm is a large molecule, probably a protein or a nucleoprotein. which presumably penetrates reacting cells, though direct and unequivocal proof of such penetration is still unavailable. Inducing substances are active on vertebrates belonging to many different classes; e.g., inductions of primary organs have been obtained by transplanting mammalian tissues into frog embryos or by transplanting tissues of a chick embryo into the embryo of a rabbit,

Induction is responsible not only for the subdivision of ectoderm into neural plate and epidermis but also for the development of a large number of organ rudiments in vertebrates. The notochord is a source of induction for the development of the adjoining somites and nephrotomes: the latter appear jointly to induce development of limb rudiments from the lateral plate mesoderm. Further examples are mentioned below in connection with development of the various organs.

Since the results of induction are different for different. Inducing organ rudiments, it must be presumed that there exist inducing substances with specific action, at least to a certain extent: thus, the lateral mesoderm induces differentiation of the skin but not neural plate from the very same kind of ectoderm. The number of inducing substances need not, however, be the same as the number of different kinds of tissues and organs, since certain differentiations could possibly be induced by a combination of two or more inducing substances, or the same inducing substance might have different effects on different tissues. It has been suggested that the regional organization of the entire vertebrate body could be controlled by the graded distribution of only two inducing substances-provisionally named the neuralizing substance and the mesodermalizing substance-along the length of the embryo. The neuralizing substance, concentrated at the anterior end, gradually decreases toward the posterior end; the mesodermalizing substance, on the

substances

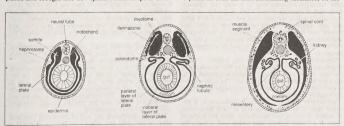

Figure 22: (Left to right) Subdivision of the mesoderm in a vertebrate embryo.

Concept

centre

of organization

other hand, is concentrated at the posterior end and decreases toward the anterior end. The differentiation of induced structures depends on the relative amounts of the two inducing substances at any given point in the embryo. Acting alone, the neuralizing substance induces only nervous tissue, which takes the form of the forebrain, and the mesodermalizing substance induces only mesodermal structures (e.g., somites, notochord).

In the amphibian embryo, induction appears to have its primary source in the dorsal lip of the blastopore, which eventually gives rise to the notochord and adjoining somites. Induction by the notochord and somites is responsible for the development of the neural plate in the ectoderm of lateral and ventral parts of the mesodermal mantle, and of the lumen of the alimentary canal in the endoderm. The dorsal lip of the blastopore for this reason has been called the primary organizer. In higher vertebrates, in which gastrulation occurs through the medium of a primitive streak, the anterior end of the streak and the Hensen's node have properties similar to those of a primary organizer. Organization centres have been found, or suspected, in embryos of animals belonging to a few other groups, in particular the insects and sea urchins, but the interpretation of the experimental results in these animals is less satisfactory than in the case of vertebrates.

The concept of an organization centre suggests that a part of the embryo differs from the rest of the embryonic tissues in being more active. The more active parts of the embryo (and also of animals in later stages of development) are particularly sensitive to certain noxious influences in their environment. If an embryo is deprived of oxygen or subjected to weak concentrations of poisons, the first parts to suffer are the most morphogenetically active ones. In vertebrate embryos the anterior end of the head is most sensitive. Early sea-urchin embryos have two centres of maximal sensitivity; one at the animal pole and the other at the vegetal pole. The damage done by noxious influences may result in actual breakdown of cells in a region of maximal sensitivity and may also lead to a depression of the developmental potential of the cells. Thus, the graded distribution of certain physiological properties appears to play a part in morphogenetic processes: physiological gradients are in fact also morphogenetic gradients.

Gradients in the embryo can be used to control development to a certain extent, by exposing the embryo to influences that, while reaching all parts, have a local effect as the result of differences in sensitivity. Disturbances of normal development often are the result of disruptions of gradients (see above Aberrations of growth: biological

malformation.).

ORGANOGENESIS AND HISTOGENESIS

The primary organ rudiments continue to give rise to the rudiments of the various organs of the fully developed animal in a process called organogenesis. The formation of organs, even those of diverse function, shares some common features, which are considered in this section. As the organs form, so do their component tissues, in a process termed histogenesis.

A germinal layer, as the name implies, is a sheet of cells. An organ rudiment may be formed and separated from such a sheet in several ways. A groove, or fold, may appear within the layer, become closed into a tube, and then separated from the original layer. A tube once formed may be subdivided into sections by constrictions and dilations of the tube at certain points. This is the way the nervous system rudiment is formed in vertebrates as already described.

Alternatively, the germinal layer may produce a round depression, or pocket. The pocket may then separate from the layer as a vesicle, or it may elongate and branch at the tip while still connected with the layer. The latter method is common in the development of various glands and also the lungs in vertebrates.

Still another method of rudiment formation in a germinal layer is by the development of local thickenings, elongated or round, and detachment from the epithelial sheet. If a lumen appears later within such a body, the result may be the same as that achieved by folding-that

is, a tube or vesicle may be formed. Indeed, the same sort of organ may develop even in related animals in either of these ways. The epithelial layer may further be cut up into segments, with the layer losing continuity, as in the formation of somites in vertebrates or similar mesodermal blocks in segmented invertebrates (e.g., annelids and arthropods).

Lastly, the cells of a germinal layer may give up their connection to each other and become a mass of loose, freely moving cells called embryonic mesenchyme. This mass gives rise to various forms of connective tissue but may also condense into more solid structures, including parts of the skeleton and the muscles.

Many organs are comprised of all three germinal layers. It is very common for glands, for instance, to derive their lining from an ectodermal or endodermal epithelium and their connective tissue (sometimes in the form of a capsule) from mesenchyme of mesodermal origin. Parts of ectoderm and endoderm cooperate also in the development of the lining of the alimentary canal, and mesoderm provides the connective tissue and muscular sheath of the canal.

In this section the development of organs of the body are dealt with according to the germinal layer that contributes the most important part, and only the development of vertebrate organs is considered.

Ectodermal derivatives

THE NERVOUS SYSTEM

The vertebrate nervous system develops from the neural plate-a thickened dorsal portion of the ectoderm-which forms a tube, as described earlier. From the very start the tube is wider anteriorly, the end that gives rise to the brain. The posterior part of the neural tube, which gives rise to the spinal cord, is narrower and stretches as the embryo lengthens. Stretching involves the head to only a very minor degree.

The brain and spinal cord. Constrictions soon appear in the brain region of the neural tube, subdividing it into three parts, or brain vesicles, which undergo further transformations in the course of development. The most anterior of the primary brain vesicles, called the prosencephalon, gives rise to parts of the brain and the eve rudiments. The latter appear in a very early stage of development as lateral protrusions from the wall of the neural tube (Figure 21), which are constricted off from the remainder of the brain rudiment as the optic vesicles. The rest of the prosencephalon constricts further into two portions. an anterior one, or telencephalon, and a posterior one, or diencephalon. The telencephalon gives rise, in lower vertebrates, to the smell, or olfactory, centre; in higher vertebrates and man, it becomes the centre of mental activities. The diencephalon, with which the eye vesicles are connected, was presumably originally an optic centre, but it has acquired, in the course of evolution, a function of hormonal regulation. The floor of the diencephalon forms a funnel-shaped depression, the infundibulum, which becomes connected with the pituitary, or hypophysis, the most important gland of internal secretion (i.e., endocrine gland) in vertebrates. Indeed, the posterior lobe of the hypophysis is actually derived from the floor of the diencephalon. Tissues of the infundibulum and the posterior lobe of the hypophysis produce certain hormones (oxytocin and vasopressin) and stimulate the production and release of other hormones from the anterior lobe of the hypophysis.

The second primary brain vesicle, the mesencephalon, gives rise to the midbrain, which, in higher vertebrates, takes part in coordinating visual and auditory stimuli.

The third primary brain vesicle, the rhombencephalon, is more elongated than the first two; it produces the metencephalon, which gives rise to the cerebellum with its hemispheres, and the myelencephalon, which becomes the medulla oblongata. The cerebellum acts as a balance and coordinating centre, and the medulla controls functions such as respiratory movements.

The cells constituting the wall of the neural tube and, later, of the brain and spinal cord become arranged in such a way that they point into the central cavity of the

Embryonic mesenchyme

Differentiation of nervous tissue tube. The differentiation of nervous tissue involves many cells abandoning their connection to the inner surface of the neural tube and migrating outward, where they accumulate as a mantle. The first cells to migrate become the neurons, or nerve cells. They produce outgrowths called axons and dendrites, by which the cells of the nervous system establish communication with one another to form a functional network. Some of the outgrowths extend beyond the confines of the brain and spinal cord as components of nerves; they establish contact with peripheral organs, which thus fall under the control of the nervous system. Cells migrating from the inner surface of the neural tube later in development become astrocytes, which are the supporting elements of nerve tissue.

The fate of nerve cells is dependent largely on whether they succeed, directly or indirectly (through other neurons), in connecting with peripheral organs. Nerve cells that fail to establish connections die. Thus, if in early stages of embryonic development, some organ, a limb rudiment for instance, is surgically removed, the nerve cells in the centres supplying nerves to such an organ are reduced in number, and the corresponding nerves also diminish or disappear. On the other hand, if an organ is introduced by transplantation into a developing embryo. the organ will be supplied by nerves from a nerve centre in which the number of cells apparently increases; no additional cells are provided, but cells that would otherwise have degenerated remain active and differentiate into functional neurons, thus satisfying the demand created by the additional organ.

Nerves do not consist entirely of outgrowths of neurons located in the brain and spinal cord. Many components of nerves are outgrowths of neurons, the cell bodies of which are located in masses called ganglia; there are three main types of ganglia: spinal ganglia, cranial ganglia, and ganglia of the autonomous nervous system. The spinal ganglia are derived from cells of the neural crest-the loose mesenchyme-like tissue that remains between the neural tube and skin after separation of the two. Part of the cells of the neural crest in the region of the trunk and tail accumulate in segmental groups (corresponding to the mesodermal somites) and provide fibres to peripheral organs and to the spinal cord. These fibres constitute the sensory pathways in the spinal nerves. The motor components of the spinal nerves-fibres that activate musclesare outgrowths of neurons lying in the spinal cord. The ganglia of the cranial nerves are produced only in part from cells of the neural crest; an additional component comes from the epidermis on the side of the head. Cells of the epidermal thickenings called placodes detach themselves and contribute to the formation of the cranial ganglia and thus of the cranial nerves.

The ganglia of the autonomous (sympathetic) nervous system are derived, as are the spinal ganglia, from neural-crest cells, but, in this case, the cells migrate downward to form groups near the dorsal aorta, near the intestine, and even in the intestinal wall itself. The outgrowths of cells in these ganglia are the nerve fibres of the sympathetic nerves (see also NERVOS AND NERVOUS SYSTEMS).

Major sense organs. The eve. As has been pointed out. the rudiments of the eyes develop from optic vesicles, each of which remains connected to the brain by an eve stalk. which later serves as the pathway for the optic nerve. The optic vesicles extend laterally until they reach the skin, whereupon the outer surface caves in so that the vesicle becomes a double-walled optic cup. The thick inner layer of the optic cup gives rise to the sensory retina of the eye; the thinner outer layer becomes the pigment coat of the retina. The opening of the optic cup, wide at first, gradually becomes constricted to form the pupil, and the edges of the cup surrounding the pupil differentiate as the iris. The refractive system of the eye and, in particular, the lens of the eye are derived not from the cup but from the epidermis overlying the eye rudiment. When the optic vesicle touches the epidermis and caves in to produce the optic cup, the epidermis opposite the opening thickens and produces a spherical lens rudiment. The lens develops by an induction by the optic vesicle on the epidermis with which it comes in contact. A further influence emanating

from the eye changes the epidermis remaining in place over the lens into a transparent area, the cornea. Influence of the optic cup on the surrounding mesenchyme causes the latter to produce a vascular layer around the retina and, outside of that, a tough fibrous or (in some animals) even a partly bony capsule called the sclera. Thus a complex interdependence of different materials produces the fully developed and functional vertebrate eye (see also SENSORY BEFETTINE Phatemetrics.

SENSORY RECEPTION: Photoreception). The ear. The main part of the ear rudiment is derived from thickened epidermis adjoining the medulla. This area of the epidermis invaginates to produce the ear vesicle, which separates from the epidermis but remains closely apposed to the medulla. The ear vesicle becomes complexly folded to produce the labyrinth of the ear. Subsequently, a group of cells of the ear vesicle becomes detached and gives rise to the acoustic ganglion. Neurons of this ganglion become connected by their nerve fibres to the sensory cells in the labyrinth, on the one hand, and with the brain (the medulla), on the other. The ear vesicle, acting on the surrounding mesenchyme, induces the latter to aggregate around the labyrinth and form the ear capsule. Further parts with various origins are added to the ear: the middle ear, from a pharyngeal pouch and the associated skeleton, and the external ear (where present), from epidermis and dermis.

The olfactory organ. The olfactory organ develops from a thickening of the epidermis adjacent to the neural fold at the anterior end of the neural plate. This thickening is converted into a pocket or sac but does not lose connection with the exterior. The openings of the sac become the external nares, and the cavity of the sac becomes the nasal cavity. Some cells of the olfactory sac differentiate as sensory epithelium and produce nerve fibres entering the forebrain. In most fishes the olfactory sac does not communicate with the oral cavity; in lungfishes and in terrestrial vertebrates, however, canals develop from the olfactory sacs to the oral cavity, where they open by internal nares. A cartilaginous capsule forms around the olfactory organ from cells believed to have been derived from the walls of the sac itself, and thus it is ectodermal in origin.

The nares and nasal cavity

Keratiniza-

Gustatory and other organs. Gustatory organs in the form of taste buds develop as local differentiations of the lining of the oral cavity but also, in fishes, in the skin epidermis. They are supplied with nerve endings, as are several other sensory bodies scattered among the tissues and organs of the developing body.

THE EPIDERMIS AND ITS OUTGROWTHS

The major part of the ectodermal epithelium covering the body gives rise to the epidermis of the skin. In fishes and aquatic larvae of amphibians, the many-layered epidermis is provided with unicellular mucous glands. In terrestrial vertebrates, however, the epidermis becomes keratinized; i.e., the outer layers of cells produce keratin, a protein that is hardened and is impermeable to water. During the process of keratinization, many cell components degenerate and the cells die; the layer of keratinized cells is therefore shed from time to time. In reptiles the shedding may take the form of a molt in which the animal literally crawls out of its own skin. It is less well known that frogs and toads also molt, shedding the surface keratinized layer of their skin (which is usually eaten by the animal). In birds and mammals, keratinized cells are shed in pieces that are sloughed off, rather than in extensive layers. In many vertebrates local thickenings of the keratinized layer appear in the form of claws, hooves, nails, and horns.

The epidermis is only the superficial layer of the skin, which is reinforced by the dermis, a connective tissue layer of a much greater thickness. The cells of the dermis are derived from mesoderm and neural-crest cells. In particular the pigment cells found in the dermis of fishes, amphibians, and reptiles are of neural-crest cells, in pigment in the skin of birds and mammals (and also in hairs and feathers) is also produced by neural-crest cells, but in these animals the pigment cells penetrate into the epidermis or deposit their pigment granules there:

The structure of the skin is further complicated by the

Formation of the optic cup Deriva-

tives of

somites

development of hairs and feathers, on the one hand, and of skin glands, on the other. Hairs and feathers development starts with a local thickening of the epidermal layer, beneath which a group of mesenchyme cells accumulate. In the case of hairs, the epidermal thickening proliferates downward and forms the root of the hair, from which the shaft then grows outward, emerging on the surface of the skin. In the case of feathers, the epidermal thickening bulges outward to form a hollow fingerlike protrusion with a connective tissue core. Secondarily, the shaft of the feather branches characteristically to produce barbs and barbules. In both cases, however, the final structure—shaff of the hair and shaft barbs and barbules of the feather—consists of keratnized and, thus, dead cells.

The skin of amphibians and mammals (but not of birds and reptiles) is provided with numerous skin glands, which develop as ingrowths from the epidermis. A peculiar type of skin gland is the mammary gland of placental mammals. In the first stage of development, mammary-gland rudiments resemble hair rudiments; they are thickenings of the epidermis with condensed mesenchyme on their inner surfaces. In some mammals (rabbit, man) two continuous epidermal thickenings called mammary lines stretch along either side of the belly of the embryo. Parts of the line corresponding in number and position to the future glands enlarge while the rest of the thickening disappears. The initial thickenings proliferate inward and produce a system of ramified cords, solid at first but hollowed out later, which become the lactiferous, or milk-bearing, ducts of the gland. Further branching at the tips of the ducts gives rise to smaller ducts and to the secretory end sacs, or alveoli, of the gland.

Mesodermal derivatives

THE BODY MUSCLES AND AXIAL SKELETON

The somites, formed in the early stages of development from the upper edges of the mesodermal mantle adjoining the notochord, are complex rudiments that subdivide and give rise to very diverse body structures. The coelomic cavity, present initially, becomes obliterated by the sideto-side flattening of the somites, so that the thinner, outer parietal layer of the somite comes in close contact with its thicker visceral layer. The visceral layer of the somite very early subdivides into two parts. The upper, dorsolateral part called the myotome (Figure 22) remains compact, giving rise to the body muscles. The lower, medioventral part of the somite, called the sclerotome, breaks up into mesenchyme, which contributes to the axial skeleton of the embryo-that is, the vertebral column, ribs, and much of the skull. The parietal layer of the somite, at a later stage, is converted into mesenchyme that, together with components of the neural crest, gives rise to the dermis of the skin and, for this reason, is called the dermatome.

The cells of the myotome are elongated in a longitudinal direction and become differentiated as muscle fibres. The myotomes, originally situated dorsally, expand on either side, pentertaing between the skin on the outside and the lateral plates of the mesoderm on the inside, until they meet midventrally; the whole body is thus enclosed in a layer of developing muscle. As the somites and myotomes are segmented, so are the muscles derived from them. Metamerism, or segmentation, a feature in the embryos of all vertebrates, remains preserved only in the adults of fishes and of terrestrial vertebrates that have clongated bodies (salamanders, snakes); it becomes largely erased in four-footed animals that depend on their limbs for locomotion.

The mesenchyme derived from the sclerotomes condenses as cartilage around the notochord and the spinal cord. It forms the cartilaginous vertebral column and ribs. In the head region it produces a part of the cartilaginous skull, mainly its posterior and ventral parts; anteriorly the somitic mesenchyme is supplemented by mesenchyme from the neural crest. Cartilaginous capsules of the olfactory organ and the ear fuse with the cartilaginous capsule surrounding the brain; to this complex are also added cartilages associated with the jaws and gill skeletion. Cartilcartilages associated with the jaws and gill skeletion. lage in the vertebral column and in the skull is replaced later in the bony fishes and in the terrestrial vertebrates by bone. At a still later stage, dermal bones are added, which, while they have no precursors in the cartilaginous skeleton, develop in the adjoining mesenchyme.

THE APPENDAGES: TAIL AND LIMBS

The tail in vertebrates is a prolongation of the body bevond the anus. It develops in early stages from the tail bud, immediately dorsal to the blastopore. Material for the tip of the tail is situated slightly forward from the edge of the blastopore. The elongation of the back of the body is greater than that of the belly; as a result the tip of the tail bud is carried beyond the blastopore and thus beyond the anus, which, in the developed embryo, marks the position of the blastopore. The consequence is that a section of the dorsal surface of the embryo comes to lie on the ventral surface of the tail; i.e., becomes inflected. The tail bud is formed from parts that have already been differentiated to a certain extent; prolongations of the neural tube and of the notochord are involved, and endoderm extends into the tail rudiment as the postanal gut, which, however, soon degenerates. The bud is also encased in ectodermal epidermis. In amphibians the somites of the tail are not derived from the chordamesodermal mantle but from the inflected posterior portion of the neural plate, which loses its nervous nature and becomes subdivided into segments corresponding to the somites of the trunk. In higher vertebrates the cells in the interior of the tail bud have an undifferentiated appearance and form a growth zone, at the expense of which parts of the tail (neural tube, notochord, somites) are extended backward as the tail elongates.

The paired limbs of vertebrates derive their first rudiments from the upper edge of the lateral plate mesoderm. The parietal layer becomes thickened, and cells escape from the epithelial arrangement and form a mesenchymal mass adjoining the cetodermal epithelium at the surface of the body. The ectodermal epithelium over the mass of mesenchyme likewise becomes thickened. In higher vertebrates, the accumulation of mesodermal cells and the thickening of the epidermis occur along the entire length of the trunk, from neck to ams, but in the middle of the trunk they soon disappear, and only the most anterior and the most posterior sections develop further into the rudiments of the forelimbs and hindlimbs, respectively. In fishes, the rudiments of the pectoral and pelve fins are more extended anteroposteriorly in earlier than in final

The mesodermal masses of the limb rudiments proliferate, and, covered with thickened epidermis, form on the surface of the body conical protrusions called the limb buds, which, once formed, possess all the materials necessary for limb development. Limb buds may be transplanted into various positions on the body or on the head and there develop into clearly recognizable limbs, conforming to their origin, whether a forelimb or hindlimb, a wing or a leg in birds. This specificity of the limb is carried by the mesodermal part of the rudiment, but a complex interaction between the mesodermal mesenchyme and the ectodermal epidermis is necessary for the normal development of the limb. In four-limbed vertebrates (tetrapods), the tips of the limb buds become flattened and broadened into hand or foot plates. The edge of the plate is indented, forming the rudiments of the digits. Meanwhile, local areas of the mesodermal mesenchyme in the interior of the limb rudiment condense; these are the rudiments of the various components of the limb skeleton. In fishes, small outgrowths from the myotomes enter the limb rudiment to form the muscles of the fins. In tetrapods, however, the limb muscles develop from the same mass of mesenchyme that gives rise to the skeleton. Thus the muscles of the body and the muscles of the limbs have different origins-the first develop from the myotomes (thus from the somites), and the second develop from the lateral plate mesoderm via the limb buds.

The nerves supplying the limbs grow into the limb rudiments from the spinal cord and the spinal ganglia. The nerves are guided in some way by the limb rudiments, for, if limb rudiments are displaced by transplantation to Formation of the tail bud

Limb buds

an abnormal position, the nerves still find their way and establish normal relationships to the limb muscles. Limb rudiments transplanted to sites very far from their normal positions induce local nerves to enter the limb, thereby making it motile.

EXCRETORY ORGANS

Nephrotome development

The kidneys of vertebrates consist of a mass of tubules that develop from the stalks of somites called nephrotomes. In some primitive vertebrates such as cyclostomes, the nephrotome in each segment gives rise to only one tubule (Figure 22), but, in the great majority of vertebrates, mesenchyme from adjacent nephrotomes fuses into a common mass that differentiates into a number of nephric tubules irrespective of the original segmentation of the mesoderm. Under primitive conditions each tubule opens by a funnel (the nephrostome) into the coelomic cavity; the opposite ends of the tubules fuse to form the collecting ducts of the kidney. A collection of capillaries (the glomerulus) becomes associated with the nephric tubule, forming its filtration apparatus. The glomerulus may be situated in the coelomic cavity opposite the nephrostome or, in all the more advanced animals, intercalated into the nephric tubule, forming with the latter a renal corpuscle of the kidney. In adults of all vertebrates above the amphibians, the nephrostomes disappear (or are never formed), so that the tubule begins with the renal corpuscle. Parts of the kidney in vertebrates can be distinguished as the pronephros (most anteriorly, at the forelimb level), the mesonephros (in the midtrunk region), and the metanephros (in the pelvic region). The three sections of the kidney develop at different stages, starting with the pronephros and ending with the metanephros. In their morphology and mode of development, the anterior parts show more primitive conditions than the posterior ones. The pronephros, developing early in embryo formation, is the functional kidney of fish and amphibian larvae. Its collecting duct opens into the hindmost part of the intestine, called the cloaca, and later also serves as the collecting duct of the mesonephros. In reptiles, birds, and mammals, the pronephros is nonfunctional, although even in these animals its duct persists as the mesonephric duct. The mesonephros develops later and replaces the pronephros as the functional kidney of adult fishes and amphibians and of the embryos of reptiles. birds, and mammals. The tubules of the mesonephros link up with the duct derived from the pronephros. The pronephric duct in fact stimulates the development of mesonephric tubules, and, in its absence, the mesonephros does not develop at all.

The metanephros is found only in reptiles, birds, and mammals. It replaces the mesonephros of the early embryonic stages and continues as the functional kidney in the postembryonic and adult life of these animals. The metanephros develops from mesenchyme derived from the nephrotomes of the posterior part of the trunk and lying dorsal to the mesonephric duct. The actual differentiation is initiated by a dorsal outgrowth of the mesonephric duct, called the ureteric bud. The ureteric bud grows in the direction of the mesenchyme and becomes the ureter. Having penetrated the mass of mesenchyme, it starts to branch, producing the collecting tubules of the kidney; the mesenchyme, meanwhile, in response to the influence of the duct and its branches, aggregates to form the excretory tubules of the kidney. The influence of the ureter is indispensable for the development of the metanephric excretory tubules, for, if the ureter fails to develop or, in its outgrowth, stops short of reaching the kidney-producing mesenchyme, no kidney develops.

CIRCULATORY ORGANS

The rudiment of the heart in vertebrates develops from the ventral edges of the mesodermal mantle in the anterior part of the body, immediately adjoining the pharyngeal region. A group of mesodermal cells breaks away from the ventral edge of the lateral plate, takes a position just underneath the pharyngeal endoderm, and becomes arranged in the form of a thin-walled tube, which will become the endocardium, or lining of the heart (Figure 23). In vertebrates with complete cleavage, the endocardial tube is single and

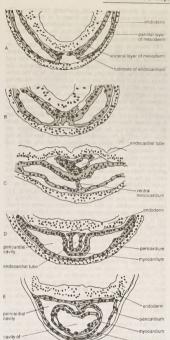

Figure 23: Development of the heart in amphibian embryos.

From O. Hertwig, Handbuch der Vergleichendenden und Experimentellen Entwicklungslehre der Wibblisten (1906). Guster Fischer Verlag.

medial from its start. In higher vertebrates with meroblastic cleavage-reptiles, birds, and mammals-the embryo in early stages of development is flattened out on the surface of the yolk sac; therefore, what are morphologically the ventral edges of the mesodermal mantle lie far apart on the perimeter of the blastodisc. As a result of this arrangement. two endocardial tubes are formed, one on either side of the embryo. Subsequently, when the embryo becomes separated from the volk sac, the two endocardial tubes meet in the midline ventral to the pharynx and fuse, producing a single heart rudiment. After the formation of the endocardium, or the lining of the heart, the coelomic cavity in the lateral plate mesoderm adjoining the heart rudiment expands slightly and envelops the endocardial tube or tubes (Figure 23). The heart muscle layer, or myocardium, develops from the visceral (splanchnic) layer of the lateral plate that is in contact with the endocardial tube; the parietal (somatic) layer of the lateral plate forms the pericardium. or covering of the heart. The portion of the coelom surrounding the heart becomes separated from the rest of the body cavity and develops into the pericardial cavity.

The endocardial tube branches anteriorly into two tubes, the ventral aortas; a similar branching of the endocardial tube posteriorly forms the two vitelline veins, which carry blood from the midgut endoderm or from the yolk sac (when present) to the heart.

In its earliest development, the heart rudiment shows a

Development of the metanephros degree of dependence on the adjoining endoderm. The whole of the endoderm can be removed in newt embryos in the neural-tube stage. In such endodermless embryos, the heart fails to develop, even though the mesoderm destined to form the heart rudiment is left intact.

Development of the heart

arches

The heart is initially a straight tube stretching in an anteroposterior direction. Rather early in development, however, it becomes twisted in a characteristic way and subdivided into four main parts: the most posterior, the sinus venosus; the atrium, which comes to lie at the anteriorly directed bend of the tube; the ventricle, occupying the apex of the posteroventrally directed inflexion; and, most anteriorly, the conus arteriosus. In the course of development in the more advanced vertebrates, the atrium and ventricle become partially or completely subdivided into right and left halves. In amphibians, only the atrium is separated into two halves, by a partition starting from the posterior end. In reptiles, a partition separates the atria and part of the ventricle. In birds and mammals, the subdivision of the heart is complete, with two atria and two ventricles.

The complete subdivision of the heart is important for separating the pulmonary, or lung, blood supply from the general body circulation. But, if this separation developed early in the embryo, it would create difficulties, since the lungs of the embryo are not functional; the enrichment of the blood with oxygen occurs instead in the placenta. The partition between the atria in mammalian embryos remains incomplete, so that blood returning from the body and from the placenta enters into the right half of the heart but is shunted (through the interatrial foramen) into the left half of the heart and thence again into general circulation. At birth, however, the interatrial foramen is closed by a membraneous flap, and oxygen-depleted blood from the body enters the right atrium, is channelled into the right ventricle, and thence to the lungs for oxygenating.

In an adult vertebrate, blood vessels extend to all parts of the body. It would seem that channels for the supply of blood are provided in proportion to the local demand of the tissues; progressively developing organs or parts with particularly intensified function always receive an increased blood supply. The rudiments of blood vessels are always aggregations of mesenchyme cells. In any blood vessel the endothelial tube is formed first, and the muscular and elastic layers are added later.

The main blood channels in vertebrates develop in certain favoured situations; namely (1) between the endoderm and lateral plate mesoderm; (2) around the kidneys. especially the pronephros and mesonephros; and (3) in connection with the heart, which is a special case of the first category.

From the paired forward extensions from the heart, the ventral aortas, loops develop between the pharvngeal clefts. The aortic These are the aortic arches (Figure 24), which served originally to supply blood to the gills in aquatic vertebrates. The arches are laid down in all vertebrates, six or more being found in cyclostomes and fishes; six are present in the embryos of tetrapods, but the first two are degenerate. The arches of the third pair develop as the carotid arteries,

supplying blood to the head. Those of the fourth pair

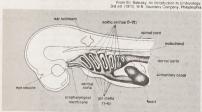

Figure 24: Relation of the aortic arches and the branchial clefts in a dogfish embryo.

(and, exceptionally, in urodeles also the fifth) join dorsally to form the dorsal aorta, providing blood to most of the body. These are the systemic arches. The arches of the sixth pair are the pulmonary arches; in embryos they carry blood to the dorsal aorta, as well as to the lungs, but in fully developed amniotes (reptiles, birds, and mammals). they carry blood only to the lungs.

The paired posterior extensions of the heart of the early embryo are the vitelline veins, whose branches spread out between the lateral plate mesoderm and the endoderm especially the endoderm of the yolk sac, when present. On their way to the heart, the vitelline veins pass through the liver and break up into a system of small channels-the hepatic sinusoids. Parts of the vitelline veins lying posterior to the liver become the hepatic portal veins, which carry blood from the intestine to the liver; the parts of the vitelline veins anterior to the liver become the hepatic veins, which carry blood fom the liver to the sinus venosus in lower vertebrates (anamniotes), but become the anterior section of the postcaval vein in amniotes.

Whereas the vitelline veins and, later, the hepatic portal vein carry blood from the endodermal parts of the embryo and from the yolk sac to the heart, the blood from the mesodermal and ectodermal parts is returned to the heart through a system of cardinal veins (Figure 25). These latter veins start their development in the form of an irregular

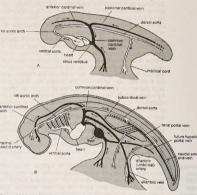

Figure 25: General arrangement of blood vessels in (A) an early amniote embryo and (B) the further development of the circulatory system. The arteries are shown in white, the veins in black

sinus around the pronephros, connected by the common cardinal veins (ducts of Cuvier), on either side, to the sinus venosus. Extensions anteriorly and posteriorly give rise to the precardinal and postcardinal veins, respectively. The postcaval vein, present in terrestrial vertebrates, is a late acquisition, both in evolution and in embryogenesis; it is a result of the intercommunication of several venous channels, including the anterior portion of the vitelline veins.

The first blood cells in vertebrate embryos form in association with the intestinal endoderm on the volk sac. Groups of mesoderm cells derived from the splanchnic layer of the lateral plate (extra-embryonically in cases in which a yolk sac is present) become so-called blood islands, which are particularly conspicuous on the yolk sac of bird embryos (in the area vasculosa). In bird's eggs, the internal cells of the blood island start producing hemoglobin (gascarrying component of blood) and become the first red blood cells (erythrocytes) as early as the second day of incubation. The outer cells of the blood islands develop into an endothelial layer and form a network of blood vessels covering part of the surface of the yolk sac. The network

Development of the cardinal veins acquires a connection to the vitelline veins and vitelline arteries (the latter being branches of the dorsal aorta); thus the blood corpuscles formed in the blood islands can enter the general blood circulation.

At later stages of embryogenesis, blood-cell formation shifts from the blood islands to the liver and, still later, to the bone marrow

The lymphatic system, in a manner similar to the blood vessels, develops by the local aggregation of connective tissue to form lymphatic vessels.

REPRODUCTIVE ORGANS

Origin of

germ cells

In considering the development of reproductive organs, distinctions must be made between: (1) the origin of sex cells (gametes), (2) the origin and differentiation of the sex glands, or gonads (ovaries and testes), and (3) the origin and development of the supporting parts of the reproductive system (e.g., genital ducts, copulatory organs).

The germ (germinal) cells, which eventually give rise to the gametes, are often segregated from the somatic, or body, cells at a very early stage—during cleavage and before the subdivision of the embryo into ectoderm, mesoderm, and endoderm. In the invertebrate nematodes, the very first of these primordial germ cells is identifiable after as few as five divisions of the egg cell. The germ cell retains the large chromosomes present in the fertilized egg; in the somatic cells the chromosomes become fragmented. Subsequently, the single germ cell gives rise, by mitotic divisions, to all the gametes in the sonad:

In vertebrates, primordial germ cells arise outside the gonads, but they cannot be distinguished in early cleavage stages. In amphibians, cytoplasm at the vegetal pole, rich in ribonucleic acids, becomes incorporated into a number of cells, which, during cleavage and gastrulation, lie among the yolky endoderm cells. Later they migrate into the mesodermal layer and become incorporated into the mesodermal layer and become incorporated into the rudiments of the gonads. In higher vertebrates, primordial germ cells can be recognized in the extra-embryonic endoderm of the yolk sac. In mammals, these cells subsequently migrate into the mesoderm and are located in the gonad rudiments. The mouse embryo, for example, originally has fewer than 100 primary germ cells during their migration, however, their numbers increase as a result of repeated divisions, to 5,000 or more in the gonads.

Although the primordial germ cells either may appear before the separation of germinal layers or be found originally in the endoderm, the gonads are invariably of mesodermal origin. In vertebrates, the first trace of gonad development is a thickening of the coelomic lining on either side of the dorsal mesentery and medial to the kidney rudiments. The thickening, elongated anteroposteriorly, is known as the germinal ridge (Figure 26). The ridge protrudes into the coelomic cavity, and the fold of thickened epithelium becomes filled with mesenchyme. At this stage the primordial germ cells invade the rudiments of the gonads and become associated with the somatic cells of the germinal ridge. In the functionally differentiated gonads, only the actual gametes and their predecessors (spermatogonia and oogonia) are derived from the primary germ cells; the supporting cells are somatic cells of local mesodermal origin. In the ovaries, the follicle cells surrounding and nourishing the young egg cells (oocytes) are of somatic origin, as are also the connective tissue and blood vessels of the gonad. In the testes, supporting elements called Sertoli cells are somatic cells, as are the interstitial cells, which are scattered between the sperm-carrying tubules of the testes and believed to be the source of male hormones. In the early stages of their development-even while

In the early stages of their development—even while the gonad rudiment is being invaded by primordial germ cells—the female and male gonads are in an indifferent stage. Only later does tissue differentiation of the gonads begin and male or female gonadal development proceed.

The genital ducts, by which the eggs and sperm are carried wavy from the gonads, are, in vertebrates, linked with the excretory system. In the male, the seminiferous tubules connect with the nephric tubules of the mesonephros, and the sperm are carried to the exterior by way of the mesonephric duct. In males of lower vertebrates, the mesonephric duct thus serves as a channel

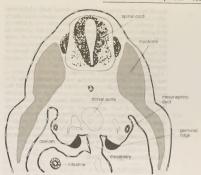

Figure 26: Transverse section of a mouse embryo showing the position of the germinal ridges and their relation to the mesonephric rudiment and the dorsal mesentery.

From 8.1 Belinksy, An introduction to Embroology 3rd ed

both for urine and for sex cells. In amniotes the development of the metanephros as the urine excreting organ has freed the mesonephric duct to carry products associated only with reproduction. In the female, a separate duct, the paramesonephric duct (Müllerian duct), develops beside the mesonephric duct. At its anterior end it utilizes the funnels of the pronephric tubules as its entrance (ostium). The paramesonephric duct develops initially in both female and male embryos. The ducts remain in an indifferent stage longer than the gonads. Eventually the sex hormones produced by the differentiating gonads cause a corresponding differentiation of the ducts. The mesonephric ducts, which become reduced in female embryos, remain in male embryos as ducts for conveying sperm (ductus deferens). The paramesonephric ducts, on the other hand, degenerate in male embryos but become the oviducts in female embryos (Figure 27). In mammals, the terminal portions of the paired oviducts differentiate as two uteri, which, in primates and man, fuse to form a single uterus. In all terrestrial vertebrates except the placental mammals, the genital ducts, as well as the ducts of excretory organs, open into the cloaca. In mammals, however, the

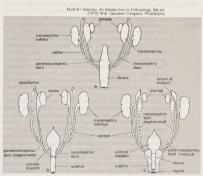

Figure 27: Transformations of the genital ducts in mammalian embryos in transition from an (A) indifferent stage to (B) the male and (C) female condition.

Development of genital ducts

Formation

vertebrate

mouth

cloaca becomes subdivided into a dorsal part, which convevs the feces, and a ventral part, which receives excretory and genital products. In male mammals the excretory and genital ducts remain connected, having the urethra as their common outlet; in females the urethra serves only for the passage of urine and the uterus opens separately by means of the vagina. In nearly all vertebrates, the male nephric duct is utilized in some degree for the conduction of sperm.

Copulatory organs have developed independently in several groups of vertebrates having internal fertilization. The penis in mammals develops from an outgrowth called the genital tubercle, located at the anterior edge of the urinogenital orifice. The tubercle is laid down in a similar way in embryos of both sexes, and the region of the urinogenital orifice remains in an indifferent state even longer than do the genital ducts. In a comparatively late stage of embryonic life the genital tubercle of male embryos encloses the urethral canal and becomes the penis; in female embryos it remains small and becomes the clitoris.

Endodermal derivatives

THE ALIMENTARY CANAL

The alimentary canal is the chief organ developing from endoderm. The way it forms depends on the type of egg cleavage. In eggs with holoblastic (complete) cleavage, after gastrulation the invaginated mass of endoderm lines the archenteron, the cavity of which becomes the alimentary canal, or gut. In eggs with meroblastic (partial) cleavageand also in mammals (despite their complete cleavage)the endoderm is produced in the form of a sheet lying flat over the volk-sac cavity. Subsequently, folds of endoderm and splanchnic mesoderm appear-first anteriorly, then laterally, and lastly posteriorly-and sink, converging ventrally under the embryo and cutting off the future gut cavity from the cavity of the yolk sac. The most anterior and posterior portions of the gut separate, but the middle part remains in open communication with the yolk sac throughout embryonic life, eventually becoming reduced to the yolk stalk, which passes through the umbilical cord.

The alimentary canal of vertebrates becomes differentiated into the oral cavity, pharynx, esophagus, stomach, and intestine. Whether derived from an archenteron or formed by folding of the endodermal sheet, the canal initially does not possess an opening at its anterior end. This is also the case in some lower chordates and echinoderms, which are grouped together with vertebrates as the Deuterostomia, or animals with secondary mouths.

In vertebrates, a mouth forms by a rupture at the anterior end, where the endoderm is in contact with ectoderm. The ectoderm of the future mouth region becomes depressed, forming a mouth invagination, or stomodaeum. The ectodermal and endodermal layers separating the cavity of the stomodaeum from the gut fuse to form the oropharyngeal membrane, which thins and ruptures, providing free passage from the exterior to the gut. Because of its mode of origin, the oral cavity is in part lined by ectoderm and in part by endoderm, the two parts becoming indistinguishable. Before the oropharyngeal membrane ruptures, however, a small pocket forms on the dorsal side of the stomodaeal invagination. This, the rudiment of the anterior lobe of the hypophysis, becomes apposed to the ventral

surface of the diencephalon and loses its connection with

the mouth cavity.

The anal opening in some exceptional cases (urodele amphibians) is derived directly from the blastopore, which persists as a narrow canal after completion of gastrulation. In other vertebrates, however, the anus develops either near the location of the former blastopore or in a corresponding region at the posterior end of the embryo, where the last remnants of mesoderm migrated to the interior. It is thus claimed that the anus in vertebrates is derived, directly or indirectly, from the blastopore. The mode of formation of the opening is somewhat similar to that of the mouth. A slight invagination of the ectoderm occurs, and a cloacal membrane forms, separating the ectodermal invagination from the gut cavity. The membrane ruptures later to provide the anus.

THE PHARYNX AND ITS OUTGROWTHS

The anterior portion of the endodermal gut, lying immediately posterior to the mouth cavity, expands laterally as the pharynx. The lateral pockets of the pharyngeal cavity, called the pharyngeal pouches, perforate the mesodermal layer, reach the ectoderm, and break through to form pharyngeal, or gill, clefts (Figure 24). In fishes and larvae of amphibians, these clefts develop gills and become respiratory organs. Pharyngeal pouches develop in the early embryos of all vertebrates, including the airbreathing terrestrial reptiles, birds, and mammals. The number of pouches has been reduced in the course of evolution from six or more to four in tetrapods, and the posterior pouches may not actually break through.

The consistent development of pharyngeal pouches and clefts indicates their importance in vertebrate development. Many parts of the vertebrate body are derived from. or dependent on, the pharyngeal pouches; for example, the aortic arches-the most important blood vessels of a vertebrate-develop between successive pharyngeal pouches (Figure 25). Skeletal visceral arches also occur between consecutive pharvngeal pouches (they do not develop if the pharyngeal pouches are prevented from developing). In adult terrestrial vertebrates, parts of the visceral arches are transformed into the hyoid apparatus, supporting the tongue, the auditory ossicles, and parts of the larynx and trachea. Furthermore, some of the material of the pharyngeal pouches is utilized for the formation of the parathyroid glands and the thymus; the former are indispensable glands of internal secretion, and the latter are a source, in mammals, of cells that produce antibodies. The pharynx also produces the rudiment of the thyroid gland as a ventral outgrowth.

THE LIVER, PANCREAS, AND LUNGS

Three additional important organs develop from the endoderm: the liver, the pancreas, and the lungs. The liver develops as a ventral outgrowth of the endodermal gut just posterior to the section that eventually will become the stomach. Initially, the liver takes the form of a tubular gland, but it soon acquires a close relationship to the blood sinuses and capillaries, forming lobules around blood vessels rather than around glandular ducts. The pancreas develops from three independent rudiments: two ventral ones, formed just posterior to the liver rudiment, and a dorsal one. The ventral and the dorsal rudiments fuse in most vertebrates to form one organ with a complicated system of ducts opening into the duodenum, a portion of the small intestine. The lungs develop from a ventral hollow outgrowth of the gut, which is located just posterior to the pharyngeal region; the outgrowth branches into a right and left trunk that grow posteriorly beside the esophagus and then expand into hollow sacs, in lower terrestrial vertebrates, or into a system of tubes, in birds and mammals.

The endodermal parts of the alimentary system are, along their entire length, encased by the splanchnic mesoderm of the lateral plates. The coelomic cavities of the right and left sides fuse ventral to the gut but remain separated dorsally by their respective walls, which form the dorsal mesentery-a double membrane by which the gut is suspended from the dorsal side of the body cavity and through which blood vessels and nerves reach the gut (Figure 22). The layer of splanchnic mesoderm next to the endoderm produces the connective tissue and muscular layers of the gut. During development of the glands of the alimentary canal (e.g., pancreas, salivary glands), the mesoderm forms a connective tissue capsule around the branching tubules of the gland. The development of the tubules is dependent on this mesodermal capsule and cannot proceed without it.

Postembryonic development

After partially developing within the egg membranes or within the maternal body, the newly formed individual emerges. The new animal is then born (ejected from the mother's body) or hatched from the egg. The condition of the new organism at the time of birth or hatching

Development of

differs in various groups of animals, and even among animals within a particular group. In sea urchins, for example, the embryo emerges soon after fertilization, in the blastula stage. Covered with cilia, the sea-urchin blastula swims in the water and proceeds with gastrulation. Frog embryos emerge from the egg membranes when the main organs have already begun to develop, but functional differentiation of the tissues is unfinished; for instance, the components of the eyes and ears are far from complete, the mouth is not yet open, and the gut is filled with yolkladen cells. Certain birds (called precocial) emerge from the egg covered with downy feathers and can run about soon after hatching, whereas others (altricial) hatch naked, with only rudiments of feathers, and are quite unable to move around. Among mammals there is a great range in the degree of development at birth. In marsupials, such as opossums and kangaroos, the young are born incompletely developed and very small; the young are then kept for a long time in the pouch of the mother, all the while firmly attached to the teats and suckling. Many small mammals are helpless at birth. Mice are born naked and blind; puppies and kittens are born covered with fur but with unopened eyes. Newborn human babies have their eyes open but cannot move themselves about for several months. Hoofed mammals, on the other hand, bear young that can stand up and run after their mothers within a few hours of birth.

Egg tooth of birds

Advan-

tages of

larvae

In birds the hard shell is broken by the hatchling's beak, which is provided with a sharp tubercle on its top. A similar "egg tooth" appears on the tip of the snout of hatchling reptiles. Many arthropods have a preformed line of fragility that allows part of the eggshell to be burst open like a lid, allowing the young to emerge. Birth in mammals is effected through the contraction of smooth muscles of the uterus

THE LARVAL PHASE AND METAMORPHOSIS

The organism emerging from the egg or from the maternal body, apart from being incompletely developed, may have an organization more or less different from that of an adult. In some cases the difference is so great that, without knowing the origin of the eggs or without following the young through their full course of development, it would be impossible to know that the young and the adult are of the same animal species. Such young, called larvae, transform into the adult form by a process of metamorphosis. The term larva also applies to young that resemble the adult form but differ from it in some substantial respect, as in possessing organs not present in the adult or in lacking an important structure (apart from sex glands and associated parts, which tend to develop later in life in most animals). Larvae in different animals have special names given to them, such as the tadpole of frogs, the caterpillar of butterflies, and the fry of fishes.

The development of the embryo into a larva rather than directly into an organism similar to the adult has various

advantages. At the time of emergence from the egg, the new individual is relatively small, and the organization that enables the adult to lead a particular mode of life may not be suitable for a miniature copy of the adult. The larva may have to procure food for itself and, being small, may not be able to feed in the same way as the adult. It also may not be able to use effectively the same defense mechanisms the adult possesses. The larval stage enables an animal to avoid such hazards; it provides a mode of life and corresponding organization better suited to the smaller size of the newly emerged organism. Another advantage is that the larva may be able to exploit an entirely different environment because its organization is very different from that of the adults. A terrestrial adult may have aquatic larvae, a flying adult may have burrowing larvae, and a parasitic adult may have a freeliving larva. A third advantage of a larval stage emerges in animals whose adult stages are sessile or restricted in their movements; the larvae can move freely, either of their own accord or on water currents. In this way the larvae of sedentary animals serve for the dispersal of the species. Lastly, the larval stage is of great advantage for certain in-

ternal parasites, which, once inside a host, cannot transfer

to another. New hosts are infected instead by the larval stages. (The usual means of attaining this end is for the parasite to produce enormous quantities of eggs and rely on the passive entry of the eggs into the new host with food. A more efficient way, however, is for a mobile larva to enter the new host actively.)

A large number of marine invertebrates possess floating larvae that have hairlike projections (cilia) as their means of locomotion. There are three main types of larvae, characteristic of large subdivisions of the animal kingdom

The planula larva of coelenterates has an elongated shape and cilia covering its entire surface. The internal organization is simple, hardly beyond differentiation into ectoderm and endoderm in the interior. The larva does not feed but serves only for dispersal.

The trochophore larva is found in many marine invertebrates. Typically, as in polychaetes, it has an alimentary canal with mouth and anus and a ring of ciliated cells arranged anterior to the mouth. It also possesses a sensory organ and rudiments of mesoderm. Cilia around the mouth bring in food-unicellular plants and other small particles. The larva thus not only serves for dispersal but also feeds and grows before it transforms into an adult worm. Other trochophore larvae are found in marine mollusks and in certain marine worms. The larva of echinoderms is similar to the trochophore in possessing a gut and a ciliary band, but the arrangement of the latter is different. The echinoderm larva also feeds and grows as

well as serves for dispersal. Larvae of very different kinds are found in many arthropods. In crustaceans the larva, called nauplius, does not differ substantially in mode of life or means of locomotion from the adult but has fewer appendages than the adult. A typical crustacean nauplius has three pairs of legs and an unpaired simple eye. Additional pairs of appendages and paired compound eyes appear in the course of a sometimes prolonged development. In insects the larva differs from the adult by the absence of wings but, in addition, may have a different mode of life and different way of feeding. Among chordates the tunicates (sea squirts) deserve attention; the larval form is a free-swimming creature, showing unmistakable relation to vertebrates, but the adult is sedentary, with much reduced nervous and muscular systems. The tadpole of a frog differs from the

adult in being totally aquatic, in possessing a tail and gills

for respiration, and in having a mouth adapted for feeding

on plants. The adult frog is adapted to land life, except

for reproductive periods, has no tail and no gills, and is an active predator.

Metamorphosis, the transformation of the larva into an adult, is a more or less complicated process depending on the degree of difference between the two forms. The transformation may be gradual, extend over a long period, and involve a number of intermediate stages; alternatively, the transformation may be achieved in one step. In the latter case, especially if the difference between the larva and adult is great, large parts of the body of the larva, including all the specifically larval organs, disintegrate (necrobiotic metamorphosis). At the same time, organs of the adult are built up, sometimes from reserve groups of cells that remain undifferentiated or nonfunctional in the larva. A good illustration of the distinction between gradual and abrupt metamorphosis occurs among the insects. In more primitive insects, such as cockroaches and grasshoppers, metamorphosis is gradual. The larva, often referred to as a nymph, has more or less the same organization as the adult, or imago; it feeds in a similar way but differs from the adults in lacking wings and in having incomplete sex organs. The wings appear in later stages of larval life; they are small at first but increase with each molt, and they attain full size and functional capacity at the last (imaginal) one. The larva of other insects, such as beetles, butterflies, and wasps, is a grub or caterpillar, a wormlike creature not even remotely resembling the adult. The difference in organization is so profound that the transformation cannot be achieved gradually, and an intermediate resting, or pupal, stage is interposed between the larva and imago. The pupa neither feeds nor moves, as the larval organs inside are destroyed and replaced with organs of the adult,

trochonhore

of metamorphosis

nymph stage

including wings and sex organs. Eventually, when formation of the adult organs is complete, the pupal skin is cast off, and the adult emerges. The destruction of the larval parts may be far reaching and include even the skin and most of the alimentary canal. The tissues of the adult are formed from groups of reserve cells that were present all along in the larva as imaginal disks.

Necrobiotic metamorphosis is observed in the tunicate larva, in which the tail, including notochord, nerve cord, and muscles, and most of the brain, including eye and statocyst, are destroyed at the same time that the large pharyngeal cavity of the adult develops. A tadpole metamorphosing into an adult frog loses its tail-the cells of which are destroyed and devoured by phagocytic cellsits gills, and its larval mouthparts; concurrently the legs of the adult frog develop progressively, the structure of the mouth and alimentary canal change, and the skin acquires a bony (keratinized) layer and a system of subcutaneous glands (Figure 28).

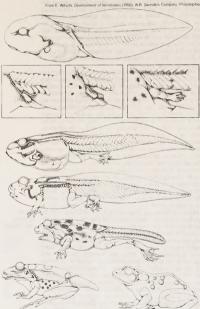

Figure 28: Stages in the metamorphosis of the frog from aquatic tadpole to terrestrial adult frog, including details of development of the hindled.

The complicated changes taking place during metamorphosis, especially in the case of necrobiotic metamorphosis, must be performed in a coordinated way. So that no changes are made prematurely and no organ systems are left behind in the general transformation, some common signal for the change must be provided. For both insect and amphibian metamorphoses, which have been the most extensively studied, the signal is a hormonal one, sent in the blood to all the cells and tissues of the body.

Metamorphosis in an insect is complicated by the fact that the rigid cuticle covering its body is very restrictive;

new features can appear only after a molt, when the old cuticle is replaced by a newly formed one. Molting in insects is caused by the action of two hormones. In the brain of insects, several groups of neurosecretory cells produce the first hormone. This brain hormone does not itself affect molting but stimulates the prothoracic gland. a loose mass of secretory cells situated in the thorax in close association with tracheal tubes. In response to the stimulation by the brain hormone, the prothoracic gland releases into the blood a second hormone, the molting hormone, or ecdysone. Under the influence of ecdysone. the tissues of the body produce a new cuticle under the old one, after which the old cuticle is shed (the actual molting). The new cuticle embodies any new developmental features that were scheduled to appear. The kind of feature that emerges after a molt is controlled by a third organ of internal secretion, the corpus allatum, secretory tissue situated posterior to the brain, near or around the dorsal aorta and usually appearing as a pair of separate or fused organs. The corpora allata emit the juvenile hormone, which, as long as it circulates in the blood, acts to perpetuate the larval form. As the larva approaches the end of its development, however, the corpora allata stop producing juvenile hormone or reduce its quantity; whereupon, the larva, at the next molt, metamorphoses into an adult. Withdrawal of the juvenile hormone is the immediate cause of metamorphosis, in conjunction with the brain hormone and ecdysone, which are responsible for the shedding of the larval cuticle and for the production of the new cuticle embodying the features of the imago. Metamorphosis through the stage of the pupa is effected by diminishing levels of juvenile hormone, which determine first the transformation of the larva into a pupa and, with further reduction of the juvenile-hormone level, the final step of transformation of the pupa into the adult.

The metamorphosis of a tadpole into a frog also depends upon two hormones: one initiating the process and the other directly influencing the tissues involved in the change. The first hormone is the thyrotropic hormone. produced by the hypophysis. It has no immediate effect on the tissues of the body but activates the thyroid gland to produce several substances, the most important of which is thyroxine. Thyroxine and other iodine-containing compounds circulate in the blood and cause changes that, in their entirety, constitute the process of metamorphosis. It is remarkable that different tissues react in different ways to the presence of thyroxine. The muscles of the tadpole's tail degenerate, whereas the muscles of the trunk and legs are not affected; in fact, the growth and development of limbs are stimulated as a part of metamorphosis. The effect of the hormone depends on the nature of the reacting cells and tissues-i.e., on their competence-just as the embryonic inductor in the earlier stages of development influences only cells with the competence for a particular kind of reaction.

DIRECT DEVELOPMENT

If an animal after birth or emergence from an egg differs from the adult in comparatively minor details (apart from not having functional sex organs), the development is said to be direct. There is no larval stage and no metamorphosis. Direct development does not mean, however, that no changes occur between birth and adulthood. One very obvious change is the growth of the animal.

The rate of growth-not absolute increase-is highest in the early stages of postembryonic life; subsequently, growth continues to slow, ceasing completely at the attainment of adulthood. The rate of growth is dependent on many factors, both external (feeding, temperature) and internal. Of the internal factors, the most important are hormones, especially the growth hormone produced by the hypophysis. If the growth hormone is produced in insufficient quantities, the result is dwarfism; if it is produced in excessive quantities, the result is gigantism.

In the case of direct development, the most important change is the attainment of sexual maturity, which is achieved in several steps and involves the action of several hormones. The gonad rudiments and rudiments of the supporting parts of the reproductive system remain

Factors influencing rate of growth

Molting and hormonal function

inactive long after birth. At the approach of adulthood, however, two sets of hormones come into action: hypophyseal hormones stimulate the gonads to activity, and gonadal hormones (produced by the gonads) cause the supporting sex organs and other sex characters to become fully developed. To become functional, the gonads must be acted upon by secretions from the hypophysis. In immature females the follicle-stimulating hormone, which alone causes the egg follicles and the oocytes to grow, and the luteinizing hormone stimulate the follicle cells to produce the female sex hormone, estrogen, which effects the development of the uterus, the milk glands, and other characteristics of the female sex. In the male, the same hypophyseal hormones are produced, with the result that the testes start to produce sperm and to secrete the male sex hormone, androgen. It appears that the luteinizing hormone is the more active in the male sex, being able to cause both spermatogenesis and androgen secretion. Androgen, in turn, brings about the development of the penis, the descent of the testicles before birth, the appearance of typical male hair growth, and other secondary sex characteristics.

Maturity and death

Sexual maturity and the ensuing reproductive activity mark the pinnacle of development and morphogenesis and, for many animals, herald the end of life. The biological goal of the entire process is achieved with the launching of the next generation, and the life cycle that runs from the formation of gametes by one generation to the formation of gametes by the next generation is completed. In many animals the females die after laying their eggs; the males may have died earlier, after pairing. Indeed, some males (spiders, praying mantises) are eaten by the females immediately after copulation.

The developmental period can only truly be said to end with the termination of an organism, for much activity continues to unfold new developmental sequences, not all of them progressive and favourable, to be sure. Senescence, or a decline in abilities, signals advancing age in mammals but is not a general occurrence in the animal kingdom. Far more animals continue to function at nearpeak capacity well into old age. And even among those species-salmons, eels, many moths-whose members die after a single reproductive act, death is relatively swift and not accompanied by a prolonged period of deterioration. In most animals the reproductive potential is not exhausted in a single act of gamete production, but the sexually mature individuals remain alive and reproduce repeatedly. In these cases life may extend long beyond the first attainment of reproductive ability and be accompanied by further growth of the individuals, as occurs in most fishes, amphibians, and reptiles, and also in mollusks and certain other invertebrates. In the case of prolonged life-spans, however, reproductive activity may cease with advancing age, and a senile involution take place, as is observed mainly in mammals and, particularly, in man. The changes taking place may be described as regressive development. In most animals, however, the end of life is not preceded by any overt traces of senility. As a general rule, then, the attainment of reproductive ability may be said to be the final phase of progressive development among animals

A gradual loss of alertness and vigour is typical of the aging pattern of primates and is especially important to man. (For additional information, see below Aging and senescence)

HUMAN GROWTH AND DEVELOPMENT

The human body, like that of most animals, develops from a single cell produced by the union of a male sex cell and a female sex cell. Human development follows closely the basic vertebrate pattern, and it departs only in certain details from the type specifically characteristic of mammals (see above Animal development). A prenatal period, in which most of the developmental advances occur, is followed by a long postnatal period. Only at about the age of 25 are the last progressive changes completed.

Human embryology: early stages

FROM FERTILIZATION TO PLACENTATION

Penetra-

ovum by

the sperm

and their

union

tion of the

Fertilization. The development and liberation of the male and female gametes are steps preparatory to their union through the process of fertilization. Random movements first bring some spermatozoa into contact with follicle cells adhering to the secondary oocyte, which still lies high in the uterine tube. The sperm then propel themselves past the follicle cells and attach to the surface of the gelatinous zona pellucida enclosing the oocyte. Some sperm heads successfully penetrate this capsule by means of an enzyme, hyaluronidase, which they secrete, but only one makes contact with the cell membrane and cytoplasm of the oocyte and proceeds farther. This is because the invading sperm head releases a substance that initiates surface changes in the oocyte cytoplasm that other competitors cannot master.

The sole successful sperm is engulfed by a conical protrusion of the oocyte cytoplasm and is drawn inward. Once within the periphery of the oocyte, the sperm advances toward the centre of the cytoplasm; the head swells and converts into a typical nucleus, now called the male pronucleus, and the tail detaches. It is during the progress of these events that the oocyte initiates its final maturation division. Following the separation of the second polar body, the oocyte nucleus reconstitutes typically and is then called the female pronucleus of the ripe egg. It is now ready to unite with its male counterpart and thereby consummate the total events of fertilization.

The two pronuclei next approach, meet midway in the egg cytoplasm, and lose their nuclear membranes. Each resolves its diffuse chromatin material into a complete. single set of 23 chromosomes. Centrioles (complex particles involved in cell division), apparently supplied by the sperm, appear, and a mitotic spindle organizes with the two sets of chromosomes arranged midway on it-ready to proceed with a typical mitosis. This climax in the events of fertilization creates a joint product named the zygote. It contains all the essential factors for the development of a new individual.

The fundamental results of fertilization are the following: (1) reassociation of a male and female set of chromosomes (thus restoring the full number and providing the basis for biparental inheritance and for variation); (2) establishment of the mechanism of sex determination for the new individual (this depending on whether the male set of chromosomes included the X- or the Y- chromosome): (3) activation of the zygote, initiating a beginning toward the production of a new individual.

Cleavage and blastulation. Cleavage. The onset of mitosis (ordinary cell proliferation by division) in the activated zygote is a first step toward development in the ordinary sense of that term, and the cells so produced are the first external sign of future body building. To this end, the relatively enormous zygote directly subdivides into many smaller cells of conventional size, suitable as early building units for the future organism. This process is called cleavage and the resulting cells are blastomeres (Figures 29A-D). The tendency for the progressive increase in cell numbers to follow a doubling sequence is soon disturbed and then lost. Each blastomere receives the full complement of paternal and maternal chromosomes.

Subdivision of the zygote into blastomeres begins while it is still high in the uterine tube. The cohering blastomeres are transported downward chiefly, at least, by muscular contractions of the tubal wall. Such transport is relatively rapid until the lower end of the tube is reached, and here cleavage continues for about two days before the multicellular cluster is expelled into the uterus. The full reason for

Formation of blastomeres

(M) Embryo of 23 days with yolk sac and opened amnion (magnified 9×) (N,O) Embryo of six weeks and fetus of three months, respectively, within halved amnion, chorion, and uterus (magnified ½×). (P,Q) Diagrams showing especially amnion growth and formation of umbilical cord; stages correspond to J and N Drawing by James F. Didusch

this delay is not clear, but it serves to retain the cleaving blastomeres until the uterine lining is suitably prepared to receive its prospective guest.

Since the human egg contains little inert yolk material, and since this is distributed rather evenly throughout the cytoplasm, the daughter cells of each mitosis are practically equal in size and composition. This type of cleavage is known as total, equal cleavage. The sticky blastomeres adhere and the cluster is still retained for a time within the gelatinous capsule-the zona pellucida-that had enclosed the growing and ovulated oocyte. There is no growth in the rapidly dividing blastomeres, so that the total mass of living substance does not increase during the cleavage period. Cleavage is not a mechanism designed primarily to distribute particular developmental qualities, either nuclear or cytoplasmic, to specific blastomeres, which then carry out assignments that give rise to particular parts of the embryo. In a sense, therefore, cleavage is essentially a nonspecific fractionating preliminary rather than a process of truly constructive development.

Morula and blastocyst. By the fourth day after ovulation, a cluster of about 12 blastomeres passes from the uterine tube into the uterus. When the cluster numbers 12 to 16 blastomeres it is called a morula (Figure 29D). By the time some 30 blastomeres have been produced, pools of clear fluid accumulate between some of the internal cells, and these spaces soon coalesce into a common subcentral cavity. The resulting hollow cellular ball is a blastula of a particular type that occurs in mammals and is called a blastocyst its cavity is the blastocoed (Figure 29F. F)

An internal cellular cluster, eccentric in position and now named the inner cell mass, will develop into the embryo. The external capsule of smaller cells, enveloping the segregated internal cluster, constitutes the trophoblast. It will contribute importantly to the formation of a placenta. During its stay within the uterine cavity, the blastocyst looses its gelatinous capsule, imbibes fluid, and expands to a diameter of 0.2 millimetre (0.008 inch); this is nearly twice the diameter of the zygote at the start of cleavage. Probably several hundred blastomeres have formed before the blastocyst attaches to the uterine lining.

Implantation and placentation. Late in the sixth day after ovulation the naked, sticky blastocyst comes into contact with the uterine lining and adheres to it (Figure 29G). The site of attachment is variable and not predetermined. The uterine lining has already been preparing, under the influence of ovarian hormones, for the reception of the blastocyst. Among these preparations has been the elaboration and expulsion, by the uterine glands, of a secretion that serves as nourishment for the blastocyst, both when it is free and during its implantation. Directly after blastocyst attachment come its establishment within the thickened uterine lining and the participation of its trophoblastic capsule in the differentiation of a placenta, a structure that enables the developing embryo to enter into a prompt, physiological dependence on the mother.

Implantation. The trophoblast of the blastocyst exerts an enzymic, destructive influence on the swollen uterine lining, leading to erosion of both the susperficial epithelium of the uterine lining and also its deeper, cellular connective tissue (Figure 29H). This early stage of invasion ends in a few days; the blastocyst is then completely buried within a more superficial and compact layer of the total uterine lining (Figure 29H, D). While the blastocyst is completing this phase of implantation, its original shell of cellular trophoblast steadily proliferates a multitude of cellular trophoblast by the compact of t

The implanted blastocyst next proceeds to establish itself as a parasite within the uters. The syncytial trophoblast becomes a spongy shell containing irregular cavities (Figure 291). This expanding mass destroys cellular connective tissue and glands encountered in its path. Both the cellular and derivative syncytial trophoblast have the capacity of ingesting such tissue. The crosive process also taps capillaries and small blood vessels, and blood liberated in this way is likewise taken up into the trophoblast. Such en-

Passage of blastomeres into uterus; formation of morula and blast-

ocvst

Syncytial trophoblast Ectopic

gulfed blood cells and fragments of tissue are presumably utilized for nourishment in the early period of establishment of the expanding blastocystic sac. Yet these erosive activities decline in intensity by the end of the third week of development, and at this time the sac is completing the first phase of its specialization (Figure 29L).

Occasionally a fertilized egg fails to reach the uterus, implanting and beginning to develop elsewhere. This outcome is called an ectopic or extra-uterine pregnancy. The commonest ectopic site is the uterine tube, but the peritoneum lining the abdominal cavity and even the interior of the ovary are also involved, though rarely. The unsuitability of all these sites for continued development usually leads to early death and resortion of the embryo.

Placentation. The irregular strands of invasive syncytial trophoblast constitute a first stage in the formation of true villi (which form part of the placenta and are briefly described below). Primitive connective tissue soon lines the interior of the blastocyst wall, and this complex (trophoblast and connective tissue jis then named the chorion. Connective tissue promptly grows into the trophoblastic strands, and blood vessels develop in the tissue. The result is the production of many chorionic villi, each resembling a tiny, branching bush (Figure 291, Ka).

In the fourth week of development, the essential arrangements have been established that make possible those physiological exchanges between mother and fetus that characterize the remainder of pregnancy. The deepest embedded portion of the chorionic wall becomes the socalled chorionic plate of the developing placenta. From the plate extend the main stems of chorionic villi, which give off progressively subdividing branches (Figure 29N, O). In general, the side branches are free, whereas apical ones tend to attach to the maternal tissue and serve as anchors. The villous trees occupy a labyrinhine space between the villi that was created by crosion of the uterine lining. Trophoblast not only covers the chorionic plate and its villi but also spreads like a carpet over the eroded surface of the maternal tissue

Tapped uterine arteries open into the trophoblast-lined intervillous space, their blood bathing the branches and twigs of the villous trees. This blood drains from the intervillous space through similarly tapped veins. Arterial blood of the embryo, and later fetus, passes through vessels of the umbilical cord to the choronic plate. Thence it is distributed to the villous stems, branches, and twigs through vessels in their connective-tissue cores. Return of this blood to the fetus is by a reverse route.

The circulation of maternal blood through the intervillous space is wholly separate from fetal blood coursing through the chorion and its villi. Communication between the two is solely by diffusive interchange. The barrier between the two circulations consists of the trophoblastic covering of villi, the connective tissue of the villous cores, and the thin lining of the capillaries that are contained in the villous cores. The placenta serves the fetus in several ways, most of which involve interchanges of materials carried in the bloodstreams of the mother and fetus. These functions are of the following kinds: (1) nutrition, (2) respiration, (3) excretion, (4) barrier action (e.g., prevention of intrusions by bacteria), and (5) synthesis of hormones and enzymes. (For functional details and for a description of the mature, expelled placenta, see REPRODUCTION AND REPRODUCTIVE SYSTEMS: Human reproduction from conception to birth: The normal events of pregnancy.)

Extra-embryonic membranes. The way in which the encapsulating membrane of the blastocyst becomes the chorion, and the most deeply embedded part of it becomes the fetal placenta, has already been described. There are still other important membranes that develop from those portions of the inner cell mass of the blastocyst that are not directly involved in becoming an embry.

Yolk sac: Cells split off from the inner cell mass of the blastocyst and fashion themselves into a primitive yolk sac (Figure 29J, Ka). The roof of the sac then folds into a tubular gut, whereas the remainder becomes a vascularized bag that attains the size of a small pea (Figure 29M). In other vertebrates, such as amphibians and birds, the yolks are is large and contains a store of nutritive yolk. But

in man and other true mammals there is practically none. A slender neck, the yolk stalk, soon connects the rapidly elongating gut with the fast growing yolk sac proper. The stalk detaches from the intestine early in the second month, but the shrunken sac commonly persists and can be found in the expelled afferbirth.

Amnion. A cleft separates the outermost cells of the inner cell mass of the blastocyst from the remainder, which then becomes the embryonic disk (Figure 29H). The splitoff, thin upper layer is the amnion, which remains attached to the periphery of the embryonic disk. As the disk folds into a cylindrical embryo, the amniotic margin follows the underfolding, and its line of union becomes limited to the ventral (frontward) body wall, where the umbilical cord attaches (Figure 29P, Q). The amnion becomes a tough, transparent, nonvascular membrane that gradually fills the chorionic sac and then fuses with it (Figure 29N, O). At the end of the third month of pregnancy, the nonplacental extent of this nearly exposed double membrane comes into contact with the lining of the uterus elsewhere. Fusion then obliterates the uterine cavity, which has been undergoing progressive reduction in size. For the remainder of pregnancy the only cavity within the uterus is that of the fluid-filled amniotic sac.

of the fluid-filled amniotic sac.

Clear, watery fluid fills the amniotic sac. The embryo is suspended in this fluid and thus can maintain its shape and mold its body form without hindrance. Throughout pregnancy the amniotic sac serves as a water cushion, absorbing jolts, equalizing pressures, and permitting the fetus to change posture. At childbirth it acts as a fluid wedge that helps dilate the neck of the uterus. When the sac ruptures, about a quart of fluid escapes as the "waters." If the sac does not rupture or if it covers the head at birth, the sac does not rupture or if it covers the head at birth,

it is known as a caul. Allantois. The allantois, a tube of endoderm (the innermost germ layer), grows out of the early yolk sue in a region that soon becomes the hindgut. The tube extends into a bridge of mesoderm (the middle germ layer) that connects embryo with chorion and will become incorporated into the umbilical cord (Figure 29P, Q). The human allantoic tube is tiny and never becomes a large sae with important functions, as it does in reptiles, birds, and many other mammals. In the second month it ceases to grow, and it soon is obliterated. Blood vessels, however, develop early in its mesodermal sheath, and these spread into the chorion and vascularize it. Throughout pregnancy they will keep the embryo in close relationship with the mother's uterine circulation.

Unbilical cord. As the ventral body wall closes in, the yolk stalk and allantois are brought together, along with their mesodermal sheaths and blood vessels (Figure 29P, Q). Enclosing everything is a wrapping of amnion. In this manner a cylindrical structure, the umbilical cord, comes to connect the embryo with the placenta (Figure 29N, Q). It will serve the embryo and fetus as a physiological lifeline throughout the period of pregnancy. The mature cord is about 1.3 centimetres (0.5 inch) in diameter, and it attains an average length of nearly 50 centimetres ((wo feet).

FORMATION OF THE THREE PRIMARY GERM LAYERS

The inner cell mass, attached to the deep pole of the implanted blastocyst, is sometimes called the embryoblast, since it supplies the materials used in the formation of an embryo. The cellular mass flattens and enters into the process of gastrulation, through which the three primary germ lavers segregate and the gastrula stage, the next advance after the blastula, begins to take form. First, cells facing the cavity of the blastocyst arrange into a layer named the endoderm (Figure 29H, 1). The thick residual layer, temporarily designated as epiblast, is the source of a definitive uppermost sheet, the ectoderm, and an intermediate layer, the mesoderm. In this second phase of gastrulation, some cells of the epiblast migrate to the midline position, then turn downward and emerge beneath as mesoderm. Such cells continue to spread laterally, right and left, between the endoderm and the residue of epiblast, which is now definitive ectoderm (Figure 29Kb).

The site where the migratory mesodermal cells leave the epiblast is an elongated, crowded seam known as the The amniotic sac

Gastru-

lation

Functions of the placenta primitive streak (Figure 29Ka), Similar migrating cells produce a thick knob at one end of the primitive streak. Their continued forward movement from this so-called primitive knot produces a dense band that becomes the rodlike notochord.

The germ layers are not segregated sheets whose cells have predetermined, limited capacities and inflexibly fixed fates in carrying out organ-building activities. Rather, the layers represent advantageously located assembly grounds out of which the component parts of the embryo emerge normally, according to a master constructional plan that assigns different parts to definite spatial positions and local sites. Thus, although the germ layers have developmental potencies in excess of their normal developmental fates, their ordinary participation in organ forming does not deviate from a definite, standard program.

The derivatives of the primary germ layers can best be presented in tabular form. In naming the germ-layer origin of an organ, only the principal functional tissue is designated (Table 1). In a few instances, such as the suprarenal (adrenal) glands and the teeth, a compound organ has important parts of different origin.

GROWTH AND DIFFERENTIATION

Growth. Growth is an increase in size, or bulk. Cell multiplication is fundamental to an increase in bulk but does not, by itself, result in growth. It merely produces more units to participate in subsequent growing. Growth is accomplished in several ways. Most important is synthesis, by which new living matter, protoplasm, is created from available foodstuffs. Another method utilizes water uptake; a human embryo of the early weeks is nearly 98 percent water, while an adult is 70 percent fluid. A third method of growth is by intercellular deposition; cells manufacture and extrude such nonliving substances as jelly, fibres, and the ground substance of cartilage and bone. Through these activities a newborn baby is several thousand million times heavier than the zygote from which it came.

It is obvious that uniform growth throughout the substance of a developing organism would merely produce a steadily enlarging spherical cellular mass. Local diversities in form and proportions result from differential rates of growth that operate in different regions and at different times. The particular program of starting times and growth rates, both externally and internally in the human embryo, constitutes its characteristic growth pattern. Abnormal growth occurs occasionally, and growth may be excessive or deficient. Also, such departures may be general or local, symmetrical or asymmetrical. General gigantism usually starts before birth, and the oversized baby continues to grow at an accelerated rate. On the other hand, an existing hereditary predisposition may not be aroused into action until some time during childhood. In a reverse manner, general dwarfism may exist before birth, the individual continuing to grow slowly and stopping at the usual time. Another type is normal in size at birth, grows normally for a while, and then comes to a premature arrest.

Differentiation. In a developing organism, differentiation implies increasing structural and chemical complexity. One kind of differentiation concerns changes in gross shape and organization. Such activities, related to molding the body and its integral parts into form and pattern, comprise the processes called morphogenesis. The processes of morphogenesis are relatively simple mechanical acts: (1) cell migration; (2) cell aggregation, forming masses, cords,

and sheets: (3) localized growth or retardation, resulting. in enlargements or constrictions; (4) fusion; (5) splitting. including separation of single sheets into separate layers, formation of cavities in cell masses, and forking of cords; (6) folding, including circumscribed folds that produce inpocketings and outpocketings: (7) bending which like folding, results from unequal growth.

A second kind of differentiation refers to progressive changes occurring in the substance and structure of cells. whereby different kinds of tissues are created. These changes, and the synthetic processes underlying them. constitute histogenesis. The zygote contains all the essential factors for development, but they exist solely as an encoded set of instructions localized in the genes of chromosomes and bearing no direct physical relationship to the future characteristics of the developing embryo. During histogenesis these instructional blueprints are decoded and transformed, through cytoplasmic syntheses, into the several types and subtypes of tissues that are the structural and functional units of organs. At first, the cells of each germ layer lack an identifiable shape and are similar in chemical composition, but an invisible type of chemical differentiation soon enters. After the elaboration of specific enzyme patterns and syntheses, certain groups of cells progressively assume distinctive characters that permit their fates to be recognized. Such early stages in definite lines of differentiation of cells are often designated by the suffix "-blast" (e.g., myoblast; neuroblast).

The emerging cell types are discrete entities, without intermediates; for example, a transitional form between a muscle cell and a nerve cell is never seen. Neither can different, local parts of a cell carry out different types of tissue specialization, such as nerve at one end and muscle at the other end; nor can a cell, once fully committed to a particular type of specialization, abandon it and adopt a new course.

Under certain conditions, differentiated cells may reverse their course and return to a simpler state. Thus, under a changed environment, cartilage may lose its matrix, and its cells may come to resemble the more primitive tissue from which it arose. Nevertheless, despite such reversal and apparent simplification ("dedifferentiation"), these cells retain their former histological specificity. Under suitable environmental conditions they can differentiate again but can only regain their previous definitive characteristics as cartilage cells.

The final result of histogenesis is the production of groups of cells similar in structure and function. Each specialized group constitutes a fundamental tissue. There are four main types of such tissues: each of the three germ lavers gives rise to sheetlike epithelia, which cover surfaces, line cavities, and are frequently glandular; ectoderm also forms the nervous tissues; mesoderm also produces the muscular tissues; it also differentiates into blood and the fibrous connective tissues (including two further specialized types, cartilage and bone).

EMBRYONIC ACQUISITION OF EXTERNAL FORM

At the end of the second week, the embryonic region is a nearly circular plate within its well-embedded, differentiating chorionic sac (Figure 29I). This embryonic disk consists of two layers (epiblast and endoderm), with a third layer (mesoderm) just starting to spread between them. A hollow, dome-shaped amnion sac attaches to the margin of the upper layer of the disk, and a hollow yolk sac is similarly continuous with the lower layer. A broad cellular bridge attaches the complex to the chorion.

Early in the third week the embryonic disk has enlarged and become pear-shaped in outline, and a well-formed primitive streak occupies the midline of its caudal (hind) half, which is narrower. Cells from the epiblast are passing through the streak and spreading laterally in both directions beneath the uppermost layer, now ectoderm (Figure 29Ka, Kb). In this way the embryonic disk becomes three layered, and the gastrula stage of development comes to an end. At the middle of the week a thickening, the head process, is extending forward from a knoblike primitive knot located at the head end of the primitive streak. These linear thickenings define the median plane of the future

"Dedifferentiation": the four types of tissue

Morphogenesis and histogenesis

Ways in

growth is

accom-

plished

which

embryo and thus divide the embryonic disk into precise right and left halves.

Toward the end of the week the disk elongates and becomes slipper-shaped in outline; a slight constriction demarcates it from the attached yolk sac. Growth has lengthened the region ahead of the now receding primitive streak. Here, in the midline, the ectoderm bears a definite gutter-like formation called the neural groove; it is the first indication of the future central nervous system. Beneath the groove the mesodermal head process presently rounds into an axial rod, the notochord, that serves as a temporary "backbone." By the end of the third week a head fold, paired lateral body folds, and a tail fold become prominent, demarcating a somewhat cylindrical embryo from the still broadly attached yolk sac (Figure 29L). The neural folds, flanking the neural groove, converge and begin to meet midway of their lengths, thereby producing a neural tube at that level. Mesoderm, alongside the notochord, begins to subdivide into paired blocks called somites, and the outlines of the somites show externally. From them, muscles and vertebrae will differentiate later. This stage, when the embryo is fashioning a neural tube, is often designated as a neurula.

In the fourth week the embryo goes beyond the external characteristics of vertebrates in general and becomes recognizable as a mammal. The week is marked by profound changes, during which the embryo acquires its general body plan. There is an increase in total length from about two to five millimetres, but size is quite variable among smaller specimens. Better correlated with the degree of development is the number of mesodermal somites, which attain their full number of about 42 during the fourth week. Some of the head of an early embryo arises from the embryonic disk in front of the primitive knot. But as the primitive streak shortens and its caudal retreat continues, such structures as the neural tube and notochord are added progressively in the wake of that retreat, and additional somite pairs also appear in steady succession.

The most important manoeuvre in the establishment of general body form is the transformation of the flat embryonic disk into a roughly cylindrical early embryo, which is attached to the yolk sac by a slender volk stalk (Figure 29M). Three factors cooperate in producing this change: (1) There is more rapid expansion of both the embryonic area and the yolk sac than in the region joining the two. of early The enlarging embryonic area at first buckles upward embryo

Factors in formation

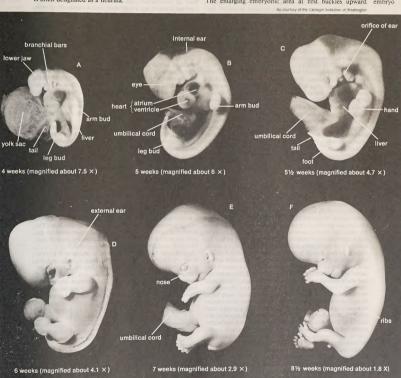

Figure 30: Human embryos from four to 81/2 weeks.

and then overlaps the more slowly growing margin. Since growth is particularly rapid at the future head end and tail end, the embryo becomes elongate. (2) In conjunction with this overgrowth there is important underfolding, again most pronounced at the front and hind ends. Underfolding is produced by differential elongation in the regions of the brain and tail bud. Conspicuous is the change in the future cardiac (heart) and foregut region, which swings beneath the brain as on a hinge. (3) A certain amount of true constriction, through growth, purses all of these parts at the site of the future umbilicus.

Throughout the entire period when the body and its parts are being laid down, developmental advances tend to appear first at the head end and then progress tailward. For this reason, many structures that extend along the body for a distance show a gradation in development. The size advantage gained initially by the head end of the embryo is relinquished very slowly. Even in an infant the relatively large head and long arms are striking. A further tendency toward progressively graded development occurs from the middorsal line in a lateral (sideward) and then ventral (frontward) direction. All such relations are the visible expressions of stages in growth and differentiation.

Early in the fourth week the cylindrical shape of the embryo is plain, even though the folding-off process is far from complete (Figure 29M). The neural tube is still open near both ends, and at the head end the broader neural folds indicate the future brain and even its three primary divisions. A pronounced bulge beneath the brain region denotes where the heart is forming precociously in order to institute a necessary, prompt circulation through

the placenta.

During the middle and late days of the fourth week there are marked advances (Figure 30A). Accelerated growth along the dorsal region bends the total body length progressively until the embryo assumes a striking C-shape, with the tips of the head and tail not far apart. Continued growth and underfolding close in much of the ventral side of the embryo, so that a free head and upper trunk, and a lower trunk and a prominent tail, are easily recognizable. Forebrain, midbrain, and hindbrain can be identified, largely because of a sharp bend in the midbrain. Local outgrowths from each side of the forebrain produce stalked eye cups, and a pair of inpocketings of the ectoderm alongside the hindbrain sink beneath the surface as otic vesicles, forerunners of the inner ears. Bulges indicative of the heart and liver are prominent. Formations called branchial arches, reminiscent of the gill arches of fishes and aquatic amphibians, become conspicuous in the future jaw-neck region. Paired swellings ("buds") off the trunk foretell the locations of the upper and lower limbs.

A five-week embryo is about eight millimetres (0.32 inch) long (Figure 30B, C), whereas at six weeks the length is about 13 millimetres (0.52 inch) (Figure 30D). New external features are olfactory pits at the tips of the bent head. An umbilical cord becomes a definite entity, its proximal end occupying a low position on the abdominal wall. The sharply bent head joins the rest of the body at an acute angle. The first pair of branchial arches branch Y-fashion into maxillary and mandibular processes (primitive upper and lower jaws). The external ears are forming around the paired grooves located between each half of the mandible and each second branchial arch. The heart, which was previously the chief ventral prominence, now shares this distinction with the rapidly growing liver. Limb buds have elongated markedly and become flattened at their outer ends. A constriction on each bud separates a paddle-like hand plate or foot plate from a cylindrical segment attached to the body wall. Predictably, the upper limbs are somewhat further advanced than the lower pair.

In the latter weeks of the second month, developmental changes advance from those that distinguish primates to a state that is recognizably human (Figure 30E). At the end of the second month (30 millimetres', or 1.2 inches'. length) the stage of the embryo ends; henceforth, until birth, "fetus" is the preferred term.

In the seventh and eighth weeks the head becomes more erect and the previously curved trunk becomes straighter (Figure 30E, F). The heart and liver, which earlier domi-

nated the shape of the ventral body, yield to a more evenly rounded chest-abdomen region. The tail, which at an earlier time was one fifth of the embryo's length, becomes inconspicuous both through actual regression and through concealment by the growing buttocks. The face rapidly acquires a fairly human appearance: eves, ears, and iaws are prominent. The eyes, previously located on the sides of the head, become directed forward; the nose lacks a bridge and so is of the "pug" type, with the nostrils directed forward instead of downward. A mandibular branch of each Y-shaped branchial arch combines with its mate to form the lower jaw. The maxillary branch on each side joins an elevation on the medial (inner) side of the corresponding postril to produce the more complicated upper jaw. Branchial arches, other than those forming the jaws and external ears, are effaced through incorporation into an emerging, recognizable neck. Limbs become jointed, and the earlier hand plates and foot plates differentiate terminal digits. Primitive external genitalia appear, but in a nondistinctive, sexless condition.

Almost all of the internal organs are well laid down at the end of eight weeks, when the embryo is little more than 25 millimetres (one inch) long. The characteristic external features are established, and subsequent growth merely modifies existing proportions without adding new structure. Similarly, the chief changes undergone by internal organs and parts are those of growth and tissue specialization. At eight weeks the neuromuscular mechanism attains a degree of perfection that permits some response

to delicate stimulation.

During the third month the young fetus clearly resembles a human being, although the head is disproportionately large (Figure 290). The previous protrusion of much of the intestine into the umbilical cord is reduced through the return of its loops into the abdomen. The ears rise to eye level and the eyelids fuse shut. Nails begin forming; ossification (bone-forming) centres appear in most of the future bones; and the sex of external genitalia becomes recognizable. (In this paragraph, and in the next two, the

Development from

the third month to

hirth

months are lunar months, of 28 days). At four months individual differences between the faces of fetuses become distinguishable. The face is broad but the eves are now less widely separated. The umbilical cord attaches higher on the abdominal wall; this location is above an expanding region between the cord and the pubis

(front bones of the pelvis) that scarcely existed previously. At five months downy hairs (lanugo) cover the body, and some head hairs appear. The skin is less transparent, Fetal movements ("quickening") are felt by the mother. At six months evebrows and evelashes are clearly present. The body is lean, but its proportions have improved. The skin is wrinkled. At seven months the fetus resembles a driedup old person. Its reddish, wrinkled skin is smeared with a greasy substance (vernix caseosa). The eyelids reopen. At eight months fat is depositing beneath the skin. The testes begin to invade the scrotum. At nine months the dull redness of the skin fades and wrinkles smooth out.

At full term (38 weeks) the body is plump and proportions are improved, although the head is large and the

males are usually in the scrotum; the greater lips of the female external genitalia, which previously gaped, are now in contact. Cranial bones meet except at some angular junctions, or "soft spots."

The average time of delivery is 280 days from the beginning of the last menstrual period, whereas the duration of pregnancy (age of the baby) is about 266 days (38 weeks; Table 2). Pregnancy may extend to 300 days, or even more, in which case the baby tends to be heavier. Premature babies born under 27 weeks of age rarely survive, whereas those more than 30 weeks old usually do survive. (For additional information on the events of delivery, see REPRODUCTION AND REPRODUCTIVE SYSTEMS: Human reproduction from conception to birth: Parturition)

Abnormal development

MULTIPLE RIRTHS

It is both unusual and abnormal for the human species to produce more than one offspring at a time. "Twins" and "twinning" are used as general terms for any number of multiple births, as the same basic principles apply

Fraternal twins stem from multiple ovulations in the same cycle. Each oocyte develops singly in a senarate follicle, is shed and fertilized individually, develops within its own chorionic sac, and forms an individual placenta. In some instances, two blastocysts implant close together and the expanding placentas meet and fuse. In such double placentas, however, the two blood circulations rarely communicate. The word dizygotic technically designates two-egg twins. Such pairs obviously are independent in sex determination and bear no more resemblance than do other children of the same parents. Properly speaking, they are merely littermates. Nearly three-fourths of all American twins are dizygotic, whereas the Japanese ratio is only one-fourth. A tendency toward such multiple births exists in some family lines.

Wholly different are those true twins who are always of the same sex and are strikingly similar in physical, functional, and mental traits. Such close identity is enforced by their derivation from a single ovulated and fertilized egg, and hence by their acquisition of identical chromosomal constitutions. This twin type is named monozygotic. Three-fourths of such pairs develop within a common chorionic sac and share a placenta; one-fourth have individual sacs and placentas. The latter condition results from a mishap before implantation, when the cleavage cells separate into two groups and then become individually implanting blastocysts. There is no discernible hereditary tendency toward the production of monozygotic twins.

Several atypical processes involving the inner cell mass or embryonic plate can produce separate embryos within a single sac: (1) The inner cells of a blastocyst may segregate into two masses. (2) Somewhat later in time, two embryonic axes may become established on a single embryonic disk. (3) A single axis may subdivide by fission or budding. (4) Duplication of any sort may combine with secondary subdivision; the Dionne quintuplets are believed to have followed this sequence, which is also normal for the regu-

lar quadruplets of the Texas armadillo.

The abnormal nature of monozygotic twinning is emphasized when the two individuals are conjoined as a 'double monster." The degree of union varies from slight to extensive, and the possession of a single or double set of internal organs depends on the intimacy of fusion at any particular level. Union occurs by the heads, upper trunks, or lower trunks; the joining may be by the dorsal, lateral, or ventral surfaces. Sometimes there is a marked disparity in the size of the two components, and in such Instances the smaller twin is called a parasite. Conjoining results from divergent growth at the front or hind end of the emerging primitive axis of an embryo, or at both ends.

FETAL DEVIATIONS

Human embryos are subject to disease, abnormal development, and abnormal growth. Decline and death can occur at any stage, but since most deaths occur in the first two or three weeks of development they usually escape notice. Probably little more than half of all zygotes reach

full-term birth. Most abnormalities resulting from faulty development originate within the first seven weeks of pregnancy, before the prospective mother is surely aware of her condition. Abnormalities that do occur in living infants tend toward the milder types, since the severe

mishaps commonly terminate development before birth. Folklore maintains that a pregnant woman may "mark" her baby through incurring physical injuries or becoming subjected to horrors or repulsive sights. As there are no nervous connections between mother and fetus, such beliefs lack foundation. Moreover, practically all of the alleged causative experiences occur long after the "related" abnormalities have been established in the embryo.

Defective health of the mother can, in some instances become a cause of the physical impairment or death of a fetus. Certain infectious diseases, for example, may result in fetal injury; such related causative organisms can be a virus (German measles), a spirochetal microorganism (syphilis), or a protozoon parasite (toxoplasmosis). Also, placental disorders, malformations of the mother's reproductive organs, and inadequate functioning of her endocrines may provide an unfavourable environment for normal development. Birth itself imposes the risk of oxygen deficiency or other injury; either may result in some malfunctioning of the brain.

TERATOLOGY

Teratology is concerned with all features of abnormal generation and development of the embryo (embryogenesis) and their end products. The incidence of defective development is high. One infant in 14 that survive the neonatal period bears an abnormality of some kind and degree, and half of these babies have more than one malformation, Internal, concealed defects are more numerous than external ones, and some defects do not become apparent until childhood. One baby in 40 is born with a structural defect that needs treatment. Some types of abnormality are commoner in males (e.g., pyloric stenosis, the narrowing of the opening between the stomach and the intestine), while other types predominate in females (e.g., dislocated hip). Besides the obvious derangements of a gross nature, there are aberrations at the molecular level known as inborn errors of metabolism. In these an enzyme deficiency blocks the course of intermediary metabolism and results in abnormal chemical functioning. Such errors involve proteins, carbohydrates, lipids, and pigments. The abnor-

mal products may be stored or excreted. Important among causes of abnormalities are hereditary factors. Such include gene mutations, which may become Mendelian dominants (e.g., fused fingers, which need be inherited from only one parent to appear in the offspring), recessives (e.g., albinism, which does not become evident unless its gene is inherited from both parents), or sexlinked factors (e.g., hemophilia). Besides the heritable defects, whose possibilities of recurrence can be estimated, there are many genetic results that are due to chance, are not passed on, and do not occur in other offspring. An unequal distribution of chromosomes during meiosis, leading to abnormal assortments, occurs in somatic (nonsex) chromosomes (e.g., Down's syndrome) and in sex chromosomes (e.g., Klinefelter's syndrome).

Environmental factors, both external and internal, are also important. Among physical agents, mechanical pressures or blows are no longer considered to be significant because of the protection supplied by the uterus and the fluid-filled amniotic sac. On the other hand, irradiation is a wholly effective physical agency, as experiments have amply proved. Various chemical agents, used experimentally on pregnant animals, are highly teratogenetic (productive of physical defects within the uterus), and at least one drug (thalidomide) has demonstrated its potency on human embryos. Deficiencies of some fetal hormones are associated causally with gross bodily defects (e.g., male hormone and false hermaphroditism, a condition in which the gonads are of one sex but some appearances suggest the other). Similarly, hormonal excess can be productive (e.g., growth-promoting hormone and gigantism). Vitamin deficiencies are effective experimentally but are not factors in ordinary substandard maternal diets. The role of infectious agents has been men-

cal twins

and identi-

Origin of

the skin

Nails,

hairs, and

tioned previously. Immunity incompatibilities may exist between mother and fetus (e.g., Rh blood factor and fetal hemolysis, the release of hemoglobin from red blood cells).

There appear to be several ways in which teratogenetic agents can affect susceptible embryonic cells. But whatever the manner of interference may be, the final result is probably either cell impairment or death or a changed rate of growth. Either of these measures puts local development out of step with adjoining parts and upsets the coordinated schedule of development.

Development of organs

ECTODERMAL DERIVATIVES

Integumentary system. The skin has a double origin. Its superficial layer, or epidermis, develops from ectoderm. The initial single-layered sheet of epithelial cells becomes multilayered by proliferation, and cells nearer the surface differentiate a horny substance. Pigment granules appear in the basal layer, at least, of all races. The epidermis of the palm and sole becomes thicker and more specialized than elsewhere. Cast-off superficial cells and downy hairs mingle with a greasy glandular secretion and smear the skin in the late fetal months; the pasty mass is called vernix caseosa. The deep layer of the skin, or dermis, is a fibrous anchoring bed differentiated from mesoderm. In the later fetal months the plane of union between epidermis and dermis becomes wavy. The permanently ridged patterns are notable at the surface of the palm and sole.

Nails develop in pocket-like folds of the skin near the tips of digits. During the fifth month specialized horny material differentiates in proliferating ectodermal cells. The reskin glands sulting nail plate is pushed forward as new plate substance is added in the fold. Fingernails reach the finger tips one month before birth. Hairs, produced only by mammals, begin forming in the third month as cylindrical pegs that grow downward from the epidermis into the dermis. Cells at the base of the peg proliferate and produce a horny, pigmented thread that moves progressively upward in the axis of the original cylinder. This first crop of hairs is a downy coat named lanugo. It is prominent by the fifth month but is mostly cast off before birth. Unlike nails, hairs are shed and replaced periodically throughout life.

Sebaceous glands develop into tiny bags, each growing out from the epithelial sheath that surrounds a hair. Their cells proliferate, disintegrate, and release an oily secretion. Sweat glands at first resemble hair pegs, but the deep end of each soon coils. In the seventh month an axial cavity appears and later is continued through the epidermis. The mammary glands, peculiar to mammals, are specialized sweat glands. In the sixth week a thickened band of ectoderm extends between the bases of the upper and lower limb buds. In the pectoral (chest) region only, gland buds grow rootlike into the primitive connective tissue beneath. During the fifth month 15 to 20 solid cords foretell the future ducts of each gland. These later canalize and open into a pit that after birth elevates into a nipple. Until late childhood the mammary glands are identical in both sexes.

Mouth and anus. Mouth. The mouth is a derivative of the stomodaeum, an external pit bounded by the overjutting primitive nasal region and the early upper and lower jaw projections. Its floor is a thin membrane, where ectoderm and endoderm fuse. Midway in the fourth week this membrane ruptures, making continuous the primitive ectodermal mouth and endodermal pharynx (throat). Lips and cheeks arise when ectodermal bands grow into the mesoderm and then split into two sheets. Teeth have a compound origin: the cap of enamel develops from ectoderm, whereas the main mass of the tooth, the dentin, and the encrusting cementum about the root differentiate from mesoderm. The salivary glands arise as ectodermal buds that branch, bushlike, into the deeper mesoderm. Berrylike endings become the secretory acini (small sacs), while the rest of the canalized system serves as ducts. The palate is described in relation to the nasal passages. A tiny pocket detaches from the ectodermal roof of the stomodaeum and becomes the anterior, or frontward, lobe of the hypophysis, also called the pituitary. The anterior lobe fuses with the neural lobe of the gland (see below).

Anus. A double-layered, oval membrane separates the endodermal hindgut from an ectodermal pit, called the proctodaeum, the site of the future anal canal and its orifice, the anus, Rupture at eight weeks creates a communication between the definitive anus and the rectum. Central nervous system. Both the brain and the spinal cord arise from an elongate thickening of the ectoderm that occupies the midline region of the embryonic disk. The sides of this neural plate elevate as neural folds, which then bound a gutter-like neural groove (Figure 29L). Further growth causes the folds to meet and fuse, thereby creating a neural tube. The many-layered wall of this tube differentiates into three concentric zones, first indicated in embryos of five weeks. The innermost zone, bordering the central canal, becomes a layer composed of long cells called ependymal cells, which are supportive in function. The middle zone becomes the gray substance, a layer characterized by nerve cells. The outermost zone becomes the white substance, a layer packed with nerve fibres. The neural tube also is demarcated internally by a pair of longitudinal grooves into dorsal and ventral halves. The dorsal half is a region associated with sensory functioning and the ventral half with motor functioning.

The gray substance contains primitive stem cells, many of which differentiate into neuroblasts. Each neuroblast becomes a neuron, or a mature nerve cell, with numerous short branching processes, the dendrons, and with a single long process, the axon. The white substance lacks neuroblasts but contains closely packed axons, many with fatty sheaths that produce the whitish appearance. The primitive stem cells of the neural tube also give rise to

nonnervous cells called neuroglia cells. Brain. The head end of the neural plate becomes expansive even as it closes into a tube. This brain region continues to surpass in size the spinal cord region. Three enlargements are prominent, the forebrain, midbrain, and hindbrain. The forebrain gives rise to two secondary expansions, the telencephalon and the diencephalon. The midbrain, which remains single, is called the mesencephalon. The hindbrain produces two secondary expansions called the metencephalon and the myelencephalon.

The telencephalon outpouches, right and left, into paired cerebral hemispheres, which overgrow and conceal much of the remainder of the brain before birth. Late in fetal life the surface of the cerebrum becomes covered with folds separated by deep grooves. The superficial gray cortex is acquired by the migration of immature nerve cells, or neuroblasts, from their primary intermediate position in the neural wall. The diencephalon is preponderantly gray substance, but its roof buds off the pineal body, which is not nervous tissue, and its floor sprouts the stalk and neural (posterior) lobe of the pituitary. The mesencephalon largely retains its early tubular shape. The metencephalon develops dorsally into the imposing cerebellum, with hemispheres that secondarily gain convolutions clothed with a gray cortex. The myelencephalon is transitional into the simpler spinal cord. Roof regions of the telencephalon, diencephalon, and myelencephalon differentiate vascular choroid plexuses (including portions of the pia matter, or innermost brain covering, that project into the ventricles,

or cavities, of the brain), which secrete cerebrospinal fluid. Spinal cord. For a time the spinal cord portion of the neural tube tapers gradually to an ending at the tip of the spine. In the fourth month it thickens at levels where nerve plexuses, or networks, supply the upper and lower limbs; these are called the cervical and lumbosacral enlargements. At this time the spine begins to elongate faster than the spinal cord. As a result, the caudal (hind) end of the anchored cord becomes progressively stretched into a slender, nonnervous strand known as the terminal filament. Midway in the seventh month the functional spinal cord ends at a level corresponding to the midpoint of the kidneys. Both the brain and the spinal cord are covered with a fibrous covering, the dura mater, and a vascular membrane, the pia-arachnoid. These coverings differentiate from local, neighbouring mesoderm.

Peripheral nervous system. In general, each craniospinal nerve has a dorsal (posterior) root that bears a ganglion (mass of nerve tissue) containing sensory nerve cells and

Origin, histogenesis, and morphogenesis of central nervous system

Neural tube lavers Histogenesis of peripheral nervous system

their fibres, and a ventral (anterior) root that contains motor nerve fibres but no nerve cells. Ganglion cells differentiate from cells of the neural crest, which is at first a cellular band pinched off from the region where each neural fold continues into ordinary ectoderm. Each of these paired bands breaks up into a series of lumps, spaced in agreement with the segmentally arranged mesodermal somites. Neuroblasts within these primordial ganglia develop a single stem and hence are called unipolar. From this common stem one nerve process, or projection, grows back into the adjacent sensory half of the neural tube; another projection grows in the opposite direction, helping to complete the dorsal root of a nerve. Neuroblasts of motor neurons arise in the ventral half of the gray substance of the neural tube. They sprout numerous short, freely branching projections, the dendrons, and one long, littlebranching projection, the axon; such a neuron is called multipolar. These motor fibres grow out of the neural tube and constitute a ventral root. As early as the fifth week they are joined by sensory fibres of the dorsal root and continue as a nerve trunk.

Cells of the neural crest differentiate into things other than sensory neurons. Among these variants are cells that encapsulate ganglion cells and others that become neurolemma cells, which follow the peripherally growing nerve fibres and ensheath them. The neurolemma cells cover some nerve fibres with a fatty substance called myelin.

Spinal nerves. Spinal nerves are sensorimotor nerves, with dorsal and ventral roots. A network called a brachial plexus arises in relation to each upper limb and a lumbosacral plexus in relation to each lower limb. The spine, elongating faster than the spinal cord, drags nerve roots downward, since each nerve must continue to emerge between the same two vertebrae. Because of their appearance, the obliquely coursing nerve roots are named the cauda equina, the Latin term for horse's tail.

Cranial nerves. Cranial nerves V, VII, IX, and X arise in relation to embryonic branchial arches but have origins similar to the spinal nerves. The olfactory nerves (cranial nerve I) are unique in that their cell bodies lie in the olfactory epithelium (the surface membrane lining the upper parts of the nasal passages), each sending a nerve fibre back to the brain. The so-called optic nerves (II) are not true nerves but only tracts that connect the retina (a dislocated portion of the brain) with the brain proper. Nerves III, IV, VI, and XII are pure motor nerves that correspond to the ventral roots of spinal nerves. The acoustic nerves (VIII) are pure sensory nerves, each with a ganglion that subdivides for auditory functions and functions having to do with equilibrium and posture; they correspond to dorsal roots. Nerves X and XI are a composite of which XI is a motor component.

Autonomic nervous system. The autonomic nervous system is made up of two divisions, the sympathetic and the parasympathetic nervous systems; it controls such involuntary actions as constriction of blood vessels. Some cells of the neural crests migrate and form paired segmental masses alongside the aorta, a principal blood vessel. Part of the cells become efferent multipolar ganglion cells (cells whose fibres carry impulses outward from ganglions, or aggregates of nerve cells) and others merely encapsulate the ganglion cells. These autonomic ganglia link into longitudinal sympathetic trunks. Some of the neuroblasts migrate farther and assemble as collateral ganglia-ganglia not linked into longitudinal trunks. Still others migrate near, or within, the visceral organs that they will innervate and produce terminal ganglia. These ganglia are characteristic of the parasympathetic system.

Some cells of certain primitive collateral ganglia leave and invade the amassing mesodermal cortex of each adrenal gland. Consolidating in the centre, they become the endocrine cells of the medulla.

Sense organs. Olfactory organ. Paired thickenings of ectoderm near the tip of the head infold and produce olfactory pits. These expand into sacs in which only a relatively small area becomes olfactory in function (Figure 30E). Some epithelial cells in these regions remain as inert supporting elements. Others become spindle-shaped olfactory cells. One end of each olfactory cell projects receptive

olfactory hairs beyond the free surface of the epithelium. From the other end a nerve fibre grows back and makes a connection within the brain.

Gustatory organ. Most taste buds arise on the tongue. Each bud, a barrel-shaped specialization within the epithelium that clothes certain lingual papillae (small projections on the tongue), is a cluster of tall cells, some of which have differentiated into taste cells whose free ends hear receptive gustatory hairs. Sensory nerve fibres end at the surface of such cells. Other tall cells are presumably inertly supportive in function

Eve. The earliest indication of an eye is an optic vesicle (sac) bulging from each side of the forebrain (Figure 30B. C). It quickly becomes an indented optic cup, connected to the brain by a slender optic stalk. Most of the cup will become the retina, but its rim represents the epithelial part of the insensitive ciliary body and iris. The thicker inner layer of the cup becomes the neural layer of the retina, and by the sixth month three strata of neurons are recognizable in it: (1) visual cells, each bearing either a photoreceptive rod or a cone at one end; (2) bipolar cells, intermediate in position: (3) ganglion cells, which sprout axons that grow back through the optic stalk and make connections within the brain. The thin outer layer of the cup remains a simple epithelium whose cells gain pigment and make up the pigment epithelium of the retina.

The lens arises as a thickening of the ectoderm adjacent to the optic cup. It inpockets to form a lens vesicle and then detaches. The cells of its back wall become tall. transparent lens fibres. Mesoderm surrounding the optic cup specializes into two accessory coats. The outer coat, the tough, white sclera, is continuous with the transparent cornea. The inner coat, the vascular choroid, continues as the vascular and muscular ciliary body and the vascularized tissue of the iris. The eyelids are folds of adjacent skin; from the inside of each upper lid several lacrimal glands bud out (see SENSORY RECEPTION: Human vision:

Structure and function of the eve).

Ear. The projecting part (auricle) of the external ear develops from hillocks on the first and second branchial Origins of arches (Figure 30C-E). The ectodermal groove between those arches deepens and becomes the external auditory canal. The auditory tube and tympanic cavity-the cavity at the inner side of the eardrum-are expansions of the endodermal pouch located between the first and second branchial arches. The area where ectodermal groove and endodermal pouch come in contact is the site of the future eardrum. The chain of three auditory ossicles (small bones) that stretches across the tympanic cavity is a derivative of the first and second arches.

The epithelium of the internal ear is at first a thickening of ectoderm at a level midway of the hindbrain (Figure 30B). This plate inpockets and pinches off as a closed sac, the otocyst. Its ventral part elongates and coils to resemble a snail's shell, thereby forming the cochlear duct, or seat of the organ of hearing. A middle region of the otocyst becomes chambers known as the utricle and saccule, related to the sense of balance. The dorsal part of the otocyst remodels drastically into three semicircular ducts, related to the sense of rotation. Fibres of the acoustic nerve grow among specialized receptive cells differentiated in certain regions of these three divisions.

MESODERMAL DERIVATIVES

Skeletal system. Except for part of the skull, all bones pass through three stages of development: membranous, cartilaginous, and osseous. The earliest ossification centres appear in the eighth week, but some do not arise until childhood years and even into adolescence.

Axial skeleton. The ventromedial walls (the walls toward the front and the midline) of the paired somites break down, and their cells migrate toward the axial notochord and surround it. Differentiation and growth of these segmental masses produce the jointed vertebrae. Ribs also grow out of each primitive vertebral mass, but they become long only in the thoracic region. Here their ventral ends join the sternum, which arises independently by the fusion of a pair of bars.

The skull has three components, different in origin. Its

Origins of autonomic nervous system

Myoblast

develop-

ment

basal region is an ancient heritage whose bones pass through the three typical stages of development. By contrast, the sides and roof of the skull develop directly from membranous primordia, or rudiments. The jaws are derivatives of the first pair of cartilaginous branchial arches but develop as membrane bone. Ventral ends of the second to fifth arches contribute the cartilages of the larynx and the hyoid bone (a bone of horseshoe shape at the base of the tongue). Dorsal ends of the first and second arches become the three auditory ossicles (the small bones in the middle ear).

Appendicular skeleton. The limb bones develop in three stages from axial condensations in the local mesoderm. The shoulder and pelvic supports are comparable sets, as

are the bones of the arms and legs.

Articulations. Some type of joint exists wherever bones meet. Joints that allow little or no movement consist of connective tissue, cartilage, or bone. Movable joints arise as fluid-filled clefts in mesoderm, which condenses periph-

erally into a fibrous capsule. Muscular system. Much of each somite differentiates into myoblasts (primitive muscle cells) that become voluntary muscle fibres. Aggregations of such fibres become muscles of the neck and trunk. Muscles of the head and some of the neck muscles originate from mesoderm of branchial arches. Muscles of the limbs seemingly arise directly from local mesoderm. In general, muscle primordia may fuse into composites, split into subdivisions, or migrate away from their sites of origin. During these changes they retain their original nerve supply. Regardless of differences in source of origin, all voluntary muscle fibres are of the same striated type (marked by dark and light stripes). Spontaneous movements begin to occur in embryos about 10 weeks old. In general, involuntary muscle differentiates from mesoderm surrounding hollow organs; only the cardiac muscle type is striated.

Vascular system. All hollow organs, including arteries, veins, and lymphatics, are lined with epithelium—the principal functional tissue—and are ensheathed with muscular and fibrous coats.

Blood vessels. Primitive blood vessels arise in the mesoderm as tiny clefts bordered by flat endothelial cells. Growth and coalescence produce networks, out of which favoured channels persist as definite vessels, while others decline and disappear. A bilaterally symmetrical system of vessels is well represented in embryos four weeks old. This early plan is profoundly altered and made somewhat asymmetrical during the second month by fusions, atrophies, emergence of new vessels, and rerouting of older ones. The alterations reflect adjustments to changing form and pattern within the developing organ systems.

Arteries cranial to the heart (headward of the heart) are mostly products of the paired aortic arches, which course axially within the branchial arches, thus interconnecting the ventral aorta with paired dorsal aortas. The third pair of aortic arches becomes the common carotids; the fourth pair, the aortic arch and brachiocephalic; the fifth pair, the pulmonary arteries and ductus arteriosus. The dorsal aortas fuse into the single descending aorta, which bears three sets of paired, segmental branches. The dorsal set becomes the subclavian, intercostal, and lumbar arteries. The lateral set becomes arteries to the diaphragm, the adrenal glands, the kidneys, and the sex glands. The ventral set becomes the celiac, mesenteric, and umbilical arteries. Axial arteries to both sets of limb buds emerge from an original plexus, but they undergo drastic alteration and extensive replacement.

The primitive veins are symmetrically bilateral. They consist of vitelline veins from the yolk sac, umbilical veins from the placenta, and precardinal and postacrdinal veins from the placenta, and precardinal and postacrdinal veins from the cranial and caudal regions (the regions toward the head and toward the tail) of the body. Drastic transformations occur in all of these, and new pairs of veins (subcardinals and supracardinals) arise also, caudal to the heart. From the vitellines come chiefly the portal and hepatic veins. The left umbilical becomes the main return from the placenta by making a diagonal channel, the ductus venosus, through the liver to the heart. The precardinal veins change their names to the internal jugulars, but near

the heart an interconnection permits both to drain into a common stem, then called the superior vena cava. Caudal to the heart, the postcardinals virtually disappear, and all blood return shifts to the right side as a new compound ressel, the inferior vena cava, becomes dominant. Pulmonary veins open into the left atrium. Vens from the limb buds organize from an early peripheral border vein. Lymphatic vessels. The lymph vessels develop independity in close association with veins. Linkages produce

Lymphant resses. The symph seeks decreap more childrently in close association with veins. Linkages produce the thoracic duct, which is the main drainage return for lymph. Masses of lymphocytes accumulate about lymphatic vessels and organize as lymph nodes. The spleen has somewhat similar tissue, but its channels are supplied with blood.

Heart. Fusion combines two endothelial tubes, and these are surrounded by a mantle of mesoderm that will become the muscular and fibrous coats of the heart. At three weeks the heart is a straight tube that is beginning to beat (Figure 29M). Starting at the head end, four regions can be recognized: bulbus, wentricle, atrium, and sinus venosus. Since the heart is anchored at both ends, rapid elongation forces it to bend. In doing this, the sinusatrium and bulbus-ventricle reverse their original relations. Further development concerns the transformation of a single-chambered heart into one with four chambers.

The atrium becomes subdivided by the growth of two incomplete partitions, or septa, placed close together and each covering the defect in the other. The ventricle also subdivides, but by a single, complete partition. A canal, connecting atria and ventricles, becomes two canals. The bulbus is absorbed into the right ventricle, and its continuation (the truncus) subdivides lengthwise, forming the aorta and the pulmonary artery. The right horn of the sinus venosus is absorbed into the right atrium, together with the superior and inferior venae cavae, which originally drained into the sinus. The transverse portion of the sinus persists as the coronary sinus. The pulmonary veins retain their early drainage into the left atrium. Important valves develop and ensure flow within the heart from atria to ventricles, and outward from the ventricles into the aorta and the pulmonary artery.

Birth initiates breathing, and the abandonment of the placental circulation follows. These changes entail a drastic rerouting of blood through the heart. As a result, the two atrial septa fuse and no longer permit blood to pass from the right atrium to the left atrium. Blood in the pulmonary artery no longer virtually bypasses the lungs; previously it had passed to the aorta directly through a shunt offered by the ductus arteriosus. As a sequel to these changes, the abandoned umblical arteries, umblical vein, ductus venosus, and ductus arteriosus all collapse and become fibrous cords.

Urinary system. Vertebrates have made three experiments in kidney production: the pronephros, or earliest type; the mesonephros, or intermediate kidney, and the metanephros, or permanent kidney. All arise from the cellular plates called nephrotomes that connect somites with the mesodermal sheets that bound the body cavity. The vestigail pronephros is represented solely by several pairs of tubules; they join separately formed excretory duets that grow downward and enter the cloaca, the common outlet for urine, genital products, and for intestinal wastes. Next tailward arise some 40 pairs of nephric (kidney) tubules that constitute the mesonephros; these tubules join the same excretory ducts, herafter called the mesonephric ducts. The two ests of mesonephric tubules serve as functioning kidneys until the 10th week.

Each permanent kidney, or metanephros, develops still farther tailward. A so-called ureteric primordium buds off each mesonephric duct, near its hind end. The ureteric stem elongates and expands terminally, thereby forming the renal pelvis and calices; continued bushlike branching produces collecting ducts. The early ureteric bud invades a mass of nephrotome tissue. The branching collecting ducts progressively break this tissue up into tiny lumps, each of which becomes a long secretory tubule, or nephron, and joins a nearby terminal twig of the duct system. Continued proliferation of ducts and nephric tissue produces over a million urine-producing tubules in each kidney.

Origins of

Origins of the kidney, urinary bladder, and urethra

The blind caudal end of the endodermal hindgut absorbs the stem of each mesonephric duct, whereupon the remainder of the duct and the ureter acquire separate openings into the hindgut. This expanded region of the gut, now a potential receptacle for feces, urine, and reproductive products, is known as a cloaca. It next subdivides into a rectum behind and a urogenital sinus in front. The sinus, in turn, will specialize into the urinary bladder and the urethra. The prostate gland develops as multiple buds from the urethra, close to the bladder.

Genital system. The genital organs begin to develop in the second month, but for a time sex is not grossly distinguishable. Also, a double set of male and female ducts arise, and not until later does the unneeded set decline. Hence, this period is commonly called the indif-

ferent stage

Origins

glands and

ducts and

external

genitalia

of sex

Gonads. Sex glands develop in a pair of longitudinal ridges located alongside the mesentery, the anchoring fold of membrane to the gut. The primordial sex cells appear first in the cloacal wall, from which they migrate upward in the gut, pass through its mesentery, and finally invade the genital ridges, where they proliferate. The testes are the earliest type of gonad to organize. They begin by developing testis cords and a testis capsule. The cords radiate from one focal point at the periphery, and thin fibrous partitions segregate groups of the cords within wedgeshaped compartments. These cords do not gain channels and become semen-producing tubules until near the time of puberty. The ovaries organize somewhat tardily by differentiating an outer portion, the cortex, and a central portion, the medulla. The cortex contains the primordial sex cells; these become surrounded by a layer of ordinary cells, thereby forming primary ovarian follicles. Both the testes and the ovaries undergo relative shifts from their early sites to lower positions in the body. But only the testes make a bodily descent; this is into the scrotum.

Genital ducts. In the male, a few mesonephric tubules on each side do not degenerate but link up with the neighbouring testis tubules. The converted mesonephric tubules and the retained mesonephric ducts become the male sex ducts. Near their terminations they outpouch seminal vesicles and then open into the urethra. In the female, a pair of ducts develops from the epithelium clothing the mesonephric ridges. These ducts, known as the uterine tubes, mostly parallel the courses of the mesonephric ducts, but at their lower ends they unite into a common

tube that becomes the uterus and vagina.

External genitalia. Both sexes develop a genital tubercle (i.e., a knob) and a pair of urogenital folds flanked by a pair of genital swellings. At three months these rudiments begin to assume male or female characteristics. In the male, the tubercle and the united urogenital folds combine as the penis, thereby continuing the urethra to its end; the genital swellings shift toward the anus, fuse, and become the scrotum. In the female, the tubercle remains small, as the clitoris; it does not contain the urethra. The urogenital folds remain unclosed as the lesser vulvar lips and are flanked by the unshifted and unfused genital swellings,

or greater lips. Coelom. The lateral mesoderm, beyond the somites and nephrotomes, splits into two layers: the somatic layer and, underlying the somatic layer, the splanchnic layer. The intervening space is the coelom. As the embryo's body folds off, its coelom becomes a single closed cavity. In it can be recognized, regionally, a provisional pericardial cavity (cavity for the heart), two pleural canals (for the lungs), and a peritoneal cavity (for the abdominal contents). A thick plate of mesoderm, the transverse septum, constitutes a partial partition just ahead of the developing liver. Two pairs of membranes grow out from the septum. One set separates the pericardial cavity from the two pleural cavities; these membranes later expand into the pericardium and enclose the heart. The other pair of membranes separates the pleural cavities from the peritoneal cavity of the abdomen. The definitive diaphragm is a composite partition, much of which is furnished by the transverse septum; lesser contributions are from the lateral body walls and the paired membranes that separated the pleural and peritoneal cavities.

ENDODERMAL DERIVATIVES

Pharvnx. The tongue is a product of four branchial arches, whose ventral ends merge in its midplane. Papillae elevate from the surface, and taste buds arise as specializations within the covering epithelium of some of them. Pharyngeal pouches are early lateral expansions of the local endoderm, alternating with the branchial arches. The first pair elongate as the auditory tubes and tympanic cavities. The second pair mark the site of the tonsils. The third pair give rise to the halves of the thymus, and the third and fourth pairs produce the two sets of parathyroid glands. The thyroid gland buds off the pharyngeal floor in the midplane and at the level of the second branchial arches.

Digestive tube. As the embryo folds off, the endoderm is rolled in as the foregut and hindgut. Continued growth progressively closes both the midbody and the midgut (Figure 29P, O). The esophagus remains as a simple, straight tube. The stomach grows faster on its dorsal side, thereby forming the bulging greater curvature; the stomach also rotates 90° so that its original dorsal and ventral borders come to lie left and right. The intestine elongates faster than the trunk, so that its loops find temporary room by pushing into the umbilical cord. Later, the loops return, completing a rotation that gives the characteristic final

placement of the small and large intestines.

When the gut folds into a tube it is suspended by a sheetlike dorsal mesentery, or membranous fold. In the region of the stomach it forms an expansive pouch, the omental bursa. Secondary fusions of the bursa and of some of the rest of the mesentery with the body wall produce lines of attachment from stomach to rectum inclusive, different from the original midplane course. Such fusions also anchor firmly some parts of the tract. A ventral mesentery, beneath the gut, exists only in the region of the stomach and liver.

Major glands. The liver arises as a ventral outgrowth of the foregut that invades the early transverse septum. Although rapid growth causes it to bulge prominently away from this septum, it remains attached to the septum and hence to the definitive diaphragm. The differentiating glandular tissue takes the form of plates bathed by blood channels. The stem of the original liver bud becomes the common bile duct, whereas a secondary outgrowth produces the cystic duct and the gallbladder.

The pancreas takes its origin from a larger dorsal bud and a smaller ventral bud, both off the foregut. The two merge and their ducts communicate, but in man it is the lesser, ventral duct that becomes the stem outlet. Secretory acini are berrylike endings of the branching ducts. Pancreatic islets arise as special sprouts from the ducts; these differentiate into endocrine tissue that secretes insulin.

Respiratory system. Nasal cavity. The first part of the respiratory system is ectodermal in origin. The olfactory sacs (see above Ectodermal derivatives: Sense organs) become continuous secondarily with a passage captured from the primitive mouth cavity. This addition is produced by a horizontal partition, the palate. It arises from a pair of shelflike folds that grow out from the halves of the primitive upper jaw and then unite. The final nasal passage

extends from the nostrils to the back of the pharynx. Larynx, trachea, and lungs. A hollow lung bud grows off the floor of the endodermal pharynx, just caudal (tailward) to the pharyngeal pouches and in the midline. It has the form of a tube with an expanded end. The entrance to this tube is the glottis, and the region about it becomes the larynx. The tube proper represents the trachea. Its terminal expansion divides into two branches, and these tubes elongate as the primary bronchi. Continued growth and budding produce two side branches from the right bronchus and one from the left. These branches and the blind ends of the two parent bronchi indicate the future plan of the lungs, with three right lobes and two left lobes. Continued branchings, through the sixth month, produce bronchioles of different orders. In the final months the smaller ducts and early respiratory alveoli (air sacs) appear, the lungs losing their previous glandular appearance and also becoming highly vascular. Until breathing distends the lungs, these organs remain relatively small.

The

complex

patterns of growth

Growth as

distance

velocity

and

Postnatal development

Human growth is far from being a simple and uniform process of becoming taller or larger. As a child gets bigger, there are changes in shape and in tissue composition and distribution. In the newborn infant the head represents about a quarter of the total length; in the adult it represents about one-seventh. In the newborn infant the muscles constitute a much smaller percentage of the total body mass than in the young adult. In most tissues, growth consists both of the formation of new cells and the packing in of more protein or other material into cells already present; early in development cell division predominates and later cell filling.

TYPES AND RATES OF HUMAN GROWTH Different tissues and different regions of the body mature at different rates, and the growth and development of a child consists of a highly complex series of changes. It is like the weaving of a cloth whose pattern never repeats itself. The underlying threads, each coming off its reel at its own rhythm, interact with one another continuously, in a manner always highly regulated and controlled. The fundamental questions of growth relate to these processes of regulation, to the program that controls the loom, a subject as yet little understood. Meanwhile, height is in most circumstances the best single index of growth, being a measure of a single tissue (that of the skeleton; weight is a mixture of all tissues, and this makes it a less useful parameter in a long-term following of a child's growth). In this section, the height curves of girls and boys are considered in the three chief phases of growth; that is (briefly) from conception to birth, from birth until puberty, and during puberty. Also described are the ways in which other organs and tissues, such as fat, lymphoid tissue, and the brain, differ from height in their growth curves. There is a brief discussion of some of the problems that beset the investigator in gathering and analyzing data about growth of children, of the genetic and environmental factors that affect rate of growth and final size, and of the way hormones act at the various phases of the growth process. Lastly, there is a brief look at disorders of growth. Throughout, the emphasis is on ways in which individuals differ in their rates of growth and development.

The changes in height of the developing child can be thought of in two different ways: the height attained at successive ages and the increments in height from one age to the next, expressed as rate of growth per year. If growth is thought of as a form of motion, the height attained at successive ages can be considered the distance travelled, and the rate of growth, the velocity. The velocity or rate of growth reflects the child's state at any particular time better than does the height attained, which depends largely on how much the child has grown in all preceding years. The blood and tissue concentrations of those substances whose amounts change with age are thus more likely to run parallel to the velocity rather than to the distance curve. In some circumstances, indeed, it is the acceleration rather than the velocity curve that best reflects physiological events.

In general, the velocity of growth decreases from birth onward (and actually from as early as the fourth month of fetal life; see below), but this decrease is interrupted shortly before the end of the growth period. At this time, in boys from about 13 to 15 years (Figure 33), there is marked acceleration of growth, called the adolescent growth spurt. From birth until age four or five, the rate of growth in height declines rapidly, and then the decline, or deceleration, gets gradually less, so that in some children the velocity is practically constant from five or six up to the beginning of the adolescent spurt. A slight increase in velocity is sometimes said to occur between about six and eight years.

This general velocity curve of growth in height begins a considerable time before birth. Figure 31 shows the distance and velocity curves for body length in the prenatal period and first two postnatal years. The peak velocity of length is reached at about four months after the mother's last menstruation. (Age in the fetal period is usually reckoned from the first day of the last menstrual period, an average of two weeks before actual fertilization, but, as a rule, the only locatable landmark.)

Growth in weight of the fetus follows the same general nattern as growth in length, except that the peak velocity is reached much later, at approximately 34 weeks after the mother's last menstrual period.

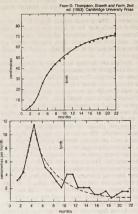

Figure 31: Curves indicating (above) growth attained and (below) velocity of growth during prenatal and early postnatal periods. The dashed line in the lower chart represents a smoothing out of the curve between points

There is considerable evidence that from about 34 to 36 weeks onward the rate of growth of the fetus slows down because of the influence of the maternal uterus, whose available space is by then becoming fully occupied. Twins slow down earlier, when their combined weight is approximately the 36-week weight of a single fetus. Babies who are held back in this way grow rapidly as soon as they have emerged from the uterus. Thus there is a significant negative association between weight of a baby at birth and weight increment during the first year; in general, larger babies grow less, the smaller more. For the same reason, there is practically no relation between adult size and the size of that person at birth, but a considerable relation has developed by the time the person is two years old. This slowing-down mechanism enables a genetically large child developing in the uterus of a small mother to be delivered successfully. It operates in many species of animals; the most dramatic demonstration was by crossing reciprocally a large Shire horse and a small Shetland pony. The pair in which the mother was a Shire had a large newborn foal, and the pair in which the mother was Shetland had a small foal. But both foals were the same size after a few months, and when fully grown both were about halfway between their parents. The same has been shown in cattle crosses.

Poor environmental circumstances, especially of nutrition, result in lowered birth weight in the human being, This seems chiefly to be caused by a reduced rate of growth in the last two to four weeks of fetal life, for weights of babies born in 36 or 38 weeks in various parts of the world in various circumstances are said to be similar. Mothers who, because of adverse circumstances in their own childhood, have not achieved their full growth potential may produce smaller fetuses than they would have, had they grown up in better circumstances. Thus two generations or even more may be needed to undo the effect of poor environmental circumstances on birth weight.

Rapid growth following small size at birth

The great rate of growth of the fetus compared with that of the child is largely due to the fact that cells are still multiplying. The proportion of cells undergoing mitosis (the ordinary process of cell multiplication by splitting) in any tissue becomes progressively less as the fetus gets older, and it is generally thought that few if any new nerve cells (apart from the cells in the supporting tissue, or neurogla) and only a limited proportion of new muscle cells appear after six postmenstrual months, the time when the velocity in linear dimensions is dropping sharply.

Prenatal and postnatal growth contrasted

The muscle and nerve cells of the fetus are considerably different in appearance from those of the child or adult. Both have little cytoplasm (cell substance) around the nucleus. In the muscle there is a great amount of intercellular substance and a much higher proportion of water than in mature muscle. The later fetal and the postnatal growth of the muscle consists chiefly of building up the cytoplasm of the muscle cells; salts are incorporated and the contractile proteins formed. The cells become bigger, the intercellular substance largely disappears, and the concentration of water decreases. This process continues quite actively up to about three years of age and slowly thereafter; at adolescence it briefly speeds up again, particularly in boys, under the influence of androgenic (male sex) hormones. In the nerve cells cytoplasm is added and elaborated, and extensions grow that carry impulses from and to the cells-the axons and dendrites, respectively. Thus postnatal growth, for at least some tissues, is chiefly a period of development and enlargement of existing cells, while early fetal life is a period of division and addition of new cells

TYPES OF GROWTH DATA

Growth is in general a regular process. Contrary to what is said in some of the older textbooks, growth in height does not proceed by fits and starts, nor does growth in upward dimensions alternate with growth in transverse ones. The more carefully measurements are taken, with precautions, for example, to minimize the decrease in height that occurs during the day for postural reasons, the more regular does the succession of points in a graph of growth become. Many attempts have been made at finding mathematical curves that fit, and thus summarize, human growth data. What is needed is a curve or curves with relatively few constants, each capable of being interpreted in a biologically meaningful way. Yet the fit to empirical data must be adequate within the limits of measuring error. The problem is difficult, partly because the measurements usually taken are themselves biologically complex. Stature, for example, consists of leg length and trunk length and head height, all of which have rather different growth curves. Even with relatively homogeneous dimensions such as the length of the radius bone in the forearm, or width of an arm muscle, it is not clear what purely biological assumptions should be made as the basis for the form of the curve. The assumption that cells are continuously dividing leads to a different formulation from the assumption that cells are adding constant amounts of nondividing material or amounts of nondividing material at rates varying from one age period to another.

Fitting a curve to the individual values, however, is the only way of extracting the maximum information from an individual's measurement data. More than one curve in seeded to fit the postnatal age range. It seems that two curves may suffice, at least for many measurements such as height and weight—one curve for the period from a few months after birth to the beginning of adolescence and a different type of curve for the adolescent spurt.

Such curves have to be fitted to data on single individuals. Yearly averages derived from different children each measured only once do not, in general, give the same curve. Thus the distinction between the two sorts of investigation is important. When the same child at each age is used, the study is called longitudinal; when different children at each age are used, it is called cross-sectional. In a crosssectional study all of the children at age eight, for example, are different from those at age seven. A study may be longitudinal over any number of years, there are shortterm longitudinal studies extending from age four to six. for instance, and full birth-to-maturity longitudinal studies in which the children may be examined once, twice, or more times every year from birth until 20 or over. Mixed longitudinal studies are those in which children join and leave the group studied at varying intervals. Both crosssectional and longitudinal studies have their uses, but they do not give the same information, and the same statistical methods cannot be used for the two types of study. Crosssectional surveys are obviously cheaper and more quickly done and can include much larger numbers of children. Periodic cross-sectional surveys are valuable in assessing the nutritional progress of a country or a socioeconomic group and the health of the child population as a whole. But they never reveal individual differences in rate of growth or in the timing of particular phases such as the adolescent growth spurt. It is these individual rate differences that throw light on the genetic control of growth and on the correlation of growth with psychological development, educational achievement, and social behaviour. Longitudinal studies are laborious and time-consuming; they demand great perseverance on the part of those who make them and those who take part in them; and they demand high technical standards, since in the calculation of a growth increment from one occasion to the next opportunities for two errors of measurement occur. In spite of these problems, longitudinal studies are the indispensable base on which the diagnosis and treatment of disorders of growth rest, for the clinical approach is a longitudinal one; and each child treated with human growth hormone, or with other hormones that affect growth, represents an attempt to alter an individual pattern of growth velocity. Averages simply computed from cross-sectional data inevitably produce velocity curves that are flatter and broader than the curve for an individual and hence not a proper basis for clinical standards. It is possible to construct curves, however, whose 50th percentile (or average) represents the actual growth of a typical individual, by taking the shape of the curve from individual longitudinal data and the absolute values for the beginning and end from large cross-sectional surveys. Figures 32 and 33 show height-attained and height-velocity curves for the "typical" boy and girl in Britain in 1965, determined in this way. By "typical" is meant that boy or girl who has the mean (average) birth length, grows always at the mean velocity, has the peak of the adolescent growth spurt at the mean age, and finally reaches the mean adult height at the mean age of cessation of growth. Practically no individual follows the 50th percentile curve of Figure 32, but most have curves of the same shape. Standards for height for clinical use are constructed around these curves.

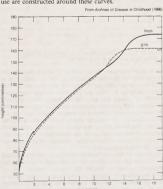

Figure 32: Individual height curves for British boys and girls in 1965 (see text).

Advantages in longitudinal and crosssectional studies Measuring the child's height

Boys' and girls' height curves. Figures 32 and 33 show the height curves from birth to maturity. Up to age two, the child is measured lying on his back. One examiner holds his head in contact with a fixed board, and a second person stretches him out to his maximum length and then brings a moving board into contact with his heels. This measurement, called supine length, averages about one centimetre more than the measurement of standing height taken on the same child, hence the break in the line in Figure 32 at age two. This occurs even when, as in the best techniques, the child is urged to stretch upwards to the full and is aided in doing so by a measurer's applying gentle upward pressure to his mastoid processes.

Figure 32 shows the typical girl as slightly shorter than the typical boy at all ages until adolescence. She becomes taller shortly after age 11 because her adolescent spurt takes place two years earlier than the boy's. At age 14 she is surpassed again in height by the typical boy, whose adolescent spurt has now started, while hers is nearly finished. In the same way, the typical girl weighs a little less than the boy at birth, equals him at age eight, becomes heavier at age nine or 10, and remains so until about age 141/2.

The velocity curves given in Figure 33 show these processes more clearly. At birth the typical boy is growing slightly faster than the typical girl, but the velocities be-

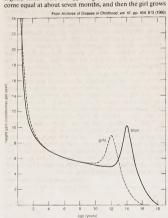

Figure 33: Typical velocity curves for supine length or height in British boys and girls in 1965 (see text).

faster until four years. From then until adolescence no differences in velocity can be detected. The sex difference is best thought of, perhaps, in terms of acceleration, the boy decelerating harder than the girl over the first four years.

Different tissues and parts of the body. The majority of skeletal and muscular dimensions follow approximately the growth curve described for height, and so also do the dimensions of the internal organs such as the liver, the spleen, and the kidneys. But some exceptions exist, most notably the brain and skull, the reproductive organs, the lymphoid tissue of the tonsils, adenoids, and intestines, and the subcutaneous fat.

In Figure 34 these differences are shown; the size attained by various tissues is given as a percentage of the birth-tomaturity increment. Height follows the "general" curve. The reproductive organs, internal and external, have a slow prepubescent growth, followed by a large adolescent spurt; they are less sensitive than the skeleton to one set of hormones and more sensitive to another.

The brain, together with the skull covering it and the

eves and ears, develops earlier than any other part of the body and thus has a characteristic postnatal curve. At birth it is already 25 percent of its adult weight, at age five about 90 percent, and at age 10 about 95 percent. Thus if the brain has any adolescent spurt at all, it is a small one. A small but definite spurt occurs in head length and breadth, but all or most of this is due to thickening of the skull bones and the scalp, together with development of the air sinuses

Growth of

the brain

the skull

and the

face

The dimensions of the face follow a path somewhat closer to the general curve. There is a considerable adolescent spurt, especially in the lower jaw, or mandible, resulting in the jaw's becoming longer and more projecting, the profile straighter, and the chin more pointed. As always

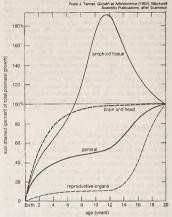

Figure 34: Major types of postnatal growth of parts and organs of the body (see text).

in growth, there are considerable individual differences, to the point that a few children have no detectable spurt at all in some face measurements.

The eve probably has a slight adolescent spurt, which is probably responsible for the increase in frequency of shortsightedness in children that occurs at the time of puberty. Though the degree of myopia increases continuously from at least age six to maturity, a particularly rapid rate of

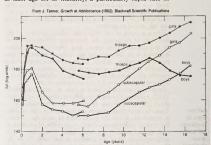

Figure 35: Amount of subcutaneous fat on the back of the arm (triceps) and the back of the body (subscapular) from birth to 16 years (see text).

change occurs at about 11 to 12 in girls and 13 to 14 in boys, and this would be expected if there was a rather greater spurt in the axial dimension (the dimension from front to back) of the eye than in its vertical dimension.

The lymphoid tissue has quite a different growth curve from the rest. It reaches its maximum amount before adolescence and then, probably under the direct influence of

sex hormones, declines to its adult value.

Development of fat

Age of

The subcutaneous fat layer also has a curve of its own, of a slightly complicated sort. Its thickness can be measured either by X-rays or, more simply, at certain sites in the body, by picking up a fold of skin and fat between the thumb and forefinger and measuring its thickness with a special, constant-pressure caliner. Figure 35 shows the distance curves of skin folds taken halfway down the back of the upper arm (the triceps) and on the body just below the angle of the shoulder blade, or scapula. Subcutaneous fat begins to be laid down in the fetus at about 34 weeks postmenstrual age, increases from then until birth and from birth onward until about nine months. (This is in the average child; the peak may be reached as early as six months or as late as 12 or 15.) After nine months, when the velocity of fat gain is zero, the fat usually decreases (that is, it has a negative velocity) until age six to eight, when it begins to increase once more. Girls have a little more fat than boys at birth, and the difference becomes more marked during the period of loss, since girls lose less than boys. From eight years on, the curves for girls and boys diverge more radically, as do the curves for limb and body fat. At adolescence the limb fat in boys decreases, while the body fat shows a temporary slowing down of gain but no actual loss. In girls there is a slight halting of the limb-fat gain at adolescence, but no loss; the trunk fat shows only a steady rise until adolescence.

Development at puberty

ALTERATIONS IN GROWTH RATE

At puberty, a considerable alteration in growth rate occurs. There is a swift increase in body size, a change in shape and composition of the body, and a rapid development of the gonads, or sex glands-the reproductive organs and the characters signalling sexual maturity. Some of these changes are common to both sexes, but most are sexspecific. Boys have a great increase in muscle size and strength, together with a series of physiological changes making them capable of doing heavier physical work than girls and of running faster and longer. These changes all specifically adapt the male to his primitive primate role of dominating, fighting, and foraging. Such adolescent changes occur generally in primates (that is, men, apes, and monkeys) but are more marked in some species than in others. Man lies at about the middle of the primate range, as regards both adolescent size increase and degree of sexual differentiation.

During the adolescent spurt in height, for a year or more, the velocity of growth approximately doubles; a boy is likely to be growing again at the rate he last experienced about age two. The peak velocity of height (P.H.V., a point much used in growth studies) averages about 10.5 centimetres per year in boys and 9.0 centimetres in girls (about 4 and 3.4 inches, respectively), but this is the "instantaneous" peak given by a smooth curve drawn through the observations. The velocity over the whole year encompassing the six months before and after the peak is naturally somewhat less. During this year a boy usually grows between 7 and 12 centimetres (2.75 and 4.75 inches) and a girl between 6 and 11 centimetres (2.35 and 4,35 inches). Children who have their peak early reach a somewhat higher peak than those who have it late.

The average age at which the peak is reached depends on peak height the nature and circumstances of the group studied more, probably, than does the height of the peak. In moderately well-off British or North American children at present the peak occurs on average at about 14.0 years in boys and 12.0 years in girls. Though the absolute average ages differ from population to population, the two-year sex difference always persists.

Practically all skeletal and muscular dimensions take part

in the spurt, though not to an equal degree. Most of the spurt in height is due to acceleration of trunk length rather than of length of legs. There is a fairly regular order in which the dimensions accelerate; leg length as a rule reaches its peak first, followed by the body breadths, with shoulder width last. The earliest structures to reach their adult status are the head, hands, and feet.

The spurt in muscle, of both limbs and heart, coincides with the spurt in skeletal growth, for both are caused by the same hormones. Boys' muscle widths reach a peak velocity of growth that is greater than that reached by girls. But, since girls have their spurt earlier, there is actually a period, from about 121/2 to 131/2, when girls on average have larger muscles than boys of the same age, as well as being taller (Figure 32). Simultaneously with the spurt there is a loss of fat, as described above

The marked increase in muscle size in boys at adolescence leads to an increase in strength, illustrated in Figure 36. Before adolescence, boys and girls are similar in strength for a given body size and shape; after, bovs

From J. Tanner. Growth at Adolescence (1962): Blackwell Scientific Publications strength of arm thrust

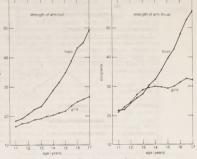

Figure 36: Strength of arm pull and thrust for boys and girls.

have much greater strength, probably due to development of more force per gram of muscle as well as to absolutely larger muscles. They also develop larger hearts and lungs relative to their size, a higher systolic blood pressure (the pressure resulting from a heart contraction), a lower resting heart rate, a greater capacity for carrying oxygen in the blood with more hemoglobin, and a greater power for neutralizing the chemical products of muscular exercise such as lactic acid. In short, the male becomes at adolescence more adapted for the tasks of hunting, fighting, and manipulating all sorts of heavy objects, as is necessary in some forms of food gathering.

It is as a direct result of these anatomical and physiological changes that athletic ability increases so much in boys at adolescence. The popular notion of a boy's "outgrowing his strength" at this time has little scientific support. It is true that the peak velocity of strength is reached a year or so later than that of height, so that a short period may exist when the adolescent, having completed his skeletal and probably also his muscular growth, still does not have the strength of a young adult of the same body size and shape. But this is a temporary phase; considered absolutely, power, athletic skill, and physical endurance all increase progressively and rapidly throughout adolescence.

The adolescent spurt in skeletal and muscular dimensions is closely related to the rapid development of the reproductive system that takes place at this time. The course of this development is outlined diagrammatically in Figure 37. The bar marked "breast" in the chart for the girls and the bars marked "penis" and "testis" in the chart for the boys represent the periods of accelerated growth of these organs. Other bars indicate the genitalia rating and the advent and development of the pubic hair. The sequence

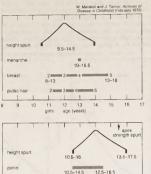

Adolescent increase in strength

Development of reproductive organs

tectio

genitalia rating

and timings that are given represent in each case average values for British boys and girls; the North American average is within two or three months of this. To give an idea of the individual departures from the average, figures for the range of age at which the various events begin and end are inserted under the first and last point of the bars. The acceleration of penis growth, for example, begins on average at about age 12½ years, but sometimes as early as 10½ and sometimes as late as 14½. The completion of penis development usually occurs at about age 141/2, but in some boys is at 121/2 and in others at 161/2. There are a few boys, it will be noticed, who do not begin their spurts in height or penis development until the earliest

age (years) Figure 37: Sequence of events at adolescence for average British boys and girls. Range of ages within which each event may begin and end is given by the figures placed directly below its start and finish. The numbers 2 to 5 within the bars indicate stage of maturity, 5 being full maturity and 2 the beginning of adolescence (see text)

95-135

maturers have entirely completed theirs. At ages 13, 14, and 15 there is an enormous variability among any group of boys, who range all the way from practically complete maturity to absolute preadolescence. The same is true of girls aged 11, 12, and 13.

13

14 16 16

The psychological and social importance of this difference in the tempo of development, as it has been called, is great, particularly in boys. Boys who are advanced in development are likely to dominate their contemporaries in athletic achievement and sexual interest alike. Conversely the late developer is the one who all too often loses out in the rough and tumble of the adolescent world, and he may begin to wonder whether he will ever develop his body properly or be as well endowed sexually as those others whom he has seen developing around him. An important part of the educationist's and the doctor's task at this time is to provide information about growth and its variability to preadolescents and adolescents and to give sympathetic support and reassurance to those who need it.

The sequence of events, though not exactly the same for each boy or girl, is much less variable than the age at which the events occur. The first sign of puberty in the boy is usually an acceleration of the growth of the testes and scrotum with reddening and wrinkling of the scrotal skin. Slight growth of pubic hair may begin about the same time but is usually a trifle later. The spurts in height and penis growth begin on average about a year after the first testicular acceleration. Concomitantly with the growth of the penis, and under the same stimulus, the seminal vesicles. the prostate, and the bulbo-urethral glands, all of which contribute their secretions to the seminal fluid, enlarge and develop. The time of the first ejaculation of seminal fluid is to some extent culturally as well as biologically determined but as a rule is during adolescence and about a year after the beginning of accelerated penis growth.

Axillary (armpit) hair appears on average some two years after the beginning of pubic hair growth; that is, when pubic hair is reaching stage 4 (Figure 37). There is enough variability and dissociation in these events, so that a very few children's axillary hair actually appears first. In boys, facial hair begins to grow at about the time that the axillary hair appears. There is a definite order in which the hairs of moustache and beard appear: first at the corners of the upper lip, then over all the upper lip, then at the upper part of the cheeks, in the midline below the lower lip, and, finally, along the sides and lower borders of the chin. The remainder of the body hair appears from about the time of first axillary hair development until a considerable time after puberty. The ultimate amount of body hair that an individual develops seems to depend largely on heredity, though whether because of the kinds and amounts of hormones secreted or because of variations in the reactivity of the end organs is not known.

Breaking of the voice occurs relatively late in adolescence. The change in pitch accompanies enlargement of the larynx and lengthening of the vocal cords, caused by the action of the male hormone testosterone on the laryngeal cartilages. There is also a change in quality that distinguishes the voice (more particularly the vowel sounds) of both male and female adults from that of children. This is caused by the enlargement of the resonating spaces above the larynx, as a result of the rapid growth of the mouth, nose, and maxilla (upper jaw).

In the skin, particularly of the armpits and the genital and anal regions, the sebaceous and apocrine sweat glands develop rapidly during puberty and give rise to a characteristic odour; the changes occur in both sexes but are more marked in the male. Enlargement of the pores at the root of the nose and the appearance of comedones (blackheads) and acne, while likely to occur in either sex, are considerably more common in adolescent boys than girls, since the underlying skin changes are the result of androgenic (male sex hormone) activity.

During adolescence the male breast undergoes changes, some temporary and some permanent. The diameter of the areola, which is equal in both sexes before puberty. increases considerably, though less than it does in girls. In some boys (between a fifth and a third of most groups studied) there is a distinct enlargement of the breast (sometimes unilaterally) about midway through adolescence. This usually regresses again after about one year.

In girls the start of breast enlargement-the appearance of the "breast bud"-is as a rule the first sign of puberty, though the appearance of pubic hair precedes it in about one-third. The uterus and vagina develop simultaneously with the breast. The labia and clitoris also enlarge. Menarche, the first menstrual period, is a late event in the sequence. Though it marks a definitive and probably mature stage of uterine development, it does not usually signify the attainment of full reproductive function. The early cycles may be more irregular than later ones and in some girls, but by no means all, are accompanied by discomfort. They are often anovulatory; that is, without the shedding of an egg. Thus there is frequently a period of adolescent sterility lasting a year to 18 months after menarche, but it cannot be relied on in the individual case. Similar considerations may apply to the male, but there is no reliable information about this. On average, girls grow about six centimetres (about 2.4 inches) more after menarche, though gains of up to twice this amount may occur. The gain is practically independent of whether menarche occurs early or late.

NORMAL VARIATIONS

Children vary a great deal both in the rapidity with which they pass through the various stages of puberty and in First signs of puberty in the girl

The first sign of puberty in the boy

Stages of puberty

the closeness with which the various events are linked together. At one extreme one may find a perfectly healthy girl who has not yet menstruated though her breasts and pubic hair are characteristic of the adult and she is already two years past her peak height velocity; and at the other, a girl who has passed all the stages of puberty within the space of two years.

In girls the interval from the first indication of puberty to complete maturity varies from 18 months to six years The period from the moment when the breast bud first appears to menarche averages 21/2 years, but it may be as little as six months or as much as 51/2 years. The rapidity with which a child passes through puberty seems to be independent of whether puberty is occurring early or late. Menarche invariably occurs after peak height velocity has been passed.

In boys a similar variability of maturation occurs. The male genitalia may take between two and five years to attain full development, and some boys complete the whole process before others have moved from the first to the second stage.

The height spurt occurs relatively later in boys than in girls. Thus there is a difference between the average boy and girl of two years in age of peak height velocity but of only one year in the first appearance of pubic hair. Indeed. in some girls the acceleration in height is the first sign of puberty; this is never so in boys. A small boy whose genitalia are just beginning to develop can be unequivocally reassured that an acceleration in height is soon to take place, but a girl in the corresponding situation may already have had her height spurt.

Sex dimorphism. The differential effects on the growth of bone, muscle, and fat at puberty increase considerably the difference in body composition between the sexes. Boys have a greater increase not only in stature but especially in breadth of shoulders; girls have a greater relative increase in width of hips. These differences are produced chiefly by the changes that occur during puberty; but other sex differentiations arise before that time. Some, like the external genital difference itself, develop during fetal life. Others develop continuously throughout the whole growth period by a sustained differential growth rate. An example of this is the greater relative length and breadth of the forearm in the male when compared with whole arm length or whole body length.

Part of the sex difference in pelvic shape antedates puberty. Girls at birth already have a wider pelvic outlet. Thus the adaptation for childbearing is present from an early age. The changes at puberty are concerned more with widening the pelvic inlet and broadening the much more noticeable hips

Physical and behavioral interaction. Children vary greatly in their tempo of growth. The effects are most dramatically seen at adolescence, but they are present at all ages from birth and even before.

The concept of developmental age, as opposed to chronological age, is an important one. To measure developmental age, there is need of some way of determining how far along his own path to maturity a given child has gone. Therefore, there is need of a measure in which everyone at maturity ends up the same (not different as in height). The usual measure used is skeletal maturity or bone age. This is measured by taking an X-ray of the hand and wrist. The appearances of the developing bones can be rated and formed into a scale of development; the scale is applicable to boys and girls of all genetic backgrounds, though girls on average reach any given score at a younger age than do boys; and blacks on average, at least in the first few years after birth, reach a given score younger than do whites. Other areas of the body may be used if required. Skeletal maturity is closely related to the age at which adolescence occurs; that is, to maturity measured by some sex character developments. Thus the range of the chronological age within which menarche may normally fall is about 10 to 161/2, but the corresponding range of bone age for menarche is only 12 to 141/2. Evidently the physiological processes controlling progression of skeletal development are in most instances closely linked with those that initiate the events of adolescence. Furthermore,

children tend to be consistently advanced or retarded during their whole growth period, at any rate after about age

There is little doubt that being an early or a late maturer may have repercussions on behaviour and that in some children these repercussions may be considerable. There is little enough solid information on the relation between emotional and physiological development, but what there is supports the common-sense notion that emotional attitudes are clearly related to physiological events.

Effects of late and early maturity

Larger size and earlier maturation. The rate of maturing and the age of onset of puberty are dependent on a complex interaction of genetic and environmental factors. Where the environment is good, most of the variability in age at menarche in a population is due to genetical differences. In many societies puberty occurs later in the poorly off, and, in most societies investigated, children with many siblings grow more slowly than children with few

During the last hundred years there has been a striking tendency for children to become progressively larger at all ages. This is known as the "secular trend." The magnitude of the trend in Europe and America is such that it dwarfs the differences between socioeconomic classes.

Modern tendency toward earlier maturity

The data from Europe and America agree well: from about 1900, or a little earlier, to the present, children in average economic circumstances have increased in height at age five to seven by about one to two centimetres (0.4 to 0.8 inch) per decade, and at 10 to 14 by two to three centimetres (0.8 to 1.2 inches) each decade. Preschool data show that the trend starts directly after birth and may, indeed, be relatively greater from age two to five than subsequently. The trend started, at least in Britain, as early as 1850.

Most of the trend toward greater size in children reflects a more rapid maturation; only a minor part reflects a greater ultimate size. The trend toward earlier maturing is best shown in the statistics on age at menarche. A selection of the best data is illustrated in Figure 38. The trend is between three and four months per decade since 1850 in average sections of western European populations. Welloff persons show a trend of about half of this magnitude, having never been so retarded in menarche as the worse

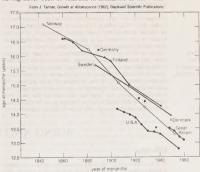

Figure 38: Secular trend in age at menarche, 1830-1960.

off. The causes of the secular trend are probably multiple. Certainly better nutrition is a major one and perhaps in particular more protein and calories in early infancy. A lessening of disease may also have contributed. Hot climates used to be cited as a potent cause of early menarche, but it seems that their effect, if any, is considerably less than that of nutrition. Some authors have supposed that the increased psychosexual stimulation consequent on modern urban living has contributed, but there is no positive evidence for this.

Developmental and chronological ages

The main hormones concerned with growth are pituitary growth hormone, thyroid hormone, the sex hormones testosterone and estrogen, and the pituitary gonadotropic (sex-gland-stimulating) hormones.

Action of growth hormone

Effects

of sex

hormones

on growth

Pituitary growth hormone, a protein with molecular weight of 21,600 and of known amino-acid composition, is secreted by the pituitary gland throughout life. Exactly what its function is in the adult is not clear, but in the child it is necessary for growth; without it dwarfism results. During fetal life it seems not to be necessary, though normally present. It is not secreted at a constant rate all day but in small bursts of activity. Secretion by the pituitary is controlled by a substance sent to it from an adjacent part of the brain. The normal stimulus for secretion is not certain, but a sharp and "unnatural" lowering of blood sugar will cause growth hormone to be secreted, and this is used as a test. The hormone decreases the amount of fat and causes protein to be laid down in muscles and viscera. Children who lack it are fat as well as small; when given it by injection, they lose fat and grow rapidly.

The hormone is peculiar in being species-specific; that is, only growth hormone from human glands is active in man. Supplies of the hormone for treating children who need it are obtained at autopsy, and supply has been limited by this. Recombinant DNA technology shows possibilities in increased manufacture of this hormone in the laboratory.

Thyroid hormone from the thyroid gland in the neck is necessary for normal growth, though it does not itself stimulate growth, for example, in the absence of pituitary growth hormone. Without thyroid hormone, however, cells do not develop and function properly, especially in the brain. Babies who lack thyroid hormone at birth are small and have insufficiently developed brains; they are known as cretins. Frequently, if the condition is diagnosed and they are treated with thyroid hormone at once, they recover completely; the longer they go without treatment, the more likely it is that the brain damage will be permanent

Thyroid lack may also develop later in childhood, when it causes a slowing of growth rate; full catch-up follows prompt treatment.

Testosterone, secreted by the interstitial cells of the testis, is important not only at puberty but before. Its secretion by the fetal testis cells is responsible for the development of certain parts of the male genital apparatus. If testosterone is not secreted at a particular and circumscribed time, the genitalia develop into the female form,

Only small amounts of testosterone circulate between birth and puberty, but at puberty the interstitial cells develop greatly in response to pituitary luteinizing hormone (see below), and testosterone is secreted in large amounts, bringing about most of the changes of male puberty. It acts on a widespread series of receptors-for example, the cells of the penis, the muscles, the skin of the face, the cartilages of the shoulder, and certain parts of the brain. Most of the adolescent growth spurt is due to testosterone.

The female sex hormones, collectively called estrogens, are first secreted in quantity at puberty by cells in the ovary. They cause growth of the uterus, vagina, and breast; they act also on the bones of the hip, causing the specifically female widening. The adolescent growth spurt in the female is probably caused by testosterone-like substances (androgens) secreted by the adrenal gland in both male and female.

The pituitary secretes two other hormones concerned in development: one, follicle-stimulating hormone (FSH), causes growth of the main portions of the ovary in the female and the sperm-producing cells in the testis of the male; the other, luteinizing hormone (LH), causes growth and secretion of the testosterone-secreting cells of the male and has an action in controlling the menstrual cycle in the female. The pituitary is caused to secrete gonadotropins by substances called releasing factors that come to it from adjacent areas of the brain, where they are made. Certain children develop all the changes of puberty, up to and including sperm production or ovulation, at an early age, either as the result of a brain lesion or as an isolated developmental, sometimes genetic, defect. The youngest mother on record was such a child; she gave birth to a full-term healthy infant by cesarean section at the age of five years and eight months. The existence of precocious puberty and the results of accidental ingestion by small children of male or female sex hormones indicate that breasts, uterus, and penis will respond to hormonal stimulation long before puberty. Evidently an increased end-organ sensitivity plays at most a minor part in puberal events.

The signal to start the sequence of events is given by the brain, not the pituitary. Just as the brain holds the information on sex, so it holds information on maturity. The pituitary gland of a newborn rat successfully grafted in place of an adult pituitary begins at once to function in an adult fashion and does not have to wait until its normal age of maturation has been reached. It is the hypothalamus in the brain, not the pituitary, that must mature before puberty begins. Small amounts of sex hormones circulate from the time of birth, and these appear to inhibit the prepuberal hypothalamus from producing gonadotropin releasers. At puberty the hypothalamic cells become less sensitive to sex hormones. The small amount of sex hormones circulating then fails to inhibit the hypothalamus; gonadotropins are released, and these stimulate the production of testosterone by the testis or estrogen by the ovary. The level of the sex hormone rises until the same feedback circuit is re-established but now at a higher level of gonadotropins and sex hormones. The sex hormones are now high enough to stimulate the growth of secondary sex characters and to support mating behaviour.

Numerous factors may retard maturation or prevent normal growth, including hormonal disorders, metabolic defects, hereditary conditions, and inadequate nutrition. For information about specific growth disorders, see EN-DOCRINE SYSTEMS: Diseases and disorders of the human endocrine system; METABOLISM; NUTRITION: Nutritional diseases and disorder. (J.M.T./Ed.)

Initiation of puberty

The role of the hypothalamus in puberty

AGING AND SENESCENCE

Life-span

It is a commonplace that organisms die, some after only a brief existence, like that of the mayfly whose adult life burns out in a day, and others like that of the gnarled bristlecone pines that have lived thousands of years. The limits of the life-span of each species appear to be determined ultimately by heredity. Locked within the code of the genetic material are instructions that specify the age beyond which a species cannot live given even the most favourable conditions. And many environmental factors act to diminish that upper age limit.

MEASUREMENT OF LIFE-SPAN

The maximum life-span is a theoretical number whose exact value cannot be determined from existing knowledge about an organism; it is often given as a rough estimate based on the longest lived organism of its species known to date. A more meaningful measure is the average life-span; this is a statistical concept that is derived by the analysis of mortality data for populations of each species. A related term is the expectation of life, a hypothetical number computed for humans from mortality tables drawn up by insurance companies. Life expectancy represents the average number of years that a group of persons, all born at the same time, might be expected to live, and it is based on the changing death rate over many past years.

The concept of life-span implies that there is an individual whose existence has a definite beginning and end. What constitutes the individual in most cases presents no problem: among organisms that reproduce sexually the in-

Definition of life-

Ageless

tissue

embryonic

dividual is a certain amount of living substance capable of maintaining itself alive and endowed with hereditary features that are in some measure unique. In some organisms, however, extensive and apparently indefinite growth takes place and reproduction may occur by division of a single parent organism, as in many protists, including bacteria, algae, and protozoans. If these divisions are incomplete, a colony results; if the parts separate, genetically identical organisms are formed. In order to consider life-span in such organisms, the individual must be defined arbitrarily since the organisms are continually dividing. In a strict sense, the life-spans in such instances are not comparable to those forms that are sexually produced.

The beginning of an organism can be defined by the formation of the fertilized egg in sexual forms; or by the physical separation of the new organism in asexual forms (many invertebrate animals and many plants). In animals generally, birth is considered to be the beginning of the life-span. The timing of birth, however, is so different in various animals that it is only a poor criterion. In many marine invertebrates the hatchling larva consists of relatively few cells, not nearly so far along toward adulthood as a newborn mammal. For even among mammals, variations are considerable. A kangaroo at birth is about an inch long and must develop further in the pouch, hardly comparable to a newborn deer, who within minutes is walking about. If life-spans of different kinds of organisms are to be compared, it is essential that these variations be accounted for. The end of an organism's existence results when irreversible changes have occurred to such an extent that the individual no longer actively retains its organization. There is thus a brief period during which it is impossible to say whether the organism is still alive, but this time is so short relative to the total length of life that it creates no great problem in determining life-span.

Some organisms seem to be potentially immortal. Unless an accident puts an end to life, they appear to be fully capable of surviving indefinitely. This faculty has been attributed to certain fishes and reptiles, which appear to

verified

250

estimated

be capable of unlimited growth. Without examining the various causes of death in detail (see DEATH) a distinction can be made between death as a result of internal changes (i.e., aging) and death as a result of some purely external factor, such as an accident. It is notable that the absence of aging processes is correlated with the absence of individuality. In other words, organisms in which the individual is difficult to define, as in colonial forms, appear not to age. (PWF)

PLANTS

Plants grow old as surely as do animals; however, a generally accepted definition of age in plants has not yet been realized. If the age of an individual plant is that time interval between the reproductive process that gave rise to the individual and the death of the individual, the age attained may be given readily for some kinds of plants but not for others. Table 3 lists maximum ages, both estimated and verified, for some seed plants.

Problem of defining age. An English oak that has 1.000 annual rings in the trunk is 1,000 years old. Fut age is less certain in the case of an arctic lupine that germinated from a seed that, containing the embryo, had been lying in a lemming's burrow in the arctic permafrost for 10,000 years.

The mushroom caps that appear overnight last for only a few days, but the network of fungus filaments in the soil (the mycelia) may be as old as 400 years. Because of important differences in structure, the life-span of higher plants cannot be compared with that of higher animals. Normally, embryonic cells (that is, cells canable of changing in form or becoming specialized) cease to exist very early in the life of an animal. In plants, however, embryonic tissue-the plant meristems-may contribute to growth and tissue formation for a much longer time, in some cases throughout the life of the plant. Thus the oldest known trees, bristlecone pines of California and Nevada, have one meristem (the cambium) that has been adding cells to the diameter of these trees for, in many cases, more than 4,000 years and another meristem (the apical) that has been adding cells to the length of these trees for the same period. These meristematic tissues are as old as the plant itself; they were formed in the embryo. The wood, bark, leaves and cones, however, live for only a few years. The wood of the trunk and roots, although dead, remains a part of the tree indefinitely, but the bark, leaves, and cones are continually in the process of dying and sloughing off.

Among the lower plants only a few mosses possess structures that enable an estimate of their age to be made. The haircap moss (Polytrichum) grows through its own stem tip each year, leaving a ring of scales that marks the annual growth. Three to five years' growth in this moss is common, but life-spans of 10 years have been recorded. The lower portions of such a moss are dead, though intact. Peat moss (Sphagnum) forms extensive growths that fill acid bogs with a peaty turf consisting of the dead lower portions of mosses whose living tops continue growing. Mosses that become encrusted with lime (calcium carbonate) and form "tufa" beds several metres thick also have living tips and dead lower portions. On the basis of their observed annual growth, some tufa mosses are estimated to have been growing for as long as 2,800 years

No reliable method for determining the age of ferns exists, but on the basis of size attained and growth rate, some tree ferns are thought to be several decades old. Some club mosses, or lycopsids, have a "storied" growth pattern similar to that of the haircap moss. Under favourable conditions some specimens live five to seven years.

The woody seed plants, such as conifers and broadleaf trees, are the most amenable to determination of age. In temperate regions, where each year's growth is brought to an end by cold or dryness, every growth period is limited by an annual ring-a new layer of wood added to the diameter of the tree. These rings may be counted on the cut ends of a tree that has been felled or, using a special instrument, a cylinder of wood can be cut out and the growth rings counted and studied. In the far north growth rings are so close together that they are difficult to count.

In the moist tropics growth is more or less continuous, so

that clearly defined rings are difficult to find. Often the age of a tree is estimated on the basis of its diameter, especially when the average annual increase in diameter is known. The source of greatest error in this method is the not infrequent fusing of the trunks of more than one tree, as, for example, occurred in a Montezuma cypress in Santa María del Tule, a little Mexican village near Oaxaca. This tree, described by the Spanish explorer Hernan Cortés in the early 1500s, was earlier estimated on the basis of its great thickness to be 6,000 years old; later studies, however, proved it to be three trees grown together. Estimates of the age of some English yews have been as high as 3,000 years, but these figures, too, have turned out to be based on the fusion of close-growing trunks, none of which is more than 250 years old. Increment borings of bristlecone pines have shown specimens in the western United States to be 4,600 years old.

Growing season of seed plants. Annuals. Plants, usually herbaceous, that live for only one growing season and produce flowers and seeds in that time are called annuals. They may be represented by such plants as corn and marigolds, which spend a period of a few weeks to a few months rapidly accumulating food materials. As a result of hormonal changes-brought about in many plants by changes in environmental factors such as day length and temperature-leaf-producing tissues change abruptly to flower-producing ones. The formation of flowers, fruits, and seeds rapidly depletes food reserves and the vegetative portion of the plant usually dies. Although the exhaustion of food reserves often accompanies death of the plant, it is not necessarily the cause of death.

Biennials. These plants, too, are usually herbaceous. They live for two growing seasons. During the first season, food is accumulated, usually in a thickened root (beets, carrots); flowering occurs in the second season. As in annuals, flowering exhausts the food reserves, and the plants die after the seeds mature.

Perennials. These plants have a life-span of several to many years. Some are herbaceous (iris, delphinium), others are shrubs or trees. The perennials differ from the above-mentioned groups in that the storage structures are either permanent or are renewed each year. Perennials require from one to many years growth before flowering. The preflowering (juvenile) period is usually shorter in trees and shrubs with shorter life-spans than in those with longer life-spans. The long-lived beech tree (Fagus sylvatica), for example, passes 30-40 years in the juvenile stage, during which time there is rapid growth but no flowering. Some plants-cotton and tomatoes, for example-are perennials in their native tropical regions but are capable of blooming and producing fruits, seeds, or other useful

annuals in the temperate zones. Longevity of seeds. Although there is great variety in the longevity of seeds, the dormant embryo plant contained within the seed will lose its viability (ability to grow) if germination fails to occur within a certain time. Reports of the sprouting of wheat taken from Egyptian tombs are living seeds unfounded, but some seeds do retain their viability a long time. Indian lotus seeds (actually fruits) have the longest known retention of viability. On the other hand, seeds of some willows lose their ability to germinate within a week after they have reached maturity.

parts in their first year. Such plants are often grown as

The loss of viability of seeds in storage, although hastened or retarded by environmental factors, is the result of changes that take place within the seed itself. The changes that have been investigated are: exhaustion of food supply; gradual denaturing or loss of vital structure by protoplasmic proteins; breakdown of enzymes; accumulation of toxins resulting from the metabolism of the seed. Some self-produced toxins may cause mutations that hamper seed germination. Since seeds of different species vary greatly in structure, physiology, and life history, no single set of age factors can apply to all seeds. (L.K.)

The oldest

Much of what is known of the length of life of animals other than man derives from observations of domesticated species in laboratories and zoos. One has only to consider how few animals reveal their age to appreciate the difficulties involved in answering the apparently simple question of how long they live in nature. In many fishes, a few kinds of clams, and an occasional species of other groups. growth is seasonal, so that annual zones of growth, much like tree rings, are produced in some part of the organism. Among game species, methods of determining relative age by indicators such as the amount of tooth wear or changes in hone structure have vielded valuable information. Bird bands and other identifying marks also make age estimation possible. But one of the consequences of the fact that animals move is that very little is known about the lifespan of most species as they exist in nature.

Maximum and average longevity. The extreme claims of longevity that are occasionally made for one species or another have consistently been proven false when subjected to critical scrutiny. Although the maximum lifespan that has been observed for a particular species cannot be considered absolute, since a limited number of individuals at best has been studied, this datum probably provides a fair approximation of the greatest age attainable for this kind of animal under favourable conditions. Animals in captivity, which provide most of the records of extreme age, are exposed to far fewer hazards than those in the wild. In the accompanying table of maximum longevity, particular species have been so selected as to encompass the known range of longevity of other members of the taxonomic group to which they belong.

Table 4: Maximum Longevity of Animals in Captivity*

animal	life-span in years	animal	life-span in years	
Mammals	12001111111	Amphibians	1 11 11	
Bat (Eptesicus fuscus)	2	European black sala-	3

Water turtle (Pseudemys scripta)	7	Rotifers Various species	0.03-0.1	
scriptuj		various species	0.03-0.1	

ased and adapted from W.S. Spector (ed.). Handbook of Biological Data. 1056

Environmental influences. Life-span usually is measured in units of time. Although this may seem eminently logical, certain difficulties may arise. In cold-blooded animals in general, the rate of metabolism that determines the various life processes varies with the temperatures to which they are exposed. If aging depends on the expenditure of a fixed amount of vital energy, an idea first proposed in 1908, life-span will vary tremendously depending on

Temperature effects

temperature or other external variables that influence lifespan. There is considerable evidence attesting at least to the partial cogency of this argument. So long as a certain range is not exceeded, cold-blooded invertebrates do live longer at low than at high temperatures. Rats in the laboratory live longest on a somewhat restricted diet that does not permit maximum metabolic rate. Of perhaps even greater significance is the fact that many animals undergo dormant periods. Many small mammals hibernate; a number of arthropods have life cycles that include periods during which development is arrested. Under both conditions the metabolic rate becomes very low. It is questionable whether such periods should be included in computing the life-span of a particular organism. Comparisons between species, some of which have such inactive periods while others do not, are dangerous. It is possible that life-span could be measured more adequately by total metabolism; however, the data that are necessary for this purpose are almost entirely lacking.

Length of life is controlled by a multitude of factors, which collectively may be termed environment, operating on a genetic system that determines how the individual will respond. It is impossible to list all the environmental factors that may lead to death. For analytical purposes it is, however, useful to make certain formal separations. Every animal is exposed to (1) a pattern of numerous events, each with a certain probability of killing the individual at any moment and, in the aggregate, causing a total probability of death or survival; (2) climatic and other changes in the habitat, modifying the frequency with which the various potentially fatal events occur; and (3) progressive systemic change, inasmuch as growth, reproduction, development, and senescence are characteristics intrinsic in the organism and capable of modifying the effects of various environmental factors.

Patterns of survival. Consider a group of similar animals of the same age. Although no two individuals can have precisely the same environment, let it be assumed that the environment of the group remains effectively constant. If the animals undergo no progressive physiological changes, the factors causing death will produce a death rate that will remain constant in time. Under these conditions, it will take the same amount of time for the population to become reduced to one-half its former number, no matter how many animals remain at the beginning of the period considered. The animals therefore survive according to the pattern of an accident curve. This is the sense in which many of the lower animals are immortal. Although they die, they do not age; how long they have already lived has no influence on their further life expectation

Another group of animals may consist of individuals that differ markedly in their responses to the constant environment. They may be genetically different, or their previous development may have caused variations to arise. Those individuals that are most poorly suited to the new environment will die, leaving survivors that are better adapted. The same result can also be achieved in other ways. If the environment varies geographically, those individuals that happen to find areas in which existence can be maintained will survive, while the remainder will die. Or, as a result of their own properties, animals in a constant environment may acclimate in a variety of ways, thus adjusting to the existing conditions. The pattern of survival that results in each of these cases is one in which the death rate declines with time, as illustrated by the selectionacclimation curve.

In the absence of death from other causes, all members of a population may exist in their environment until the onset of senescence, which will cause a decline in the ability of individuals to survive. In a sense they can be considered to wear out as does a machine. Their survival is best described by individual differences among members of the population that determine the curvature of the survival line (wearing-out curve). The more the population varies, the less abrupt is the transition from total survival to total death.

Under the actual conditions of existence of animals the three types of survival (accident pattern, selectionacclimation pattern, wearing-out pattern) above all enter

as components of the realized survival pattern. Thus in animals that are carefully maintained in the laboratory, survival is approximately that of the wearing-out pattern. Environmental accidents can be kept to a minimum under these conditions, and survival is almost complete during the major part of the life-span. In all known cases, however, the early stages of the life-span are characterized by a noticeable contribution of the selection-acclimation pattern. This must be interpreted as a result of developmental changes that accompany the early life of the individuals and of selective processes that operate on those organisms whose genetic constitutions are ill fitted for that environment

In some of the larger mammals in nature, the existing evidence points to a similar survival pattern. In a variety of other animals, however, and including fishes and invertebrates, mortality in the young stages is so high that the selection-acclimation curve predominates. One estimate places the mortality of the Atlantic mackerel during its first 90 days of life as high as 99,9996 percent. Since some mackerel do live for several years, a mortality rate that decreases with age is indicated. Similar considerations probably apply to all those animals that have larval stages that serve as dispersal mechanisms.

When the postjuvenile portion of the life-span is considered by itself, a number of animals for which such information has been gathered-including primarily fishes and birds-have survivorship curves that are dominated by the accident pattern. In these species in nature, death from old age apparently is rare. Their chance of surviving to an advanced age is so small that it may be statistically negligible. In modern times, human predation is a large factor in the mortality of these species in many cases. Since deaths from fishing and hunting are largely independent of age, once an animal has reached a certain minimum size, such a factor only makes the survival curve steeper but does not change its shape. One consequence of such increased mortality is that fewer old and large individuals are noticed in a population.

More complex survival patterns, such as the hypothetical one illustrated, undoubtedly exist. They should be looked for in those species in which extensive reorganization of the animal is part of the normal life cycle. In effect, these animals change their environment radically, in some cases several times during a lifetime. The frog offers a familiar example. During its period of early development and until shortly after hatching, the animal is subject to major internal, and some external, change. As a tadpole it is adjusted to an aquatic, herbivorous life. The metamorphosis to the terrestrial, carnivorous adult form is accompanied by varied physiological stresses that must be expected to produce a temporary increase in mortality rate. In some insects the eggs, larvae, pupae, and adults are exposed to and respond to quite different environments, and a survivorship pattern even more complex than that described by the composite curve may exist.

The same species will exhibit changed survival in different environments. In captivity an animal population may approach the wearing-out pattern; in its natural habitat survivorship may vary with age in a quite different way. Although one can assign a maximum potential life-span to an individual-while realizing that this maximum may not be attained-it is impossible to specify the survivorship pattern unless the environment is also specified. This is another way of saying that life-span is the joint property of the animal and the environment in which it lives.

HUMAN LIFE-SPAN

The exact duration of human life is unknown, although there is presumably a maximum life-span for the human race established in the genetic material. At first thought, this statement seems irrational. Surely no human being can live 1,000 years. Even though all may agree that the likelihood of an individual living 1,000 years is infinitesimal, there is no scientific proof that this statement is or is not true. The indeterminacy of the maximum limit of human life is made more comprehensible if one chooses a number that may appear to be a more reasonable limit.

Since there is no verified instance of a person having

Highest mortality in aquatic animale

Effects of metamorphosis lived 150 years, this number may, for purposes of illustration, be arbitrarily accepted as the maximum limit of the span of human life. But if the possibility is admitted that an individual may live exactly 150 years, there is no valid reason for rejecting the possibility that some other individual may live 150 years and one minute. And if 150 years and one minute is accepted, why not 150 years and two minutes, and so on? Thus, based on existing knowledge of longevity, a precise figure for the span of human life cannot be given.

Studies on longevity. Much information concerning the inheritance of longevity has come from the study of genealogical records of nobility and landed gentry. The early genealogical studies were criticized on the grounds that the downward trend in the death rate (attributable generally to scientific advancements) introduced a spurious correlation in statistics derived from records extending over long periods of time. It was argued that in some instances records were included of persons who, at the time of the study, had not had the opportunity of living out their possible life-span. The general finding of such investigations was that the expectation of life of sons of long-lived parents (i.e., those living to age 70 years or older) was greater than that of sons of shorter-lived parents (i.e., those having attained less than age 50 at the time of death).

An American biostatistician attempted to avoid the defects of genealogical studies by collecting records of the family histories of 365 nonagenarians (90-year-old persons) and of a comparison group of 143 individuals of varying ages, selected because all of their six immediate ancestors were dead. The study introduced the concept of "total immediate ancestral longevity," or TIAL-the sum of the ages at death of the two parents and the four grandparents of a given person-as a measure of longevity. This number is unlikely to be greater than 600 or less than 90. The average TIAL of the nonagenarians and centenarians definitely exceeded that of the comparison group. This held true not only for the six immediate ancestors as a group but also for each category-father, mother, paternal and maternal grandparents. In the same study, investigators also computed the expectation of life for sons of fathers as classified in three groups by age at death: (1) under age 50, (2) from age 50 to age 79, and (3) age 80 or over. The expectation of life for the three groups at birth was 47.0, 50.5, and 57.2 years, respectively. The same relative ranking continued through the lifetime of the sons, their expectation of life at age 40 being 27.3, 28.9, and 32.0 years, respectively.

While certain doubts have been raised about the validity of these as well as earlier studies, taken at their face value, these data show clearly that long-lived persons had parents and grandparents who lived longer than the parents and grandparents of shorter lived persons.

Since longevity is important in life insurance underwriting, several studies have been made of the relationship between heredity and the life-span by an analysis of life insurance records. Such analyses showed that policyholders both of whose parents were living when the policy was written live longer than those whose parents were dead when the policy was written. These results are in conformity with those obtained from genealogical records and family histories.

Each of the various types of studies of the inheritance of longevity—epicalogical records, life insurance records, and family histories of the general population—has limitations that restrict the applicability of the findings. The principal studies indicate, nevertheless, that the children of long-lived parents are more likely to be long-lived than are the children of short-lived parents. Conversely, the immediate ancestors—parents and grandparents—of long-lived persons on the average are older at death than are the immediate ancestors of persons who die at a relatively young age. These studies support the conclusion, mentioned earlier, that longevity is determined in part by heredity.

Actual versus possible life-span. It should be observed that this conclusion relates to the inheritance of longevity—the observed expression of the span of life—and not to the span of life itself. The actual length of life itself is

shorter than the possible life-span, since the former reflects the effect of unfavourable environmental factors. In the absence of any biological data from which the maximum limit of the span of life can be determined precisely, an estimate of the limit must be obtained from observation of the actual length of life of persons who already have died. But such observations cannot establish a fixed limit for the span of life.

The estimation of the length of the span of life from observed data is a form of sampling from a large but incomplete population. The tabulation of the ages at death of a large number of persons from a large general population of the United States will give an asymmetrical frequency distribution with two modes, or peaks, of highest frequency: the first at age less than one year and the second between ages 75 and 80 years. The frequency distribution is bounded by age zero at the lower limit but there is no boundary at the upper limit. The number of deaths of persons whose length of life is near the upper limit of this frequency distribution (e.g., 100 years or more) varies from year to year. The age of the oldest person dying also varies from year to year.

The number of deaths of centenarians (100-year-old persons) depends in part upon the number of deaths counted. Ages at death are frequently unverified, so that the true numbers of centenarians almost certainly deviate from those given in official vital statistics. Moreover, only a very small proportion of the deaths that have occurred throughout the history of the human race have been registered. The potential number of future deaths greatly exceeds the number that already has occurred. Statistical theory supports the expectation that as the total number of deaths continues to increase, the death of a person whose length of life will be longer than that of any person previously known will be recorded.

Observation of the length of life of persons who have died can show that it is possible for a human being to live to the oldest age recorded as of any specified date and can provide an estimate of the relative frequency or probability of that event. But such observations do not provide a logical basis for fixing any age as the maximum possible limit of the life-sons.

The continuation of the worldwide decline in the death rate will naturally result in an increase in the number of persons who live until age 100 years or more. Since the number of persons who may live to an advanced age, such as 110 or 115 years, is directly related to the number of persons who live to age 100, an increase in the latter number will increase the probability that the death of an individual attaining some greater age (e.g., 115 years) will be recorded at some future date.

Many instances of persons alleged to have died at an age considerably greater than 100 years have been recorded. Statements concerning the age at death of biblical characters such as Methuselah can be dismissed, since scientific verification is impossible. Three of the most frequently cited cases of more recent times are: Thomas Parr, who died in November 1635 at the alleged age of 152 years; Henry Jenkins, who died in December 1670 at the alleged age of 169 years; and Catherine, countess of Desmond, who died in 1604 at the alleged age of 140 years. William Harvey, a famous English physician, performed an autopsy on Thomas Parr and the account of the autopsy was cited for many years as evidence that Harvey-in his paperhad confirmed Parr's age. Quite apart from the fact that it is impossible accurately to determine the age of a person by an autopsy, Harvey made no attempt to verify Parr's age but merely referred to the current estimates. Subsequent investigations have revealed that no proof exists of the age at death of any of these three individuals and that

their reported ages were based solely upon hearsay.

An example with more definite documentation is that of
Christian Jacobsen Drakenberg, stated to have been born
on November 18, 1626, and to have died on October 9,
1772, aged 145 years and 325 days. Although the authenticity of his age was attested to by many persons, including
two celebrated Scandinavian actuaries, later investigations
cast doubt upon the record. It is difficult to accept the
statements concerning Drakenberg's age at death, since

The TIAL

Influence

of heredity

Famous age records

this age is more than 30 years greater than the next oldest verified age at death-a difference that in itself casts doubt on its authenticity.

Of eight individuals for whom records substantiate the fact that each had lived more than 108 years, seven were females. Six of the eight were more than 110 years old at death. The oldest was Pierre Joubert, who was born July 15, 1701, and died November 16, 1814, aged 113 years and 124 days. Discounting the Drakenberg record, this is the oldest age at death that has been generally accepted

It may be concluded that the span of human life is at least 114 years, but that this is not the maximum upper limit. This does not mean the span of life of each individual now living or to be born in the future is at least 114 influencing years. The span of life, since it is determined by heredity. varies from one individual to another as do other genetically determined traits

Factors

life-span

of man

A significant proportion of human embryos and fetuses die before birth. Other infants at birth have defects that limit their span of life to a few years. Some malformations (e.g., certain cardiovascular defects) are developmental rather than genetic in the strict sense of the word and can be corrected so that the length of life of such persons

In the past the length of life of most individuals has been considerably shorter than their possible span of life because of unhealthful environmental factors. As these factors are increasingly brought under control or eliminated, the actual length of life will approach more closely the span of life. At the end of the 18th century the expectation of life at birth in North America and northwestern Europe was about 35 or 40 years. By 1970 it exceeded 70 years, and at some future date the death of a person at an authenticated age of more than 114 years can be expected.

There is no evidence that the span of human life has increased since the beginning of recorded history. Neither is there any evidence that the death rate of centenarians has decreased. The expected increase in the number of centenarians results from a decrease in the death rate at ages under 100 years and not from any demonstrable increase in the maximum length of the span of life. The remarkable increase in the average length of life during the past 2,000 years-from 20-25 years to 70 years under favourable conditions-has increased the likelihood that a person may live to the maximum limit of his span of (P.W.F.) life

Aging: general considerations

Aging consists of the progressive changes that take place in a cell, an organ, or the total organism with the passage of time. It is a process that goes on over the entire adult life-span of any living thing. Gerontology, the study of the aging process, is devoted to the understanding and control of all factors contributing to the finitude of individual life. It is not concerned exclusively with debility, which looms so large in human experience, but deals with a much wider range of phenomena. Every species has a life history in which the individual life-span has an appropriate relationship to the reproductive life-span and to the mechanism of reproduction and the course of development. How these relationships evolved is as germane to gerontology as it is to evolutionary biology. It is also important to distinguish between the purely physicochemical processes of aging and the accidental organismic processes of disease and injury that lead to death.

Gerontology, therefore, can be defined as the science of the finitude of life as expressed in the three aspects of longevity, aging, and death, examined in both evolutionary and individual (ontogenetic) perspective. Longevity is the span of life of an organism. Aging is the sequential or progressive change in an organism that leads to an increased risk of debility, disease, and death; senescence consists of these manifestations of the aging process.

The viability (survival ability) of a population is characterized in two actuarial functions: the survivorship curve (A in Figure 39) and the age-specific death rate, or Gompertz function (B in Figure 39). The relation of such fac-

tors as aging characteristics, constitutional vigour, physical factors, diet, and exposure to disease-causing organisms to the actuarial functions is complex; there is, nevertheless, no substitute for them as measures of the aging process

and of the effect of environmental or genetic modifiers. The age-specific mortality rate is the most informative actuarial function for investigations of the aging process. It was first pointed out by an English actuary, Benjamin Gompertz, in 1825 that the mortality rate increases in geometric progression-i.e., by a constant ratio in successive equal age intervals. Hence, a straight line, known as the Gompertz function, results when death rates are plotted on a logarithmic (ratio) scale. The prevalence of many diseases and disabilities rises in the same geometrical manner as does the mortality rate, important exceptions being some infectious diseases and diseases arising from disturbances of the immunological system. Although the life tables of most species are remarkably similar in form, even closely related species can differ markedly in the relative incidence of the major causes of death. (G.A.Sa.)

BIOLOGICAL THEORIES OF AGING

Aging has many facets. Hence there are a number of theories, each of which many explain one or more aspects of aging; there is, however, no single theory that explains all of the phenomena of aging.

Genetic theories. One theory of aging assumes that the life-span of a cell or organism is genetically determinedthat the genes of an animal contain a "program" that determines its life-span just as eye colour is determined genetically. Although long life is recognized often as a familial characteristic, and short-lived strains of fruit flies, rats, and mice can be produced by selective breeding, other factors clearly can significantly alter the basic genetic program of aging.

Another genetic theory of aging assumes that cell death is the result of "errors" introduced in the formation of key proteins, such as enzymes. Slight differences induced in the transmission of information from the deoxyribonucleic acid (DNA) molecules of the chromosomes through ribonucleic (RNA) molecules (the "messenger" substance) to the proper assembly of the large and complex enzyme molecules could result in a molecule of the enzyme that would not "work" properly. These so-called error theories have not yet been firmly established, but studies are in

As cells grow and divide, a small proportion of them undergo mutation; that is, they become "different" with a change in their chromosome structure that is then reproduced when they again divide. The "somatic mutation" theory of aging assumes that aging is due to the gradual accumulation of mutated cells that do not perform normally.

Non-genetic theories. Other theories of aging focus attention on factors that can influence the expression of a genetically determined "program." One of these is the "wear-and-tear" theory, which assumes that animals and cells, like machines, simply wear out. Animals, however, unlike machines, have some ability to repair themselves, so that this theory does not fit the facts of a biological system. A corollary to the wear-and-tear theory is the presumption that waste products accumulate within cells and interfere with function. The accumulation of highly insoluble particles, known as "age pigments," has been observed in muscle cells in the heart and nerve cells of both human beings and other animals.

With increasing age, tendons, skin, and even blood vessels lose elasticity. This is due to the formation of crosslinks between or within the molecules of collagen (a fibrous protein) that give elasticity to these tissues. The "cross-linking" theory of aging assumes that similar crosslinks form in other biologically important molecules, such as enzymes. These cross-links could alter the structure and shape of the enzyme molecules so that they are unable to carry out their functions in the cell.

Another theory of aging assumes that immune reactions, normally directed against disease-producing organisms as well as foreign proteins or tissue, begin to attack cells of the individual's own body. In other words, the system that produces antibodies loses its ability to distinguish between

Cell errors and muta-

immunity control theories

Actuarial functions

The signif-

patterns in

and live longer.

icance

insects

of aging

"self" and foreign proteins. This "autoimmune" theory of aging is based on clinical rather than on experimental evidence.

These theories all attempt to explain aging in terms of cellular and molecular changes. Actually, age changes are much more marked in the overall performance of an individual than in cellular processes that can be measured. The age decrement in the ability to perform muscular work is much greater than any changes that can be detected in the enzyme activities of the muscles that perform the work. It is possible that aging in an individual is actually due to a breakdown in the control mechanisms that are required in a complex performance. (N.W.S.F.G.)

NATURAL HISTORY OF AGING

Reproduction and aging. Reproduction is an all-important function of an organism's life history, and all other vital processes, including senescence and death, are shaped to serve it. The distinction between semelparous and iteroparous modes of reproduction is important for an understanding of biological aging. Semelparous organisms reproduce by a single reproductive act. Annual and biennial plants are semelparous, as are many insects and a few vertebrates, notably salmon and eels. Iteroparous organisms, on the other hand, reproduce recurrently over a reproductive span that usually covers a major part of the total life-span.

In semelparous forms, reproduction takes place near the end of the life-span, after which there ensues a rapid senescence that quickly leads to the death of the organism. In plants the senescent phase is usually an integral part of the reproductive process and essential for its completion. The dispersal of seeds, for example, is accomplished by processes—including ripening and fall (abscission) of fruits and drying of seed pods—that are inseparable from the overall senescence process. Moreover, the onest of plant senescence is invariably initiated by the changing levels of hormones, which are under systemic or environmental control. If, for example, the hormone axis is prevented, by experimental means, from influencing the plant, the plant lives longer than normal and undergoes an atypical

prolonged pattern of senescent change. Useful inferences can be drawn from the study of the aging processes of insects that display two distinct kinds of adaptive coloration: the procryptic, in which the patterns and colours afford the insect concealment in its native habitat; and the aposematic, in which the vivid markings serve as a warning that the insect is poisonous or bad tasting. The two adaptation patterns have different optimal species survival strategies: the procryptics die out as quickly as possible after completing reproduction, thus reducing the opportunity for predators to learn how to detect them; the aposematics have longer post-reproductive survival, thus increasing their opportunity to condition predators. Both adaptations are found in the family of saturniid moths, and it has been shown that the duration of their post-reproductive survival is governed by an enzyme system that controls the fraction of time spent in flight: procryptics fly more, exhaust themselves, and die quickly; aposematics fly less, conserve their energies.

These examples indicate that in semelparous forms, in which full vigour and function are required until virtually the end of life, senescence has an onset closely coupled with the completion of the reproductive process and is governed by relatively simple enzymatic mechanisms that can be modified by natural selection. Such specific, genetically controlled senescence processes are instances of programmed life termination.

The iteroparous forms include most vertebrates, most of the longer-lived insects, crustaceans and spiders, cephalopod and gastropod mollusks, and perennial plants. In contast to semelparous forms, iteroparous organisms need not survive to the end of their reproductive phase in order to reproduce successfully, and the average fraction of the reproductive span survived varies widely between groups: small rodents and birds in the wild survive on the average only 10 percent to 20 percent of their potential reproductive lifetimes; whales, elephants, apes, and other large ductive lifetimes; whales, elephants, apes, and other large

mammals in the wild, on the other hand, live through 50 percent or more of their reproductive spans, and a few survive beyond reproductive age. In iteroparous forms the onset of senescence is gradual, with no evidence of specific systemic or environmental initiating mechanisms; senescence manifests itself early as a decline in reproductive performance. In species that grow to a fixed body size, decline of reproductive capacity begins quite early and accelerates with increasing age. In large egg-laying reptiles, which attain sexual maturity while relatively small in size and continue to grow during a long reproductive span, the number of eggs laid per year increases with age and body size but eventually levels off and declines. The reproductive span in such cases is shorter than the life-span.

These comparisons illustrate the influence exerted by factors of population dynamics on the evolution of reproductive and bodily (somatic) sensecence. The proportional contribution of an individual to the rate of increase of the iteroparous population obviously diminishes as the number of his living progeny increases. In addition, his reproductive capacity diminishes with age. These facts imply that there is an optimum number of litters per lifetime. Whether or not these influences of population dynamics lead to the evolution of adaptive sensecence patterns has long been debated by gerontologists but has not yet been investigated definitively.

Species differences in longevity and aging. That there are large differences in life-span between some species of animals has long been known, but only recently have the data become adequate for statistical analysis. Maximum life-span provides an estimate of the potential longevity of mammalian and avian species because of the sharp upper limit of the survival curves in life tables. Also, it is superior to the average life-span because the latter is influenced by environmental factors unrelated to aging (e.g., human protection).

Maximum life-span as an indicator of longevity

The taxonomic stratification of longevity can be seen among the mammals. Primates, generally, are the longest lived group, although some small prosimians and New World monkeys have relatively short life-spans. The murid (mouselike) rodents are short-lived; the sciurid (squirrellike) rodents, however, can reach ages two to three times longer than the murids. Three traits have independent correlations with life-span; brain weight, body weight, and resting metabolic rate. The dependence of life-span on these traits can be expressed in the form of an equation: $L = 5.5E^{0.54}S^{-0.34}M^{-0.42}$. Mammalian life-span (L) in months relates to brain weight (E) and body weight (S) in grams and to metabolic rate (M) in calories per gram per hour. The positive exponent for E(0.54) indicates that longevity of mammals has a strong positive association with brain size, independent of body size or metabolic rate. The negative coefficient for metabolic rate implies that life-span decreases as the rate of living increases, if brain and body weight are held constant. The negative partial coefficient for body weight indicates that the tendency for large animals to be longer lived results not from body size but rather from the high positive correlation of body weight with brain weight and its negative correlation with metabolic rate. The same kind of relation of L to E, S, and M holds for birds, but there is a tendency for birds to be longer lived than mammals of comparable brain and body size despite their higher body temperatures and metabolic rates. The larger reptiles have life-spans exceeding those of mammals of comparable size, but their rates of metabolism are about ten times lower, so that their total lifetime energy expenditures are lower than those for mammals. The more highly cephalized animals (i.e., those with higher brain weight), especially the primates, have greater lifetime energy outputs; the total lifetime energy output per gram of tissue is about 1,200,000 calories for man and 400,000 calories for domestic animals such as cats and dogs.

The above relations hold for the homeothermic mammals, those with nearly constant body temperature. The heterothermic mammals, which are able to enter daily torpor, or seasonal hibernation, thereby reduce their metabolic rates more than tenfold. The insectivorous bats of temperate latitudes are the most dramatic example; although they have life-spans in excess of 20 years, almost 80 percent of that time is spent in deep torpor. As a result, their lifetime energy expenditures are no greater than are those of other small mammals.

The longevities of arthropod species extend from a few days to several decades. The extremely short-lived insects have a brief single reproductive phase; the longer lived spiders and crustaceans are iteroparous, with annual reproductive cycles

The inheritance of longevity. The inheritance of longevity in animal populations such as fruit flies and mice is determined by comparing the life tables of numerous inbred populations and some of their hybrids. The longevity of sample populations has been measured for more than 40 inbred strains of mice. Two experiments concur in finding that about 30 percent of longevity variation in female mice is genetically determined, whereas the heritability in male mice is about 20 percent. These values are comparable to the heritabilities of some physiological performances, such as lifetime egg or milk production, in domestic animals.

The slope of the Gompertz function line indicates the rate of actuarial aging. The differences in longevity between species are the result primarily of differences in the rate of aging and are therefore expressed in differences in slope of the Gompertz function. Three species that vary in longevity, such as the opossum (seven years), rabbit (12) years), and cat (20 years), would have Gompertz functions like the three lines in B (see Figure 39), and they would

Rate of

aging

have survival curves like the corresponding curves in 39A.

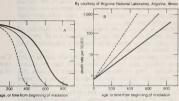

Figure 39: The relation of survivorship curves (A) to age-specific mortality rate curves (B). These curves also exemplify differences in the rate of aging and the accelerated aging due to continued exposure to ionizing radiation.

Comparison of life tables between mouse strains of a single species indicates that the strain differences result primarily from differences in age-independent hardiness factors. If strains differ in hardiness, the less hardy have death rates higher by a constant multiple at all ages, as shown by the parallel Gompertz functions. It is frequently found that the first-generation (F1) hybrids of two inbred strains live longer than either parent. There has been no direct comparison of hybrid and inbred mice with regard to the rates of their biochemical aging processes, but lifetable comparisons indicate that hybrid vigour is an increase of age-independent vigour and not a decrease in the rate of aging.

Recent research indicates that much of the variation in survival time between mouse strains is attributable to differences in inherited susceptibility to specific diseases. An important task of gerontology is to determine the extent of such genetic influences on aging.

The inheritance of longevity in humans is more difficult to investigate because length of life is influenced by socioeconomic and other environmental factors that generate spurious correlations between close relatives. A number of studies have been published, most of them pointing to some degree of heritability with regard to length of life or susceptibility to major diseases, such as cancer and heart disease. Although there is disagreement about the degree of heritability of longevity in man, the evidence for genetic transmission of susceptibility to coronary heart disease and related diseases is strong, as is the evidence that monozygotic (genetically identical) twins tend to have more similar life-spans than do like sex dizygotic (genetically different, fraternal) twins.

SENESCENCE IN PLANTS

The growth of the vascular plant depends upon the activity of meristems, which are, in a sense, always embryonic, Continued indefinitely, this mode of growth could mean immortality; indeed, the longest lived individual organisms ever to have existed on earth have been certain species of trees. Plants and plant parts, however, do die, and death is often not the consequence of accident or environmental stress but of physiological decline-aging, or senescence. Various kinds of physiological senescence and death occur and may affect particular cells, tissues, organs, or the whole plant. In the formation of the vessels of the xylem, cells conclude their differentiation by dying and contribute their empty walls to the conducting tissue. Individual organs such as leaves usually have a limited life-span. Entire shoot systems may gradually die back in the aerial parts of perennial plants, which overwinter underground, And, finally, the whole plant may die after a limited period of growth and the completion of reproduction. This behaviour is found in many annual plants, which complete their life cycle in a single growing season. The life-span may extend to two years, as in biennial plants, or longer, as in banana and certain bamboos, which die after flowering and fruiting.

In the examples cited above, the death of cells, organs, or individual plants appears to be "programmed" and, in some sense, adaptive. This is clearly so with the death of individual cells during differentiation, when residual products contribute to the effective function of the entire plant body. The death of leaves and of shoot systems is part of the plant's adaptation to the cycle of the seasons. In annual species, the death of the whole individual may be viewed in a similar way. The succession of generations in this case is carried on by seeds: the sacrifice of the parent plant may, in fact, contribute to the success of the seedling by making available to the seed a pool of reserves derived from the breakdown of parent tissues.

Certain features characterize the onset of senescence. The cells show degenerative changes often associated with the accumulation of breakdown products. Metabolic changes accompany the degeneration. Respiration may increase for a period, but the rate ultimately declines as the cellular apparatus degenerates. Synthesis of proteins and nucleic acids ceases, and, in some instances, disintegration of cells has been associated with the release of enzymes through the disruption of membrane-bounded bodies called lysosomes.

The death of individual cells in tissues such as the xylem appears to be governed by internal factors, but senescence often depends upon interaction of tissues and organs. The presence of young developing leaves often accelerates the aging of older leaves; removal of the younger leaves retards the senescence of the older ones, suggesting control by competition for nutrients. A similar effect is seen in annual plants, in which the development of fruits and seeds is associated with the senescence and, ultimately, the death of the rest of the plant; the removal of reproductive structures slows the rate of aging. In these instances competition obviously has some effect, but it does not sufficiently explain why older, mature organs suffer in competition with those still in active development. The link may lie partly in the capacity of developing organs to draw nutrients to themselves, even from older parts of the plant. Developing organs thus provide "sinks" toward which nutrients tend to move. The senescence of organs drained in this way could result from the progressive loss of certain key constituents; should leaf protein, for example, turn over by breakdown of proteins to their aminoacid constituents and then be resynthesized, a steady drain of amino acids from the leaf would progressively deplete the proteins in the leaf.

Sinks" can be only part of the explanation, however, for in detached leaves of plants such as tobacco, protein synthesis decreases, and protein content falls, while the amino-acid content actually rises. Senescence in such instances can hardly depend on the withdrawal of nutrients. Furthermore, leaf senescence can be retarded locally by the

grammed death of plant cells

Nutritional "sinks"

application of cytokinins, hormones that stimulate plant cell division. Parallel effects have been demonstrated with growth substances of the auxin type in other plant systems. In the same way that active buds and fruits form sinks for nutrients from elsewhere in the plant, a cytokinin-treated area of a leaf attracts nutrients from other parts of the leaf. Although the metabolism of isolated leaves may differ in many respects from that of attached leaves, leaf senescence probably does not result only from nutrient drainage but also from the synthetic activity of leaf tissues, which may be under hormonal control from other parts of the plant. The root may be important, for roots are known to export cytokinins to the shoot.

Daily length of darkness

Environmental factors, primarily photoperiod (daily length of darkness) and temperature, play important parts in governing senescence and death in plants. In annual plants, death is the natural conclusion of development; thus, conditions accelerating development automatically advance senescence. This is readily seen in short-day plants, in which precocious reproduction upon exposure to long dark periods is followed by early death. Senescence may be retarded in these cases, however, by hormonal treatments of the kind known to delay degeneration and death in detached leaves. Competition for nutrients between vegetative and reproductive structures cannot be the primary cause of death, for, in species such as hemp, the male plants-which do not produce seeds-die earlier than the females under short-day (long-night) conditions.

In perennial plants, leaf fall is associated with approaching winter dormancy. In many trees leaf senescence is brought about by declining day length and falling temperature toward the end of the growing season. Chlorophyll, the green pigment in plants, is lost; yellow and orange pigments called carotenoids become more conspicuous; and, in some species, anthocyanin pigments accumulate. These changes are responsible for the autumn colours of leaves. There are some indications that day length may control leaf senescence in deciduous trees through its effect on hormone metabolism, for both gibberellins and auxins have been shown to retard leaf fall and to preserve the greenness of leaves under the short-day conditions of autumn.

From the foregoing it may be seen that senescence and death are important in the general economy of plants. The paradox that death contributes to survival is resolved when it is understood that the death of the part contributes to the better adaptation of the whole-whether organ, individual, or species. Viewed in this way, death is no more than another-albeit the ultimate-manifestation of development.

(J.H.-H.)

SENESCENCE IN MAMMALS

Changes in body composition, metabolism, and activity. The lean body mass, consisting of the skeletal muscles and all other cellular tissues, decreases steadily after physical maturity until, in extreme old age, it may be reduced to two-thirds its value in young adults. Body weight, however, usually increases with age, because stored fat and body water increases in excess of the loss of lean body mass. The relative amount of extracellular fluid increases with age during adult life, after decreasing steadily throughout fetal and postnatal development. Despite appearances, therefore, all tissues, even the skin, become more laden with water as a consequence of aging. The steady loss of voluntary (striated) muscle tissue mass throughout adult life depends somewhat on the pattern of physical activity. Evidence indicates that a large part of the loss of muscle mass with age is the result of disuse and atrophy rather than loss of muscle fibres.

The decrease of lean body mass is accompanied by a decrease in the level of overall metabolic activity. Basal metabolism is greatest during the period of most rapid mass growth; it then declines rapidly until physical maturity is reached and more slowly thereafter. In the rat the slow phase of decrease amounts to about 20 percent over a three-year period. The interior body temperature is maintained, despite lower heat production, by decreased blood flow through the skin with a consequent decrease of heat loss; the "cooling of the blood" with age, therefore, does not occur in the degree that might be inferred from the decrease in skin temperature. The amount of voluntary physical activity, such as running in an exercise wheel, typically decreases with age but varies considerably between individual animals.

Changes in structural tissues. The structural integrity of the vertebrate organism depends on two kinds of fibrous protein molecules, collagen and elastin. Collagen, which constitutes almost one-third of the body protein, is found in skin, bone, and tendons. When first synthesized by cells called fibroblasts, collagen is in a fragile and soluble form (tropocollagen). In time this soluble collagen changes to a more stable, insoluble form that can persist in tissues for most of an animal's life. The rate of collagen synthesis is high in youth and declines throughout life, so that the ratio of insoluble to soluble collagen increases with age. Insoluble collagen then builds up with age as a result of synthesis exceeding removal, much like another fibrous tissue, the crystalline lens of the eye. With increasing age, the number of cross-linkages within and between collagen molecules increases, leading to crystallinity and rigidity, which are reflected in a general body stiffness. There is also a decrease in the relative amount of a mucopolysaccharide (i.e., the combination of a protein and a carbohydrate) ground substance; a measure of this, the hexosamine-collagen ratio, has been investigated as an index of individual differences in the rate of aging. An important consequence of these changes is decreased permeability of the tissues to dissolved nutrients, hormones, and antibody molecules.

The rate of aging of collagen is related to the overall metabolic activity of the animal; rats kept on low calorie diets have more youthful collagen than fully nourished rats of the same age.

Elastin is the molecule responsible for the elasticity of blood vessel walls. With age, progressive loss of elasticity of vessels occurs, presumably because of fragmentation of the elastin molecule.

The cross-linkage of collagen is chemically similar to the cross-linkages that occur in skins when they are tanned to leather. This similarity has stimulated proposals that chemicals that inhibit cross-linkage in tanning will retard aging. Such compounds have been tried on animals, but

the problems of toxicity have not yet been solved.

Tissue cell loss and replacement. The tissues of the body fall into two groups, according to whether or not there is continuous renewal of tissue cells. At one extreme are nonrenewal tissues such as nerves and voluntary muscles, in which no new cells are formed (at least in mammals) after a certain stage of growth. In renewal tissues such as the intestinal epithelium and the blood, on the other hand. some cell types live only one or a few days and must be replaced hundreds of times in the life-span of even a short-lived animal such as the rat. Between these limits lie many organs, such as liver, skin, and endocrine organs, that have cells that are replaced over periods ranging from a few weeks to several years in man.

A peripheral nerve is a convenient object to study because the total number of fibres in the nerve trunk can be counted. This has been done for the cervical and thoracic spinal nerve roots of the rat, the cat, and man. In the ventral and dorsal spinal roots of man, the number of nerve fibres decreases about 20 percent from age 30 to age 90. In the cat, the rat, and the mouse, however, the data do not consistently indicate a decrease of number of spinal root fibres with age. In man the number of olfactory nerve fibres, which serve the sense of smell, decreases by age 90 to about 25 percent of the number present at birth, and the number of optic nerve fibres, serving vision, decreases at a nearly comparable rate.

There is a striking decrease in the number of living cells in the cerebral cortex of the brain of humans with age. The cerebellar cortex of the rat and man is about as susceptible to age deterioration as is the cerebral cortex. Other parts of the brain are not so obviously marked by aging,

There is, in short, a tendency for the higher and more recently evolved levels of the nervous system to undergo more severe aging loss than do other regions, such as the brain stem and spinal cord. It is not yet known how much Chemical retardation of aging

of the loss of brain cells results from conditions within the brain itself and how much results from extrinsic causes. such as deterioration of the blood circulation. The nutrition and maintenance of nerve cells, or neurons, in the central nervous system depends to a considerable extent on neuroglia, small cells that surround the neurons. The absolute number of these cells apparently does not decrease with age, but some of the microscopic changes seen in the neurons of old persons are similar to the changes produced by starvation or physical exhaustion.

It has been shown that after an attack of measles, the virus remains in the host's body for the remainder of life and infrequently gives rise to a rapidly progressing degeneration of the cerebral cortex. This virus or other inapparent viruses may also be responsible for the individual differences in onset of senility in man.

The renewal tissues are typically made up of a population of proliferative cells, which retain the capability for division, and a population of mature cells, produced by the proliferative cells and with limited life-spans. The production of cells must balance the steady loss and also compensate quickly for unusual losses caused by injury or disease, so each renewal tissue has one or more channels of feedback control to adjust production to demand. Aging of renewal tissues is expressed in several ways, including decrease in the number of proliferative cells, decrease in the rate of cell division, and decrease in responsiveness to feedback signals. Changes of these factors in the bloodforming tissues of the mouse are small, yet the bloodforming tissues do suffer an aging deficit, for the ability to respond to extreme or repeated demand is significantly reduced in older mice.

Senescence

of renewal

tissues

The intact skin has a cell turnover time of several weeks, with the capability, shared by all renewal tissues, of temporarily increasing the rate of cell production by a large factor in response to injury. The rate of wound healing decreases with age, rapidly at first and more slowly as age increases.

One of the most regular and striking aging processes is the decrease in the ability to focus on both close and distant objects. This loss in visual accommodation is the result in part of a weakening of the ciliary muscle of the eye and of a decrease in the flexibility of the lens. A further contributing factor, however, is that the lens continues to grow throughout life at a rate that diminishes with age. This growth is the result of continuous division of epithelial cells near an imaginary midline of the lens, giving rise to fresh cells that differentiate into the precisely aligned lens fibres. Once formed, the fibres remain permanently in place.

An important feature of the renewal mechanism is the stem cell. These cells, which may normally continue to divide at a low rate throughout life, under conditions of increased demand enter a compensatory proliferative phase during which they divide rapidly. Blood-forming tissue has a stem-cell population that responds to injury readily in youth, but its capacity diminishes with age. The increased incidence of anemia in old age and the reduced capacity to respond to blood loss have been attributed to depletion of the blood-forming stem cells. Stem-cell populations have not been identified with certainty in other proliferative tissues. The intestinal mucosa, in particular, has a high cell-division rate without any clear indication of a reserve population of stem cells.

Mammalian cell cultures. Dividing cells from various mammalian tissues can be grown in vitro (outside the body) under careful laboratory control. Various lines of cancer cells have been grown in continuous culture for many decades. In the early period of tissue-culture techhology it was claimed that certain chicken cells (fibrobiasts) had been maintained in culture for 20 years. This led to the belief that dividing cells were potentially immortal and focussed interest on nondividing cells as the seat of the aging process. This view has lost standing in recent years. It has now been established that a population (clone) of fibroblasts has a finite life history in culture. It has a period of healthy growth, during which it can be transferred, or "split," several dozen times, indicating that the cells have undergone more than that number of generations. The cultures, however, go into a senescent phase and die out, usually before the 50th transfer, Occasionally, the chromosomes in a cell in the culture undergo a mutation (change) that results in a loss of a growth-limiting factor, leading to the establishment of a subclone capable of indefinite growth. This happens fairly often in cultures of mouse cell strains but only rarely in cultures of human cells. Such mutations usually involve chromosomal rearrangements or changes in the number of chromosomes.

The present view, therefore, is that dividing mammalian cells with a normal chromosomal complement have a limited growth potential and that the capacity for indefinite growth shown by cancer cells and transformed cells is the result of the loss of a growth-limiting factor. The number of transfers that cell strains can undergo decreases as the age of the donor increases, in a way reminiscent of the decreased turnover rate of fibroblasts in living chickens and of the decreased rate of wound healing with age.

Changes in tissue and cell morphology. There are numerous instances of tissue changes with age. The atrophy of tissues of moderate degree is usual. The shrinkage of the thymus is especially striking and important in view of its role in immunological defense. The diminution of cellular tissue and replacement by fatty or connective tissue is prominent in marrow and skin. In the kidney, entire secretory structures (nephrons) are lost. The secretory cells of the pancreas, thyroid, and similar organs decrease

in numbers. An important age change is the accumulation of pigments and inert-possibly deleterious-materials within and between cells. The pigment lipofuscin accumulates within heart muscle cells; it is not detectable at ten years of age but rises to almost 3 percent of the cell volume by age 90. Amyloid substance, a protein-carbohydrate complex, increases in tissues in middle age; it is presumably a product of autoimmune reactions, immune reactions misdirected against the organism itself. In an extreme case of a rare autoimmune disease, amyloid disease, particular organs are virtually choked with amyloid substance. Trace metals also accumulate in various tissues with age, and although the amounts are very small, certain metals can poison enzyme systems, stimulate mutations, or cause cancer.

AGING AT THE MOLECULAR AND CELLULAR LEVELS

Aging of genetic information systems. The physical basis of aging is either the cumulative loss and disorganization of important large molecules (e.g., proteins and nucleic acids) of the body or the accumulation of abnormal products in cells or tissues. A major effort in aging research has been focussed on two objectives: to characterize the molecular disruptions of aging and to determine if one particular kind is primarily responsible for the observed rate and course of senescence; and to identify the chemical or physical reactions responsible for the agerelated degradation of large molecules that have either informational or structural roles. The working molecules of the body, such as enzymes and contractile proteins, which have short turnover times, are not thought to be sites of primary aging damage. The deoxyribonucleic acid (DNA) molecules of the chromosomes appear to be potential sites of primary damage, because damage to DNA corrupts the genetic message on which the development and function of the organism depend. Damage at a single point in the DNA molecule can be followed by the synthesis of an incorrect protein molecule, which may result in the malfunction or death of the host cell or even of the entire organism. Attention therefore has been given to the somatic mutation hypothesis, which asserts that aging is the result of an accumulation of mutations in the DNA of somatic (body) cells. Aneuploidy, the occurrence of cells with more or less than the correct (euploid) complement of chromosomes, is especially common. The frequency of aneuploid cells in human females increases from 3 percent at age 10 to 13 percent at age 70. Each DNA molecule consists of two complementary strands coiled around each other in a double helix configuration. Evidence indicates that breaks of the individual strands occur with a higher frequency than was once suspected and that virtually all such breaks are repaired by an enzymatic mechanism that

Wasting of tissues with age

damage

destroys the damaged region and then resynthesizes the excised portion, using the corresponding segment of the complementary strand as a model. The mutation rate for a species is therefore governed more by the competence of its repair mechanism than by the rate at which breaks occur. This may help to explain why the mutation rates of different species are roughly proportional to their generation times and justifies research to determine whether the enzymatic mechanisms involved are accessible to control. It remains to be seen whether a reduction of mutation rates will retard the onset of generalized aging or of a

specific disease process. There are, however, serious objections to the somatic mutation theory. The wasp Habrobracon is an insect that reproduces parthenogenetically (i.e., without the need of sperm to fertilize the egg). It is possible to obtain individuals with either a diploid, or paired, set of chromosomes, as in most higher organisms, or a haploid, single, set, Any gene mutation in a haploid cell at an essential position would result in loss of a vital process and impairment or death of the cell; in a diploid cell a serious mutation is often compensated for by the complementary gene and the cell can carry on its vital functions. Experiments have shown that haploid wasps live about as long as diploids, implying either that mutations are not a quantitatively important factor in aging or that parthenogenetic species have compensated for the vulnerability of their haploids by developing an increased effectiveness of DNA repair.

Chromosomes can be separated into DNA and protein molecules, but with increasing difficulty in older cells. The isolated DNA of old animals, however, does not differ from that of the young. Although most of the DNA in a given cell at a given time is repressed (i.e., blocked from functioning), it is more repressed in old animals; it is not yet known whether this is a primary age change or a consequence of reduced cell metabolism arising from

Aging of the immunological system. Another important molecular information system of the body is the immunological system, part of which, the thymus-dependent subsystem, is specialized for defense against invading microorganisms and for the as yet poorly understood role of detecting and removing body cells that have changed in such ways that they are no longer recognized by the body as part of its own substance, leading to the autoimmune reactions mentioned above. The immunological system has been implicated in the body's defenses against cancer. Cancerous growths (neoplasms) are thought to arise from single cells that undergo a drastic transformation as a result of either a genetic mutation or the activation of a latent (hidden) virus that may have been transmitted genetically from parent to offspring. The control of cancer susceptibility by genetically governed defense mechanisms has been indicated by the breeding of high and low cancer susceptibility in mice. There is a growing body of evidence that the thymus-dependent immunological system is instrumental in repressing the development of cancer.

One piece of evidence is that the immunosuppressive procedures of organ transplantation are often followed by a greatly increased incidence of neoplasms. The thymusdependent system can itself, however, give rise to agerelated autoimmune disease, in which the immunological system perceives normal body tissue as foreign and attacks it with antibodies. The initial step in these diseases is considered to be a somatic mutation in a single cell of the immunological system. Such considerations are the basis of several immunological theories of aging, which seek to explain the phenomena of senescence in terms of mutations in the immunological system.

Aging of neural and endocrine systems. The loss of psychological and neurophysiological capacities with age is undoubtedly the result, in large part, of the loss of neurons, but deficiencies in the metabolic processes of the surviving cells are demonstrably involved. The ability of the eye to dark-adapt (i.e., increase its sensitivity at low light levels) decreases with age, but part of that decrease can be restored by breathing pure oxygen. Various mental processes in old people are also found to be improved by breathing oxygen. The establishment of a memory trace

(connections in the brain that are associated with memory) involves the synthesis of protein; any slowed induction of protein synthesis, as from lower oxygen intake, with age could be a factor in the deficits of learning and memory

A general characteristic of aging of the endocrine system is that the cells that once responded vigorously to hormones become less responsive. A normal chemical in cells, cyclic adenosine monophosphate (AMP), is thought to be a transmitter of hormonal information across cell membrane; it may be possible to identify the specific sites in the membrane or the cell interior at which communication breaks down.

INTERNAL AND EXTERNAL CAUSES OF AGING

External environmental agents. Ionizing radiations. The shortening of life caused by ionizing radiations (e.g., X-rays) has been determined for many species, including mice, rats, hamsters, guinea pigs, and dogs. The occurrence of some diseases, such as leukemia, may increase disproportionately after irradiation, with the degree of increase influenced by age and sex.

The permanent nature of radiation damage is shown by the comparison of life-spans of irradiated and control populations. An irradiated population dies out like a chronologically older unirradiated population. Members of a population given a single dose of X-rays or gamma rays in early adult life die of the same diseases that afflict the unirradiated control population, but they die months or even years earlier.

Continuous irradiation throughout life at low dose rates (daily doses from one-thousandth to one-tenth the dose that would kill immediately) speeds the mortality process. It is not yet clear if the molecular damage produced by such irradiation is the same as the molecular changes that accompany natural aging. Studies of animals and of cells grown in culture suggest that large doses of radiation kill by producing deleterious rearrangements of chromosomes in the proliferative cell population. Such aberrations also increase with age, but they seem to be less important in the natural aging process. At low radiation doses, chromosome aberrations become relatively less important than other effects, and the primary radiation damage in these conditions may bear a closer relation to the aging lesion. Under conditions of low-dose irradiation, however, the only definite effect is slightly increased cancer incidence; a generalized aging effect has not yet been observed.

Natural radioactivity in the body, arising mostly from radioactive potassium and radium, and natural background irradiation, from the Earth and from cosmic rays, are not major contributors to the aging process, even in the longlived human species. They are responsible, however, for a small percentage of cancer incidence. Although the dose to the body from medical radiations is a fraction of the background level and the radiation from nuclear weapon test fallout is less than 1 percent of the background, both sources contribute to cancer induction in proportion to their amounts.

Temperature. Flour beetles, fruit flies, fishes, and other poikilothermic (temperature-variable) organisms live longer at the lower range of environmental temperature. These observations led to the rate-of-living hypothesis, which, simply stated, holds that an organism's life-span is dependent on some critical substance that is exhausted more rapidly at higher temperature. Careful analysis of the data on temperature-longevity relations shows, however, that the rate-of-living hypothesis is inadequate in its original form. The most telling evidence comes from experiments in which fruit flies were kept at one temperature for part of their lives and at another temperature for the remainder. The results are not consistent with the rate-ofliving hypothesis, but no satisfactory theory has appeared as yet to take its place. An important factor that has not yet been adequately taken into account is the relation of metabolic efficiency to temperature. The energy cost of the biosynthetic processes studied has been discovered to be minimal at an intermediate temperature in the range to which the species is adapted and to increase at higher or lower temperatures. A related phenomenon holds for

The aging effect of natural radiation

Aging and cancer

longevity; the number of calories expended by fruit flies per lifetime is maximal at an intermediate temperature, so the rate of aging per calorie is minimal at that temperature

There is a question of the degree to which aging occurs as a result of heat destruction (thermal denaturation) of proteins. Thermal denaturation is predominately a disruption of the folding of molecules, which requires the breaking of numbers of low-energy bonds. It seems not to be a strong contributing factor to aging. There is still the possibility that rare events, such as mutations, may arise to a significant degree from thermal denaturation.

Physical wear of nonrenewable structures. One of an animal's most important assets is its chewing apparatus, including jaws and teeth. Adaptation to tooth rate of wear is especially important for animals that consume large quantities of grass and herbage. Such adaptations include higher tooth crowns (hypsodonty), larger grinding area, and longer tooth growth period. Tooth wear may be limiting for survival in adverse environments, but, on the whole, it is not an important life-limiting characteristic. The same can be said for other external organs subject to physical wear.

Infectious disease and nutrition. The populations in poor environments, characterized by high rates of infectious disease and poor nutrition, have higher death rates than populations in good environments at all ages, yet there is no positive evidence that disadvantaged populations experience a higher rate of aging.

Rats kept on diets restricted in calories live longer and have lower cancer incidence than do rats that are allowed to eat at will; maximum longevity, however, is achieved at a nutritional level that keeps the animal sexually immature and below normal weight.

Internal environment: consequences of metabolism. The metabolic activities of organisms produce highly reactive chemicals, including strong oxidizing agents. The internal structure of the cell, however, minimizes the harmful effects of such agents; the critical reactions take place within enclosed structures such as ribosomes, membranes, or mitochondria, and counteractive enzymes such as peroxidases are present in abundance. It is nevertheless likely that low concentrations of these reactive substances can reach vital molecules and contribute to the characteristic rate of aging injury. Experiments in which mice are fed low levels of antioxidants such as butylated hydroxytoluene (BHT) have been encouraging but are still somewhat equivocal.

Membranes are the site of much of the metabolic activity of cells; they provide the barriers that keep incompatible reactions separated. Certain membrane structures, called lysosomes, contain enzymes capable of digesting the cell if released; the stability of cells and organisms is therefore very much bound up with the stability of membranes. A number of drugs, including corticosteroids, salicylates, and antihistamines, act by stabilizing cell membranes against inflammatory stimuli. Some of them are found to prolong life in fruit flies and to prolong survival of cells in vitro. The mode of action of these drugs is connected to substances called prostaglandins, which can alter specific (G.A.Sa.) membrane characteristics.

Human aging

Aging and

integrity

membrane

Aging begins as soon as adulthood is reached and is as much a part of human life as are infancy, childhood, and adolescence. Gerontology (the study of aging) is concerned primarily with the changes that occur between the attainment of maturity and the death of the individual. The goal of research in gerontology is to identify the factors that influence these changes. Application of this knowledge is expected to reduce the disabilities now associated with aging.

Human aging has many aspects, both for the individual and for society, but the primary ones fall into three major categories; namely, biological-physiological, psychologicalbehavioral, and social-economic.

The biological-physiological aspects of aging include both the basic biological factors that underlie aging and the general health status. Since the probability of death increases rapidly with advancing age, it is clear that changes must occur in the individual which make him more and more vulnerable to disease. For example, a young adult may rapidly recover from pneumonia, whereas an elderly

person may die. (See above Biological theories of aging.) Physiologists have found that the performance of many organs such as the heart, kidneys, brain, or lungs shows a gradual decline over the life-span. Part of this decline is due to a loss of cells from these organs, with resultant reduction in the reserve capacities of the individual. Furthermore, the cells remaining in the elderly individual may not perform as well as those in the young. Certain cellular enzymes may be less active, and thus more time may be required to carry out chemical reactions. Ultimately the cell may die.

EFFECT OF AGING OF THE BODY SYSTEMS

Cardiovascular system. Diseases of the heart are the single largest cause of death after age 65. Thus, with increasing age the heart becomes more vulnerable to disease Even in the absence of detectable disease, the heart undergoes deleterious changes with advancing age. Structural changes include a gradual loss of muscle fibres with an infiltration of fat and connective tissue. There is a gradual accumulation of insoluble granular material (lipofuscin, or "age pigment") in cardiac muscle fibres. These granules, composed of protein and lipid (fat), make their first appearance by the age of 20 and increase gradually, so that by the age of 80 they may occupy as much as 5-10 percent of the volume of a muscle fibre.

The heart also shows a gradual reduction in performance with advancing age. The amount of blood pumped by the heart diminishes by about 50 percent between the ages of 20 and 90 years. There are marked individual differences in the effects of age. For example, some 80-year-old individuals may have cardiac function that is as good as that of the average 40-year-old individual.

Under resting conditions, the heart rate does not change significantly with age. During each beat, however, the muscle fibres of the heart do not contract as rapidly in the old as in the young. This reduction in power, or rate of work, is due to the age-associated reduction in the activities of certain cellular enzymes that produce the energy required for muscular contraction.

In spite of these changes, the heart, in the absence of disease, is able to meet the demands placed upon it. In response to physical exercise it can increase its rate to double or triple the amount of blood pumped each minute, although the maximum possible output falls, and the reserve capacity of the heart diminishes with age.

Arteriosclerosis, or hardening of the arteries, increases markedly in incidence with age, and is often regarded as part of aging. This is not necessarily true. Arteriosclerosis may appear even in adolescents. It is a progressive disorder and is present to some extent in practically all individuals by middle life. It is, therefore, impossible to make a clear distinction between the effects of aging and the effects of disease in blood vessels in human beings. In some animal species, as, for example, the rat, that do not develop arteriosclerosis, age changes in the heart and blood vessels can be identified

In general, blood vessels become less elastic with advancing age. There is a progressive thickening of the walls of larger blood vessels with an increase in connective tissue. The connective tissue itself becomes stiffer with increasing age. This occurs because of the formation of crosslinks both within the molecules of collagen, a primary constituent of connective tissue, and between adjacent collagen fibres. These changes in blood vessels occur even in the absence of the deposits on the arterial wall characteristic of atherosclerosis, which interfere with blood flow through the arteries. The gradual loss of elasticity increases with resistance to the flow of blood so that blood pressure may increase. This in turn increases the work that the heart must do in order to maintain the flow of blood

While both systolic and diastolic blood pressures (blood pressures at contraction and dilation of the heart, respectively) increase with age, the rate of systolic increase exceeds that of diastolic so that the pulse pressure widens (see Table 5). The increase in pressure stops in the eighth

disease

Blood vessels and blood pressure

Table 5: Mean Blood Pressure in Adults by Age and Sex, 1960-62

(millimetres	of	mercury)
--------------	----	----------

age (years)	n	nen	women	
	systolic	diastolic	systolic	diastolic
18-24	121.7	71.6	111.8	69,4
25-34	124.7	76.4	115.6	72.9
35-44	128.6	80.7	122.8	78.0
45-54	133.8	83.2	133.8	82.0
55-64	140.3	83.1	146.6	84.9
65-74	148.0	81.0	160.2	83.7
75-79	154.3	79.4	156.6	79.3

decade of life, and there may even be a slight decline in pressure in extreme old age.

On the average, obese people have higher blood pressures than those with normal body weights. Since the incidence of obesity increases with age at least up to the age of 55-60, this factor may contribute in part to the increase in blood pressure with age.

Digestive system. Loss of teeth, which is often seen in elderly people, is more apt to be the result of long-term neglect than a result of aging itself. The loss of teeth and incidence of oral disease increase with age, but, as programs of water fluoridation are expanded and the incidence of tooth decay in children is reduced, subsequent generations of the elderly will undoubtedly have better teeth than the present generation.

While it is true that the secretion by the stomach of hydrochloric acid, as well as other digestive enzymes, decreases with age, the overall process of digestion is not significantly impaired in the elderly. Sugar, proteins, vitamins, and minerals are absorbed from the stomach and intestine as well in the elderly as in the young. Some investigations indicate a slight impairment in fat absorption, but the reduction is probably of little practical significance.

These findings have important implications for nutrition of the elderly. There is no evidence that the intake of any nutrient, such as vitamins and minerals, need be increased in the elderly because of impaired absorption. Nutritional deficiencies can be avoided as long as the diet is varied to assure adequate intake of all nutritional elements. Deficiencies are most likely to develop from poor eating habits. such as excessive intake of carbohydrate with a reduction in protein. In the elderly these deficiencies are most apt to be in the intake of protein, calcium, iron, vitamin A, and thiamine (also called vitamin B₁).

Nervous system. Changes in the structures of the brain due to normal aging are not striking. It is true that with advancing age there is a slight loss of neurons (nerve cells) in the brain. This is because, in the adult, neurons have lost the capacity to form new neurons by division. The basic number of neurons in the brain appears to be fixed by about the age of 10. The total number of neurons is extremely large, however, so that any losses probably have only a minor effect on behaviour. Since the physiological basis of memory is still unknown, it cannot be assumed that the loss of memory observed in elderly people is caused by the loss of neurons in the brain.

Neurons are extremely sensitive to oxygen deficiency. Consequently, it is probable that neuron loss, as well as other abnormalities observed in aging brains, results not from aging itself, but from disease, such as arteriosclerosis, that reduces the oxygen available to areas of the brain by reducing the blood supply.

There are probably functional changes in the brain that account for the slowing of responses and for the memory defects that are often seen in the elderly; and even small changes in the connections between cells of the brain could serve as the basis for marked behavioral changes, but, until more is known about how the brain works, behavioral changes cannot be related to physiological or structural changes. It is known that, because of the slow course of aging, the nervous system can compensate and maintain adequate function even in centenarians.

Human behaviour is highly dependent on the reception

and integration of information derived from sensory organs, such as the eye and ear, as well as from nerve endings in skin, muscle, joints, and internal organs. There is, however, no direct relation between the sensitivity of receptors and the adequacy of behaviour, because the usual level of stimulation is considerably greater than the minimum required for stimulation of the sense organs. In addition, an individual adapts to gradual impairments in one sensory organ by using information available from other sense organs. Modern technology has also provided glasses and hearing aids to compensate for reduced acuity in the sense organs.

The incidence of gross sensory impairments, of which many are the result of disease processes, increases with age. One survey conducted in the United States classified 25.9 per 1,000 persons aged 65-74 as blind, in contrast to 1.3 per 1.000 aged 20-44 years. In the age group 65-74, 54.7 per 1,000 persons were classified as functionally deaf, compared with 5.0 per 1,000 in the age range 25-34 years.

Vision. Visual acuity (ability to discriminate fine detail) is relatively poor in young children and improves up to young adulthood. From about the middle 20s to the 50s there is a slight decline in visual acuity, and there is a somewhat accelerated decline thereafter. This decline is readily compensated for by the use of eyeglasses. There is also reduction in the size of the pupil with age. Consequently, vision in older people can be significantly improved by an increase in the level of illumination.

Aging also brings about a reduction in the ability to change the focus of the eye for viewing near and far objects (presbyopia), so that distant objects can ordinarily be seen more clearly than those close at hand. This change in vision is related to a gradual increase in rigidity of the lens of the eye that takes place primarily between the ages of 10 and 55 years. After age 55 there is little further change. Many people in their 50s adopt bifocal glasses to compensate for this physiological change.

The sensitivity of the eye under conditions of low illumination is less in the old than in the young; that is, "night vision" is reduced. Sensitivity to glare is also greater in the old than in the young.

The incidence of diseases of the eye, such as glaucoma and cataracts (characterized, respectively, by increased intra-ocular pressure and opaque lenses), increases with age, but recent advances in surgery and the development of contact lenses have made it possible to remove cataracts and restore vision to many individuals.

Hearing. Hearing does not change much with age for tones of frequencies usually encountered in daily life. Above the age of 50, however, there is a gradual reduction in the ability to perceive tones at higher frequencies. Few persons over the age of 65 can hear tones with a frequency of 10,000 cycles per second. This loss of perception of high frequencies interferes with identifying individuals by their voices and with understanding conversation in a group, but does not ordinarily represent a serious limitation to the individual in daily life. Listening habits and intellectual level play an important role in determining the ability to understand speech, so that there is often a disparity between measurements of pure tone thresholds and ability to perceive speech.

Other sensory impairment. After the age of 70 other sense organs may show a reduction in sensitivity. Reduced taste sensitivity is associated with atrophy and loss of taste buds from the tongue in the elderly. The effect of aging on the sense of smell has not been precisely determined because this sense is extremely difficult to assess quantitatively; in addition, smoking and exposure to occupational odours and noxious substances in the air influence sensitivity to smells.

Sensitivity to pain is difficult to evaluate quantitatively under controlled laboratory conditions. There is some evidence that it diminishes slightly after the age of 70

There is a general slowing of responses in the elderly. Reflexes become slightly more sluggish and the speed of conduction of impulses in nerves is slightly slowed. Old people require more time to respond to the appearance of a light than do young. The slowing with age is greater in situations where a decision must be made. For example,

Loss of perception of high quencies

Changes in the brain

more time is required to initiate a response in experiments in which the instructions are "Press the button with your right hand when the green light comes on, but with your left hand when the red light comes on" than if the instructions are, "Push the button if either light comes on." From these and other experiments it is concluded that the primary site of slowing of responses is within the brain rather than in the end organ (eve) itself.

Skin. The primary age change in the skin is a gradual loss of elasticity. Although this basic change plays a role, other factors, such as exposure to the weather and familial traits, also contribute to the development of wrinkles and the pigmentation associated with senescence. The ability of the skin to take up slack and remain closely adherent to the underlying structures is due to the presence of fibres of the proteins elastin and collagen. Studies of the minute structures of the skin show a gradual reduction in elastin. In addition, the collagen fibres show an increase in crosslinks, which greatly restricts the elastic properties of the collagen network.

The effectiveness of facial massage in retarding the development of wrinkles has not been evaluated under carefully controlled conditions. The application of creams containing female sex hormone stimulates regeneration of skin and improves its elastic properties. Other effects, which may be undesirable or even hazardous, may follow repeated administration of these hormones.

Endocrine system. Because of the importance of hormones in the regulation of many physiological systems, impairments in endocrine (ductless) glands have traditionally been cited as important determinants in aging.

Thyroxine, the hormone secreted by the thyroid gland, regulates the level of activity of all the cells of the body. When thyroxine secretion is reduced, all metabolic processes proceed at a reduced rate and basal metabolism falls. (Metabolism consists of the chemical changes taking place within the cells of an organism during the processes of growth and restoration of tissues and the production of energy necessary for bodily processes; basal metabolism is the metabolism, as measured by the rate at which heat is given off, when an organism is in a resting and fasting state.) Since basal metabolism decreases with age, it seemed reasonable to ascribe aging to a loss of thyroid function, but this assumption has proved to be incorrect. Experimental studies have shown that the ability of the thyroid gland to produce thyroxine is not reduced in the elderly, and that there is a reduction in the utilization of thyroxine in various tissues of the body. Further studies of cellular metabolism are needed to find out why this is so.

Since aging is associated with reduced ability to adjust to stresses, and since the adrenal cortex (the outer part of the adrenal gland) plays a role in many of these adjustments. numerous attempts have been made to assess senescent changes in the function of the adrenal cortex. Although after the age of 50 there is a reduction in blood levels of the hormones secreted by the adrenal cortex, the ability of the gland to produce hormones when stimulated by the experimental administration of adrenocorticotrophic hormone (ACTH), the pituitary hormone that regulates the activity of the adrenal cortex, has been shown to be as good in the old as in the young.

The pituitary gland is often referred to as the master gland of the body, since it produces hormones that stimulate the activities of other endocrine glands, such as the

adrenal, the thyroid, and the ovary. It was therefore once assumed that reduction in the function of these glands associated with aging is due to lack of proper stimulation from the pituitary gland. Methods for determination of the very small amounts of these regulating hormones present in the blood have been developed and as yet no systematic studies of age differences in blood levels of these hormones

have been reported.

The pancreas secretes insulin, the hormone that regulates the utilization of sugar and other nutrients in the body. When the pancreas fails to produce adequate amounts of insulin, diabetes occurs. One test for diabetes involves measuring the rate of removal of sugar from the blood, that is, the glucose-tolerance test. One characteristic of aging is a reduction in the rate of removal of excess sugar

from the blood. At present it is not known whether this represents the early stages of diabetes or whether it is a normal age change. It does appear in aged individuals who do not show any of the other symptoms of diabetes. Furthermore, it has been shown that, unlike the diabetic. elderly subjects can, with additional stimulation, produce more insulin. In normal young persons the pancreas releases more insulin in response to even a slight rise in blood sugar levels. In the elderly, the sensitivity of the pancreas is reduced so that a higher level of blood sugar is required to stimulate it to action. With maximum stimulation the pancreas in the aged can produce as much insulin as the pancreas in the young.

It has long been known that the excretion of both male and female sex hormones diminishes with age. In the activity female, the excretion of estrogens (female sex hormones) falls markedly at the menopause (see REPRODUCTION AND REPRODUCTIVE SYSTEMS: The human reproductive system: The female reproductive system: Menopause). In the male, the excretion of androgens (male sex hormones and their degradation products) falls gradually over the age span 50-90, so that the existence of a male "climacteric" is highly improbable

Sexual activity, as reported in interview studies, diminishes progressively between the ages of 20 and 60 in both males and females. In males the frequency of marital intercourse falls from an average of four per week in 20year-olds to one per week in 60-year-olds. Practically all males aged 20-45 reported some level of sexual activity. Between the ages of 45 and 60 only about 5 percent of males reported loss of sexual activity.

Few systematic studies have been made of sexual behaviour in individuals over the age of 60, but clinical reports indicate that at least some males remain sexually active at 90.

There are wide individual differences in the level of sexual activity in both males and females. In human beings, sexual behaviour is influenced more by psychological and social factors than by the levels of sex hormones circulating in the blood. Nevertheless, the use of male sex hormones has had a long, and stormy, history as a rejuvenating agent for males. Attempts to rejuvenate elderly males by injecting crude extracts from testicles of animals, as well as various androgenic compounds, were made, but the effects, if any, were only transitory. In the early 1900s, sex glands from other animals were transplanted into human beings, but the results were questionable and the side effects were often disastrous. At about the same time, an operation was devised in which the spermatic ducts were tied off. It was assumed that preventing the loss of sperm would stimulate the sex glands to produce androgenic hormones which would rejuvenate the individual. None of these assumptions proved correct, so that the operation was soon abandoned as a rejuvenating procedure.

Since tissue loss does occur with aging, the administration of anabolic hormones (hormones that promote the buildup of tissues) may represent an important future development. The compounds that are currently available have a number of undesirable side effects and cannot be used routinely. Chemists and pharmacologists continue research to produce new steroids that will have anabolic effects without the undesirable side effects.

Skeletal system. With aging, the bones gradually lose Calcium calcium. As a result they become more fragile and are more likely to break, even with minor falls. Healing of fractures is also slower in the old than in the young. Recent advances in orthopedic surgery, with the replacement of parts of a broken bone or joint with new structures or the introduction of metallic pegs to hold broken parts together, have been of great value to elderly people

The incidence of osteoporosis, a disease characterized by a loss of calcium and minerals from bone, also increases with age. It occurs more frequently in women after menopause than in men and is especially evident in the spinal column. Back pain is a primary symptom of the disease. It can be treated by increasing calcium intake in

association with the administration of anabolic hormones. The mobility of joints diminishes with age and the incidence of arthritis increases.

Sexual

Hormones of pituitary and of pancreas

Thyroid

adrenal

hormones

and

Respiratory system. Vital capacity, or the total amount of air that can be expelled from the lung after a maximum inspiration, diminishes with age, as does the total volume of air that can be contained in the lungs. In contrast, the amount of air that cannot be expelled from the lung increases. These changes in respiratory mechanisms are primarily a reflection of the increased stiftness of the bony cage of the chest and decreased strength of the muscles that move the chest during respiration.

The lung also contains elastin and collagen to give it elastic properties. As indicated previously, the formation of cross-links in elastin and collagen that takes place with aging reduces the elastic properties of the lung.

The transfer of oxygen and carbon dioxide from the air in the lungs to the blood is influenced by the amount of blood flowing through the lungs as well as by the amount of air moved in and out. The characteristics of the membranes that separate blood and air in the lungs are also important in maintaining an adequate supply of oxygen to the body. Although with age there is a slight reduction in the amount of oxygen that can be moved from the air to the blood in the lungs, the reduction becomes apparent only when large amounts of oxygen tat can be moved from the air to the blood in the lungs, the reduction becomes apparent only when large amounts of oxygen transfer in the lungs of elderly subjects is the lack of appropriate adjustment of the blood flow to the air sacs in the lungs cel delify subjects is the sacs in the lungs.

Incidence of emphysema Emphysema, abnormal distension of the lungs with air, is a lung disease reaching its highest incidence between the ages of 45 and 65. In the United States the death rate from emphysema increased by almost 400 percent between 1950 and 1960. Although the exact causes of the disease are still unknown, the presence of noxious or toxic agents in the air may be a contributing factor. Many studies have shown a relationship between the incidence of emphysema and bronchtits (inflammation of the bronchi) and smoking. Among British physicians detail rates from bronchits were six times higher in those smoking 25 cigarettes a day than in nonsmokers.

Effects of

cigarettes a day than in nonsmokers. Measurements of lung function are significantly lower in cigarette smokers than in nonsmokers of the same age. Values for cigarette smokers are, on the average, about equal to those of nonsmokers who are 10–15 years older. There is evidence, however, that when cigarette smokers quit smoking, measurements of pulmonary function closely approach those of nonsmokers within one to two years, even in the case of heavy smokers 50–60 years old.

Kidney. The kidney removes wastes from the body by separating them from the blood and forming urine. In this process many substances are accumulated in the urine at a higher concentration than in the blood. With advancing age the concentrating ability of the kidney falls, so that a greater volume of water is required to excrete the same amount of waste material. This loss in concentrating ability is probably partially offset by a decrease in the excretory load because of reduced activity, alterations in food intake, and the reduction in muscle mass of the elderly. These changes in kidney function may not be reflected in urine volume, since volumes fluctuate widely at all ages and are determined primarily by fluid intake.

The reduction in renal (kidney) function is due in part to a gradual reduction in blood flow the kidney. Since the kidney receives a great excess of blood (about 25 percent of the blood pumped by the heart each minute), the reduction with age does not normally result in an accumulation of waste products in the blood. Any such accumulation is the result of disease that damages the kidney. The reduced concentrating ability of the kidney results from a loss of some of the nephrons, the functional elements of the kidney, and the reduced activity of cellular enzymes.

Regulatory mechanisms. Some physiological characteristics, such as the mechanisms that regulate the acidity of the blood or its sugar level, are adequate to maintain normal levels under resting conditions even in very old people; however, the aged require more time than the young to reestablish normal levels when changes from the normal occur.

In order to test the effectiveness of control mechanisms of the body, physiologists produce changes experimentally and determine the rate of recovery. When the acidity of the blood is increased to the same extent in old and young subjects, it is returned to normal within 6-8 hours in the young; in the elderly 18-24 hours are required.

Similarly, the rate of return to fasting levels after sugar has been administered intravenously or orally is slower in the old than in the young. The response to insulin, which accelerates the removal of sugar from the blood, is also diminished in the elderly.

The body's physiological mechanisms for adjusting to changes in environmental temperature are less adequate in the old than in the young. Consequently older people may prefer more uniform and slightly higher temperatures than the young. High temperatures are also more hazardous to the elderly. The incidence of heat prostration in hot weather increases with ase.

Exercise is one of the physiological stresses of daily living. In reasonable amounts it is a valuable stimulus to maintain physiological vigour. A number of studies have indicated a lower incidence of cardiovascular disease among adults who indulge in physical activity than in those who do not. The capacity to perform muscular work diminishes progressively in the elderly. Muscle strength diminishes, however, the reduction in strength is less in muscles that continue to be used throughout adult life than in those that are not. Thus a part of the reduction in muscle strength may be an attorboy of disuse.

Maximum work capacity is reduced in the elderly, largely because of the inability to deliver enough oxygen to the working muscles. In the young, the need for oxygen is met for the most part by increasing the heart rate. Under conditions of maximum work, young adults can increase their heart rate to over 200 beats per minute; the elderly to only about 150 per minute. In addition, the transfer of oxygen from the lungs to the blood is reduced in the elderly under conditions of strenuous exercise.

With less than maximum exercise, there is a greater increase in blood pressure, heart rate, and respiration in the old than in the young; that is, a given work load induces a greater physiological stress in the old than in the young. Furthermore, recovery of blood pressure, heart rate, and respiration to resting values takes longer in the old.

Premature aging. Progeria is an extremely rare disease of early childhood characterized by many of the superficial aspects of aging, such as baldness, thinning of the skin, prominence of blood vessels of the scalp, and vascular disease. These children have the general appearance of "little old men." They rarely live beyond the age of 15–18. Death is usually caused by cardiovascular disease.

The disease is extremely rare. In fact, only about 50 cases have been identified for study. In spite of the appearance of premature aging, these patients fail to show an acceleration of other age changes, except for the early development of cardiovascular disease. Most tests of physiological and psychological functions give values which are normal for their chronological age. It is doubtful whether the child with progeria is suffering only from accelerated aging; rather, progeria should be regarded as a rare disease with a superficial resemblance to senescence.

PSYCHOLOGICAL ASPECTS OF AGING

The most outstanding psychological features of aging are the impairment in short-term memory and the lengthening of response time. Both of these factors contribute to lower scores of the elderly on standard tests of "intelligence." When the aged are given all the time that they wish on tests that are not heavily dependent on school skills, their performance is only slightly poorer than that of young adults. Age decrements are negligible on tests that depend on vocabulary, general information, and well-practiced activities.

Experimental studies on learning show that, although the elderly learn more slowly than the young, they can acquire new material and can remember it as well as the young. Age differences in learning increase with the difficulty of the material to be learned.

Aged people tend to become more cautious and rigid in their behaviour and to withdraw from social contacts. These behaviour patterns may be the result of social Exercise and work

Intellectual functions in the aged

institutions and expectancies rather than an intrinsic phenomenon of aging. Many persons who "age successfully" make conscious efforts to maintain mental alertness by continued learning and by expansion of social contacts with individuals in a younger age group.

RIRI IOCDADUS

Growth. General texts include SCOTT F. GILBERT, Developmental Biology, 4th ed. (1994), an attempt to integrate the new advances in molecular biology with cellular and organismal processes: KEITH ROBERTS et al. (eds.), Molecular and Cellular Basis of Pattern Formation (1991); J.D. MURRAY, Mathematical Biology, 2nd, corrected ed. (1993); N.K. WESSELLS and JANET L. HOPSON, Biology (1988); and LEON WEISS (ed.), Histology. Cell and Tissue Biology, 5th ed. (1983). D'ARCY WENTWORTH THOMPSON, On Growth and Form, 2nd ed. (1942, reissued 1992), also available in an abridged ed. edited by JOHN TYLER BONNER (1961, reissued 1992), is the classic mathematical treatment of the dynamics of growth. PETER L. ANTONELLI (ed.), Mathematical Essays on Growth and the Emergence of Form (1985), is a collection of articles. Other useful texts include a HABENICHT (ed.), Growth Factors, Differentiation Factors, and Cytokines (1990); MICHAEL B. SPORN and ANITA B. ROBERTS (eds.), Peptide Growth Factors and Their Receptors. 2 vol. (1990); and MICHAEL J. REISS, The Allometry of Growth and Reproduction (1989).

Specific treatments of plant growth are JAMES D. MAUSETH. Botany: An Introduction to Plant Biology, 2nd ed. (1995); ARTHUR W. GALSTON, PETER J. DAVIES, and RUTH L. SATTER, The Life of the Green Plant. 3rd ed. (1980): KINGSLEY R. STERN Introductory Plant Biology, 5th ed. (1991); and J.E. DALE and F.L. MILTHORPE (eds.), The Growth and Functioning of Leaves (1983). DENNIS R. CAMPION, GARY J. HAUSMAN, and ROY J. MARTIN (eds.), Animal Growth Regulation (1989), for advanced readers, explores growth regulation primarily in domesticated

animals

Malformations in the plant world are the topic of GEORGE N. AGRIOS, Plant Pathology, 3rd ed. (1988), a college-level text that presents the effect of pathogens on host growth and functioning in chapters 3-5; R. HEITEFUSS and P.H. WILLIAMS (eds.), Physiological Plant Pathology (1976); P.G. AYRES (ed.), Effects of Disease on the Physiology of the Growing Plant (1981), a compilation of seminar papers; WILLIAM F. BENNETT (ed.), Nutrient Deficiencies & Toxicities in Crop Plants (1993); and R.D. DURBIN (ed.), Toxins in Plant Disease (1981).

Animal malformations including human malformations are discussed in Birth Defects Original Article Series (monthly), authoritative articles on congenital malformations and abnormalities; MARY LOUISE BUYSE (ed.), Birth Defects Encyclopedia (1990); Congenital Malformations Worldwide: A Report from the International Clearinghouse for Birth Defects Monitoring Systems (1991); and ADAM S. WILKINS, Genetic Analysis of An-

imal Development, 2nd ed. (1993).

Biological regeneration is explored by CHARLES E. DINSMORE (ed.), A History of Regeneration Research: Milestones in the Evolution of a Science (1991); JOHN F. FALLON et al. (eds.), Limb Development and Regeneration, 2 vol. (1993); FREDERICK J. SEIL (ed.), Neural Regeneration (1994), highly technical symposium papers; JOHN G. NICHOLLS, The Search for Connections. Studies of Regeneration in the Nervous System of the Leech (1987), a short, highly readable monograph; HARRY J. BUNCKE (ed.), Microsurgery: Transplantation—Replantation: An Atlas-Text (1991); GERALD WEISSMANN (ed.), The Cell Biology of Inflammation (1980); DAVID EVERED and JULIE WHELAN (eds.), Fibrosis (1985), symposium papers; ROBERT P. MECHAM (ed.), Regulation of Matrix Accumulation (1986); ELIZABETH D. HAY (ed.), Cell Biology of Extracellular Matrix, 2nd ed. (1991); and ERKKI RUOSLAHTI and EVA ENGVALL (eds.), Extracellular Matrix Components (1994).

General features of biological development. A classic work that laid the foundation for the modern interpretation of development in terms of gene activities is THOMAS H. MORGAN, Embryology and Genetics (1934, reprinted 1975). Overviews of biological development include JONATHAN BARD, Morphogenesis: The Cellular and Molecular Processes of Developmental Anatomy (1990); LEON W. BROWDER (ed.), The Cellular Basis of Morphogenesis (1986), a comprehensive synthesis of developmental biology drawing upon knowledge from molecular biology, anatomy, and genetics; MERTON BERNFIELD (ed.), Molecular Basis of Morphogenesis (1993); V.E.A. RUSSO et al., Development: The Molecular Genetic Approach (1992); and JAMES D. WATSON et al., Molecular Biology of the Gene, 4th ed., 2 vol. (1987), for advanced undergraduate and graduate students. MONTGOMERY SLATKIN (ed.), Exploring Evolutionary Biology: Readings from American Scientist (1995), collects 31 essays and articles.

Studies of more specialized topics include RICHARD R. RIB-CHESTER, Molecule, Nerve, and Embryo (1986), a college text;

MARIT NILSEN-HAMILTON (ed.), Growth Factors and Signal Transduction in Development (1994), describing the interactions of growth factors and their receptors and the subsequent signal transduction pathways they activate in directing developmental processes; MICHAEL T. ZAVY and RODNEY D. GEISERT (eds.), Embryonic Mortality in Domestic Species (1994); and P.A. HAUSEN and METTA RIEBESELL, The Early Development of Xenopus laevis: An Atlas of the Histology (1991), on the key model (frogs) for developmental and embryological studies in vertebrates.

Plant development. JIRT SEBANEK (ed.), Plant Physiology, trans. from Czech (1992), covers plant growth, development, and the resistance of plants to unfavourable abiotic and biotic effects. LINCOLN TAIZ and EDUARDO ZEIGER, Plant Physiology (1991), includes treatment of plant developmental processes; as does P.F. WAREING and I.D.J. PHILLIPS, Growth and Differentiation in Plants, 3rd ed. (1981). KALLIOPI A. ROUBELAKIS-ANGELAKIS and KIEM TRAN THANH VAN (THANH VAN KIEM TRAN) (eds.), Morphogenesis in Plants: Molecular Approaches (1993), presents advances in molecular and cellular biology pertaining to plant morphogenesis with particular reference to alternative approaches in solving difficulties of plant morphogenic expression. JIŘÍ ŠEBÁNEK, ZDENĚK SLADKÝ, and STANISLAV PRO-CHÁZKA (eds.), Experimental Morphogenesis and Integration of Plants (1991; originally published in Czech, 1983), addresses morphogenesis and structural integration in plants including possible ways of regulating these processes with regard to the practical needs of agriculture, horticulture, and silviculture

Specific topics are treated in ROGER V. JEAN, Mathematical Approach to Pattern and Form in Plant Growth (1984; originally published in French, 1983); CLIVE W. LLOYD (ed.). The Cytoskeleton in Plant Growth and Development (1982); F.A.L. CLOWES, Morphogenesis of the Shoot Apex (1972); THOMAS A. HILL, Endogenous Plant Growth Substances, 2nd ed. (1980). a historical look at the discovery and significance of plant hormones; L.w. ROBERTS, P.B. GAHAN, and R. ALONI, Vascular Differentiation and Plant Growth Regulators (1988); THOMAS C. MOORE, Biochemistry and Physiology of Plant Hormones, 2nd ed. (1989); RICHARD N. ARTECA, Plant Growth Substances: Principles and Applications (1996); KARL J. NIKLAS, Plant Allometry: The Scaling of Form and Process (1994), the application of allometry to the studies of evolution, morphology, physiology, and reproduction of plants; ONKAR D. DHINGRA and JAMES B. SINCLAIR, Basic Plant Pathology Methods, 2nd ed. (1995), with more than 1,800 literature citations that can serve as research sources; B.M. JOHRI (ed.), Embryology of Angiosperms (1984): V. RAGHAVAN, Embryogenesis in Angiosperms: A Developmental and Experimental Study (1986); L.T. EVANS, Daylength and the Flowering of Plants (1975); RICHARD E. KENDRICK and BARRY FRANKLAND, Phytochrome and Plant Growth, 2nd ed. (1983); AUGUST DE HARTOGH and MARCEL LE NARD (eds.), The Physiology of Flower Bulbs (1993); and J. DEREK BEWLEY and MICHAEL BLACK, Seeds: Physiology of Development and Germination. 2nd ed. (1994), covering in chronological sequence the most important events in seed development and the maturation, germination, and postgermination stages of seedling establishment.

Animal development. General textbooks covering the subject include J. BRACHET and H. ALEXANDRE, Introduction to Molecular Embryology, 2nd totally rev. and enlarged ed. (1986); and GERALD M. EDELMAN, Topobiology: An Introduction to Molecular Embryology (1988). A history of the study of animal development is contained in the work by Gilbert, cited above. HANS SPEMANN, Embryonic Development and Induction (1938, reprinted 1988; originally published in German, 1936), is a classic exposition of the experimental method in embryology. Additional useful works are ROBERT WALL, This Side Up: Spatial Determination in the Early Development of Animals (1990); D.R. JOHNSON, The Genetics of the Skeleton: Animal Models of Skeletal Development (1986); JOHN PHILLIP TRINKAUS, Cells into Organs: The Forces That Shape the Embryo, 2nd ed. (1984); ELIZABETH S. WATTS (ed.), Nonhuman Primate Models for Human Growth and Development (1985); MATTHEW H. KAUFMAN, The Atlas of Mouse Development (1992); CLAUDIO D. STERN and PHIL W. INGHAM (eds.), Gastrulation (1992); BRIAN K. HALL, The Neural Crest (1988); BRIGID HOGAN et al. Manipulating the Mouse Embryo: A Laboratory Manual, 2nd ed. (1994); and the work by Wilkins, cited above.

Human growth and development. Overviews of the topic are provided by MANUEL HERNÁNDEZ (M. HERNÁNDEZ RODRÍGUEZ) and JESÚS ARGENTE (eds.), Human Growth: Basic and Clinical Aspects (1992), conference proceedings; FRANK FALKNER and J.M. TANNER (eds.), Human Growth, 3 vol. (1978-79), with vol. 1 and 3 in a 2nd ed. (1986); BARRY BOGIN, Patterns of Human Growth (1988), a sophisticated discourse for advanced students and researchers in bioanthropology; and ESMAIL MEISAMI and PAOLA S. TIMIRAS (eds.), Handbook of Human Growth and Developmental Biology, 3 vol. in 7 (1988-90).

Explorations of human embryology include STEPHEN G.

GILBERT, Pictorial Human Embryology (1989), an atlas for the health professional and the general reader; KEITH L. MOORE and T.V.N. PERSAUD, The Developing Human: Clinically Oriented Embryology, 5th ed. (1993); JAN LANGMAN, Langman's Medical Embryology. 7th ed. by T.W. SADLER (1995), a concise presentation: and JAN S. ZAGON and THEODORE A. SLOTKIN (eds.), Maternal Substance Abuse and the Developing Nervous System (1992)

On human anatomy, ELAINE N. MARIEB, Human Anatomy and Physiology, 3rd ed. (1995); and ALEXANDER P. SPENCE, Basic Human Anatomy, 3rd ed. (1990), are widely used introductory texts for undergraduate students. Various aspects of human anatomy are covered in KEITH L. MOORE and ANNE M.R. AGUR, Essential Clinical Anatomy (1995); FRANK J. SLABY, SUSAN K. MCCUNE, and ROBERT W. SUMMERS, Gross Anatomy in the Practice of Medicine (1994); ANNE M.R. AGUR and MING J. LEE, Grant's Atlas of Anatomy, 9th ed. (1991); RONALD G. WOLFF, Functional Chordate Anatomy (1991), a textbook that integrates body functions across systems; KURT E. JOHNSON, Human Developmental Anatomy (1989); KENNETH M. BACKHOUSE and ralph t. hutchings, A Color Atlas of Surface Anatomy: Clinical and Applied (1986); Henry Clay, Anatomy of the Human Body, 30th American ed. edited by CARMINE D. CLEMENTE (1985); JAMES E. CROUCH, Functional Human Anatomy, 4th ed. (1985); W. HENRY HOLINSHEAD, Textbook of Anatomy, 4th ed. (1985); and ROBERT L. BACON and NELSON R. NILES, Medical Histology: A Text-Atlas with Introductory Pathology (1983).

GILBERT B. FORBES, Human Body Composition: Growth, Aging, Nutrition, and Activity (1987), is a good source of introductory information for general readers. HAN C.G. KEMPER (ed.), Growth, Health, and Fitness of Teenagers: Longitudinal Research in International Perspective (1985), reports on a study of age-related changes in the physical growth and physical activity and performance of teenagers in The Netherlands, ROBERT M. MALINA and CLAUDE BOUCHARD, Growth, Maturation, and Physical Activity (1991), is a well-organized textbook for students interested in human growth and its relation to body composition and physical performance. R.J. SHEPHARD and J. PAŘÍZKOVÁ (eds.), Human Growth, Physical Fitness, and Nutrition (1991), contains a nicely presented, invaluable collection of research papers for health scientists and clinicians concerned with nutrition and physical fitness in children during their growing years. DAVID SINCLAIR, Human Growth After Birth, 5th ed. (1989), provides a clear, basic textbook for nursing and other health profession students and general readers.

Aging and senescence. Life-span: Studies of longevity include LEONID A. GAVRILOV and NATALIA S. GAVRILOVA, The Biology of Life Span: A Quantitative Approach, rev. and updated ed. (1991; originally published in Russian, 2nd ed., rev. and updated, 1991); and JOEP M.A. MUNNICHS et al. (eds.), Life-Span and Change in Gerontological Perspective (1985), a report of diverse research on behavioral development across the lifespan. United Nations Demographic Yearbook includes mortality statistics for all countries, showing the influence of economic, social, and climatic factors on mortality.

Aging: General considerations are addressed by JOHN A. BEHNKE, CALEB B. FINCH, and GAIRDNER B. MOMENT (eds.),

The Biology of Aging (1978), a collection of articles; MICHAEL R. ROSE, Evolutionary Biology of Aging (1991), a provocative treatise that proposes an explanatory theory of aging grounded in evolutionary biology; ROBERT R. KOHN, Principles of Mammalian Aging, 2nd ed. (1978), with emphasis on the role of interstitial tissue changes in the aging process; BERNARD L. STREHLER, Time, Cells, and Aging, 2nd ed. (1977), an examination of cellular and molecular mechanisms and theories of aging; BRIAN CHARLESWORTH, Evolution in Age-Structured Populations, 2nd ed. (1994), a theoretical consideration of the consequences of age-structure and age-specific differences in reproduction and mortality, which also considers the broader issue of life-history evolution and hence treats senescence as a part of the continuum of development; CALEB E. FINCH, Longevity, Senescence, and the Genome (1990), an encyclopaedic treatment of the theories of aging, the statistical methods for evaluating aging, and the full range of empirical methods used to study the aging process for all levels of biological organization, ranging from molecules to populations, with tables and summaries of observed maximum life spans and mortality rates; and ROBERT E. RICKLEFS and CALEB E. FINCH, Aging: A Natural History

Human aging: GEORGE L. MADDOX et al. (eds.), The Encyclopedia of Aging, 2nd ed. (1995), is an extensive general reference. General principles are addressed in PAOLA S. TIMI-RAS (ed.), Physiological Basis of Aging and Geriatrics, 2nd ed. (1994); IMRE ZS.-NAGY, The Membrane Hypothesis of Aging (1994), a comprehensive, multidisciplinary description of the cell maturation and aging process; ARTHUR K. LABIN (ed.), Practical Handbook of Human Biologic Age Determination (1994), covering metabolic profiles, organ system approaches, biological measurements, and nonhuman model studies; ROBERT ARK-ING. Biology of Aging: Observations and Principles (1991); and ALEXANDER P. SPENCE, Biology of Human Aging (1989).

The following provide advanced knowledge on various aspects of geriatrics and gerontology: JEAN M. LAUDER et al. (eds.), Molecular Aspects of Development and Aging of the Nervous System (1989); CLAIRE MURPHY, WILLIAM S. CAIN, and D. MARK HEGSTED (eds.), Nutrition and the Chemical Senses in Aging: Recent Advances and Current Research Needs (1989); ALLAN L. GOLDSTEIN (ed.), Biomedical Advances in Aging (1990); and STEVEN R. GAMBERT (ed.), Handbook of Geriatrics (1987). The essentials of geriatric medicine are presented in WILLIAM REICHEL, Care of the Elderly: Clinical Aspects of Aging, 4th ed. (1995), a comprehensive clinical approach geared to the practicing physician; M.R.P. HALL, W.J. MacLENNAN, and M.D.W. LYE, Medical Care of the Elderly, 3rd ed. (1993); and Contemporary Geriatric Medicine (biennial).

Additional works include ALAN J. SINCLAIR and KEN W. WOOD-HOUSE (eds.), Acute Medical Illness in Old Age (1995); RICHARD L. BYYNY and LEON SPEROFF, A Clinical Guide for the Care of Older Women: Primary and Preventive Care, 2nd ed. (1996): CORNELIUS L.E. KATONA, Depression in Old Age (1994): MAR-GRET M. BALTES and PAUL B. BALTES (eds.), The Psychology of Control and Aging (1986); and GERALD FELSENTHAL, SUSAN J. GARRISON, and FRANZ U. STEINBERG (ed.), Rehabilitation of the Aging and Elderly Patient (1994).

Guyana

uyana (the Co-operative Republic of Guyana) is an independent republic and member of the Commonwealth located in the northeastern corner of South America. It is bordered by Venezuela to the west, Brazil to the southwest and south, Suriname (along the Courantyne River) to the east, and the Atlantic Ocean to the north. Its total area of 83,000 square miles (215,000 square kilometres) is largely uninhabited, and most of the country's inhabitants occupy the narrow coastal strip. The capital and chief port is Georgetown.

Present-day Guyana reflects its British colonial past and its reactions to that past. It is the only English-speaking country of South America. Since independence in 1966, Guyana's chief economic assets—its sugarcane plantations and bauxite industry—have come under government control, as has most of the country's commerce. Guyana's populace is mainly of colonial origin, although a small number of aboriginal Indians are scattered throughout the forested interior.

The more numerous coastal peoples are chiefly descendants of slaves from Africa and indentured workers from India, who were originally imported to work the coastal sugarcane plantations. Racial problems between the latter two groups have played a disruptive role in Guyanaese society.

Politically, Guyana has moved on a steady course toward socialism from the time of independence, although after the death of the first prime minister, Forbes Burnham, in 1985, ties with Western powers were strengthened. This article is divided into the following sections:

Physical and human geography

THE LAN

Relief. The narrow plain that extends along the country's Atlantic coast has been modified considerably by humans. Much of the area, which measures only about 10 miles (16 kilometres) at its widest point, has been reclaimed from the sea by a series of canals and some 140 miles of dikes. The coastal plain's inland border is generally marked by canals that separate the plain from interior swamps. South of the coastal zone the forested land rises gently and has sandy soils.

About 40 miles inland from the coast is a region of undulating land that rises from 50-foot (15-metre) hills on the coastal side of the region to 400-foot (120-metre) ones on the western side. The area is between 80 and 100 miles wide and is widest in the southeast. It is covered with sands, from which it takes its name as the white-sands (zanderij) region. A small savanna region in the east lies about 60 miles from the coast and is surrounded by the white-sands belt. The sands partly overtie a low crystalline plateau that is generally less than 500 feet in elevation. The plateau forms most of the country's centre and is penetrated by igneous rock intrusions that cause the numerous rapids of Guyana's rivers.

Beyond the crystalline plateau, the Kaieteurian Plateau lies generally below 1,600 feet above sea level; it is the site of the spectacular Kaieteur Falls, noted for their sheer 741-foot initial plunge. The plateau is overlain with sand-stones and shales that, in the south, form the extensive Rupununi Savanna region. The Acarai Mountains (Serra Acarai), which rise to about 2,000 feet, rim the plateau on the southern border, and it is crowned on the western frontier by the Pakaraima Mountains, which rise to 9,094 feet (2,772 metres) in Mount Roraima. The Rupununi Savanna is bisected by the east-west Kanuku Mountains,

which rise to almost 3,000 feet.
Drainage. Guyana's four main rivers—the Courantyne,
Berbice, Demerara, and Essequibo—all flow from the
south and empty into the Atlantic along the eastern section of the coast. Among the tributaries of the Essequibo.

the Potaro, Mazaruni, and Cuyuni drain the northwest, and the Rupununi drains the southern savanna. The coast is cut by shorter rivers, including the Pomeroon, Mahaica, Mahaicony, and Abary.

The rivers are part of the watershed of the Amazon and Orinoco rivers, and the headwaters of the Rupununi in Brazil are often confused with those of the Amazon. Drainage is poor, because the average gradient is only one foot per mile, and there are swamps and flooding in the mountains and savannas. The rivers are not suitable for long-distance transportation because they are broken by interior falls, and in the coastal zone their mouths and estuaries are blocked by mud and by sandbars that may occur two to three miles out to sea.

Soils. The coastal soils are fertile but acidic. The fineparticle, grayish blue clays of the coastal plain are composed of alluvium from the Amazon deposited by the south equatorial ocean current and of much smaller amounts of alluvium from the country's rivers. They overlie white sands and clays and can support intensive agriculture but must be subjected to fallowing to restore fertility. Pegarss soil, a type of tropical peat, occurs behind the coastal clays and along the river estuaries, while silts line the banks of the lower rivers. Reef sands occur in bands in the coastal plain, especially near the Courantyne and Essequibor ivers. The rock soils of the interior are leached and infertile, and the white sands are almost pure quartz.

Climate. High temperatures, heavy rainfall with small seasonal differences, high humidity, and high average cloud cover provide climatic characteristics of an equatorial lowland. Temperatures are remarkably uniform. At Georgetown the daily temperature varies from 74 to 86 to 76 (23 to 30 °C), and the mean temperature is about 80 °F (27 °C). The constant heat and high humidity are mitieated near the coast by the trade winds.

Rainfall derives mainly from the movement of the intertropical front, or doldrums. It is heavy everywhere on the plateau and the coast. The annual average at Georgetown is about 90 inches (2,290 millimetres), and on the interior Rupununi Savanna it is about 70 inches. On the coast a long wet season, from April to August, and a short Coastal soils

Major rivers

The

coastal

regions

wet season, from December to early February, are sufficiently well marked on the average, but in the southern savannas the short wet season does not occur. Total annual rainfall is variable, and seasonal drought can occur in July and August when the southeast trade winds parallel the coast. Variations in Guvana's climatic patterns have a determining effect on tropical crop production.

Plant and animal life. Many plants of the coast, such as the mangrove and various saltwater grasses, grow in shallow brackish water and help to protect or extend the land. The wet savanna behind the coast has coarse tufted grasses and a wide scattering of palms, notably the coconut, truli, and manicole, High rain forest, or selva, covers about three-fourths of the land area and is of extraordinary variety and magnificence. Prominent trees include the greenheart and the wallaba on the sandy soils of the northern edge, the giant mora and crabwood on swampy sites, the balata and other latex producers, and many species such as the siruaballi and hubaballi that vield handsome cabinet woods. The interior savanna is mostly open grassland, with much bare rock, many termite hills, and clumps of ita palm.

All forms of animal life are immensely varied and abundant, though few, apart from birds and insects, are normally visible. The tapir is the country's largest land mammal, and the jaguar is the largest and fiercest of the cats, which also include the ocelot; monkeys and deer are the most common animals. Among the more exotic species are the sloth; great anteater; the capybara, or bush pig: and armadillo. Birds include the vulture, kiskadee, blue sacki, hummingbird, kingfisher, and scarlet ibis of the coast and lower rivers; and the macaw, tinamou, bellbird, and cock-of-the-rock in the forest and savanna. The caiman (a reptile similar to the alligator) is the most common of the larger freshwater creatures. The giant anaconda, or water boa, is the largest of the many kinds of

The country is divided traditionally between the coast, where most of the population is concentrated, and the interior. The coastal population is heterogeneous, its inhabitants descended from the labourers brought in to work the sugarcane plantations. The interior, despite scattered ranching and mining settlements, is largely the province of the indigenous Indians.

Guyanes society is predominantly rural, most of the people occupying wilages in the coastal region. The highest population concentrations are along the estuary of the
Demerara River and between the mouths of the Berbice
and Courantyne rivers. Village units are of distinctive rectangular shapes, with the settlement areas nearest the ocean
and connected to one another by the coastal highway;
each village's farmlands extend inland, often for several
miles, and are separated from neighbouring village lands
by canals. Villages range in size from several thundred to
several thousand persons. The commonly found wood and
concrete-block dwellings are usually built on stilts above
the flood-prone land and are connected by footbridges to
the streets, which are built over the drainage and irrigation canals.

Georgetown is the country's main port and its largest cities below sea level and is protected by dikes along both the river and the sea. Other important towns include the interior bauxite-mining centre of Linden and the market centre of New Amsterdam, located on the mouth of the Berbice River. Agricultural centres, such as the sugarcane plantation of Port Mourant, east of New Amsterdam, and the rice centre of Anna Regina, north of the Essequibo River estuary, provide commercial and marketing functions in the rural areas of the coastal zone.

THE PEOPLE

The indigenous peoples of Guyana are collectively known as Amerindians and constitute about 4 percent of the population. Indian groups include the Warao (Warrau), Arawak, Carib, Wapistana (Wapishana), Arecuna, the mixed "Spanish Arawak" of the Moruka River, and many more in the forest areas. The Makusi (Macussi or Macushi) are the most prominent of the savanna peoples. Sizable concentrations of Amerindians inhabit the far west along the border with Venezuela and Brazil. They are rarely seen in the populated coastal 'areas, although a few have interbred with blacks and East Indians. Since 1970, traditional Amerindian lands near the international borders have come under government control, although Amerindians continue to hold village lands informally

throughout Guyana's interior.

The other major elements in the population are predominantly coastal dwellers. Descendants of African slaves form the oldest group; they abandoned the plantations after full emancipation in 1838 to become independent peasantry or town dwellers. The Afro-Guyanese constitute about one-third of the population. The East Indians came mostly as indentured labour from India to replace Africans in plantation work. They form the largest racial group in the country—about half the population—and have been increasing more rapidly than the others. The East Indians are the mainstay of plantation agriculture, and many are independent farmers and landowners, have done well in trade, and are well represented among the professions.

The Chinese and Portuguese also entered originally as agricultural labourers but are now rarely found outside the towns. They are active in business and the professions, and their influence is disproportionate to their numbers; they have not been increasing, however, and together they constitute only a tiny percentage of the population. Europeans other than Portuguese are few, and most are shorterm inhabitants. While every kind of racial mixture may be found, mulattoes (presons of mixed white and black

ancestry) are by far the most common. Most of them live in towns, and a high proportion are in clerical or profes-

The major religions are Christian (chiefly Anglican and Roman Catholic) and Hindu. Fundamentalist Protestantism has made inroads in the 20th century, mainly in Georgetown. There is also a sizable minority of Muslims. Animistic religions are still practiced by some of the Amerindian peoples. The official and principal language is English, but a croele patois is spoken throughout the country. Hindi and Urdu are heard occasionally among older Fast Indians.

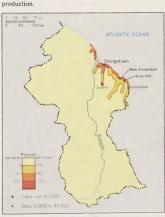

Immigration is no longer important, and by the late 20th century the number of foreign-born, long-term residents was insignificant. Enugration has been a drain on the country's human resources as thousands of persons have left annually, going mainly to the United States, Canada, England, and Caribbean islands. Many of the emigrants have been skilled and professional people whose loss has intensified the country's severe economic problems. East Indians have emigrated in large numbers to flee what they consider political persecution, a number of them having sought part-time work across the Courantyne River in western Suriname.

THE ECONOMY

Since independence Guyana has remained locked into a typical colonial economic dependency on agricultural and mined products, most notably sugarcane and bauxie. Independence brought economic reforms under a socialistleaning government, but the effect on the old economic cycle has been minimal. Although the government permits a three-sector economy—private, public, and cooperative the public sector remains heavily dominant.

the public sector remains heavily dominant. Government management of the economy has become direct and significant. During the 1970s the government nationalized U.S. and Canadian bauxite holdings; in 1976 it nationalized the vast holdings of the Booker McConnell companies in Guyana, which included coastal sugarcame plantations as well as an array of light manufacturing and commercial enterprises. By the mid-1980s it was estimated that the government controlled directly more than 80 percent of Guyana's economy. All nationalized businesses have been reorganized under the Guyana State Corporation. The state-owned Guyana Sugar Corporation controls the sugarcane plantations, and the Guyana Mining Enterprise Ltd. was established to oversee local mineral

Nationalization in the 1970s

Population density of Guyana.

Chief ethnic groups

Rural

society

The Guyanese economy has deteriorated under government management policies. Members of the ruling People's National Congress (PNC) political party have been placed in managerial positions, leading to the exodus of former managers and clerical workers. Declining output, a reliance on volatile external commodity markets, and a reduced tax base have all increased financial deficits. External debt has risen precipitously, and a devalued currency has been eroded by speculation in the local black market. Reduced fuel imports have led to widespread power outages, and a government austerity program all but eliminated imported food and consumer goods. Guyana's per capita income (estimated at about \$600 in the late 1980s) places it among the world's poorest countries. Improvements in economic conditions became dependent upon foreign aid and a variety of regional and reciprocal trade agreements.

Trade associations have an important influence in Guvanese government. The Trade Union Congress is an association of major unions, among which are the Guyana Mine Workers' Union, which is composed almost exclusively of black workers, and the Guyana Agricultural and General Workers' Union is a predominantly East Indian association

Resources. The most important mineral resource is the extensive bauxite deposits between the Demerara and Berbice rivers. There are also significant deposits of manganese at Matthews Ridge in the northwest, about 30 miles east of the Venezuelan frontier. Diamonds occur in the Mazaruni and other rivers of the Pacaraima Mountains. Gold is found in both alluvial and subsurface deposits. Other minerals include copper, iron ore, molybdenite (the source of molybdenum), nickel, white sand (used in glass manufacture), kaolin (china clay), and graphite. The government has encouraged oil exploration, but no significant reserves have been found.

The main biological resource consists of the hardwoods of the tropical rain forest and especially the greenheart tree, which is resistant to termites, decay, and marine erosion. The shrimps off the coast and a few inland fishes form the basis of the nation's fishing industry, and the grasses of the savanna regions are used for cattle grazing.

Most of Guyana's energy must be imported; domestic electricity is produced largely by thermal generation and is available only on the coastal plain and along the lower reaches of the rivers. Hydroelectric potential in Guyana is considerable, especially at Tiger Hill on the Demerara River and Tiboku Falls on the Mazaruni. Development

Sugarcane fields and communities at Ogle, east of Georgetown

is hampered, however, by the remoteness of the falls and the large amounts of capital needed for generation and transmission facilities.

Agriculture, forestry, and fishing. Agriculture is concentrated on the narrow sea-level coastal plain between the Esseguibo and Courantyne rivers. Land-use patterns still reflect early Dutch and British water-control techniques. Arable land is laid out in strips between the sea or a river and inland swamps. It is protected on all sides by dikes and canals that are used for both irrigation and drainage. The land reclaimed from the sea is fertile but acidic; lost fertility must be returned to the soil by periodic fallowing or the addition of fertilizers.

Food crops include cassava, corn (maize), bananas, vegetables, and citrus fruits. Cash crops are mainly sugarcane and rice but also include coffee and cacao. Both sugarcane and rice are cultivated through a combination of mechanization and hand labour. Agricultural production increased during the mid-20th century, mainly because mechanization extended cultivable lands, although output stagnated in later decades as the entire economy foundered. East Indian workers overwhelmingly predominate in agriculture.

Livestock production is carried out on the Rupununi Savanna and on the coastal plain. Animals include beef cattle, dairy cattle, pigs, goats, sheep, and poultry

Forestry activities are hampered by the lack of adequate transportation, the difficulty of cutting the extremely hard wood of Guyana's trees, and the shortage of facilities for the sawing, storing, and shipping of timber. Most of the timber produced for the domestic market and for export is from the greenheart tree.

Many fishing facilities have been improved, and total production has increased as fishing has become a more important part of the economy. Shrimping is carried out primarily for export.

Industry. Guyana is one of the world's largest producers of bauxite. All alumina (aluminum oxide occurring in hydrated form in bauxite) and most of the bauxite mined is produced at Linden. The rest of the country's bauxite mining takes place on the Berbice River; a processing

Bauxite production

plant also operates downriver at Everton. Diamonds continue to be mined by hand and by suction dredges in the interior rivers. Gold is mined by individual prospectors, and large-scale Canadian-financed gold mines

were opened late in the 1980s. The country's many rice mills, like its rice fields, are generally small-scale and individually owned, although there are several large government mills along the coast. Other domestic industries are oriented toward the replacement of consumer imports such as cigarettes and matches, edible oils, margarine, beverages, soap and detergents, and clothing. Refined sugar, stock feeds, and rum and beer are also produced.

Finance and trade. The Bank of Guyana, established in 1965, has the sole right of note issue and acts as banker to the government and other banks. The country's major commercial banks include three local banks and branches of Canadian and Indian banks. Other financial services are provided by the Guyana Cooperative Agricultural and Industrial Development Bank and the New Building Society; insurance companies, most of which are foreignowned; and more than 1,500 cooperative societies, which serve as savings institutions and offer agricultural credit. Guyana's major trading partners are the United States, the United Kingdom, and Trinidad and Tobago. Guyana joined the Caribbean Free Trade Association (Carifta) in 1965 and then became a member of the Caribbean Community and Common Market (Caricom), which replaced Carifta in 1973. The major exports are bauxite and alumina, sugar, and rice. Shrimps, diamonds, molasses, rum, and timber are also sold abroad. Major imports include fuels and lubricants, machinery, vehicles, textiles, and foods.

Transportation. The limited road and highway system is partly paved and partly made of burnt clay. The few hundred miles of paved roads are mostly in the coastal zone. The interior has few roads.

Guyana's coastal railway, established in 1848 as South America's first rail line, was discontinued in the 1970s,

Sources of energy

Trade

tions

associa-

Colonial

influence

ending passenger service. A remaining freight line connects the manganese mines at Matthews Ridge with Port Kaituma on the Kaituma River, and another transports bauxite between Ituni and Linden.

Guyana Airways Corporation operates scheduled domestic and international flights. Timehri International Airport, established in 1968 and located 25 miles from Georgetown, is the country's main airport and is served by several international airlines. Domestic commercial and privaaircraft, chiefly carrying passengers and equipment, use landing strins and the quieter stretches of rivers.

Barges and small boats carry people and agricultural products in the canals of the coastal estates and villages. Larger boats traverse the estuants that intersect the coastal plain. A pontoon bridge across the Demerara River opened in 1978; it is the only bridge to link major segments of the coastal plain. Bauxite is loaded into occangoing ships at Linden and manganese ore at Port Kaituma, but otherwise the country's external trade passes through Georgetown, which maintains connections with the West Indies, Suriname, French Guiana, the United Kingdom, Canada, and the United States.

GOVERNMENT AND SOCIAL CONDITIONS

Government. Guyana became an independent member of the Commonwealth in 1966 and in 1970 became a cooperative republic, involving citizens' organizations in government. Under the constitution of Oct. 6, 1980, exceutive power is vested in the president, who leads the majority party in the unicameral National Assembly and holds office for the assembly's duration. The president appoints the Cabinet, which is responsible to the National Assembly. The minority members of the assembly elect an opposition leader. The assembly is elected by universal adult suffrage for a term of five years.

The right to vote belongs to all Guyanese citizens 18 years of age or older. Voting is carried out by secret ballot under a system of proportional representation. Votes are cast for lists of candidates compiled by the political parties, and seats are allocated proportionally among the lists.

Since independence in 1966, Guyana has been ruled by one party, the People's National Congress. Initially identified with the urban black populace, the PNC essentially established a one-party state under the direction of its first leader, Forbes Burnham. The PNC won power in an election marked by numerous reports of irregularities, many of which were related to the Guyana Defence Force (GDF), a military unit established in 1965 with strong ties to the PNC. Both the GDF and the police force are overwhelminely black.

The People's Progressive Party (PPP), the PNC's official opposition, is the traditional party of the rural East Indians; smaller parties include the Working People's Alliance (WPA), a newer party founded by the historian Walter Rodney and headed by black labour leaders and intelligentias allied against alleged PNC corruption.

Local government is administered principally through the Regional Democratic Councils, each led by a chairman; they are elected for terms of up to five years and four months in each of the country's 10 regions.

Guyana has two legal traditions, the British common law and the Roman-Dutch code, the latter now largely relegated to matters of land tenure. The constitution is the supreme law of the land. The court structure consists of magistrate courts for civil claims of small monetary value and minor offenses, the High Court, with original and appellate jurisdiction in civil and criminal matters, and the Court of Appeal, with appellate authority in criminal cases. The Court of Appeal and the High Court together constitute the Supreme Court.

constitute the Spirmer Court.

Education is free and compulsory. Primary and secondary instruction are separate, although the lack of facilities makes it necessary to hold some secondary classes in primary schools. In 1976 the government assumed full responsibility for education from nursery school to university. Government authority was extended out to the private primary schools. Teachers are expected to teach loyalty to both the PNC described to piecews. The principal university is the University of Guyana.

founded in 1963 and subsequently housed at Turkeyen, in the eastern part of Greater Georgetown. The school has also become politicized, attendance there being contingent upon prospective students completing a year of national service, usually at camps in Guyana's interior. Thus many Guyanese seek education and training abroad. There are also a number of other colleges, including technical and teacher-training schools.

Health and welfare. Health standards declined after independence: Many doctors and other trained personnel have emigrated, and economic austerity programs have reduced supplies of medicine and soap. Food shortages have created widespread malnutrition, especially in Georgetown. Diseases formerly under control, notably beriberi and malaria, had reappeared by the early 1980s, and sanitation problems have also increased.

itation problems have also increased. Under colonial rule public health was centred around government and plantation health clinics. After independence a universal health care system was instituted, and most hospital facilities came under government control. Health problems arise particularly along the easily flooded coast, where the many ditches and ponds provide ideal environments for the spread of disease. A minimal government pension plan for the sick and aged has continued beyond independence, its effectiveness reduced by inflation. Government housing projects, confined mainly to the Georgetown area, have not produced expected results.

The national social structure was inherited from the period of British colonial rule, under which the majority of East Indian and Afro-Guyanese labourers were directed by white planters and government officials. A poorly defined local middle class composed of teachers, professionals, and civil servants, and including a disproportionate number of Chinese and Portuguese, emerged during colonialism. Since independence the PNC political clite has replaced the white plantocracy at the apex of Guyana's social order. The Amerindians remain apart from the country's social structure as they did under the British.

CULTURAL LIFE

Postindependence Guyanese culture still bears the imprint of its colonial heritage. Guyanese were taught to respect and covet European values during the colonial era, and this has not changed despite government exhortation. Yet ethnic identity continues to be important, with daily life centring around ethnic and family groups; the mother-and grandmother-dominated family among blacks differs from the father-oriented East Indian family. Men of both groups often commute long distances to work along the coastal highway. Daily dress normally does not distinguish one group from another.

one group from another.

Amerindian culture, which remains uninfluenced by national politics, is recognized as an important element in Guyanese museum displays and as an inspiration in local music and painting. Cultural institutions are concentrated in Georgetown, including the Guyana Museum, which includes the Guyana Zoo, with its impressive collection of animals from northern South America. Guyanese writers have made notworthy contributions to literature; the works of Wilson Harris, A.J. Seymour, and Walter Rodney are among the foremost.

Much recreational activity is based upon the festivities that accompany Hindu, Muslim, and Christian holidays. The Guyanese share the passion for cricket that is prevalent throughout the English-speaking Caribbean.

The government has taken nearly complete control over local news media, including the one radio station and Media the single daily newspaper. Objections against censorship have been on the rise from opposing political and church groups. In 1988 Guyana's first television station was established under government control.

tablished under government control.

of British

Guiana

Christ. The Warrau Indians may have arrived first, followed by Arawak and Carib tribes. The early communities practiced shifting agriculture supplemented by hunting. Christopher Columbus sighted the Guyana coast in 1498, and Spain subsequently claimed, but largely avoided, the area between the Orinoco and Amazon deltas, a region long known as the Wild Coast. It was the Dutch who finally began European settlement, establishing trading posts upriver in about 1580. By the mid-17th century they had begun importing slaves from West Africa to cultivate sugarcane. In the 18th century the Dutch, joined by other Europeans, were moving their estates downriver toward the fertile soils of the estuaries and coastal mud flats. Laurens Storm van's Gravesande, governor of Essequibo from 1742 to 1772, coordinated these development efforts.

Guyana changed hands with bewildering frequency during the wars (mostly between the British and the French) from 1780 to 1815. During a brief French occupation, Longchamps, later called Georgetown, was established at the mouth of the Demerara; the Dutch renamed it Stabroek and continued to develop it. The British took over in 1796 and remained in possession, except for short intervals, until 1814, when they purchased Demerara, Berbice, and Essequibo, which in 1831 were united as the

colony of British Guiana.

The slave trade was abolished in 1807, when there were about 100,000 slaves in Berbice, Demerara, and Essequibo. After full emancipation in 1838, black freedmen left the plantations to establish their own settlements along the coastal plain. The planters then imported labour from several sources, the most successful group being indentured workers from India. Indentured labourers who had earned their freedom settled in their own coastal villages near the estates, a process that became established in the late 19th century during a serious economic depression caused by competition with European sugar beet production.

Settlement proceeded slowly, but gold was discovered in 1879, and a boom in the 1890s helped the colony. The North Western District was organized in 1889 and was the cause of a dispute in 1895 when the United States supported Venezuela's claims to the territory. Venezuela revived its claims on British Guiana in 1962, an issue that went to the United Nations for mediation in the early

1980s but which remains unresolved.

The British inherited from the Dutch a complicated constitutional structure. Changes in 1891 led to progressively greater power being held by locally elected officials, but reforms in 1928 invested all power in the governor and the Colonial Office. In 1953 a new constitution-with universal adult suffrage, a bicameral elected legislature,

and a ministerial system-was introduced.

From 1953 to 1966 the political history of the colony was stormy. The first elected government, formed by the People's Progressive Party led by Cheddi Jagan, seemed so procommunist that the British suspended the constitution in October 1953 and dispatched troops. The constitution was not restored until 1957. The PPP split along racial lines, Jagan leading a predominately East Indian party and Forbes Burnham leading a party of African descendants, the People's National Congress. In the elections of 1957 and 1961, the PPP was returned with working majorities. From 1961 to 1964 severe rioting involving bloodshed between rival blacks and East Indians and a long general strike led to the return of British troops.

To answer the PNC allegation that the existing electoral system unduly favoured the East Indian community, the British government introduced for the elections of December 1964 a new system of proportional representation. Thereafter the PNC and a smaller, more conservative party formed a coalition government, led by Burnham, which took the colony into independence under its new name, Guyana, on May 26, 1966. The PNC gained full power in the general election of 1968, which was characterized by questionable rolls of overseas voters and widespread claims of electoral impropriety. On Feb. 23, 1970, Guyana was proclaimed a cooperative republic within the Commonwealth. A president was elected by the National Assembly, but Burnham retained executive power as prime minister. Burnham declared his government to be socialist and in the later 1970s sought to reorder the government in his favour. In 1978 one of the most bizarre incidents in modern history occurred in Guyana when some 900 members of a religious cult in a commune known as Jonestown committed mass suicide at the behest of their leader, Reverend Jim Jones.

In 1980 under a new constitution, Burnham became executive president, with still wider powers, after an election in which international observers detected widespread fraud. In the following years Burnham was faced with an economy shattered by the depressed demand for bauxite and sugar and a restive populace suffering from severe commodity shortages and a near breakdown of essential public services. Burnham enforced austerity measures, and he began leaning toward Soviet-bloc countries for support. Burnham died in 1985 and was succeeded by the prime minister, Hugh Desmond Hoyte, who pledged to continue Burnham's policies. In elections held that year Hoyte won the presidency by a wide margin, but once again charges of vote fraud were raised. In the late 1980s the administration, facing worsening financial and economic problems, moved to liberalize the economy.

RIBLIOGRAPHY

Physical and human geography: General information can be found in WILLIAM B. MITCHELL et al., Area Handbook for Guyana (1969), dated but still useful; K.F.S. KING, Land and People in Guyana (1968); and FRANCIS CHAMBERS (comp.), Guyana (1989), an annotated bibliography, For statistical information, see the Statistical Digest (annual). For natural resources, see VINCENT ROTH (comp.), Handbook of Natural Resources of British Guiana (1946), and Notes and Observations on Animal Life in British Guiana, 1907-1941; A Popular Guide to Colonial Mammalia (1941); and D.B. FANSHAWE, The Vegetation of British Guiana, a Preliminary Review (1952). An early botanical study is WALTER E. ROTH (trans. and ed.), Richard Schomburgk's Travels in British Guiana, 1840-1844, 2 vol. (1922-23; originally published in German, 1847-48). Studies of the indigenous population include COLIN HENFREY, A Gentle People: A Journey Among the Indian Tribes of Guiana (1964; U.S. title, Through Indian Eyes, 1965), which also provides a lively travel account; MARY NOEL MENEZES, British Policy Towards the Amerindians in British Guiana, 1804-1873 (1977); and ANDREW SANDERS, The Powerless People: An Analysis of the Amerindians of the Corentyne River (1987). DWARKA NATH, A History of Indians in Guyana, 2nd rev. ed. (1970), examines the East Indian population, RAYMOND T. SMITH, British Guiana (1962, reprinted 1980), is an outstanding sociological survey, and The Negro Family in British Guiana (1962, reissued 1971), is an anthropological classic. Economic aspects of the sugar industry are dealt with in ALAN H. ADAMSON, Sugar Without Slaves: The Political Economy of Guyana (1972), on the 19th century; JAY R. MANDLE, The Plantation Economy: Population and Economic Change in Guyana, 1838-1960 (1973); WALTER RODNEY, A History of the Guyanese Working People, 1881-1905 (1981); and CLIVE Y. THOMAS, Plantations, Peasants, and State. A Study of the Mode of Sugar Production in Guyana (1984). Views of the country's political situation are presented in LEO A. DESPRES, Cultural Pluralism and Nationalist Politics in British Guiana (1967); JACQUELINE ANNE BRAVEBOY-WAGNER, The Venezuela-Guyana Border Dispute: Britain's Colonial Legacy in Latin America (1984); HENRY B. JEFFREY and COLIN BABER, Guyana: Politics, Economics, and Society: Beyond the Burnham Era (1986); and CHAITRAM SINGH, Guyana: Politics in a Plantation Society (1988), a survey of postindependence politics

History: An early history of Guyana is c.a. HARRIS and J.A.J. De VILLIERS (comps.), Storm van's Gravesande: The Rise of British Guiana, trans. from Dutch, 2 vol. (1911, reprinted 1967), extracts from his dispatches written between 1738 and 1772. ALLAN YOUNG, The Approaches to Local Self-Government in British Guiana (1958), deals mainly with the 19th century. BRIAN L. MOORE, Race, Power, and Social Segmentation in Colonial Society: Guyana After Slavery, 1838-1891 (1987), is a history of race relations. THOMAS J. SPINNER, JR., A Political and Social History of Guyana, 1945-1983 (1984), provides an overview of recent events, CHEDDI JAGAN, The West on Trial: The Fight for Guyana's Freedom, rev. ed. (1972, reissued 1980), is a vivid account of preindependence turmoil by a former prime minister. LATIN AMERICAN BUREAU, Guyana: Fraudulent Revolution (1984), takes a closer look at Burnham's government.

Independence

Gymnosperms

vmnosperms are a group of vascular plants whose seeds are not enclosed by a ripened ovary (fruit). In 1825 the Scottish botanist Robert Brown distinguished gymnosperms from the other major group of seed plants, the angiosperms, whose seeds are surrounded by an ovary wall. The seeds of many gymnosperms (literally, "naked seed") are borne in cones and are not visible. These cones, however, are not the same as fruits. During pollination, the immature male gametes, or pollen grains, sift among the cone scales and land directly on the ovules (which contain the immature female gametes) rather than on elements of a flower (the stigma and carpel) as in angiosperms. Furthermore, at maturity, the cone expands to reveal the naked seeds. Gymnosperms were considered at one time to be a class of seed plants, called Gymnospermae, but taxonomists now tend to recognize four distinct divisions of extant gymnospermous plants (Coniferophyta, Cycadophyta, Ginkgophyta, Gnetophyta) and to use the term gymnosperms only when referring to the nakedseed habit. Some of the divisions of gymnosperms are not closely related to others, having been distinct groups for hundreds of millions of years. Currently, about 60-70 genera are recognized, with a total of 700-800 species. Gymnosperms are distributed throughout the world, with extensive latitudinal and longitudinal ranges.

THE GYMNOSPERMS: AN OVERVIEW

GENERAL FEATURES

Coniferophytes 452

Diversity in size and structure. Among the gymnosperms are plants with stems that may barely project above the ground and others that develop into the largest of trees. Cycads resemble palm trees, with fleshy stems and leathery, featherlike leaves. The tallest cycads reach 19 metres (62 feet). Zamia pygmaea, a cycad native to Cuba, has a trunk less than 10 centimetres (four inches) in height. Of the gnetophytes, Ephedra (joint fir) is a shrub and some species of Gnetum are vines, while the unusual Welwitschia has a massive, squat stem that rises a short distance above the ground. The apex is about 60 centimetres in diameter. From the edge of the diskshaped stem apex arise two leathery, straplike leaves that grow from the base and survive for the life of the plant. Most gymnosperms, however, are trees. Of the conifers, the redwoods (Sequoia) exceed 100 metres in height and, while Sequoiadendron (giant redwood) is not as tall, the trunk is more massive.

Distribution and abundance. Although since the Cretaceous period (144 to 66.4 million years ago) gymnosperms have been gradually displaced by the more recently evolved angiosperms, they are still successful in many parts of the world and occupy large areas of the Earth's surface. Conifer forests, for example, cover vast regions of northern temperate lands in North America and Eurasia. In fact, they grow in more northerly latitudes than do angiosperms. Vascular plants that occur at the highest altitudes are the gnetophyte Ephedra. Land in the Southern Hemisphere is rich in conifer forests, which tend to be more abundant at higher altitudes. Gymnosperms that occupy areas of the world with severe climatic conditions are adapted to conserving water; leaves are covered with a heavy, waxy cuticle, and pores (stomata) are sunken below the leaf surface to decrease the rate of evaporation.

Cycads are distributed throughout the world but are concentrated in equatorial regions. As a natural population, Ginkgo originally appeared to have been confined to mountains of southeastern China; extensive artificial propagation has altered this natural distribution. Distribution of gymnosperms in the distant past was much more extensive than at present. In fact, gymnosperms were dominant in the Mesozoic era (245 to 66.4 million years ago), during which time some of the modern families originated (Pinaceae, Araucariaceae, Taxodiaceae).

Importance to humans and ecology. Some of the oldest living things on earth are gymnosperms. Redwoods live for thousands of years, and some specimens of the bristlecone pine, found in the White Mountains of California, approach 5,000 years in age.

Gymnospermous plants are widely used as ornamentals. Conifers are often featured in formal gardens and are used for bonsai. Yews and junipers are often low-growing plants cultivated for ground cover. Conifers are effective windbreaks, especially those that are evergreen. Cycads are used as garden plants in warmer latitudes, and some may even thrive indoors. Their leathery green foliage and sometimes colourful cones are striking. Ginkgo is a hardy tree, and although it once approached extinction, it is now cultivated extensively and survives such challenging habitats as the streets of New York City. Some gymnosperms are weedy in that they invade disturbed areas or abandoned agricultural land. Pines and junipers are notorious invaders, making the land unusable.

Horticultural 11505

Most of the commercial lumber in the Northern Hemisphere is derived from the trunks of conifers such as pine, Douglas fir, spruce, fir, and hemlock. Araucaria. kauri, and Podocarpus are important conifers of the Southern Hemisphere used for lumber. The wood is straightgrained, light for its strength, and easily worked. Wood of gymnosperms is often called softwood to differentiate it from the hardwood angiosperms. Wood of angiosperms typically has more kinds of elements than does softwood of gymnosperms. In addition to its use in building construction, gymnospermous wood is used for utility poles and railroad ties. Aromatic wood of cedar is frequently used in the construction of closets or clothes chests and apparently repels cloth-eating moths. Most plywood is gymnospermous. Fibres of conifers make up paper pulp and may occasionally be used for creating artificial silk or other textiles. Conifers are frequently planted in reforestation projects. Conifer bark is often the source of compounds involved in the leather tanning industry. Bark is also used extensively as garden mulch.

From conifer resins are derived turpentine and rosin. A hardened form of resin from a kauri (Agathis australis), called copal, is used in the manufacture of paints and varnishes. Some resins, such as balsam (from hemlock) and dammar (from Agathis) are used in the preparation of mounting media for microscope slides. Resins may also have medicinal uses. Many types of amber are derived from fossilized resin of conifers. Commercially useful oils are derived from such conifers as junipers, pines, hemlock, fir, spruces, and aborvitae. These oils serve as air fresheners, disinfectants, and scents in soaps and cosmetics.

Seeds are often food sources. Pine seeds are a delicacy caten plain or used as a garnish on bakery products. Seeds of Ginkgo and cycads may be poisonous unless detoxified. "Berries" (in reality the fleshy cones) of juniper are used to flavour gin.

NATURAL HISTORY

In all living gymnosperm groups, the visible part of the plant body, i.e., the growing stem and branches, represents

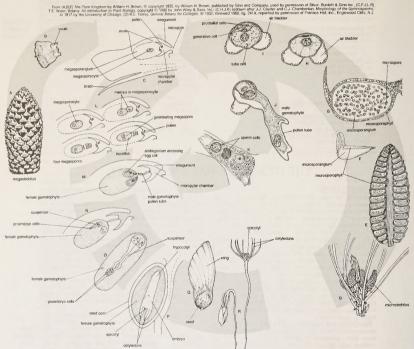

Figure 1: Stages in the life cycle of a pine.

Alternation of generations

Pollination

the sporophyte, or asexual, generation (Figure 1), rather than the gametophyte, or sexual, generation.

In most gymnosperms the pollen cones, called microstrobili, contain reduced leaves called microsporophylls. Microsporangia, or pollen sacs, are borne on the lower (abaxial) surfaces of the microsporophylls. The number of microsporangia may vary from two in many conifers to hundreds in some cycads. Within the microsporangia are cells, called microsporocytes, which undergo meiotic division to produce haploid microspore.

The gametophyte phase begins when the microspore, while still within the microsporagium, begins to germinate to form the male gametophyte. A single microspore nucleus divides by mitosis to produce a few cells. At this stage the male gametophyte (called a pollen grain) is shed

and transported by wind or insects.

Ovulate cones, called megastrobili, may be borne on the same plant that bears microstrobili (as in confers) or on sparate plants (as in cycads and Ginkgo). A megastrobilus contains many ovuliferous scales, called megasporophylis, that contain megasporae, within which a single cell (a megasporocyte) undergoes meiotic division to produce four hapioid megaspores. Pipically three degenerate, leaving one functional megaspore, which is retained within the megasporangium. The female gametophyte begins development within the megaspore intitial divisions of the megaspore nucleus are mitotic without accompanying divisions of the cytoplasm. As the number of free nuclei multiplies, the megasporaejium, integument, and megaspore wall expand. Cell walls eventually develop around the nuclei. At this stage the ovule is ready to be fertilized.

Before fertilization can take place, however, the mature male gametophyte (the pollen grain) must be transported to the female gametophyte-the process of pollination. In many gymnosperms, a sticky "pollination droplet" oozes from a tiny hole in the megasporangium (the micropyle) and pollen grains are caught in the droplet. The droplet is then resorbed through the micropyle into the megasporangium. The pollen grain settles on the surface of the megasporangium, where the male gametophyte further develops. A pollen tube emerges from the grain and grows through the megasporangium toward the multicellular eggcontaining structure called the archegonium. The egg and sperm continue to mature, the nucleus of the latter undergoing additional divisions resulting in two male gametes, or sperm. (Sperm cells have flagella in cycads and Ginkgo but not in any other seed plants.) By the time the pollen tube reaches the archegonium, both the egg and sperm are fully mature, and the egg is ready to be fertilized.

The nuclei of the two sperm are injected into the egg cell: one nucleus dies, and the other unites with the egg nucleus to form a diploid zygote. The nucleus of the fertilized egg begins the development of a new spropohyte generation by dividing a number of times; the resulting multicellular structure becomes the embryo of the seed (Figure 2). Food for the developing embryo is provided by the massive, starch-filled female gametophyte that surrounds it. The time interval between pollination and maturation of the embryo into a new sporophyte generation varies among different groups, ranging from a few months to over one year (in pine, for example). The integument develops into the seed cost, while the female gametophyte is a source of

food for the developing embryo during germination. In some gymnosperms (e.g., cycads, finkgo) the seed coat (sarrotesta) consists of two layers. In some cycads the sarcotesta is brightly coloured. The sarcotesta of Ginkgo seeds is foul-smelling when ripe. Attached to the seed coat in pine and related confers is a thin membranous winglike structure, which remains with the seed at its release and serves as a wing that may assist in the distribution of the seed. Members of the order Tavales have a fleshly structure, an aril, surrounding the actual seed. Cones of juniper are fleshy, and the entire fleshy unit drops off or is picked off by birds. Juniper seeds pass through the digestive tracts of birds and are thus distributed effectively.

At maturity, a gymnosperm embryo has two or more seed leaves (the cotyledons). Cycads, Ginkgo, and gnetophytes have two cotyledons in the embryo; pine and other conifers may have several (eight is common; some

have as many as 18). Below the attachment point of the cotyledons is the hypocoty), which emerges through the seed coat during germination, bends downward, and eventually establishes the root system. Above the attachment point of the cotyledons is the epicotyl, the tip of which contains the shoot tip and leaves. In cycads and *Ginkgo* the cotyledons remain within the seed and serve to digest the food in the female gametophyte and absorb it into the developing embryo. Conlifer cotyledons typically emerge from the seed and become photosynthetic after digesting and absorbing the food in the female gametophyte.

FORM AND FUNCTION

General features. The visible part of the gymnospermous plant body represents the sporophyte generation. Typically, a sporophyte has a stem with roots and leaves and bears the reproductive structures. The vascular system contains two conducting tissues, the xylem and phloem. The xylem is a tissue containing nonliving cells whose walls form a conducting system of "pipes" through which water and minerals are conducted from the roots to the shoots. The sturdy nature of the xylem makes it useful in support as well. The phloem, like the xylem, is a conducting tissue; its cells, however, are living and distribute the sugars, amino acids, and organic nutrients manufactured in the leaves to the nonphotosynthetic tissues of the plant. When the plant is actively growing, the phloem may also conduct stored nutrients from the roots to the developing shoots.

Stems. The stems, roots, and branches of vascular plants undergo secondary growth, which takes place from stem and branch growth tissue, called the vascular cambium. Stems of conifers are characteristically woodly with a consistency of the place of the

Maturation of the embryo Xylem and phloem

in the xylem and living cells that store materials and provide for lateral conduction (vascular rays) in the phloem. The growth tissue of the stem and branches (the vascular cambium) contributes more xylem each growing season, forming concentric growth rings in the wood. Tracheids produced by the vascular cambium early in the growing season are larger, and the walls thinner, than those formed later in the growing season. This results in the characteristic light and dark bands of wood. Some conifers have additional cell types, such as fibres and axially elongated xylem parenchyma cells that store food. Phloem is also simpler than that of angiosperms, consisting of foodconducting cells (sieve cells) and storage cells. Phloem rays traverse the phloem tissue.

Stems of Ginkgo are anatomically similar to those of conifers. Ginkgo and cedar have two kinds of branches: elongated major branches and dwarf lateral branches. The dwarf shoot bears a cluster of leaves; at the end of the growing season the shoot develops a terminal bud that elongates the following year to produce a new set of leaves. After several years these dwarf shoots develop into short, stubby outgrowths from the stem. Stems of cycads are typically short and squat, although the Australian cycad Macrozamia hopei may reach 19 metres. In the centre is a large, fleshy pith surrounded by a cylinder of xylem and phloem. There never is as much secondary vascular tissue as is found in conifers, however, Interspersed among the thin-walled tracheids are abundant vascular rays. The wood, consequently, is not as dense as in conifers.

Leaves. Leaves of gymnospermous plants are extremely variable. Most gymnosperms are evergreen, with leaves lasting more than one growing season. Others are deciduous and drop their leaves at the end of every growing season. Bald cypress (Taxodium), larch (Larix), and dawn redwood (Metaseguoia) are examples of deciduous conifers. Ginkgo also sheds its leaves in the autumn. Among the conifers, leaves are always simple; that is, the blade is a single unit. Leaves may be small and scalelike (e.g., Thuja) or needlelike (Abies, Picea, Pinus) or have a broad blade (Araucaria, Agathis). In some conifers (Taxodium) small branch fragments with numerous needlelike leaves are dropped at the end of the growing season.

Cycad leaves are compound, with thick, leathery leaflets borne in a featherlike (pinnate) arrangement on a main axis (rachis). Produced among the normal photosynthetic leaves of cycads are reduced, pointed, stiff, scalelike leaves called cataphylls. These contribute to the persistent "armour" on the trunk surfaces.

Ginkgo resembles an angiospermous tree in that the woody stem is frequently and irregularly branched and bears broad leaves, which are fan-shaped with dichotomously branched veins. The leaves of Gnetum look much like those of dicotyledonous angiosperms. Ephedra has small, scalelike leaves.

In certain conifers, such as pine and cedar, leaves are borne on dwarf lateral branches that do not elongate, but are telescoped. In cedar, the dwarf lateral shoots grow forward each year producing a new cluster of needles each-season. In pine, however, the number of needles per cluster is small (one to eight) and no more needles are produced on the dwarf shoot after the first year.

Ephedra and Gnetum do not produce extensive vascular cylinders; Ephedra is shrubby, while some species of Gnetum are vines. The stem of Welwitschia is somewhat turnip-shaped and does not project very high above the ground. The apex is broad and concave, with leaves and reproductive structures borne along the edges. Gnetum, unlike most gymnosperms, has vessels in the xylem. Perforations (pores) at the ends of the conducting elements connect them to adjacent elements.

Roots. Filaments of the fungi called endomycorrhizae live within the cells of the roots of certain gymnosperms, especially conifers. Endomycorrhizal fungi are apparently parasitic, but not destructively so. In cycads, blue-green algae grow in nodules in the roots. These roots may grow opposite to the force of gravity and may form corallike masses on the ground surface, hence the term "coralloid roots." It is thought that these fungi and blue-green algae fix atmospheric nitrogen into a form usable by the plant.

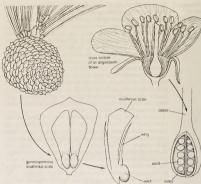

Figure 3: Comparison of gymnosperm cone and angiosperm

The seed in gymnosperms is borne exposed (the example above is pine). The angiosperm seed is enclosed within a carpel.

Modified from Life: An Introduction to Biology by George Gaylord Simpson and William S. Back, ⊚ 1957, 1965 by Harcourt Brace Jovanovich, Inc., and reproduced with their cormi-

Strobili. In most conifers the pollen-bearing and ovulebearing components (the microsporangia and megasporangia, respectively) are borne on the same plant, though separately (monoecious). A pollen-bearing cone, the microstrobilus (Figure 3), consists of a central axis on which are borne, in a close helical arrangement, reduced, fertile leaves (the microsporophylls). On the lower surfaces of the microsporophylls are borne elongated microsporangia: two microsporangia per microsporophyll are common, but some genera have more. The ovulate cone, the megastrobilus, is more complex than the microstrobilus. The megastrobilus bears seeds on flattened dwarf branches, all of the parts of which are fused (ovuliferous scales). Subtending the ovuliferous scale on the cone axis is a reduced scale leaf, or bract. In some conifers the bract is not recognizable because it has been fused to the ovuliferous scale.

In Ginkgo, microsporangia and megasporangia are borne on separate trees (i.e., it is dioecious). A Ginkgo microstrobilus is borne on a dwarf shoot among the fan-shaped leaves. The microstrobilar axis bears stalked appendages at the ends of each of which are two microsporangia directed downward. A megastrobilus is not recognized as such. Among the leaves of a dwarf shoot on a plant other than one bearing microstrobili are borne elongated, slender stalks, each with a pair of terminal ovules. Usually only one ovule matures into a seed.

Cycads also are dioecious, and all genera bear microstrobili consisting of an axis with microsporophylls inserted in a close, helical arrangement. The microsporophylls are reduced leaves with abaxial sporangia. In the genus Cycas, ovules are borne among the edges of the stalk of a reduced leaf with a bladelike region still present. These modified leaves, or megasporophylls, are clustered at the apex of the plant but not arranged in a cone. All other genera of cycads, however, have megastrobili, with the megasporophylls reduced and not leaflike in appearance. Each megasporophyll has a stalk with an expanded distal portion, on the inner face of each of which develop two

Ephedra, of the Gnetophyta, may have both microstrobili and megastrobili on the same plant, or they may occur on separate plants. The two remaining genera of Gnetophyta, Gnetum and Welwitschia, are dioecious,

EVOLUTION AND PALEOBOTANY

The first seed plants to have evolved were gymnospermous in the sense that the seeds were naked. The earliest plants seedlike bodies are found in rocks of the Late Devonian epoch (374 to 360 million years ago). During the course of the evolution of the seed habit, a number of morphological modifications were necessary. First, all seed plants are heterosporous: two kinds of spores (microspores and megaspores) are produced by the sporophyte. Hence, it is assumed that the ancestors of seed plants must have been heterosporous. Sporangia of plants that do not bear seeds typically lack an integument. The origin of the integument in seed plants was made clear by a study of Early Carboniferous (360 to 320 million years ago) ovules from Scotland. One example, Genomosperma kidstonii. consists of an elongated megasporangium with one functional megaspore. Arising from the base of the megasporangium were eight elongated, fingerlike processes that loosely surrounded the megasporangium. In a related species, G. latens, these eight fingerlike processes were fused at the base into a cup, with eight free tips. These tips tended to cover the megasporangium rather closely, as opposed to the flared appendages in G. kidstonii. Ultimately these fingerlike appendages were almost completely fused into a continuous integument surrounding the megasporangium. A small hole, the micropyle, is left at the apex of the megasporangium where the integument does not quite cover its tip.

In searching for seed-plant ancestors it is necessary to look for a heterosporous type of plant bearing leaves and also having an internal structure similar to that of seed plants. The extinct division Progymnospermophyta provides such an ancestral condition. The best-known progymnosperm is the late Devonian Archaeopteris, originally assumed to be a fern with wedge-shaped, subdivided leaflets (pinnules) and sporangia borne on appendages taking the place of pinnules. What was first interpreted as the frond axis was shown to have internal structure like that of Callixvlon. known as late Devonian stems and wood fragments assumed to be gymnospermous. Callixylon wood is like that of many conifers, consisting of tracheids and vascular rays, with closely spaced circular bordered pits on the radial walls of the tracheids. Pits are clustered, separated from other clusters by an area of the wall lacking pits. What were assumed to be pinnae of the frond of Archaeonteris are actually branches, and the so-called pinnules are helically arranged leaves. At least some species are known to be heterosporous, hence Archaeopteris has many of the features to be anticipated in a seed-plant ancestor.

From progymnosperms such as Archaeopteris could have arisen more than one group of gymnosperms. Those with compound leaves (e.g., pteridosperms and cycads) have leaves that would correspond to a flattened branch system of Archaeopteris. Those with simple leaves (e.g., conifers) have leaves that are probably the equivalent of the wedge-

shaped Archaeopteris leaves. The earliest recognized group of gymnospermous seed plants are members of the division Pteridospermophyta (pteridosperms, or seed ferns). These plants originated in the late Devonian and were widespread toward the end of the Paleozoic era (570 to 245 million years ago). Descendants persisted into the Mesozoic. In habit, Paleozoic seed ferns resembled some progymnosperms in that they were small trees with fernlike leaves (the equivalent of a progymnospermous flattened branch) bearing seeds. While Paleozoic seed ferns resembled ferns externally, the internal structure was like that of gymnosperms. Secondary vascular tissues were common in stems of seed ferns. The wood, however, was composed of thin-walled tracheids and abundant vascular rays, suggesting that stems were fleshy like those of cycads. Pteridosperm seeds were very similar to those of cycads. Many were large, with an outer, softer seed coat and a harder, inner seed coat. Within an ovule ready for fertilization was a massive female gametophyte with several archegonia. There has been one report of a pollination droplet in a Carboniferous pteridosperm ovule and a report of a pollen tube emerging from a pollen grain in the micropyle of a seed-fern ovule, suggesting that transport of the sperm through a pollen tube (siphonogamy) was in existence as far back as the Paleozoic. In some pteridosperms the seed was contained

within a cupule; some botanists interpret the cupule as a

precursor of an angiosperm carpel. Pollen grains, however, landed directly on the micropyle of the ovule. Pollenbearing organs were variable among the pteridosperms; in many cases the microsporangia were elongated and fingerlike and were produced in clusters or were fused into compound organs. Mesozoic seed ferns are less well defined, and the concept of pteridospermy is used loosely to refer to plants with fernlike foliage bearing seeds.

It is generally conceded that from the pteridosperms arose members of the division Cycadophyta. The first cycads appeared in the Permian period (286 to 245 million years ago). Some of these presumed cycads differ from extant members in that megasporophylls were undivided, unlike those of Cycas, considered to be primitive among cycads, in which the distal portion of the megasporophyll may be pinnately divided. Other Permian megasporophylls, from China, are more like those of Cycas. Cycad remains, especially leaves, are abundant in Mesozoic rocks. For this reason paleobotanists often refer to the Mesozoic era as the "age of cycads." The earliest well-known cycads appear to have had slender stems, sometimes branched with leaves not borne close together, unlike the situation in extant cycads in which leaves are densely crowded at the apex of the plant. There is evidence that these earliest cycads were deciduous. Megasporophylls of Mesozoic cycads are essentially like those of extant cycads. The megasporophyll of the Triassic Palaeocycas is like that of Cycas. Jurassic megasporophylls are like those of most other cycads. Extant cycads are now limited in geographic distribution to the warmer parts of the earth.

Coexisting with the cycads during the Mesozoic was another group of gymnosperms, the cycadeoids (division Cycadeoidophyta-sometimes called the Bennettitophyta). Although they are superficially similar in habit to the cycads, with a squat trunk and often pinnately divided leaves, their reproductive structures were different, and their actual relationship is not close. Typically seeds were borne on the surface of a fleshy receptacle. Among the seeds were sterile structures, called interseminal scales. that held the seeds tightly together. Pollen organs were quite similar among the forms in the sense that all had a whorl of modified leaves (microsporophylls) on which were borne compound microsporangia.

Conifers (division Coniferophyta) appeared first toward the end of the Late Carboniferous epoch (320 to 286 million years ago). Some of the earliest conifers (class Cordaitopsida) were trees with long, strap-shaped leaves. Trunks were similar to those of extant conifers, with dense, compact wood; small, thick-walled tracheids; and narrow vascular rays. Reproductive axes were slender, bearing narrow bracts in the axils of which were small, budlike shoots with helically arranged scales. On some of the topmost scales were borne elongated microsporangia. Buds on other axes bore ovules instead of microsporangia.

By the late Paleozoic there came into existence another group of extinct conifers, the Voltziales (class Coniferopsida). In general habit they must have resembled some of the extant araucarias (e.g., Norfolk Island pine), with whorled, flattened branches bearing helically arranged, needlelike leaves. Reproductive axes were generally homologous with those of the Cordaitales, but they were more compact, with the bracts on the ovule-bearing axes obscuring the axillary fertile buds. During the end of the Paleozoic and in the early Mesozoic, these axillary buds underwent further transformation. The sterile, non-seedbearing part became flattened, with the scales fused together. The ovule-bearing portion was situated toward the upper surface (away from the bract). The ovuliferous scale of a conifer seed cone, then, may be interpreted as an axis bearing bracts in the axils of which are modified woody ovuliferous scales derived from lateral buds.

Modern families of conifers began to appear in the Mesozoic era. Members of the Taxodiaceae, the family to which redwoods and bald cypress are assigned, appeared first in the Jurassic period. Metasequoia, the dawn redwood, is also a member of this family. Discovered first as fossils in Miocene (23.7 to 5.3 million years ago) deposits, it was assumed to have become extinct until it was discovered growing in Szechwan province in China. Its distribution First

Earliest conifers

Earliest gymnosperms

During late Triassic times there existed a type of conifer (Compostrobus) that had many features of the Pinacea. Seed cones had woody ovuliferous scales subtended by bracts with two ovules on the upper surface of each ovuliferous scale. More typical pinaceous remains occurred later in the Mesozoic. Coniferophytes were the dominant vegetation just before the appearance of the angiosperms.

The division Ginkgophyta, represented today by only one living species, Ginkgo biloba, was much more widespread in past ages. Gymnosperms that were presumed to be ginkgophytes existed as far back as the Permian period. In Mesozoic rocks, Ginkgo leaves are commonly found throughout the world. The oldest fossil ginkgophytes had leaves much more dissected than the typical Ginkgo leaf, resembling more closely the leaves found on new growth in extant unknows.

The fossil record of the division Gnetophyta is obscure, and its origin is not clear. Pollen grains similar to those of Ephedra and Welwitschia are found as far back as the Permian period. Megafossil remains of possible gnetophytan plants occur in Late Cretaeous (97.5 to 66.4 million years ago) deposits. The plant is unlike any existing one, but venation of the foliage is similar to that of leaves of Welwitschia. Pollen grains are typically gnetophytan.

CLASSIFICATION

Distinguishing taxonomic features. Gymnosperms differ from angiosperms most obviously on the basis of the naked-seed habit in the former and the enclosure of seeds within a fruit in the latter. The pollen grain of gymnosperms, when shed from the microsporangium, has more than two cells (three in cycads and four in Ginkgo and conifers). Furthermore, gymnosperm pollen lands on the ovule directly, whereas in angiosperms pollen lands on the stigma of a carpel and germinates there, with the pollen tube growing through stigmatic and stylar tissues to reach the ovule. In angiosperm pollen tubes, a total of three cells make up the male gametophyte; gymnosperms have more. The female gametophyte in gymnosperms is much larger than that of angiosperms and serves as the source of food for the developing embryo sporophyte. The female gametophyte of angiosperms consists normally of just a few cells. Both sperm cells in an angiosperm pollen tube are functional, one fertilizing the egg, the other joining with two other nuclei of the female gametophyte. Division of this latter cell forms a multicellular tissue (endosperm) in which food is stored for the embryo. Gymnospermous ovules typically have only one integument; most angiosperms have two.

Annotated classification. Older classifications considered all seed plants to be assignable to a single division, Spermatophyta. The Angiospermae and Gymnospermae were two classes that made up the division. More recent classifications recognize that the characteristic of naked seed is not important enough to be used to tie all plants with that feature into one group. Classification of gymnosperms now recognizes four separate divisions. Groups marked with a dagger (1) are known only from fossils and have no living members.

†DIVISION PTERIDOSPERMOPHYTA

Late Devonian to Jurassic; seed plants resembling tree ferns with compound, frondlike leaves; seeds and microsporangia borne on the leaves; most stems with secondary vascular tissues.

DIVISION CYCADOPHYTA

Permian to the present; palmlike plants; leaves usually permiantly compound; diocelous; seeds borne in megastrobili until acduced megasporophylis, each bearing inwardly directed seeds (except for the living each seeds); microstrobili with microsporophylis bearing abaxial microsporangia; 11 extant

†DIVISION CYCADEOIDOPHYTA (BENNETTITOPHYTA)

Triassic (Permian?) to the Cretaceous; cycadlite plants; leaves usually pinnately compound (some entire); voules borne on the surface of a fleshy receptacle and separated by interseminal scales; microsporangia compound and borne on fingerlike structures fused at the base

*DIVISION GLOSSOPTERIDOPHYTA

Permian; trees with tongue-shaped leaves with net venation; trunks with compact conifer-like wood; seeds borne on, or associated with, leaves; microsporangia borne on tongue-shaped leaves.

DIVISION CONIFEROPHYTA

Late Carboniferous to the present; woody plants, usually trees, with simple leaves; wood compact; microstrobilus bearing microsporophylls with elongated abaxial microsporangia; seeds borne on megastrobili; ovule with a single integument.

+Class Cordaitopsida

Mississippian to the Permian (or perhaps into the Mesozoic); trees; leaves elongated, strap-shaped; wood compact, coniferlike; fertile shoots slender and elongated with fertile buds borne in the axils of reduced leaves or bracts.

Class Coniferopsida

Late Carboniferous to the present; mostly trees; leaves scalelike, needleik, or flat and bladelike; wood compact; microstrobili with reduced microsporophylls with abaxial sporangia; megastrobili usually bearing woody ovulferous scales derived from flattened dwarf branches; seeds borne on the upper surface; 50 general.

Class Taxopsida

Triassic to the present; trees or shrubs; leaves needlelike; microstrobili with microsporophylls bearing abaxial microsporrangia; seeds not in megastrobili but terminating dwarf shoots and surrounded by a fleshy aril; 5 genera.

DIVISION GINKGOPHYTA

Permian to the present; dioecious trees with fan-shaped leaves; bilobed or with more lobes, especially in fossil forms; microstrobili borne among leaves on dwarf shoots; ovules on stalks borne among leaves; I extant genus.

DIVISION CNETOPHYTA

An artificial group containing 3 orders: Ephedrales, shrubs with reduced leaves and jointed stems; Welwitschiales, plants with a massive, fleshy stem bearing 2 large, leathery, strapshaped leaves; and Gnetales, vines, shrubs, or trees with flattened angiospermoid leaves.

Critical appraisal. The classification presented above emphasizes that all gymnospermous plants are not closely related to each other. The characteristic of naked seeds was apparently derived among seed plants more than once. The fossil record indicates that the seed-ferm-cycadophyte complex was separate from the conifer line from the very beginning. Plants called pteridosperms may not all belong together, Mesozoic forms were quite different from the Palezozoic ones. In fact, it cannot even be determined in some instances that seeds were actually borne on leaves in the Mesozoic forms. Glossopterids, in a sense, have seed-fern characters in that seeds were borne on fernike leaves (although they were entire). The wood of glossopterids, however, is more like that of conifers.

Several fossil groups were not included in this classification because their relationships are still obscure. Some of these groups are in the orders Pentoxylales, Vojnovskyales, and Czekanowskiales. (T.De.)

THE GYMNOSPERM DIVISIONS

Coniferophytes

The division Coniferophyta embraces living and fossil plants that usually have needle-shaped, evergreen leaves and seeds attached to the scales of a woody, bracted cone. Three English names—cedar, cypress, and pine—are each applied to unrelated kinds of conifers. Among living gym-

nosperm divisions, the coniferophytes show little similarity to the Cycadophyta and Gnetophyta but share several vegetative and reproductive traits with the Ginkgophyta. Coniferophytes are most abundant in cool temperate and boreal regions, where they are important timber trees and ornamentals, but they are most diverse in warmer areas, including tropical mountains.

Ginkgo

barlien gymnosperms

Variety among conifers

Diversity of size and structure. The coniferophytes are the most varied gymnosperms (Figure 4). The world's oldest trees are the 4,900-year-old bristlecone pines (Pinus longaeva) of desert mountains in California and Nevada. The largest trees are the giant sequoias (Sequoiadendron giganteum) of the Sierra Nevada of California, reaching heights of more than 95 metres and weights of at least two million kilograms (4.4 million pounds; compared to 190,000 kilograms for the largest recorded blue whale). Wherever conifers grow, especially in temperate climates, one of these species is usually the tallest tree. In fact, the very tallest trees are the redwoods (Sequoia sempervirens) of coastal California, some of which are more than 110 metres tall.

The world's smallest trees probably are also conifers: the natural bonsai cypresses (Cupressus goveniana) and shore pines (Pinus contorta) of the pygmy forests (adjacent to the towering redwood forests) of the northern California coasts. On the sterile, hardpan soils of these astounding forests, the trees may reach full maturity at under 0.2 metre (7.9 inches) in height, while individuals of the same species on richer, deeper soils can grow to more than 30 metres. Other conifers, such as the pygmy pine (Lepidothamnus laxifolius) of New Zealand, the smallest

Figure 4: Representative conifers (Top left) Male (at left and top) and female (right) cones redwood (Sequoia sempervirens); (top right) seeds and fruit, Japanese yew (Taxus cuspidata); (centre left) female cone, Araucaria cunningamii; (bottom left) fruit, totara (Podocarpus totara); (bottom right) male (top) and female (bottom) cones, iodgepole pine (Pinus contorta).

conifer, are always shrubby and may mature as shorter plants (five centimetres in height) than the pygmy cypress, but with greater spread.

Distribution and abundance. Conifers almost cover the globe, from within the Arctic Circle to the limits of tree growth in the Southern Hemisphere. At these extremes, they often form pure stands of one or a few species. The immense boreal forests (or taiga) of northern Eurasia and North America are dominated by just a dozen species of conifers, with even fewer adjunct kinds of hardwoods. The richest north temperate conifer forests are those of midlatitude mountain systems, where conifers also dominate in numbers. At lower latitudes and moderate elevations are found warm temperate woodlands and forests of pine (Pinus), oak (Quercus, a hardwood), and juniper (Juniperus), which vary in composition and density across Eurasia and North America.

Most tropical conifers are confined to cooler mountain areas where they form solid stands or grow with tropical hardwoods, while a few species inhabit lower elevations. The dammars (Agathis), for instance, dominate lowland tropical rain forests in Malaysia. Indonesia and the Philippines, where they support an important forest industry, Conifers are widespread in southern temperate regions as well, generally with less dominance than in the north. Their greatest diversity is found in the humid portions of the three southern continents, but the largest areas are occupied by semiarid open woodlands of cypress pine (Callitris) in Australia and sederboom (Widdringtonia) in southern Africa.

Conifer species are unevenly distributed. The Eurasian Distribucontinent is richest in conifers, but every region has its own endemic genera and species. The most widely distributed genera are junipers (Juniperus) and pines (Pinus), both of which cover the northern continents and extend well into the tropics. Spruces (Picea) and firs (Abies) are only slightly more restricted. Podocarpus is the most widely distributed genus on the southern continents, followed by Decussocarnus

At the other extreme, the most narrowly restricted endemic genera are Austrotaxus, Neocallitropsis, and Parasitaxus of New Caledonia, an island with the richest conifer flora in the world for its size (14 genera and 44 species). Other highly local genera include Athrotaxis, Diselma, and Microcachrys in Tasmania, Fitzrova and Saxegothaea in Chile, Sequoiadendron in California, and Metasequoia and Pseudotaxus in China. Most conifer genera fall between these extremes, with scattered distributions on one or more continents.

Economic importance. Conifers provide all the world's softwood timber, the major construction wood of temperate regions, and about 45 percent of the world's annual lumber production. Softwoods have always had many general and specialty applications. The original great cedar (Cedrus libani) forests of the Middle East were felled to float the warring imperial navies of the ancient world. The same fate later befell the tall North American white pines (Pinus strobus) that masted the dominating British navies of the 18th and 19th centuries. Medieval archers drew longbows of the elastic yew wood (Taxus baccata). Victims of war and other dead in East Asia have been buried from earliest recorded times in coffins of sugi (Cryptomeria japonica) and sanmu (Cunninghamia lanceolata), relatives of the equally decay- and termite-resistant redwood (Sequoia sempervirens) and bald cypress (Taxodium distichum). In the family Cupressaceae are the fragrant cedars. Some are still used to line the chests that protect fine fabrics and furs against insects, but the wonderful fragrance of sharpened lead pencils has disappeared as eastern red cedar or pencil cedar (Juniperus virginiana) has been superseded by tropical hardwoods

The domination of softwoods in lumber construction in northern temperate regions has been further extended by composite products such as plywood, particleboard, and chipboard. Other processed softwood products include paper and plastics derived from chemically treated wood pulp of spruces (Picea), tannins from the bark of hemlock (Tsuga canadensis), and naval stores (including turpentine) from many pines. Foods and beverages from conifers

tion

construc-

include pine nuts and gin, which is flavoured with juniper berries. Canadian balsam, from resin blisters on the bark of the balsam fir (Abies balsamea) of northeastern North America, is used as a mounting medium for microscopic preparations.

Conifers are popular ornamentals in parks, cemeteries, and other public places, as well as around private homes and gardens. Although few species are grown indoors as houseplants, the traditional Christmas tree of western Europe and North America brings the fragrance and freshness of the forest into homes during the depth of the northern winter.

NATURAL HISTORY

All conifers share a typical seed-plant life cycle with a long-lived, dominant, photosynthetic, diploid sporophyte and a reduced, transient, dependent, haploid gametophyte (Figure 5). All phases of this general life cycle vary among

Sporophyte phase. The sporophytes of all conifers are

trees or shrubs. They have a life span that ranges from a few decades to more than 4,000 years. The ecological role and way of life of this sole photosynthetic phase of the conifer life cycle varies with the size, form, and habitat of each species. Where conifers are ecologically dominant, as in the boreal and montane forests of the Northern Hemisphere, including the Douglas fir forests of western North America, they may make up 90 percent or more of all the living matter and they contribute greatly to the biosphere through photosynthesis.

Fires play an important role in many conifer forests. Most Importance conifers contain highly flammable resins. The flammability of these trees increases during hot, dry fire weather. when the water content of the living needles is drastically reduced. Few adult conifers can withstand a conflagration. The giant sequoia (Sequoiadendron giganteum) is an outstanding exception because it has insulating bark more than 50 centimetres thick.

Despite their susceptibility to fires, many conifers actually depend on these apparent catastrophes for regeneration.

Figure 5: Life cycle of the coniferophytes (A) The pollen cone differentiates during summer and fall. Pollen mother cells begin meiosis in October; meiosis becomes arrested during winter and resumes in February. (B) Pollen mother cells form tetrads of single-celled microspores. (C) One-celled stage; microspore undergoes successive stages, culminating in (D) mature, five-celled pollen grains, which usually are shed early in April (pollination), after which pollen divides into two male cells (gametes). The stages of ovule and female gametophyte development occur during March, April, and May. (E) An ovule. (F) Melosis occurs and four haploid megaspores are formed. (G) Three megaspores degenerate and one enlarges; pollination occurs. (H) The stigmatic tip grows inward, drawing pollen in; the megaspore divides without cell-wall formation (I) Cell-wall formation after hundreds of nuclei have formed. (J) The large egg cell fills the archegonium before fertilization. (K) After fertilization, nuclei divide. (L) Cell walls form. (M) Primary suspensor cells elongate, forcing embryo (lower) tier through archegonial wall (N) Elongation of suspensor cells and embryonal tube cells pushes embryo deep into female gametophyte tissue. (O) A section through the seed shows a dormant embryo embedded in

the female gametophyte.

The zygote

In such fire-dependent forests (including giant Sequoia groves. Douglas fir forests, boreal forests, low latitude pine forests, and Australian cypress pine woodlands), the dominant conifers are unable to regenerate among the more shade-tolerant species that grow up around them with time. Fires clear the understory to bare soil, stimulating the germination and establishment of seeds. Most of these species have cones that protect the seeds from the worst of the fire and then open to scatter them on the ash-fertilized seed bed. In the boreal forests of Eurasia and North America or in the pine forests of the southeastern United States, the cycle of fires and regeneration may repeat itself every 80 to 120 years, while the giant Sequoia is a firedependent successional species with individuals that can live for more than 3,000 years.

Contribution of flooding

At the other extreme are flooded swamp forests of hald cypress (Taxodium) in the southeastern United States and shuaisuong (Glyptostrobus) in southeastern China, Reproduction of these trees is as attuned to flooding as that of fire species is to scorched earth. Their seeds have air and resin pockets that allow them to float away to slightly raised areas revealed by receding floodwaters.

Without extremes of fire and flood, mesophytic species living in temperate and tropical mixed forests may dominate or grow scattered among other trees. The conifers with broad, flat blades rather than needle leaves almost all live in moist forests, as do most species whose seeds have fleshy structures that attract birds or small mammals.

Gametophyte phase. The gametophytes of conifers, like those of other seed plants, live out their brief, nonphotosynthetic lives almost entirely within the spore wall. All of their nutrition is derived from the parent sporophyte. The female gametophyte is never released from the tree until the seed matures. The male gametophyte is briefly separated from the sporophyte when pollen is released into the wind. These pollen grains contain an immature male gametophyte enclosed and dispersed in the microspore wall (Figure 5). In the Pinaceae, three successive divisions of the microspore produce a four-celled pollen grain within the microsporangium. It has two tiny prothallial cells (the last body remnants of the old free-living gametophyte). a tube cell, and a generative cell. After pollination, the tube cell develops the pollen tube and the generative cell divides to form a sterile cell and a spermatogenous cell. Prior to fertilization, the spermatogenous cell divides again to produce two male gametes. Other conifers share the later phases of male gametophyte development with the Pinaceae, but vary in the number of prothallial cells, from none in Cephalotaxus, Sciadopitys, Cupressaceae, and Taxaceae to as many as 40 in Agathis of the Araucariaceae, which has the most complex male gametophytes among the seed plants. Unlike the ovule (megasporangium), which houses a solitary female gametophyte, each microsporangium produces hundreds or thousands of pollen grains.

Megaspore maturation

The pollen

grain

The female gametophytes of conifers are more massive and complex than their male counterparts and basically resemble gametophytes of Ginkgo and the cycads. The life history of the female gametophyte begins with a protracted series of free nuclear divisions in the megaspore. At the end of these divisions, there may be up to 2,000 nuclei in a thin layer of cytoplasm pressed against the megaspore wall by a giant central vacuole. Cell walls then form between adjacent nuclei and gradually extend into the central vacuole until the entire gametophyte is filled with radially elongated alveolar cells that are equivalent to the prothallial cells of the pollen grain. This stage is followed by the appearance of archegonia at the micropylar end of the ovule. One to eight archegonia are usual in the female gametophyte of conifers, but there may be up to 200 in some species, each of which can produce an embryo if fertilized. Each archegonium has a single huge egg cell capped by a ventral canal cell and separated from the micropylar surface of the gametophyte by a short neck made up of one or two layers of neck cells. The archegonial end of the female gametophyte usually protrudes from the megaspore wall, which might otherwise prevent pollen tube penetration and fertilization.

Pollination. Like Ginkgo, but unlike at least some cy-

cads and gnetophytes, all conifers are pollinated by wind. Pollen may be produced in enormous quantities, particularly by species of true pine (Pinus), which can blanket the surface of nearby lakes and ponds with a vellow scum of pollen. The pollen grains of many Pinaceae and Podocarpaceae have air bladders, which orient them in a pollination droplet exuded by the ovules so that, when this droplet is withdrawn back into the ovule, the pollen tube will penetrate the nucellus to the archegonium. The pollen grains of families that lack prothallial cells are more or less spherical, lack air sacs, and can extend a pollen tube anywhere on their surface so that precise orientation is unnecessary. Some conifers lack a pollination droplet mechanism. Douglas fir pollen grains land on an enlarged, stigmalike growth of the micropyle, whence the pollen tubes grow into the nucellus and archegonium. The pollen grains of the Araucariaceae land on the scales of the female cone, and the pollen tubes reach the micropyle by burrowing into the cone scales.

Fertilization and embryogeny. After passing through the nucellus, the pollen tube presses between the neck cells of the archegonium and ruptures to release the tube nucleus. sterile cell, and the two male gametes (sperms). The ventral canal cell seems to help the male gametes enter the egg. One of the sperms fertilizes the egg nucleus to form the zygote, the first cell of the new sporophyte generation.

The conifer zygote has fewer free nuclear divisions than do Ginkgo or the cycads. While many divide twice to form four free nuclei in the centre of the egg cytoplasm, there may be from zero to six free nuclear divisions. The nuclei usually move away from the micropyle, and cell-wall formation accompanies further cell divisions. The embryo develops and is fed by the nutritive tissue of the female gametophyte. The embryo rapidly enlarges at the expense of the maternal tissue and initiates typical sporophytic organization, consisting at maturity of a single axis with a root apex at one end and a shoot apex at the other, surrounded by two to eight cotyledons.

Germination. The mature seed consists of the dormant embryo embedded in remnants of the female gametophyte and megasporangium (nucellus) and surrounded by a seed coat. The seed coat of conifers is similar to that of other gymnosperms, developing from an integument with three distinct layers. Only the hard middle stony layer is evident in most conifers, protecting the embryo between seed release and germination. The outer fleshy layer is most prominent in those conifers, such as Cephalotaxaceae and some Taxaceae, whose seeds are dispersed by animals. The inner fleshy layer functions in the early development of the ovule, but persists only as a thin, papery membrane in the mature seed.

Germination proceeds immediately upon dispersal to a suitable site in many tropical conifers, but most cool temperate species require a winter period of cold, moist stratification before they will germinate. After the embryo absorbs water, a seedling root breaks through the seed coat and turns down into the soil.

The stem below the cotyledons elongates and lifts them above the ground. As the cotyledons begin to photosynthesize, they produce the energy needed for the early growth of shoots. The seedling shoot is densely clothed with needle-shaped juvenile leaves for a varying time until adult foliage forms; some cedars of the family Cupressaceae produce their first flattened side shoots within just a few nodes, while the longleaf pine (Pinus palustris) of the southeastern United States remains in a juvenile "grass" stage for years.

FORM AND FUNCTION

The basic organization of the conifer sporophyte resembles that of other seed plants. The four main organs (stems, leaves, roots, and sporangia) are all usually distinct from one another and have well-defined physiological functions. The considerable variation that occurs in these organs are commensurate with the varied environments in which the different species grow.

Stem. Stems raise the photosynthetic leaves into the light and provide a channel for nutrients between the leaves and the roots. Most of the diameter of mature conifer function

Bark

stems consists of secondary xylem (wood) produced by the vascular cambium, a permanent cylinder of dividing cells that lies just inside the bark. Because the growth of most conifers is cyclic, the wood generally consists of distinct growth rings. These are delimited by the juxtaposition of small dark cells from the end of a growing season with larger, lighter cells that mark resumption of growth. In temperate conifers, these rings correspond to annual growth flushes since no wood is formed during winter dormancy. Tropical species may lack this correspondence unless their habitat has strong seasonal variation in rainfall. Otherwise, they may have more than one growth ring in a year, each accompanying a new flush of leaves and branches

The wood of conifers is generally more uniform and simpler in structure than that of flowering plants. One type of cell, the tracheid, serves both to transport water and to support the trunk so that conifers lack the more textured wood associated with the mixture of vessel elements and fibres in hardwoods. The wood may have longitudinal resin canals lined with living cells, but most of its living cells are found in the rays that extend horizontally from the centre of the stem to the vascular cambium. The pits, the tiny thinnings that connect adjacent wood cells, are quite varied among conifer families and genera and are one of the chief features used to identify conifer woods.

The bark that clothes the trunks may be thin, smooth, and flaky, peeling annually to reveal fresh bright colours, as in the lacebark pine (Pinus bungeana) of China and the tecate cypress (Cupressus guadalupensis) of southern and Baia California, or it may accumulate in broad, colourful plates, as in the ponderosa pine (Pinus ponderosa) of western North America, or as thick, fireproof, fibrous ridges on the giant sequoias (Sequoiadendron giganteum). The practiced eve can distinguish different species of cooccurring conifers by their bark alone.

Some conifers have transient special determinate twigs called short shoots that carry most of the photosynthetic leaves. In the bald cypress (Taxodium) and dawn redwood (Metasequoia), these short shoots look like double-sided combs and are shed each fall, to be followed by new ones in the same spots on the branches when growth resumes the following spring. The short shoots of pine (Pinus), the bundles of two to five (rarely one or eight) needles, are retained for up to 20 years but are finally shed and almost never grow out as branches. In contrast, the peglike short shoots of larch (Larix) and true cedar (Cedrus), like those of Ginkgo, are permanent, elongating slowly and producing new needles each year. The flattened sprays of branchlets of cedars in the family Cupressaceae may act like short shoots, falling intact after a relatively brief life, or they may provide the framework for further branching.

The strangest conifer shoots are the phylloclades that give the celery pine (Phyllocladus) its name. These flattened branches look like fern fronds, are green, and are the main photosynthetic organs of the tree. The true leaves are tiny scales that contribute little to overall food production.

Leaves. Leaves are specialized photosynthetic organs. The varied leaves of conifers are attached singly along the stems in a helical pattern or in opposite pairs or trios. Many Cupressaceae and a few other conifers have reptilian scale leaves only a few millimetres long. Diverse needleand claw-shaped leaves range in length from about one centimetre in many conifers to more than 30 centimetres in some species of pine. Broad, flat, oblong blades up to 30 centimetres long occur in Agathis and some species of Decussocarpus from East Asia, and the monkey puzzle tree (Araucaria araucana) of Chile has hefty triangular wedges. The notched needles of the Japanese umbrella pine (Sciadopitys verticillata) are the oddest leaves among living conifers. They can be needlelike phylloclades or a pair of longitudinally fused needles. The largest coniferophyte leaves were those of the extinct genus Cordaites, with great paddle- or strap-shaped leaves up to one metre long and 15 centimetres wide.

Most conifer leaves, whatever their shape, minimize water loss. The reduced surface area of the scale- to needleshaped leaves is an obvious example, but even the broader forms often have a thick, waxy coating that makes them waterproof. The gas-exchange openings of the leaves (stomates) are usually confined to a pair of narrow bands on the undersurface and are deeply sunken into chambers that separate them from direct contact with the dry air surrounding the leaf.

Roots. Roots gather water and mineral nutrients from the soil and anchor and support the above-ground portions. Most conifers have rather shallow, if wide-spreading, root systems, making the trunks highly susceptible to wind and surface disturbance. Even the largest conifers are no exceptions, and many of the individual giant sequoias (Sequoiadendron giganteum) in national parks in California are ringed by fences to reduce damage to the roots by the footsteps of millions of admiring visitors. The roots are the least-studied parts of the conifers but appear to be relatively uniform throughout the group. The specialized roots (called haustoria) by which the only parasitic conifer, Parasitaxus ustus, attaches to the roots of its conifer hosts are an exception, but the oddest root structures are the "knees" of bald cypresses (Taxodium distichum), conical masses of woody tissue that emerge from the swamp waters around each tree. They probably help aerate the roots, which need oxygen to survive and function.

The fine feeding roots of conifers, like those of many flowering plants, do not work alone. They get a boost in their work by associating with specialized fungi whose structural filaments (hyphae) intermingle with them to form mycorrhizae. There are two distinct types of mycorrhizal associations among the conifers. The majority of species have vesicular-arbuscular mycorrhizae, called endomycorrhizae because the fungal hyphae actually penetrate the cells of the roots. All of the Pinaceae, and only the Pinaceae, have the other kind of root symbiosis, called ectomycorrhizal because the fungi sheath the rootlets and hyphae pass between the outer root cells without penetrating them. Each year, new roots grow out from the sheath and are recolonized only when the fungi later resume active growth. Ectomycorrhizal fungi reproduce through the attached mushrooms that are seen sprouting in pine forests, whereas endomycorrhizal fungi do so underground.

Strobili. The sporangia of vascular plants are technically asexual, but in the seed plants, because the gametophytes are wholly dependent upon the sporophyte and the female gametophyte even remains within the megasporangium, sexual terminology is extended to the sporophyte and sporangium-bearing organs. In all coniferophytes the organs containing microsporangia ("male") are separate from those bearing megasporangia ("female"). and in Cephalotaxus, some junipers (Juniperus), and the family Taxaceae these are found on different individuals.

The microsporangia of all conifers are attached to the scales of a simple pollen cone, or microstrobilus. The pollen cones usually consist of thin, parchmentlike scales (microsporophylls), each carrying two or more microsporangia on the lower surface. The number of scales and their size is quite variable, so that the overall length of the microstrobilus ranges from about two millimetres in some cypress (Cupressus) species to more than 20 centimetres in some Araucaria species.

Wide variations in the female (megasporangiate) reproductive structures among the conifers are the main basis for their classification. Most living conifers have a seed cone that is interpreted as a compound strobilus; each cone scale, inserted in the axil of a bract, is equivalent to an entire simple pollen cone. Fossil evidence shows how each ovule-bearing dwarf shoot of ancestral conifers was reduced and fused to form a single cone scale. Like the leaves, the bracts and scales are spirally arranged or occur in pairs or trios on the axis, and modern conifers have at least some fusion between each bract and its scale. The bracts and scales, or combined scales, vary in texture from woody to leathery, or even fleshy in bird-dispersed junipers (Juniperus) and the family Podocarpaceae. The number and size of cone scales varies widely among conifers, leading to seed cones that range from three mil limetres long and less than one gram in Microbiota of the Amur region of Russia to more than 40 centimetres long in the sugar pine (Pinus lambertiana) of California

Associations

Variations among megasporangia

Leaf function and more than 2.2 kilograms in some araucarians and the coulter pine (Pinus coulteri) of California.

The megasporangiate strobili of Cephalotaxus and most Podocarpaceae have the same basic structure as other conifer cones, but are so reduced and dominated by their much larger seeds that they do not look like cones. Even greater modification in the family Taxaceae has completely eliminated any trace of strobilar organization, and the solitary seeds sit at the tip of a short branch in a fleshly aril, a cup-shaped outgrowth of the seed stalk.

CLASSIFICATION

Distinguishing taxonomic features. Extant conifers differ from other gymnosperms in combining simple pollen cones with compound seed cones (or solitary terminal seeds in family Taxaceae). Although not possessed by all species, only conifers have needle leaves (of a variety of shapes) and pollen with bladders. Some other features, although not exclusive to coniferophytes, are also more common in them than in other gymnosperms. These include flattened, winged seeds (also in Welwitschia), scalelike foliage leaves (also in Ephedra), and the growth habit of a normal tree or shrub (also in Ginkgo)

Annotated classification. With more than 50 genera and 550 species, classification of the extant coniferophytes remains controversial. Disagreements exist throughout the classification, so that the numbers of orders, families, genera, and species are all disputed. The classification outlined here reflects current opinion for living conifers but simplifies extinct groups because the number of families to be recognized among the fossils is so uncertain. Extinct groups are indicated by a dagger (†).

†CLASS CORDAITOPSIDA

Paleozoic; strap-shaped leaves, up to 1 metre long, much larger than those of true conifers; both pollen and seed cones were compound and open, each bract with an axillary branch bearing numerous scale leaves surrounding pollen sacs or ovules; generally considered the ancestors of the Coniferales.

CLASS CONIFEROPSIDA

Contains coniferophytes; ovules attached to the scales of a condensed compound seed cone; families defined by seedcone structure

†Families Walchiaceae and Voltziaceae

Paleozoic and Mesozoic; show many stages in the transformation of the seed-bearing dwarf shoots of cordaiteans into the unified, flattened seed scales of modern conifers; foliage resembled that of araucarians; include Walchia, Voltzia, and Voltzionsis.

†Family Cheirolepidiaceae

Mesozoic; scales shed from the cone together with the seeds; large bracts remain attached to the axis in a semblance of a complete cone; distinctive pollen, called Classopollis; foliage resembles that found in the modern Cupressaceae; great variety of life-styles.

Family Pinaceae

Largest and most widespread and abundant modern conifer family in the Northern Hemisphere; woody, usually thin, cone scales carry two winged seeds and are fused to the bracts only at their bases; bracts usually hidden by the scales in mature seed cones but may be prominently exserted in some species; leaves are most often needlelike and spirally arranged, either singly or in clusters; pine (Pinus), spruces (Picea), firs (Abies), and larches (Larix) are all found across the Northern Hemisphere, while Douglas firs (Pseudotsuga) and hemlocks (Tsuga) are restricted to North America and Asia, Cathaya, Keteleeria, and Pseudolarix are restricted to China, and the true cedars (Cedrus) occur from Morocco to the Himalayas; 10 to 12 extant genera: about 200 species.

Family Araucariaceae

From Triassic; massive seed cones with a single large seed on each cone scale; highly reduced scales completely fused to the much larger bracts; species of Araucaria have branches densely clothed with prickly, spirally arranged, clawlike-towedge-shaped leaves; dammars (Agathis) have well-separated, oppositely arranged oval or oblong leaves; found in South America, Southeast Asia, and Australasia; 2 extant genera and 30 to 40 species

Family Sciadopityaceae

Umbrella pine (Sciadopitys verticillata) usually included in the Cupressaceae, but recent work confirms its isolation from that family; seed cones superficially resemble those of the giant sequoia (Sequoiadendron giganteum), but the equal-sized scales and bracts fused for only about two thirds of their length, each having 5 to 9 seeds; foliage consists of whorls of about 15 to 20 double needles separated by stem segments with spirally arranged, nonphotosynthetic scale leaves; endemic to Japan.

Family Cupressaceae Although species of this family are traditionally divided between two families, Cupressaceae for the cypresses (Cupressus) and similar genera and Taxodiaceae for the much more varied genera allied to the bald cypress (Taxodium) and redwood (Sequoia), present evidence shows that all belong to a single family; scales of seed cone intimately fused to the bracts; scale complexes vary in texture, shape, and arrangement on the cone; most have 3 to 5 seeds per scale, but the number ranges from 1 to about 20; leaves vary in shape from scales to clawlike or needlelike and are spirally arranged or in opposite pairs or whorls of 3; several genera, usually referred to as cedars (such as Calocedrus, Chamaecyparis, Libocedrus, and Thuia) have flattened sprays of frondlike branches closely covered with scale leaves; considerable diversity in both the Northern (18 genera) and Southern (11 genera) hemispheres; 50 or more species of junipers (Juniperus) are widespread, exceeding even the pines in their coverage of the Northern Hemisphere; other genera include Athrotaxis, Callitris, Cryptomeria, Cunninghamia, Dis-elma, Fitzrova, Metasequoia, Microbiota, Neocalitropsis, Sequoiadendron, and Widdringtonia

Family Podocarpaceae

Seed cone is reduced, with 1 to few highly modified, brightly coloured, fleshy scales, each called an epimatium and surrounding a single seed; most with spirally arranged, yewlike needles, but scale leaves and opposite, broad, oblong blades (up to 30 cm long and 5 cm wide) are also found; about 130 species in 6 to 18 genera, including Decussocarpus, Lepidothamnus, Microcachrys, Parasitaxus, Phyllocladus, Podocarpus, and Saxegothaea

Family Cenhalotaxaceae

Seed cones highly modified with a few opposite pairs of small bracts, each with a greatly reduced scale remnant strongly dom-inated by a pair of ovules; only 1 ovule develops into a large seed with a fleshy seed coat; leaves are large yewlike needles carried in opposite pairs; found in East Asia, the plum yews (Cephalotaxus) are the second smallest and most local extant conifer family; 1 genus and 4 to 7 species.

Family Taxaceae

Solitary ovules borne at the end of a dwarf shoot bearing densely spiraled scale leaves; mature seeds surrounded by a fleshy aril and may also have fleshy seed coats; Taxus seed is highly toxic; pollen cones and flattened, needlelike leaves are more like those of other conifers than are their seeds; widely distributed in the Northern Hemisphere, while Torreya is found in restricted areas of both North America and East Asia, Amentotaxus and Pseudotaxus are localized in China, and Austrotaxus is endemic to New Caledonia; 5 genera and 16 species often segregated into an order separate from the Coniferales because of absence of seed cone. (J.E.Ec.)

Cycadophytes

Although some botanists prefer to restrict the term cycadophyte to the members of the division Cycadophyta, three groups of primitive seed plants are discussed here, of which the seed ferns (division Pteridospermophyta) and cycadeoids (division Cycadeoidophyta) are represented only by extinct forms. A third order, Cycadales (cycads), is today represented by 10 or 11 living genera and some 130-160 species.

The cycadophytes encompass a diverse collection of mostly extinct primitive seed plants that probably had their origins among the progymnosperms of the Devonian period (408 to 360 million years ago), possibly among a primitive, long-extinct group of non-seed-bearing plants, the Aneurophytaceae, in which disposition of fertile structures and patterns of branching bear some resemblance to those of seed ferns.

GENERAL FEATURES

Diversity. Seed ferns. A number of lines of seed-bearing gymnospermous plants are discernible among fossil plants of the late Paleozoic era (570 to 245 million years ago) and early to middle Mesozoic era (245 to 66.4 million years ago). Among them a rather loose assemblage of forms, referred to as seed ferns, or pteridosperms, is well represented. The Carboniferous period (360 to 286 million years ago) especially has been called the "age of ferns" because of the abundance of fossilized fernlike leaves.

Figure 6: Representative cycadophytes om (Medulfosa noei, Cycadeoidea, and Williamsonia) A.S. Foster and E.M. Gilfo seman and Cc., Medulfosa noei redrawn from W.N. Stewart and T. Delevoryas, reduction to Paleobotary, copyright © 1947 by McGraw-Hill, Inc., (Zamia skinni

In time, many of these "ferns" were recognized as seed plants, and it has been determined that seed ferns were a dominant vegetation in the late Paleozoic. Seed ferns generally are characterized as having been slender trees or, in some cases, woody, climbing vines, but generally with large, fernlike fronds.

Seed-fern

foliage

Characteristic seed-fern foliage consisted of large compound leaves composed of second- and sometimes thirdorder branches (Figure 6). The latter bore fernlike leaflets, hence the name seed fern, although they are only remotely related to true ferns. Seed-fern stems generally possessed variable amounts of soft, loose wood and relatively large zones of cortex and pith; in this respect they resembled the stems of cycads and differed considerably from the stems of conifers, which have compact wood and relatively small

zones of cortex and pith. Reproductive organs of seed ferns were borne upon the foliage; single ovules and seeds were borne in place of pinnae, while male organs often occurred as compound pollen organs composed of partially or wholly united microsporangia. As in other gymnosperms, the ovule consisted of one megasporangium within a single integument. It is believed that, as the reproductive cycle progressed, the megasporangium, also called the nucellus, probably gave rise first to a quartet of megaspores. One of these then produced a large fleshy female gametophyte bearing several archegonia, each with a single egg. Following pollination and fertilization, the ovule developed into a seed with an embryo nested in the fleshy female gametophyte, which served as a food source during germination and seedling growth.

Cycadeoids. Although a few groups of pteridosperms persisted from the late Paleozoic era well into the Mesozoic, the common cycadophytes of the latter ages were members of the Cycadeoidophyta (also known as Bennettitophyta). They are well represented in the later Mesozoic era, well into the Cretaceous period (144 to 66.4 million years ago), by members of the genus Cycadeoidea, which had rather squat, barrel-shaped, unbranched trunks and once-pinnate compound leaves (Figure 6). The stems were armoured with the persistent bases of leaves; internally there was a thick pith surrounded by a narrow zone of vascular tissue from which vascular strands extended directly into the leaf bases. The fossilized trunks of these plants display scattered strobili among leaf bases of the characteristic armour. Fossil cycadeoids are widespread but are especially abundant in the Black Hills region of South Dakota.

Earlier in the Mesozoic era, cycadeoids of a more slender, branching form, exemplified by Williamsonia, were abundant (Figure 6). As in Cycadeoidea, the fronds were single pinnate compound leaves.

The feature that set the cycadeoids apart from other cycadophytes was the compound strobili, which some, but not all, possessed. These strobili were composed of both male and female sporophylls, in some cases subtended by a system of bracts. Although often described as flowerlike and indeed sometimes depicted as having a floral, rosette form, cycadeoid "flowers," unlike true flowers (found in the angiosperms), were composed of sporophylls bearing "naked" (i.e., gymnospermous) ovules. They are not now considered to have given rise to any group of the true angiospermous flowering plants.

Although cycadeoids flourished for millions of years, and must therefore be considered as a highly successful line of plants, they eventually became extinct in the Cretaceous period.

Cycads. The living cycads are for the most part palmlike, cone-bearing plants, generally of low stature (Figure 6). Although few genera, species, and individuals exist, they are extremely important plants in terms of the information that can be gained from studying them. Their reproduction is very primitive in that they rely on flagellated, motile male gametes (spermatozoids), a feature linking them with other plants fertilized by motile flagellated sperm (zooidogamous), such as ferns, club mosses, and other vascular cryptogams. Without knowledge of fertilization in the cycads and Ginkgo, it is highly unlikely that scientists would have more than remote theories as to the reproductive modes of seed ferns and other extinct groups of seed plants. Research on cycad reproduction is also providing information on the early origins of insect pollination, long thought to have evolved along with the relatively more recent angiosperms, or flowering plants.

Distribution and abundance. Seed-fern fossils are found in both the Northern and Southern hemispheres, but many more have been described from Europe and North America than from other regions, primarily because many of the paleobotanical studies are concentrated there. Pteridosperms have been identified in Australia and India in recent years. In both hemispheres, seed ferns are common in coal measures, from which it may be inferred that, ecologically, they were plants of warm humid climates.

Abundant fossils of cycadeoids and cycads have been discovered and described from the Mesozoic era. The oldest remains of undisputed cycads date from the Triassic

Cycadeoid features

Fossil

period, 245 to 208 million years ago (e.g., Leptocycas, Antarcticycas), but some problematic forms (e.g., Primocycas, Archaeocycas) are of Paleozoic age. Most Mesozoic cycads resembled extant genera (e.g., Cycadites, Pseudocycas. Cycadospadix), and some are referred to present genera (e.g., Macrozamia zamoides, Zamia coloradensis). Fossil forms have been found in many places where they are now extinct (for example, Greenland, Antarctica, Alaska, Argentina, France, Austria), testifying to much milder climates in now temperate and even subarctic

Ten genera of cycads are widely recognized. There are three endemic Australian genera-Macrozamia (14 species), Lepidozamia (two species), and Bowenia (two species); four American and Caribbean genera-Microcycas (one species), Zamia (about 35 species), and Ceratozamia and Dioon (10 species each); and two African genera-Encephalartos (about 40 species) and Stangeria (one species). The genus Cycas, with about 24 species, is the most wide-ranging, extending from eastern Australia westward across the Pacific and Indian oceans to Madagascar and the east coast of South Africa. In addition to the above well-known genera, a recent collection of cycad specimens from northwestern Colombia included a new genus now described under the name Chigua, Chigua reveals features hitherto undescribed in any American genus or species, for the specimens, which in most respects resemble Zamia, are unique in having leaflets with midribs and lateral veins, a characteristic formerly known only in Stangeria.

Ecology and habitats. Cycads are plants of subtropical habitats, where they occupy a variety of ecological situations ranging from rain forests, to mesophytic savannas, to near-desert scrublands. Now nowhere abundant in nature, wild populations of cycads in many regions are endangered. Only recently have Australian cycads been removed from the noxious weeds list (because of certain toxic properties dangerous to cattle) to a protected status.

NATURAL HISTORY

"Func-

conifers"

tional

Sporophyte phase. As in other gymnosperms, the large, woody plant is the sporophyte phase of the life cycle and typically is diploid in chromosome number. All cycads may be called "functional conifers," for all species bear strobili; these strobili are of a simple type, unlike those of true conifers, which bear more complex, compound strobili. It is not considered that this feature of cycads indicates anything other than a parallelism in evolution.

Cycad males and females are morphologically alike except for their sporophylls. Male sporophylls (microsporophylls) are spatulate organs bearing large pollen sacs (microsporangia) in clusters (sori) on their lower (abaxial) surfaces (Figure 7). Up to 200 cubic centimetres of pollen are produced by a single cone of Cycas rumphii, and some other species produce similar volumes. It was once estimated that one pollen cone of Encephalartos produced seven billion pollen grains having a total volume of about 300 cubic centimetres. While this enormous production

Figure 7: Male and female reproductive structures of

(A) Microsporophylls and microsporangia of two cycads (B) Megasporophylls and ovules of two cycads.

would seem to be consistent with a system of wind dispersal, observations and controlled experiments strongly suggest that in most, or perhaps all, cycads, insect pollen vectors are necessary for effective pollination of ovules. The Mexican cycad Zamia furfuracea, for example, is pollinated by a small snout weevil, Rhopalotria mollis, which lays its eggs and completes its reproductive cycle in male cones. Emerging adults then carry pollen to female cones and pollination of ovules and subsequent fertilization of

eggs occurs. Gametophyte phase. As in all other gymnosperms, male Gametoand female sporophytes of cycads produce, respectively, male and female gametophytes. The male gametophyte phase of the life cycle begins in the microsporangium with meiotic production of tetrads of microspores followed by the division of each haploid microspore into a three-celled pollen grain. Because it is multicellular, the pollen grain is considered to be an immature male gametophyte, but its further development into a sexually mature organism occurs only after it has been shed from the microsporangium and transported as a pollen grain to a megasporophyllspecifically, to an ovule, within which the male gametophyte grows to maturity

Concurrently with pollen development, the ovule differentiates, and at the time of pollination it consists of a large megasporangium (nucellus) enclosed within a fleshy integument. At this time an opening at its distal end (the micropyle) permits pollen to enter the ovule. Over the next three to five months, the male gametophyte develops into a haustorial pollen tube, which eventually penetrates the nucellus and partially projects into an archegonial

Meanwhile in the nucellus, a single megaspore mother cell undergoes meiosis, forming a tetrad of haploid megaspores, only one of which survives to divide mitotically many times and form a large fleshy female gametophyte. The female gametophyte grows at the expense of nucellar tissue but remains enclosed within its remains. At its micropylar end, this gametophyte develops from one to many archegonia (commonly one to six in most cycads and up to 100 in Microcycas, only five or six of which are functional). Each archegonium is composed of a quartet of neck cells beneath which is a large egg. This egg is the largest known in the plant kingdom, being about three millimetres in length.

The development of male and female gametophytes is synchronized, and during the final week or so before fertilization, the male gametophyte forms large, multiflagellated spermatozoids. In all species but Microcycas, there is just one pair of sperm per pollen tube; in Microcycas, spermatozoids number about 12 to 16 per tube. What actually triggers sperm release into the archegonial chamber is unknown, but when it happens, the spermatozoids quickly move through the archegonial neck into the egg cytoplasm. One sperm loses its flagellature, and fusion of egg and sperm nuclei takes place. Subsequently, the zygote forms a single large embryo, other eggs meanwhile aborting. In the Florida cycad, Zamia pumila, the reproductive cycle occurs over a period of about 14 months, cones first becoming visible in October, pollination occurring in December, fertilization taking place in late May and early June, and embryogenesis and seed maturity being completed the following December. Similarly slow reproduction is typical also for other genera and species.

As far as is known, cycad seeds have no dormant period or after-ripening requirements and in some cases actually begin germinating while still attached to sporophylls. Possibly some germination inhibitors are present in the outer fleshy layer of the seed, because its removal often accelerates germination, and treatment with scarifying agents also may enhance germinability. The germinating embryo remains attached to the female gametophyte for as long as two years, absorbing nutrition through its cotyledons, which remain embedded in the female gametophyte. The seedling rapidly develops a flesh taproot and root growth.

The outer layer of the seeds of Cycas circinalis and C rumphii are thick and somewhat fibrous, and experiments which show them to be capable of long immersion in brine suggest that long-distance dispersal by ocean currents

Seed development

Stem size

may account for the presence of these species on remote Pacific islands. Little is known of natural seed dispersal of other cycads, but their bright red seed coats suggest a visual signal to animals. Mockingbirds, squirrels, and coatis are reported to disperse them. In general, however, cycad seeds, which are rather heavy, are poorly dispersed, and most germinate at the base of the parent, where they often languish and die.

FORM AND FUNCTION

Stem. Stems of cycads are characteristically short and stout, and while most genera have some species with subterranean, tuberlike stems, a majority of species are arborescent (Figure 6). The taller cycads include Microcycas calocoma (up to 10 metres high), Macrozamia moorei (up to 18 metres), Dioon spinulosum (up to 16 metres), Lepidozamia hopei (up to 18 metres), and Encephalartos altensteinii (up to 20 metres), but most of the arborescent (treelike) species have trunks only two to three metres high. The stems of most arborescent species are covered with an armour composed of the hardened leaf and cataphyll bases, but internally they are rather soft and fleshy, with a thick parenchymatous cortex, a large pith, and scanty woody tissue (Figure 8). In most cycads, the woody tissue is on the order of five to 10 millimetres wide, but Dioon spinulosum has an exceptional amount of wood, in some specimens up to 10 centimetres wide. This may constitute evidence of the primitive nature of the genus, because seed ferns also generally had stems with considerably more wood than those of most living cycads. Even in Dioon, there is no evidence of annual growth rings, so that age estimates must rely on other evidence, most often on counts of the whorls of leaf scars, which can be related to annual or biennial production of new leaf flushes. On this basis, it has been estimated that some cycads (notably Dioon and Macrozamia) may be as much as 1,000 years

Figure 8: (A) Cone domes in a longisection of a Dioon stem. (B) Diagram of sympodial cycad stem architecture with axes much lengthened. (C) Diagram of a five-year-old stem apex of Zamia, illustrating lateral growth (arrow) resulting from action of a primary thickening meristem. (D) Cross section of a stem of Zamia showing girdling leaf traces.

old however, it is doubtful that most cycads are that old. Species of Macrozamia, Encephalartos, and Cycas often develop additional cylinders of vascular tissue, apparently formed from vascular cambia originating in the cortex. The result is a condition in which concentric rings of xylem and phloem are present, often two or three, but in exceptional cases, as many as 14. The xylem of cycad seedlings and that of some subterranean stems (Stangeria, Zamia) is composed of scalariform tracheids; in older stems, the tracheids exhibit primitive, multiseriate, bordered pits.

Another feature of those cycad stems in which terminal cones are produced is the presence of "cone domes" in the pith (Figure 8A). In longitudinal sections, the pith appears partitioned horizontally at intervals by vascular tissue. Each cone dome represents the displacement of a cone axis to one side as a result of the initiation and

growth of the new vegetative apex.

The cycad stem grows from the tip (apically); the only lateral buds and branches are those unusually placed (adventitious) stems, whose buds arise by regeneration after the apical growth tissue (meristem) has been destroyed or as a result of wounding. Apical dominance and lack of branching bring about an apparent single-stemmed (monopodial) growth form, so that older plants become quite palmlike. This appearance, however, is deceptive. because in more than half the genera the apical meristem is converted from a vegetative to a reproductive function in that it is transformed into a strobilus (cone). A new vegetative meristem arises to one side of the cone meristem; subsequent growth and enlargement further displace the cone or cones to the side, so that the monopodial appearance is maintained even though the type of growth is actually sympodial (Figure 8). Only members of three genera (Macrozamia, Lepidozamia, Encephalartos) have cones initiated to the side and are truly monopodial; the remaining eight are considered sympodial.

Cycads have such thick stems that rearrangements of internal vascular connectives are not externally apparent. The cycad trunk is about as thick at its crown as at its base, thus furthering the resemblance to palms. Such stems, termed pachycaulous, result as in palms from activity of a primary thickening meristem (PTM) lateral to the apical meristem (Figure 8), which produces much greater increments of cortical parenchyma than would result if only an apical meristem were present. This is an important difference between cycadophytes and coniferophytes, for in the latter there is no PTM and the stem at its apical end is relatively smaller than at its base.

A further characteristic of cycad stems not occurring in cycadeoids, seed ferns, or coniferophytes is the presence of girdling leaf traces. In cacad stems, the vascular strands follow a circuitous route to the leaf bases, which is clearly seen in cross sections of stems. Girdling leaf traces are an important means of distinguishing between cycad and cycadeoid fossils (Figure 8).

Roots. Cycad seedlings initially form a stout, fleshy taproot that persists in subterranean forms for many years but is augmented by secondary roots which also are quite thick and fleshy. The taproots, larger secondary roots, and, in some cases, underground stems, have contractile elements in the pith and cortex that draw the stem more deeply into the ground.

Branch roots are of two kinds: long-branching geotropic roots and short-branching apogeotropic roots, which are referred to as coralloid because of their irregular, beady appearance. The coralloid roots contain symbiotic cyanobacteria (blue-green algae), which fix nitrogen and, in association with root tissues, produce such beneficial amino acids as asparagine and citrulline.

The taproot does not persist long in arborescent cycads but is replaced by large adventitious roots, which obscure the basic taproot system of the seedling. In all cycads, young roots are diarch with a parenchymatous cortex and an outer cover of epidermal scales. In this aspect they also resemble seed ferns. Older roots become triarch or tetrarch, eventually developing substantial amounts of wood and an outer covering of periderm.

Leaves. The leaves of cycads are for the most part oncepinnately compound; however, in the genus Bowenia, the

Stem growth

develop-

ment

Variation in leaf structure leaves are bipinnate and quite fernlike. Stangeria also has fernlike leaves, and before cones were found to be associated with them the plant was described as a fern in the genus Lomaria. Stangeria leaves and those of the recently described Chigua are unique in possessing pinnately veined leaflets with midribs and side veins. Cycas pinnae also have midribs, but these lack side veins altogether. Pinnae of all other cycads have dichotomously branching, more or less parallel veins. The size of the cycad leaf is variable: Zamia pygmaea, the smallest cycad, has leaves about 20-30 centimetres long, while some species of Macrozamia, Lepidozamia, Ceratozamia, and Cycas have leaves three metres in length.

In cross section, the pinnae of most cycads are rather thick and sclerophyllous. The stomata are sunken and are of the type known as haplocheilic; that is, the guard cells arise directly from the mother cell, as contrasted with the syndetocheilic type, in which the guard cells are one division removed from the mother cell. The haplocheilic type is found in living conifers, pteridosperms, cycads, Ginkgo, and some others but not in the Cycadeoidea.

Sporophylls and strobili. Cycads are universally dioecious. Male plants produce pollen by leaf homologues called microsporophylls, and female plants produce ovules by leaf homologues known as megasporophylls (Figure 7). In all cycads, the microsporophylls are arranged spirally about a cone axis; in all cycads but Cycas, megasporophylls are similarly arranged. Megasporophylls of Cycas do not form a true cone but are arranged in two to three whorls at the stem apex. Later the stem resumes vegetative growth, and the megasporophylls then are interposed between whorls of foliar leaves and cataphylls; the usual arrangement is two to three whorls of leaves, then several whorls of cataphylls, followed by megasporophylls, but variations in this sequence are not unusual

The megasporophyll of the Asian Cycas revoluta is considered to most typify the ancestral seed-fern condition. Each megasporophyll consists of a stalk, a fertile portion bearing two to six oyules, and an expanded terminal blade having fringelike "pinnae" (Figure 7). An evolutionary series of plant forms probably led toward the biovulate, peltate megasporophylls of such forms as Encephalartos, Ceratozamia, Microcycas, and Zamia (Figure 7). Microsporophylls similarly vary among cycads; those of Cvcas are the more leaflike, those of Zamia less so (Figure 7). Microsporangia, which are found on the abaxial surface of microsporophylls, are usually numerous-several hundred in Cycas, several dozen in Zamia-and arranged in small clusters of two to five. They are the equivalent of sori of ferns and of pteridosperms. The cycad microsporangium resembles a clamshell, being somewhat flattened with an elongate suture (Figure 7).

CLASSIFICATION

Many botanists believe that extant gymnosperms represent at least two evolutionary lineages: one that leads to the extant conifers, taxads, and possibly Ginkgo and the Gnetales; and another that leads to the cycadophytes, represented today by seed ferns, cycadeoids, cycads, and perhaps others. Cycadophytes probably had their origins among the Devonian progymnosperms (Progymnospermopsida), although the particular antecedents are unknown.

DIVISION CYCADOPHYTA

Gymnospermous plants possessing compound leaves, ovules have I integument; seeds borne on either the foliage or megasporophylls; soft, loose wood contains scalariform tracheids and tracheids with multiseriate bordered pits; stem cross sections show wide zones of pith and cortex

+DIVISION PTERIDOSPERMOPHYTA (seed ferns)

Primitive, primarily Paleozoic, primarily small trees or woody vines; large compound fronds; leaf-borne ovules; and microsporangia more or less united as synangia; subdivided into several groups; two orders, Caytoniales and Glossopteridales, persisted into Cretaceous, the latter sometimes included with pteridosperms, but commonly ranked separately and thought to be closely related to certain primitive angiosperms.

*DIVISION CYCADEOIDOPHYTA (BENNETTITOPHYTA)

Mesozoic; common and cycadlike; differ from cycads in having direct leaf traces, in sometimes being monoecious, and sometimes having bisexual cones.

DIVISION CYCADOPHYTA

Late Paleozoic? to the present; woody, coniferous plants with compound leaves, simple cones; flagellate motile male gametes; stout, fleshy stems; 4 families currently are recognized

Family Cycadaceae

Generally restricted to species of Cycas; foliar, multiovulate megasporophylls arranged in an indeterminate strobilus; pinnae with a single midrib but lacking lateral, branch veins: 24

species defined. Family Zamiaceae

Singly pinnate compound leaves, bearing leaflets with parallel, dichotomously branching veins (Chigua, if included, would be an exception); simple cones; female cones with biovulate megasporophylls; a total of about 112 species includes Macrozamia. Lepidozamia, Ceratozamia, Encephalartos, Zamia, Microcycas, and Dioon.

Family Stangeriaceae

Fernlike leaves bearing pinnae with a prominent midrih and numerous dichotomously branching lateral veins; simple cones. female cones with biovulate megasporophylls; includes only Stangeria paradoxa, a southern African cycad.

Family Boweniaceae Differ from other cycads in possessing bicompound leaves; one genus. Bowenia, with 2 species

Gnetophytes

The gnetophytes (division Gnetophyta) are characterized as a small group of vascular seed plants that are represented by only three genera: Ephedra, Gnetum, and Welwitschia (Figure 9). There are about 35 species in the genus Ephedra, 30 or more in Gnetum, but only one in Welwitschia. The three genera exhibit their great diversity in the immense variety of form and size among the various species.

GENERAL FEATURES

Most species of Ephedra are branched shrubs or small trees while others are vinelike, often clambering over other vegetation. Species are distributed in dry and cool regions in both the Eastern and Western hemispheres. In the Western Hemisphere. Ephedra occurs in desert areas in the southwestern United States, part of Mexico, and a wide area in South America. In the Eastern Hemisphere. certain species occur in China and in the Himalayas from Afghanistan to Nepal and Tibet at elevations of 2,700 to 4,350 metres (10,300 to 14,300 feet). Ephedra, known as

Figure 9: Representative gnetophytes (Left) Close-up of the shrub and the mature. fleshy seed cones of Ephedra. (Right) Foliage eaves and mature seeds of Gnetum gnemon. (Bottom) Welwitschia mirabilis, showing two gigantic leaves and terminal seed cones on a system of branches.

Importance Ma-huang, has been a common medicine in China for thousands of years. The effective product, ephedrine, is prescribed for colds, to break a fever and induce sweating, and as a decongestant. Stem fragments of species in the southwestern United States and Mexico are used in the preparation of Mormon tea, Mexican tea, squaw tea, and desert tea. The drug ephedrine is now manufactured synthetically.

Most of the 30 species of Gnetum are lianas that climb high into trees of tropical rain forests in central Africa, Asia, northern South America, and islands between Australia and Asia. One species, G. gnemon, is a tree about nine metres tall. The leaves are large, much like those of many flowering plants. The seeds are eaten cooked or roasted, and young leaves also are eaten.

The most unusual and geographically restricted gnetophyte is Welwitschia mirabilis, which is unlike any other known plant in the world. It occurs in the Namib Desert of southwestern Africa near the coast of Angola and Namibia, as well as inland to about 150 kilometres. (Rainfall on the Namib Desert ranges from zero to 100 millimetres [four inches] per year). There are only two large, permanent, arching leaves; they split, and the tips die when they touch the hot sand. It is not clear how the plant obtains sufficient water to meet its needs. There is a taproot that may extend downward for one to 1.5 metres before it divides into numerous thin roots, which must tap a supply of water not available to other plants of the desert.

FORM AND FUNCTION

Stem. In Ephedra the stems are jointed, the basis for the common name joint fir. The leaves are arranged in pairs on the stem or in whorls of three with their bases forming a sheath around the stem at a node. The leaves of most species are reduced or scalelike, although in some species they may grow to three centimetres in length. The leaves of most species have two veins that are connected to two axial stem vascular bundles. The bulk of photosynthesis occurs in the green stems. Reduction in leaf surface may be related to the necessity of reducing water loss through the process of transpiration, a requirement for existence in a desert environment.

Leaves. The leaves of Ephedra, Gnetum, and Welwitschia are strikingly different in form and venation and provide morphological characters that are definitive for each of the genera.

The leaves of Gnetum resemble those of the angiosperms (the flowering plants) in form, structure, and venation, Two leaves at a node are broad and have a pinnate venation system (one midvein with lateral secondary veins that run to the leaf margin) and a meshwork of smaller veins. Older stems become hard by the production of wood (secondary xylem).

A conspicuous vegetative feature of Welwitschia is the presence of two large permanent leaves. When a seed germinates, two seed leaves (cotyledons) emerge, followed by the production of the two permanent leaves. Soon after the development of the two leaves, growth activity shifts away from the tip of the stem (the apical meristem) to the bases of the two permanent leaves. Growth in this region takes place in a meristematic zone, which adds tissue at the base of each leaf. This development results in a bilobed crown and later to a circular concave disk surmounted by a band of meristematic tissue, which continues to contribute new tissue to the two large leaves. Thus, growth in Welwitschia has shifted from developing height to developing the two leaves outward. The leaves are perpetuated by the basal meristem at the rate of eight to 15 centimetres per year. The leaves become split and frayed in old plants. A leaf of one giant was reported to have an unbroken width of 1.8 metres and a length of 6.2 metres, of which 3.7 metres were of living tissue. Some plants are estimated to be 1,500 to 2,000 years old.

It is not known for certain how a plant with gigantic leaves such as Welwitschia can exist in a desert and carry on photosynthesis if the pores (stomata) of a leaf remain open during the heat of the day. It may be that Welwitschia has the type of photosynthesis in which stomata are open only at night. Carbon dioxide (CO2) is stored in organic acids and then used during the day in photosynthesis. There are also about 100 days of brief morning fog. Water accumulates on the leaves and is thought to enter them, although the process has never been proved. More recently CO, has been shown to be taken up during the daylight hours through open stomata, leading to a tremendous loss of water by transpiration for the purpose of cooling the leaf surface.

One of the physical features that distinguish the gnetophytes from other gymnospermous divisions is the presence of vessels in the xylem (wood). A vessel is a longitudinal row of cells, called vessel members, which have several to many circular perforations in their end walls at maturity, providing an efficient pathway for the movement of water in the plant body. The possession of vessels is characteristic of the flowering plants (angiosperms) as well, and has led to speculation that gnetophytes, especially Gnetum, may have been close to the ancestral stock of some angiosperms.

Reproductive structures and function. The reproductive structures of anetophytes are contained within strobili, or cones (Figure 10). Most species are dioecious; i.e., one individual plant produces either pollen-producing or seedproducing cones, called microsporangiate and megasporangiate strobili, respectively. The two types of strobili are basically the same, consisting of oppositely arranged bracts in the axils of which are short fertile shoots.

Strobili and sporophylls

(Left) E.M. Gifford: (right) from A.S. Foster and E.M. Gifford, Jr., Morphology and Evalution of Vascular Plants, copyright @ 1989 by W.H. Freeman and Co., redrawn from Sanwal, Phytomorphology, 12:243 (1962) eporangiophore

Figure 10: Reproductive structures of the gnetophytes. (Left) Pollen-producing strobili (cones) of Ephedra. The microsporangiophores extend out between the cone scales, and a pair of scalelike leaves appears at the nodes. (Right) Organization of the microsporangiate strobilus (cone) of Gnetum gnemon with (right) a longitudinal section through a node, showing four developing microsporangiate fertile shoots and one abortive ovule.

In Ephedra each fertile shoot of a pollen cone consists of an elongated modified structure, a microsporophyll or a microsporangiophore, which terminates in a cluster of sporangia, called microsporangia, that house the haploid reproductive cells (spores). The microsporangia are surrounded by a pair of bracteoles (scalelike leaves). Meiotic divisions in cells of the microsporangia produce the haploid pollen grains.

When shed from the microsporangia, the pollen grains (or male gametophytes) consist of five cells contained within the pollen-grain wall. The pollen grains are boatshaped, with longitudinal ridges and furrows that run from one end of the grain to the other. Pollen of this type has been identified in the fossil record from the Permian (286 to 245 million years ago) to the present.

Megasporangiate, or seed-producing, strobili (female cones) consist of oppositely paired bracts in the axils of which are fertile shoots consisting of paired bracteoles

Welwitschia enclosing an ovule—the forerunner of a seed. The ovule consists of a delicate inner envelope, called an integument, that encloses a tissue (nucellus) in which a cell divides meiotically to produce a row of haploid cells called megaspores. One megaspore greatly enlarges and undergoes mitotic divisions, producing multiple nuclei that are not surrounded by walls. After 500 to 1,000 nuclei are produced, cell walls begin to form, converting the megagaretophyte (or female gametophyte) into a cellular structure. At the upper end, egg-bearing protective structures called archegonia are formed, each of which contains a happiod egg cell.

Pollination and embryogeny. Just before the transfer of pollen grains to the ovule (pollination) some cells of the nucellus degenerate and a viscous solution is extruded through the opening (micropyle) of the now-extended integument. A pollination drop is formed at the tip of the integument. Transfer of pollen may be either by wind or insects. The pollination drop is very high in sugar content and attracts insects. As the sugary pollination drop dries, the pollen grains are pulled inward through the integument and come to rest on the nucellus. The pollen grain germinates, and a pollen tube enters the egg cell of the archegonium. A mature male gamete (sperm) fuses with the mature egg nucleus, bringing about fertilization. Eight or more diploid nuclei are produced and soon become surrounded by cellulose-containing walls. Each of these young embryos may develop, although only one generally reaches a fully developed stage in the mature seed. A seed consists of an embryo with two seed leaves (cotyledons), a stem axis, and a root, embedded in nutritive tissue of the female gametophyte. The pair of protective bracteoles become hard, and the seed is also surrounded by fleshy bracts that may become ivory, red, or orange in colour, perhaps an adaptation for animal dispersal. There appears to be no resting stage or dormant period for the seed, which may germinate immediately upon dispersal.

The strobil of Gnetum are compact or may become elongate with conspicuous nodes and internodes. In a microsporangiate, or pollen-producing, strobilus there are two fused bracts at each node forming a cup-shaped structure (collar) that encloses numerous fertile shoots. Each fertile unit consists of two bracteoles enclosing a microsporophyll or microsporangiophore with two sporangia at the tip. There may also be a top whorl of abortive ovules at each node.

The megasporangiate (ovulate) strobilus likewise consists of conspicuous nodes, each with a fused pair of bracts subtending several ovules. Each ovule comprises an integument and two ensheathing structures called envelops. In Gnetum, in contrast to Ephedra, fertilization occurs before the haploid female gametophyte becomes completely cellular. Nuclei become surrounded by membranes. A pollen tube pushes into the female gametophyte, and a male gamete fertilizes an egg. Several pollen tubes may enter the female gametophyte, resulting in more than one fertilization, although normally only one embryo develops to maturity. The seeds become fleshy and often are brightly coloured.

In Welwitschia, branched reproductive shoot systems arise from the meristematic tissue at the bases of the two large permanent leaves. In both types of strobili, paired bracts and fertile shoots develop from the axils, as is true of the other two genera of gnetophytes. The fertile shoot of a microstrobilus has two pairs of bracteoles, the inner pair of which are fused, enclosing six microsporangiophores and a sterile ovule. In a megastrobilus the fertile shoot is made up of a pair of basal bracteoles and a pair of fused bracteoles arrounding an ovule.

At the time of pollination the integument of a fertile ovule in the female elongates and a pollination drop is formed at the tip. A cell in the nucellus of the female ovule undergoes meiosis, but no cell walls are formed between the four haploid nuclei. The four nuclei and their derivatives undergo repeated mitoses without cell-wall formation. Only later do cell walls form around several nuclei. No archegonia are formed. Subsequent development of the female gametophyte is without parallel in other gymnosperms or in angiosperms (Figure 11).

Some of the multinucleate female gametophyte cells grow into the nucellus of the ovule, into which the nuclei migrate. Pollen tubes, which grow downward in the nucellus from the male pollen grains after pollination, meet and fuse with the upwardly growing multinucleate tubes of the female gametophyte. "Fertilization bulbs" are formed, within which fusion takes place between a male gamete and one nucleus of the female gametophyte cells. A zygote is formed, and the young embryo then grows downward within the female gametophyte tube toward the cellular female gametophyte.

The later stages of embryo development take place within the tissue of the female gametophyte. A mature, ripe seed consists of a dicotyledonous embryo embedded in the female gametophyte and surrounded by papery fused brechels, constituting a "wing," which probably assists in seed dispersal.

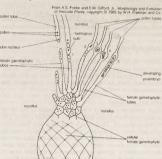

Figure 11: (Left to right) The stages in fertilization and promethyo development in Welvischla. (1) Certain multinucleate female gametophyte cells form tubes that grow up into the nucellus. Pollen tubes growing down in the nucellus meet the upward-growing tubes of the female gametophyte. (2) Wall dissolution occurs, and fertilization takes place in the 'fertilization bulb' to form a zygote (3). (4) The zygote divides, forming a two-celled proembryo. (5) The proembryo grows down inside the female gametophytic tube toward the nutritive issues below.

CLASSIFICATION Annotated classification.

DIVISION GNETOPHYTA

Longitudinal files of cells with pores in end walls (vessels) in xylem (wood); dioccious; strobili (cones) consist of bracts, in the axils of which are the reproductive structures, which have been likened to flowers of angiosperms.

Order Ephedrales

Shrubs to small trees; small leaves with 2 or 3 veins; mature cones often become fleshy and brightly coloured; 1 family, Ephedraceae; 1 genus, *Ephedra*, with about 35 species.

Order Gnetales

Mostly vines, but a few trees; large flat leaves that have reticulate venation; seeds may be brightly coloured; 1 family, Gnetaceae; 1 genus, *Gnetum*, with about 30 species.

Order Welwitschiales

Monotypic; 2 immense, permanent leaves, which become split and frayed with age; seeds with winglike extensions that may aid in dispersal; restricted to Namib Desert of Africa and vicinity, 1 family, Welwitschia microblis;

Critical appraisal. There have been attempts to demonstrate that the gnetophytes form a link between gymnosperms and angiosperms. Proponents of this concept cite the compound nature of both the pollen-producing and seed-producing strobili (some botanists have interpreted the strobili as "inflorescences", i.e., the axillary ferrile shoots of both types of cones are considered to be flowers); and the presence of vessels in the xylem (wood).

Fertilization

Reproduction in Welwitschia a major difference between gnetophytes and all other gymnosperms. In recognition of these similarities, a classification has been proposed that placed the gnetophytes in the group Chlamydospermae, a group between the gymnosperma and the angiosperms. The word "chlamydospermae" means a seed with a "cloak," or envelope, a reference to pairs of brateoles (scalelike structures) that surround a seed, similar to the ovary wall of the flowers of angiosperms. In another system the three genera are placed in one family in the order Gratelae.

More recently, the trend has been to establish a major group, the Gnetophyta (a division) or Gnetopsida (a class), consisting of three orders—Ephedrales, Gnetales, and Welwitschiales—each comprising one family and one genus. This system recognizes that there are certain shared characteristics but at the same time recognizes that there are significant differences between them.

are significant uniterities eleverate in the fossil record has been based primarily upon the presence of pollen grains resembling those of Ephedra and Welwitschia. Leafy shoots with gnetalean features from the Early Cretaceous have been found associated with Welwitschia-type pollen.

Ginkgophytes

Maidenhair tree bilobed nature of its leaves and its resemblance to the leaves of the maidenhair fern. G. biloba may be the oldest living seed plant, and it is regarded by some as one of the wonders of the world.

GENERAL FEATURES

Fossil leaves with similar form and venation to the living Ginkgo have been found in the Jurassic period (208 to 144 million years ago). These fossils have been described from such geographically separated areas as Australia, western North America, Mongolia, Alaska, England, and central Europe. The fossils vary greatly in form and are usually described as species of the genus Ginkgoites. Almost the same degree of variation in leaf form can be found on a living Ginkgo tree, however. Some paleobotanists, therefore, have recommended the abandonment of the genus Ginkgoites and the recognition of several species of

There is one type of ginkgophyte-leaf in the fossil record that is generally regarded as a distinct form and is given the generic designation Baiera. The leaf is deeply lobed into four segments and lacks a stalk (petiole). Following the Mesozoic era, Ginkgo declined progressively in its distribution, and some botanists believe that China was the last natural home of the maidenhair tree. Whether Ginkgo still exists in the wild state in China is unsettled. Although some evidence supports the view that the stands of trees in southeastern China are of a natural origin, some botanists contend that they may represent the offspring of trees cultivated in temple gardens for thousands of years. The latter may well be the case because, after the outer fleshy seed coat is removed, the seed kernel has been, and is still today, used as food in China and Japan. For 3,000 years or longer, extracts of the Ginkgo leaf have been recommended in Chinese medicine as benefiting the heart and lungs. Ginkgo has been investigated for its effects in the treatment of asthma, toxic shock syndrome, and various circulatory disorders.

FORM AND FUNCTION

Stem. At maturity a *Ginkgo* tree can reach heights of 20 to 30 metres (65 to 100 feet). Young trees often have a central trunk with regular, lateral branching; in older trees the branching is irregular.

A conspicuous feature of Ginkeo is the possession of long branches and short, or spur, branches. Leaves are produced on long branches during the spring growth. In subsequent years, clusters of leaves are formed on the lateral short branches. Ginkgo is deciduous, and the leaves of some varieties turn a beautiful golden colour in the autumn. The colour varies to some extent among horticultural varieties. There is some plasticity in growth form in that a short branch may become a long branch or the tip

of a long branch may be converted to a short branch. The interplay between these two types of branches accounts for the more irregular shape of the older trees. Branching appears to be controlled by the distribution of auxin, a naturally occurring plant hormone.

The trunk diameters of the older specimens of *linkgo* may become large as a result of secondary growth. The vascular cambium gives rise to secondary phloem and secondary xylem (wood) for the conduction of water and dissolved minerals. The growth activity of the vascular cambium is sustained in the trunk and long shoots and produces a rather hard wood with well-defined growth rings. The activity of the vascular cambium persists in short shoots, but only a limited amount of soft wood is produced each year.

Deaves. One of the most distinctive features of G bloba is the foliage leaf (Figure 12), which consists of a leaf stalk (petiole) and a fan-shaped dichotomously veined blade, or lamina. Although bloba (or bilobed) correctly describes the form of many clinkgo leaves, there is a great range of variation in the degree of lobing and dissection among leaves of the same tree. Bilobed and undivided leaves occur on spur or short branches, while most of the leaves on the upper part of a long branch are divided by a deep sinus into two lobes, each of which is further dissected into segments. Multilobed leaves also occur on new branches (sucker shoots) arising from the tree trunk at ground level.

(Ton) Sonia Cook (bottom) John H. Gerard

Figure 12: Representative features of Ginkgo. (Top) Ovuliferous structures on spur branch. Note bilobed, fan-shaped structure of the leaf. (Bottom) Mature seeds attached to a short branch.

The dichotomous venation pattern in a leaf blade is a striking morphological characteristic of Ginkgo. Two vascular bundles extend through the petiole and give rise to two systems of dichotomously branched veins. This type of venation was also present in the leaves of extinct members of the Ginkgoales. Such a system of venation is often referred to as an open type, devoid of vein fusions. It has been shown, however, that vein unions may occur with some regularity.

Reproductive structures and function. Completion of the entire reproductive cycle, from the advent of pollination to the production of seeds with well-developed embryos, takes about 14 months. Pollination and the deVariation in leaf lobing

Distribution of Ginkgo

velopment of the sexual, or gametophytic, phase of the life cycle occur in the first year (April to September), but embryo development is not completed until the spring of the following year.

Ginkgo is dioecious, which means that pollen-producing structures and ovules are produced on separate trees. The reproductive structures are restricted to the spur branches. where they are evident in the spring in the axils of bud scales and foliage leaves.

The pollen-producing strobilus is a loose, pendulous, catkinlike structure consisting of a main axis to which are attached numerous appendages, each of which usually bears two microsporangia at its tip. Meiosis occurs in cells of the microsporangia, giving rise to numerous haploid microspores. Cell divisions take place within the microspores, resulting in the formation of five-celled pollen grains (male gametophytes).

Ovuliferous

structures

Ovuliferous structures (Figure 12) also arise in the axils of bud scales and the foliage leaves of spur branches. Each consists of a stalk that bears two or sometimes three or more erect ovules. An ovule is composed of an integument (the future seed coat) surrounding a tissue called the nucellus. It is in the nucellus that meiosis occurs, resulting in the formation of four haploid megaspore cells. It is at about this time that pollen grains are released from the microsporangia of male trees. The pollen (male gametophyte) is carried by wind currents and adheres to a pollination droplet, which exudes from the micropyle at the tip of the integument. Retraction of the droplet brings the pollen grains into a pollen chamber in the nucellus, where they develop into multibranched pollen tubes (male gametophytes).

One of the megaspores in the ovule that results from meiosis enlarges and undergoes a succession of free nuclear divisions (without wall formation). After about 8,000 haploid nuclei are produced, cell walls begin to form, After the female gametophyte becomes cellular, archegonia (normally two) are initiated at the surface toward the micropylar end of the ovule. An archegonium consists of

neck cells and a large egg cell.

The basal end of the filament-like male gametophyte becomes suspended in a cavity above the female gametophyte (called the fertilization chamber). The spermatogenous cell of a male gametophyte divides, resulting in the production of two multiflagellated sperm. The sperm and the contents of the pollen tube are released into the fertilization chamber. The sperm swim in the liquid for a brief period of time. Approximately 1,000 flagella are attached to a spiral band at the anterior end. A sperm enters an archegonium and fuses with the egg nucleus. Ginkgo and the cycads are the only seed-producing plants that have motile sperm.

The growth of the embryo (embryogenesis) may begin shortly after fertilization but continues after the developing seeds fall to the ground. The embryo grows into the nutritive tissue of the female gametophyte. A seed at maturity (Figure 12) consists of a dicotyledonous embryo, nutritive tissue of the female gametophyte, and the seed coat, which is made up of a hard inner layer and a fleshy, orange-coloured outer layer. Because of the presence of butyric acid, upon decay the fleshy layer emits an odour similar to rancid butter.

CLASSIFICATION

In earlier systems of classification, Ginkgo was placed in the class Coniferopsida, along with conifers (e.g., pine, fir, spruce). In recent years Ginkgo and its fossil allies have been placed in a separate group, the division Ginkgophyta (sometimes classified as the class Ginkgopsida), in recognition of the many characteristics outlined above. The early ancestral stock of Ginkgo extends back in the fossil record to a time coordinate with the ancestors of the conifers, but the two groups appear to have evolved independently.

DIVISION GINKGOPHYTA

Large trees; leaves typically fan-shaped and bilobed, or with more lobes, especially in fossil forms; leaves borne mainly on spur (short) branches; male and female trees; seeds with a fleshy outer layer that upon decay, emits an odour of rancid butter, a single order, Ginkgoales; a single family, Ginkgoaceae; a single extant genus, Ginkgo; 2 extinct genera, Ginkgoites and Raiera

BIBLIOGRAPHY. General works providing comprehensive coverage of the gymnosperms include K.R. SPORNE, The Morphology of Gymnosperms: The Structure and Evolution of Primitive Seed-Plants, 2nd ed. (1974), a compact summary discussing both living and extinct groups; THOMAS N. TAYLOR, Paleohotany: An Introduction to Fossil Plant Biology (1981), an excellent survey of fossil plants, including the history of the various gymnosperm groups and especially strong on the evolution of seeds; CHARLES JOSEPH CHAMBERLAIN, Gymnosperms: Structure and Evolution (1935, reprinted 1966), a classic description of the life history and morphology of all extant groups; w. DAL-LIMORE and A. BRUCE JACKSON, A Handbook of Coniferae and Ginkgoaceae, 4th ed., rev. by s.g. HARRISON (1966), a well-Ginkgoaceae, an ed., iev. by s.o. Harrison (1906), a weir-illustrated discussion of many representative types, including cultivated forms; and ERNEST M. GIFFORD and ADRIANCE S. FOSTER, Morphology and Evolution of Vascular Plants, 3rd ed. (1989), focusing on the structure and reproduction of vascular plants, including the gymnosperms.

For conifers, see GERD KRÜSSMANN, Manual of Cultivated Conifers, 2nd rev. ed. (1985; originally published in German, 1983), an extensively illustrated account of cultivars and species of conifers used in gardens; D.M. VAN GELDEREN and J.R.P. VAN HOEY SMITH, Conifers (1986), a pictorial work complementing Krüssmann's book with colour photographs; N.T. MIROV, The Genus Pinus (1967), a thorough treatment of all aspects of the biology of the many species of this important temperate genus; GEORGE S. ALLEN and JOHN N. OWENS. The Life History of Douglas Fir (1972), a detailed description of the reproductive cycle of the conifer; RUDOLF FLORIN, "Evolution in Cordattes and Conifers," Acta Horti Bergiani 15(11):286–388 (1951), a summary of the definitive research on the evolution of seed cones in coniferophytes, and "The Distribution of Conifer and Taxad Genera in Time and Space," Acta Horti Bergiani 20(4):122-312 (1963), an important survey, with thorough maps of distributions of living and fossil coniferophytes; CHARLES B. BECK (ed.), Origin and Evolution of Gymnosperms (1988), a collection of studies of fossil conifers with important discussions of early species; J.A. HART, "A Cladistic Analysis of Conifers: Preliminary Results," Journal of the Arnold Arboretum 68:269-307 (July 1987), a new approach to discovering relationships among conifer genera; and J.E. ECKENWALDER, "Re-evaluation of Cupressaceae and Taxodiaceae: A Proposed Merger," *Madroño* 23(5):237-256 (1976), an original look at family relationships among extant conifers.

A survey of cycadophytes is found in HAROLD C. BOLD, CONSTANTINE J. ALEXOPOULOS, and THEODORE DELEVORYAS, Morphology of Plants and Fungi, 5th ed. (1987). Other works include CHARLES JOSEPH CHAMBERLAIN, The Living Cycads (1919, reprinted 1965), the best comprehensive work on the cycads; CYNTHIA GIDDY, Cycads of South Africa, 2nd rev. ed. (1984), an excellent introduction to cycad morphology, noted for its beautiful colour illustrations of Encephalartos species in natural habitats; DIVYA DARSHAN PANT, Cycas and the Cycadales, 2nd ed. (1973), a fine presentation of all aspects of the life of Cycas and a valuable general reference to their anatomy and morphology; and PAL GREGUSS, Xylotomy of the Living Cycads, with a Description of Their Leaves and Epidermis, trans, from Hungarian (1968), which emphasizes the structure of cycad xylem and includes important information on the

habits and leaf morphology of cycads.

General treatments of the gnetophytes and ginkgophytes are found in Peter H. RAVEN, RAY F. EVERT, and SUSAN E. EICH-HORN, Biology of Plants, 4th ed. (1986). WILSON N. STEWART, Paleobotany and the Evolution of Plants (1983), offers a more detailed account of the fossil record of Ginkgo; and CHRIS H. BORNMAN, Welwitschia: Paradox of a Parched Paradise (1978). is a brief study of Welwitschia mirabilis.

Fertilization -

The House of Habsburg

The House of Habsburg (also spelled Hapsburg; also known as the House of Austria) was one of the greatest of the sovereign dynasties of Europe.

The name Habsburg is derived from the castle of Habsburg, or Habichtsburg ("Hawk's Castle"), built in 1020 by Werner, bishop of Strasbourg, and his brother-in-law, Count Radbot, in the Aargau overlooking the Aar River, in what is now Switzerland. Radbot's grandfather, Guntram the Rich, the earliest traceable ancestor of the house, may perhaps be identified with a Count Guntram who rebelled against the German king Otto I in 950. Radbot's son Werner I (died 1096) hore the title count of Habsburg and was the grandfather of Albert III (died c. 1200), who was count of Zürich and landgrave of Upper Alsace. Rudolf II of Habsburg (died 1232) acquired Laufenburg and the "Waldstätte" (Schwyz, Uri, Unterwalden, and Lucerne), but on his death his sons Albert IV and Rudolf III partitioned the inheritance. Rudolf III's descendants, however, sold their portion, including Laufenburg, to Albert IV's descendants before dying out in 1408.

AUSTRIA AND THE RISE OF THE HABSBURGS IN GERMANY Albert IV's son Rudolf IV of Habsburg was elected German king as Rudolf I in 1273. It was he who, in 1282, bestowed Austria and Styria on his two sons Albert (the future German king Albert I) and Rudolf (reckoned as Rudolf II of Austria). From this date the age-long identification of the Habsburgs with Austria begins (see AUSTRIA). The family's custom, however, was to vest the government of its hereditary domains not in individuals but in all male members of the family in common, and, though Rudolf II renounced his share in 1283, difficulties arose again when King Albert I died (1308), After a system of condominium had been tried, Rudolf IV of Austria in 1364 made a compact with his younger brothers that acknowledged the principle of equal rights but secured de facto supremacy for the head of the house. Even so, after his death the brothers Albert III and Leopold III of Austria agreed on a partition (Treaty of Neuberg, 1379); Albert took Austria. Leopold took Styria, Carinthia, and Tirol.

King Albert I's son Rudolf III of Austria had been king of Bohemia from 1306 to 1307, and his brother Frederick I had been German king as Frederick III (in rivalry or conjointly with Louis IV the Bavarian) from 1314 to 1330. Albert V of Austria was in 1438 elected king of Hungary, German king (as Albert II), and king of Bohemia; his only surviving son, Ladislas Posthumus, was also king of Hungary from 1446 (assuming power in 1452) and of Bohemia from 1453. With Ladislas the male descendants of Albert III of Austria died out in 1457. Meanwhile the Styrian line descended from Leopold III had been subdivided into Inner Austrian and Tirolean branches.

Frederick V, senior representative of the Inner Austrian line, was elected German king in 1440 and crowned Holy Roman emperor, as Frederick III, in 1452-the last such emperor to be crowned in Rome. A Habsburg having thus attained the Western world's most exalted secular dignity, a word may be said about the dynasty's major titles. The imperial title at this time was, for practical purposes, hardly more than a glorification of the title of German king; and the German kingship was, like the Bohemian and the Hungarian, elective. If Habsburg was to succeed Habsburg as emperor continuously from Frederick's death in 1493 to Charles VI's accession in 1711, the principal reason was that the hereditary lands of the Habsburgs formed an aggregate large enough and rich enough to enable the dynasty to impose its candidate on the other German electors (the Habsburgs themselves had an electoral vote only in so far as they were kings of Bohemia).

For the greater part of Frederick's reign it was scarcely foreseeable that his descendants would monopolize the imperial succession so long as they did. The Bohemian and Hungarian kingdoms were lost to the Habsburgs for nearly 70 years from the death of Ladislas Posthumus in 1457; the Swiss territories, lost in reality from 1315 onward (see switzerland), were finally renounced in 1474; and Frederick's control over the Austrian inheritance itself was long precarious, not only because of aggression from Hungary but also because of dissension between him and his Habsburg kinsmen. Yet Frederick, one of whose earliest acts in his capacity as emperor had been to ratify, in 1453, the Habsburgs' use of the unique title of "archduke of Austria" (first arrogated for them by Rudolf IV in 1358-59), may have had some prescient aspiration toward worldwide empire for the House of Austria: the motto A.E.I.O.U., which he occasionally used, is generally interpreted as meaning Austriae est imperare orbi universo ("Austria is destined to rule the world"), or Alles Erdreich ist Österreich untertan ("The whole world is subject to Austria"). He lived long enough to see his son Maximilian make the most momentous marriage in European history (see below); and three years before his death he also saw the Austrian hereditary lands reunited when Sigismund of Tirol abdicated in Maximilian's favour (1490)

Before explaining what the Habsburgs owed dynastically to Maximilian, mention can be made of a physical peculiarity characteristic of the House of Habsburg from the emperor Frederick III onward: his jaw and his lower lip were prominent, a feature supposed to have been inherited by him from his mother, the Mazovian princess Cymbarka, Later intermarriage reproduced the "Habsburg lip" more and more markedly, especially among the last

Habsburg kings of Spain.

THE WORLD POWER OF THE HABSBURGS

Even before Frederick III's time the House of Habsburg had won much of its standing in Germany and in central Europe through marriages to heiresses. Frederick's son Maximilian carried this matrimonial policy to heights of unequalled brilliance. First he himself in 1477 married the heiress of Burgundy, Charles the Bold's daughter Mary, with the result that the House of Habsburg, in the person of their son Philip, inherited the greater part of Charles the Bold's widespread dominions: not the duchy of Burgundy itself, which the French seized, but Artois, the Netherlands, Luxembourg, and the County of Burgundy or Franche Comté. Secondly, though he failed after Mary's death in 1482 to secure Brittany also by a similar coup (France frustrated his proxy marriage to the Breton heiress Anne), he procured Philip's marriage, in 1496, to Joan, prospective heiress of Castile and Aragon; thus securing for his family not only Spain, with Naples-Sicily and Sardinia, but also the immense dominions the Spaniards were about to conquer in America. Maximilian's matrimonial achievements were the occasion of the famous hexameter Bella gerant alii, tu felix Austria nube ("Let others wage wars: you, fortunate Austria, marry").

Since Philip I of Castile died prematurely, his son was already ruler of the Burgundian heritage and of Spain when, in 1519, he succeeded Maximilian as ruler of the Habsburgs' Austrian territories. In the same year he was elected Holy Roman emperor as Charles V.

The threat of force as well as an enormous expenditure in Charles V bribes was necessary to secure Charles's election. Besides the fact that many of the German princes were reluctant to saddle themselves with so mighty a sovereign, there was the opposition of France, which saw itself already halfencircled, from the northeast clockwise to the southwest, by Charles's possessions. Dating from Maximilian's Burgundian marriage, antagonism between the French kings

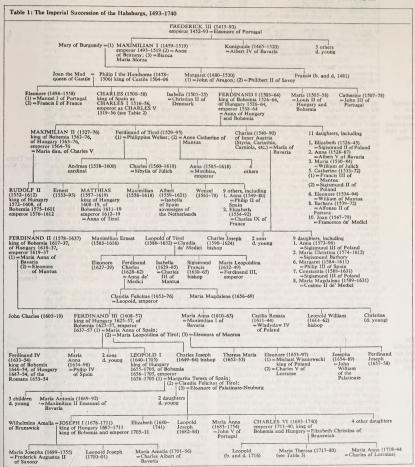

Maximilian: the Burgundian and Spanish marriages

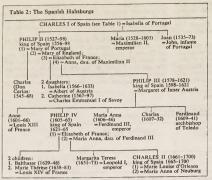

The emperor Frederick

Charles V's responsibilities at the time of his becoming emperor were moreover too great for one man to assume, as he himself could acknowledge: they had to be divided. By the Treaty of Brussels (1522) he assigned the Habsburg-Austrian hereditary lands to his brother, the future emperor Ferdinand I. In 1521 Ferdinand had married Anna.

daughter of Louis II of Hungary and Bohemia; and Louis II's untimely death in 1526, after his defeat by the Turks in the Battle of Mohäcs, prompted Ferdinand to stand as candidate for his succession, to which, despite rivals, he was elected.

The Habsburgs reached the zenith of their power before the end of the 16th century: the duchy of Milan, annexed by Charles V in 1935, was assigned by him to his son, the future Philip II of Spain, in 1540; Philip II conquered Portugal in 1580; and the Spanish dominions in America were ever expanding. There were, however, three faults in the power structure—two of them historical accidents the

External and internal weaknesses in the 16th century

third an effect of the Habsburg dynasty's own measures for self-preservation.

In the first place, the ascendancy of Charles V coincided with the outbreak of the Protestant Reformation in Germany, which was to spread turmoil for decades over Europe from the Netherlands to Hungary. As Charles, from his Spanish upbringing, was imbued with ideas of Catholic uniformity and as his successors, with the exception of the enigmatic Maximilian II, sought also to realize those ideas, religious resistance to the Habsburgs' authority came to aggravate or to camouflage political resistance. At the same time, the papacy, overawed though it was by the Spanish military presence in Italy, did not always subscribe to the Habsburg's special policy for Catholicism.

Secondly, Ferdinand's accession to Hungary meant that the Habsburgs had to bear the brunt of the Ottoman Turkish drive from the Balkans into central Europe, just as Habsburg Spain had to confront Turkish incursions into the western Mediterranean. The great victory of Lepanto (1571), won by a Habsburg bastard, did not end these troubles, which were exploited, against the dynasty, by Hungarian dissidents and, more covertly, by France.

The third flaw in the Habsburg edifice was latent in the 16th century. Mindful of what they had won by marriages, the Habsburgs sought to preclude rival dynasties from turning the tables on them by the same means: to keep their heritage in their own hands, they began to intermarry more and more frequently among themselves. The result, in a few generations, was a fatal inbreeding that brought the male line of Charles V to extinction.

By a series of abdications toward the end of his life Charles V transferred his Burgundian, Spanish, and Italian possessions to his son Philip II and his functions as emperor to his brother Ferdinand, who succeeded him formally as such after his death (1558). This division of the dynasty between imperial and Spanish lines was definitive; Ferdinand's male descendants were Holy Roman emperors until 1740 (for the emperors from Frederick III to Charles VI see Table 1), Philip's were kings of Spain until 1700 (see Table 2). The imperial line was inevitably concerned to maintain its position in Bohemia and to assert itself against the Turks in divided Hungary, because the loss of the two kingdoms would have meant the reduction of its possessions to what the Habsburgs had had hereditarily before Frederick III's time (the Austrian duchies and scattered holdings in Swabia and in Alsace)-a reduction that in turn would have compromised its chances of continuing to be elected to the German kingship. Philip II of Spain remained territorially the greatest sovereign in the Western world until his death in 1598; but the Revolt of the Netherlands (see LOW COUNTRIES), which he proved unable to subdue, was an irritation that his English and French enemies did their worst to inflame.

Cooperation between imperial and Spanish Habsburgs in the 17th century failed to maintain the hegemony that the dynasty had enjoyed in the 16th. For the imperial line, religious troubles in Germany and in central Europe went on even when the domestic conflict between the insane emperor Rudolf II and his brothers was over (1612); and the Bohemian insurrection of 1618 gave rise to that chain of wars involving the Austrian Habsburgs that, because it was prolonged until 1648, is known conventionally as the Thirty Years' War. For the Spanish Habsburgs, their truce of 1609 with the Dutch ended in 1621, whereupon the renewed conflict in the Netherlands became merged with the struggles of their Austrian cousins. The Peace of Westphalia (1648) finally abolished Habsburg sovereignty over the northern Netherlands, severely restricted the emperor's authority over the other German princes, and transferred the Habsburg lands in Alsace to France; however, the ordinance of 1627, whereby the Bohemian crown had been converted into a hereditary one for the Habsburgs, was permitted to stand.

France from the late 1620s had made the most of the Thirty Years' War to distress the Habsburgs of both lines, and peace with the imperial line did not prevent France from continuing its war against the Spanish until 1659, when by the Peace of the Pyrenees it obtained Gravelines, most of Artois, and part of Hainaut, together with some places south of Luxembourg.

The next 30 years saw the end of the Habsburg dynasty's claim to European hegemony in any real sense. The aggressions of Louis XIV of France, from 1667 onward, took territory after territory from the Spanish Habsburgs-large parts of Flanders, the rest of Artois, and other areas in the Netherlands, as well as the whole Franche Comté and, in 1684, the stronghold of Luxembourg-and demonstrated at the same time that the imperial Habsburgs, preoccupied as they were with the Turkish assault from Hungary, could not effectively defend the German frontier west of the Rhine. After being saved from the crisis of the Turkish siege of Vienna in 1683, the imperial Habsburgs did indeed obtain one dynastically significant successthe conversion, in 1687, of the Hungarian crown into an hereditary one for themselves-but by this time it was plain to Europe that the most formidable dynasty was no longer the Habsburg but the Bourbon. In the War of the Grand Alliance (1689-97) the rising powers that 100 years earlier had been Habsburg Spain's principal enemies and feeble France's most fluent encouragers, the Dutch and English, led those supporting the Habsburgs against Louis XIV.

Apart from the Bourbon ascendancy, there was a further reason for other powers to watch with jealous solicitude over the fate of Spain. The physical debility of Charles II of Spain was such that no male heir could be expected The Thirty Years' War

The challenge of 17thcentury France

The imperial and the Spanish lines

The Snanich succession

to be born to him, and the question of his succession was one of great concern to the European powers. Up to 1699 it was understood that his crowns would pass to the electoral prince of Bavaria, Joseph Ferdinand, son of his niece Maria Antonia, daughter of the emperor Leopold I; and this arrangement was generally acceptable because, by transferring the Spanish inheritance to the Bavarian House of Wittelsbach, it would not necessarily upset the balance of power between the imperial Habsburgs and Bourbon France. In 1699, however, when Joseph Ferdinand died, the moribund Charles II's next natural heirs were the descendants (1) of his half-sister, who had married Louis XIV of France, and (2) of his father's two sisters, of whom one had been Louis XIV's mother and the other the emperor Leopold I's. Critical tension developed: on the one hand neither the imperial Habsburgs nor their British and Dutch friends could consent to their Bourbon enemy's acquiring the whole Spanish inheritance; on the other neither Bourbon France nor its British and Dutch enemies wanted to see an imperial Habsburg reunite in one pair of hands most of what the emperor Charles V had had in 1519. Charles II in the meantime regarded any partition of his inheritance as a humiliation to Spain: dying in 1700, he named as his sole heir a Bourbon prince, Philip of Anjou, the second of Louis XIV's grandsons. The War of the Spanish Succession ensued.

THE HABSBURG SUCCESSION IN THE 18TH CENTURY

To allay British and Dutch misgivings, Leopold I and his elder son, the future emperor Joseph I, in 1703 renounced their own claims to Spain in favour of Joseph's brother Charles, so that he might found a second line of Spanish Habsburgs distinct from the imperial; but when Joseph I died, leaving only daughters, in 1711, and was succeeded by his brother as emperor (Charles VI) and as ruler of the Austrian, Bohemian, and Hungarian lands, the British and the Dutch lost interest in making him king of Spain and together began serious negotiations with France. Their Treaties of Utrecht (1713), which recognized the Bourbon accession to Spain and to Spanish America, virtually forced the hand of the reluctant Charles, who made peace with France by the Treaty of Rastatt in 1714: out of the whole inheritance of the Spanish Habsburgs, he had finally to content himself with the southern Netherlands and with the former Spanish possessions on the mainland of Italy, together with Mantua (annexed by him in 1708) and Sardinia. Sardinia, however, was exchanged by him in 1717 for Sicily, which the peacemakers of Utrecht had assigned to the House of Savoy. With characteristic obstinacy, Charles remained technically at war with Bourbon Spain until 1720, when an armistice was declared (formal

recognition of the Bourbon accession came only in 1725). Meanwhile the extinction of the Spanish Habsburgs' male line and the death of his brother Joseph left Charles, in 1711, as the last male Habsburg. He had therefore to consider what should happen after his death. No woman could rule the Holy Roman Empire, and furthermore the Habsburg succession in some of the hereditary lands was assured only to the male line. In order, therefore, to secure the indivisibility of his Habsburg inheritance he issued his famous Pragmatic Sanction of April 19, 1713, prescribing that, in the event of his dying sonless, the whole inheritance should pass (1) to a daughter of his, according to the rule of primogeniture, and thence to her descendants; next (2) if he himself left no daughter, to his late brother's daughters, under the same conditions; and finally (3) if his nieces' line was extinct, to the heirs of his paternal aunts. The attempt to win general recognition for his Pragmatic Sanction was Charles VI's main concern from 1716 onward (his baby son died in that year). By 1738, at the end of the War of the Polish Succession (in which he lost both Naples and Sicily to a Spanish Bourbon but got Parma and Piacenza for the Habsburgs in compensation), he seemed to have won his point: Saxony, Bavaria (grudgingly and with an express reservation), Spain, Russia, Prussia, Hanover-England, and finally France (with a reservation about third-party rights) had all, in one way or another, acknowledged the Pragmatic Sanction. His hopes were illusory: less than two months after his death, in

1740, his daughter Maria Theresa had to face a Prussian invasion of Silesia, which unleashed the War of the Austrian Succession. Bavaria then promptly challenged the Habsburg position in Germany; and France's support of Bavaria encouraged Saxony to follow suit and Spain to try to oust the Habsburgs from Lombardy. Great Britain came, late enough, to support Maria Theresa rather out of hostility toward France than out of loyalty to the Pragmatic Sanction.

HABSBURG-LORRAINE

The War of the Austrian Succession cost Maria Theresa most of Silesia, part of Lombardy, and the duchies of Parma and Piacenza (Treaty of Aix-la-Chapelle, 1748) but left her in possession of the rest of her father's hereditary lands. Moreover, her husband, Francis Stephen of Lorraine, who in 1737 had become hereditary grand duke of Tuscany, was finally recognized as Holy Roman emperor, with the title of Francis I. He and his descendants, of the House of Habsburg-Lorraine (see Table 3), are the dynastic continuators of the original Habsburgs.

The peace of 1748 did not last long. Prussia was not satiated by the seizure of Silesia from the Habsburgs, and they in turn were even more determined to recover Silesia than anxious to ensure the protection of their outlying possessions in the Netherlands against the continuing danger of French attack. The so-called Diplomatic Revolution, which preceded the Seven Years' War of 1756-63, was the product, basically, of these situations: finding that their former British friends were more interested in conciliating Prussia than in abetting Austro-Russian plans for destroying it, the Habsburgs played their part in the "reversal of alliances" by achieving-without territorial profit-a reconciliation with France, hitherto their longest-standing enemy. An Austro-French entente was subsequently maintained until 1792: the marriage of the archduchess Marie-Antoinette to the future Louis XVI of France (1770) was intended to confirm it.

To secure their imperial status in Germany against Prussian enterprises, the Habsburgs exerted themselves to consolidate and to expand their central European bloc of territory. For this purpose Tuscany and the Netherlands were practically irrelevant. Tuscany in fact was kept separate from the ancient Habsburg inheritance: when the emperor Francis I died (1765), his eldest son, the emperor Joseph II, became coregent with his mother of the Austrian dominions, but Joseph's brother Leopold became grand duke of Tuscany; and similarly when Leopold succeeded to Joseph's titles (1790), his own second son succeeded to Tuscany as Ferdinand III. Thereafter the Tuscan branch of the Habsburgs remained distinct from the senior or imperial line.

The northeastward expansion of Habsburg central Europe, which came about in Joseph II's time, was a result not so much of Joseph's initiative as of external events: the First Partition of Poland (1772), which gave him Galicia and Lodomeria, was a Russo-Prussian arrangement disgusting to his conscientious mother, who remembered Silesia; and his subsequent acquisition of Bukovina (1775). geopolitically logical though it was as bridging a gap between his Transylvanian and his new Galician lands, was a side effect of the Russo-Turkish Treaty of Küçük Kaynarca (1774).

Joseph II was considerably more interested in westward expansion, over Bavaria, which would have both strengthened his western frontier strategically and enhanced his status among the German princes politically. Prussia's forceful opposition, however, reduced his gains in the War of the Bavarian Succession to the Innviertel (1779) and frustrated his plan for ceding the Netherlands to the House of Wittelsbach in exchange for Bavaria five years later (1784).

The French Revolutionary and Napoleonic Wars brought a kaleidoscopic series of changes. Three were clearly significant for the future of the House of Habsburg: (1) the formal dissolution of the Holy Roman Empire in 1806, in anticipation of which Leopold II's successor Francis II had in 1804 begun to style himself "hereditary emperor of Austria," a title that, as Francis I, he could retain come of Prussia

Pragmatic Sanction and the Austrian succession

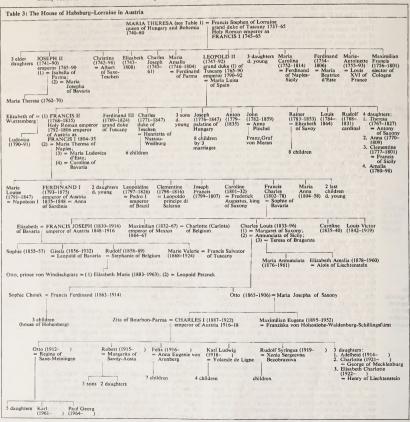

The

what might; (2) the definitive renunciation of the southern Netherlands by the Habsburgs in 1797; and (3) the awakening of the spirit of nationalism in the modern sense.

On Napoleon's downfall the Congress of Vienna (1814-15) inaugurated the Restoration, from which the battered House of Habsburg naturally benefitted. Francis I of Austria recovered Lombardy (lost in 1797), Venetia and Dalmatia (both of them acquired in 1797 but lost in 1809), and Tirol (lost also in 1809); Ferdinand III of Tuscany recovered his grand duchy; another Habsburg was recognized as sovereign duke of Modena, because his father, a brother of the Holy Roman emperors Joseph II and Leopold II, had in 1771 married the heiress of the House of Este; and Napoleon's Habsburg consort, Marie Louise, received the duchies of Parma and Piacenza for her lifetime (after which they were to revert to the Bourbons). The territory of Salzburg, which the Habsburgs had acquired in 1803 but lost to Bavaria in 1809, was finally restored to Austria in 1816. Though the Congress of Vienna did not restore Austrian rule over "Western Galicia" (the Habsburgs' share under the Third Partition of Poland in 1795, lost likewise in 1809), a small part of that area, namely the territory of Cracow, was annexed by Austria in 1846

The history of the House of Habsburg for the century following the Congress of Vienna is inseparable from that of the Austrian Empire, a bastion of monarchical conservatism that the forces of nationalism-German, Italian, Hungarian, Slav, and Romanian-gradually eroded. The first territorial losses came in 1859, when Austria had to cede Lombardy to Sardinia-Piedmont, nucleus of the emergent kingdom of Italy, and could do nothing to prevent the same power from dispossessing the Habsburgs of Tuscany and of Modena. Next, the Seven Weeks' War of 1866, in which Prussia, exploiting German nationalism. was in alliance with Italy, forced Austria both to renounce its hopes of reviving its ancient hegemony in Germany and to cede Venetia. After this disaster the Habsburg emperor

National. ism against the dynasty

Francis Joseph took a step intended to consolidate his "multinational empire": in 1867, to conciliate Hungary, he granted to that kingdom equal status with the Austrian Empire in what was henceforth to be the Dual Monarchy of Austria-Hungary. The result, however, was that the Magyars, jealous of their unique parity with the Germans and of their superiority over the non-Magyar peoples of their kingdom, rejected any suggestion of conciliating the Slavs and the Romanians of the Dual Monarchy by similar measures. The ardent German nationalists of the Austrian Empire, as opposed to the Germans who were simply loyal to the Habsburgs, took the same attitude as did the Magyars.

Remote from Austria's national concerns but still wounding to the House of Habsburg was the fate of Francis Joseph's brother Maximilian: set up by the French as emperor of Mexico in 1864, he was executed by a Mexican firing squad in 1867. No less grievous to the dynasty and of more concern to Austria-Hungary was the suicide of the crown prince Rudolf in 1889, though his fitness for the imperial and royal succession was questionable; and the scandalous misconduct of certain archdukes and archduchesses, in the imperial and in the Tuscan lines alike, further impaired the Habsburgs' personal prestige. The assassination of Francis Joseph's Wittelsbach consort Elizabeth in 1898 was to be followed in less than two decades by an assassination of far greater consequence.

In 1878 Austro-Hungarian forces had "occupied" Bosnia and Herzegovina, which belonged to decadent Turkey. In 1908 that territory had been formally annexed to Austria-Hungary, in a manner that was outrageous not only to Serbia (which coveted Bosnia for itself) but also to Serbia's patron, Russia. Visiting the Bosnian capital. Saraievo, in 1914, the archduke Francis Ferdinand, heir presumptive to the Dual Monarchy (and incidentally legatee, from 1875, of the rights of the House of Austria-Este to Modena), was shot to death by a nationalist Serb. A month

later the First World War was beginning.

World War I led to the dismemberment of the Habsburg Empire. While Czechs, Slovaks, Poles, Romanians, Serbs, Croats, Slovenes, and Italians were all claiming their share of the spoil, nothing remained to Charles, the last emperor and king, but "German" Austria and Hungary proper. On November 11, 1918, he issued a proclamation recognizing Austria's right to determine the future form of the state and renouncing for himself any share in affairs of state, and on November 13 he issued a similar proclamation to Hungary. Even so, he did not abdicate his hereditary titles either for himself or for the Habsburg dynasty. Consequently the national assembly of the Austrian Republic passed the "Habsburg Law" of April 3, 1919, banishing all Habsburgs from Austrian territory unless they renounced all dynastic pretensions and loyally accepted the status of private citizens. In Hungary, however, the collapse of the republican regime at the end of 1919 raised strong royalist hopes of a Habsburg restoration, and after the conclusion of the Treaty of Trianon (June 1920) Charles twice tried to return (March and October 1921). Under pressure from the other European powers, especially those of the Little Entente (Czechoslovakia, Yugoslavia, and Romania), the Hungarian parliament on November 3, 1921, decreed the abrogation of Charles's sovereign rights and of the Pragmatic Sanction.

Habsburg property rights in Austria, forfeited under the law of 1919, were restored in 1935 but withdrawn again by the German chancellor Adolf Hitler in 1938. After World War II the Allied Control Council in Austria in January 1946 declared that it would support the Austrian government in measures to prevent any return of the Habsburgs, and the law of 1919 was written into the Austrian State Treaty of 1955. In June 1961 the Austrian government rejected an application by the archduke Otto, head of the House of Habsburg, to be allowed to return to Austria as a private citizen, but in 1963 the administrative court of Austria ruled that Otto's application was legal. Because of Socialist opposition to his return, however, he was not granted a visa until June 1966 after the People's Party had won a majority in that year's general election. (J.R.-S.)

BIBLIOGRAPHY. For the English-language reader, the most comprehensive introduction to the subject remains WILLIAM COXE, History of the House of Austria, 3rd ed., 4 vol. (1847-53. reprinted 1901-05), an oft-neglected work covering Habsburg history from 1218 to 1848. ADAM WANDRUSZKA, The House of Habsburg: Six Hundred Years of a European Dynasty (1964, reprinted 1975; originally published in German, 1956), covers this same period in a brief but authoritative manner. Students able to read German will find a wealth of information in the multivolume series Die Habsburgermonarchie, 1848-1918, ed. by ADAM WANDRUSZKA and PETER URBANITSCH (1973-

Dy ADAM WANDRUSZKA and FETER GRBANINGR (1973). One of the best works on the early years of the Habsburg dynasty is ROBERT J.W. EVANS, The Making of the Habsburg Monarchy, 1550–1700 (1979, reissued 1985). Works in English on the Habsburgs in the 19th and 20th centuries vary in scope and in quality, C.A. MACARTNEY, The Habsburg Empire, 1790-1918 (1968, reprinted with corrections, 1971), also available in a condensed, more accessible version, The House of Austria: The Later Phase, 1790-1918 (1978), provides a masterly survey by an expert. A.J.P. TAYLOR, The Habsburg Monarchy, 1809-1918: A History of the Austrian Empire and Austria-Hungary, new ed. (1948, reprinted 1976), is rather severely critical of the dynasty's failings.

Other studies include DOROTHY GIES MCGUIGAN, The Habsburgs (1966); VICTOR L. TAPIÉ, The Rise and Fall of the Habsburg Monarchy (1971; originally published in French, 1969); HUGH TREVOR-ROPER, Princes and Artists: Patronage and Ideology at Four Habsburg Courts, 1517-1633 (1976, reissued 1991), an illustrated study; ROBERT A. KANN, A History of the Habsburg Empire, 1526-1918 (1974); and JOHN LYNCH, Spain

Under the Habsburgs, 2 vol., 2nd ed. (1981).
EDWARD CRANKSHAW, The Fall of the House of Habsburg (1963, reprinted 1983), together with his lavishly illustrated The Habsburgs: Portrait of a Dynasty (1971), makes a brilliant and easily readable vindication of the last emperor, ARTHUR J. MAY, The Hapsburg Monarchy, 1867-1914 (1960), is fair and scholarly, with a good bibliography, and is continued in his The Passing of the Hapsburg Monarchy, 1914-1918, 2 vol. (1966). Z.A.B. ZEMAN, The Breakup of the Habsburg Empire, 1914-1918 (1961, reprinted 1977), gives a just account of a subject usually misrepresented. Additional studies of the fall of the Habsburg dynasty include OSCAR JÁSZI, The Dissolution of the Habsburg Monarchy (1929, reissued 1961); and ALAN SKED. The Decline and Fall of the Habsburg Empire, 1815-1918 (1989).

Genealogical detail is available in WALTHER MERZ, Die Habsburg (1896), which contains 19 tables; and MICHEL DUGAST ROUILLÉ, Les Maisons souveraines de l'Autriche, Babenberg, Habsbourg, (Habsbourg-d'Espagne), Habsbourg-Lorraine, (Lorraine) (1967), also well-tabulated and with illustrations. Discussions of physical heredity are found in OSWALD RUBBRECHT, L'Origine du type familial de la maison de Habsbourg (1910); WILHELM STROHMAYER, Die Vererbung des Habsburger Familientypus (1937); and JOHN LANGDON-DAVIES, Carlos, the King Who Would Not Die (also published as Carlos, the Bewitched, 1963).

There have been several good studies of economic development during the Habsburg reign. DAVID F. GOOD, The Economic Rise of the Habsburg Empire, 1750-1914 (1984), is a solid survey. More advanced students may examine JOHN KOMLOS, The Habsburg Monarchy as a Customs Union: Economic Development in Austria-Hungary in the Nineteenth Century (1983). Also worthy of inspection is JOHN KOMLOS (ed.), Economic Development in the Habsburg Monarchy in the Nineteenth Century. Essays (1983), International relations and Habsburg foreign policy are the subjects of H.G. KOENIGSBERGER, The Habsburgs and Europe, 1516-1660 (1971); F.R. BRIDGE, The Habsburg Monarchy Among the Great Powers, 1815-1918 (1990); and SAMUEL R. WILLIAMSON, JR., Austria-Hungary and the Origins of the First World War (1991). (J.R.-S./Ed.)

World War I and after

Hamburg

he Free and Hanseatic City (Freie und Hansestadt) of Hamburg, on the Elbe River, is the second smallest of the 16 Länder (states) of Germany, with a territory of only 292 square miles (755 square kilometres). It is also the most populous city in Germany after Berlin and one of the largest and busiest ports in Europe. The official name, which covers both the Land and the town, reflects Hamburg's long tradition of particularism and self-government. Hamburg and Bremen (the smallest of the Länder) are, in fact, the only German city-states that still keep something of their medieval independence. The characteristic individuality of Hamburg has been proudly maintained by its people so that, in many spheres of public and private life, the city's culture has retained its uniqueness and has not succumbed to the general trend of standardization.

Hamburg, nonetheless, is a cosmopolitan city in its out-

look. Although comparatively few foreigners live there. many pass through it. The city has dealings with a large number of nations, and it has more consulates than any other city in the world, except New York City. Shipping and trade have been Hamburg's lifeblood for centuries. Not surprisingly, its harbour has remained the city's most important feature.

Among Hamburg's many other facets are a network of canals reminiscent of Amsterdam; lakes, parks, and verdant suburbs full of gracious houses; elegant shopping arcades; richly endowed museums; and a vibrant cultural life. These are among the attractions that have contributed to a growing tourist industry. Although it was badly damaged during World War II, Hamburg has succeeded in maintaining a sense of old-world grace alongside its thriving commercial life.

Physical and human geography

THE LANDSCAPE

Site. Hamburg stands at the northern extremity of the Lower Elbe Valley, which at that point is between five and eight miles (eight and 13 kilometres) wide. To the southeast of the old city, the Elbe divides itself into two branches, the Norderelbe and the Süderelbe; but these branches meet again opposite Altona, just west of the old city, to form the Unterelbe, which flows into the North Sea some 65 miles downstream from Hamburg. Two other rivers flow into the Elbe at Hamburg-the Alster from the north and the Bille from the east.

The city layout. The nucleus of the city is the Altstadt (Old Town), the former medieval settlement, bounded by the harbour and by a string of roads that follow the line of the old fortifications. Within this core there are few great buildings to remind the visitor of the city's thousand-year history apart from the five principal churches-Sankt Jacobi, Sankt Petri, Sankt Katharinen, Sankt Nikolai, and Sankt Michaelis-and none of these is in its original condition. Fire has destroyed almost all the older residences and warehouses, and what was left untouched by conflagration has often been rebuilt for contemporary purposes. There are, however, a few scattered survivals of older buildings. Moreover, the layout of the old city centre can still be detected in some of the ancient street names and in the Fleete (canals), which connect the Alster with the docks on the Elbe. One of the best views of the inner city is to be enjoyed from the Lombardsbrücke (Lombard Bridge), whence the towers of the five churches can be seen rising high against a skyline that is still relatively harmonious despite the presence of modern skyscrapers.

At the heart of Hamburg is a lake, measuring 455 acres (184 hectares), formed by the damming of the Alster and divided by the Lombardsbrücke into the Binnenalster (Inner Alster) and the Aussenalster (Outer Alster). Around the latter are elegant suburbs such as Rotherbaum, Harvesterhude, and Uhlenhorst. Many waterways, navigable by pleasure boats, run into the Aussenalster.

Architecture. The last intact ensemble of traditional Hamburg architecture is to be found in the Deichstrasse, one side of which backs onto the Nikolai canal. Its tall, narrow houses, resembling those of Amsterdam, were originally built from the 17th through the 19th century. It was in one of them, number 42, now a restaurant, that the devastating fire of 1842 broke out. Afterward the houses were rebuilt in the old style. Today the street is a protected area, and in recent years it has undergone extensive restoration. Many traditional restaurants are found there.

Another survival of older architecture is in the Krameramtswohnungen, near Sankt Michaelis. Consisting of two half-timbered brick buildings on either side of a narrow courtyard, it was built as a series of dwellings for the widows of shopkeepers and is the only surviving 17thcentury construction of its kind in the city. Thoroughly restored between 1971 and 1974, it now forms a delightful secluded alleyway housing a restaurant, small shops, and a branch of the Museum für Hamburgische Geschichte (Museum of Hamburg History).

Of Hamburg's five great churches, the most imposing is probably Sankt Michaelis, an 18th-century Baroque-style Protestant church with a rich white-and-gold interior. It was destroyed by fire in 1906, rebuilt, devastated again during World War II, and restored yet again after the war.

The prosperous years 1890-1910 brought an abundance of fine architecture, examples of which can be seen in the spacious and elegant patrician houses around the Aussenalster. Many of these are now occupied by consulates. Another period of architectural flowering came in the 1920s and 1930s when there was a revival of the use of the traditional north German dark red brick as a building material, led by the architects Fritz Höger and Fritz Schumacher. A good example is Höger's Chilehaus, a massive office building constructed between 1922 and 1924.

More recently Hamburg has acquired its quota of starkly functional modern buildings, such as the Congress Centrum (Congress Centre; opened 1973) and the Fernsehturm (Television Tower), 271.5 metres (891 feet) high, but there is now a strong tendency to renovate old houses

rather than to demolish and build afresh. Thus the townscape of Hamburg as a whole has a human quality lacking in many German cities.

Climate. Hamburg has mild winters, late springs, relatively cool summers, high humidity, and frequent fog. The mean winter temperature is 34.2° F (1.2° C), and the mean summer temperature is 62.4° F (16.9° C)

THE PEOPLE

In 1965 the city had about 1,850,000 inhabitants, but since then the population has been slowly decreasing. More than three-fourths of the residents are Protestants, and the remainder are predominantly Roman Catholic. There is a small Muslim community, which includes many Turkish Gastarbeiter ("guest workers"), and the Jews, of whom there had been 27,000 in 1933 (when Hitler took power), now number only about 1,000.

THE ECONOMY

Industry. Having absorbed Altona, Harburg, and Wandsbek in 1937, Hamburg has become Germany's maior industrial city. All processing and manufacturing industries are represented there. Hamburg treats most of the country's copper supplies, and the Norddeutsche Affinerie, on Veddel, is Europe's second largest copperworks. The chemical, steel, and shipbuilding industries are also important, although shipbuilding has declined as a result of competition from Japan and Korea. Hamburg is also the most important centre in Germany, after Berlin, for newspaper and periodical publishing. Three nuclear plants, at Krümmel, Stade, and Brunsbüttel, provide power at a reasonable cost to the industries bordering the Unterelbe and to parts of Hamburg.

Trade. In the period of German partition, Hamburg handled more than half of West Germany's foreign trade, not only in the form of shipping cargo but also as rail and airfreight. Chief among imports are vegetable oils and fats, tea, coffee, petroleum, tropical fruit, and uncured tobacco. Exports include machinery, electrotechnical products, processed petroleum fuel and lubricants, copper, and pharmaceutical products.

The greatest economic centre of Germany, Hamburg since 1960 has become the site of first-class trade fairs. Many of the fairs and conventions are held at the Ernst-Merck-Halle exhibition grounds, located south of the Planten un Blomen park. An especially popular event is the international boat show, held each winter.

Transportation. The harbour is Hamburg's "gateway to the world." More than 15,000 ships from over 100 countries pass through it each year. The city's Übersee-Zentrum is the world's largest roofed warehouse, and the Waltershof container terminal is the largest of its kind on the continent.

Harbour and city are well served by the German railway network, and the city has a good system of buses and underground trains. To relieve the central city from longdistance traffic, a tunnel was built (opened in 1977) under the Elbe as a part of the Stockholm-Lisbon highway.

The airport of Hamburg-Fuhlsbüttel, which dates from 1911, is one of the oldest in Europe. It has two runways from which even the largest jet-propelled aircraft can still take off.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. According to the constitution of June 6, 1952, legislative authority is vested in the Bürgerschaft (State Parliament), which comprises 120 members elected for a four-year term.

The Bürgerschaft elects the government, the Senat, which is organized on a collegiate basis; the president, or erster Bürgermeister ("first mayor"), is elected by the Senat itself annually, although in practice each incumbent normally stays in office at least four years. The Senat as a whole represents the Free and Hanseatic City of Hamburg in its dealings with the other federal Länder, with the federal government, and with foreign states. Each senator is responsible for a particular department, but administrative problems of a local nature are delegated to the district offices and to the local authorities.

The magnificent Rathaus (City Hall), where the Senat and the Bürgerschaft meet, in the centre of the city near the Binnenalster, was built late in the 19th century in the Neo-Renaissance style.

Hamburg's coat of arms displays a three-towered castle, intended to represent the Hammaburg, silver (argent), on a red (gules) field, its design being derived from the city's great seal of 1241. The state flag likewise shows a white castle on a red field. The state's anthem, "Stadt Hamburg an der Elbe Auen" ("City of Hamburg by the Meadows of the Elbe"), was written by G.N. Bärmann in 1828 and set to music by Albert Methfessel.

The Rathaus on the Alsterfleet in Hamburg.

Education. The Universität Hamburg, founded in 1919. is one of the largest in Germany, with some 46,000 students and faculties covering virtually every discipline except certain technological subjects. A second university, the Technische Universität Hamburg-Harburg, began classes in 1982. Hamburg also has state schools for music and interpretative art and for the sculptural arts, as well as some 250 research centres covering such areas as hydrography, oceanography, tropical medicine, shipbuilding, economics, meteorology, and particle acceleration.

CULTURAL LIFE

Among Hamburg's six principal museums, the Kunsthalle, founded in 1868 by Alfred Lichtwark, an outstanding patron of artists, is one of Europe's most remarkable galleries. It is particularly notable for its collection of 19thand 20th-century works, including many of the German Romantic school. The Museum für Kunst und Gewerbe (Museum of Art and Crafts), founded in 1877 by the jurist Justus Brinckmann, has one of the most significant

Industrial impor-

tance to

Germany

The port of Hamburg collections of ancient artifacts in Germany and is also famous for its examples of Asian art and of Jugendstil (Art Nouveau). The Museum für Hamburgische Geschichte, which has grown from a collection of local antiquities started in 1839, contains a wide range of exhibits, from costumes to parts of old buildings and from architect's drawings to models of ships, shown in such a way as to present an impressive conspectus of the state's history. The Museum für Völkerkunde (Museum of Ethnology and Prehistory), founded in 1878, has impressive collections in its own fields. The Altonaer Museum, opened in 1863, specializes in north German subjects, with special attention to Schleswig-Holstein, and houses Germany's largest collection of old ships' figureheads. The Helms-Museum, in the Harburg district, is a local museum for the part of Hamburg south of the Elbe but also houses antiquities representing the prehistory and early history of the whole territory. The Ernst-Barlach-Haus, in Jenisch Park, was founded in 1961-62 by another great patron of the arts, Hermann F. Reemtsma, to make his private collection accessible to the public. Hamburg's once famous Zoological Museum was destroyed by bombs in 1943 after a century

Music and drama in Hamburg of existence.

The Hamburg Staatsoper, which dates from 1678, has won world renown. Its performances of classical and contemporary works bear comparison with those given by the great opera houses of Vienna, Milan, London, and New York City. The Deutsche Schauspielhaus, a leading theatre, enjoyed a particularly high reputation from 1955 to 1963, when Gustaf Gründgens directed and performed there. The Thalia-Theater, founded in 1843, with a multifaceted program that includes plenty of light entertainment, is popular with local audiences. All three establishments are generously funded by the state. The numerous other theatres include the tiny Piccolo-Theater and the Hansa-Theater, said to be the last genuine variety theatre in the German-speaking world. Plays of a local character or in Plattdeutsch (Low German) are performed in the Ohnsorg-Theater and sometimes in the Sankt Pauli-Theater, which dates from 1841 and is Hamburg's oldest playhouse.

The birthplace of Mendelssohn and Brahms, Hamburg has a sustained tradition of musical activity. Three great orchestres—the Phillbarmonische Staatsorchester, the Symphonie-Orchester des Norddeutschen Rundfunks, and the Hamburger Symfoniker—familiarize the public with classical and contemporary compositions. There are also groups specializing in chamber music, in choral performances, and in church music; and orchestras, choirs, singers, and instrumentalists from other parts of Germany or from abroad are also invited to Hamburg. The fo-cal point of Hamburg's musical life is the Neo-Baroque Musikhalle, built in 1904–1904 with money donated by the

shipowner Carl Laeisz.

An important aspect of Hamburg's history is its prominence as a centre of newspaper and periodical publishing, which dates to the 17th century. By 1830 Hamburg had more newspapers than any other city in Germany. In the 1920s Berlin began its ascendancy as a press centre, and Hamburg fell into second place, which it still occupies, Its daily newspapers include the Hamburger Abendblatt, the Hamburger Morgenpost, and the Bild-Zettung. In addition, a wide range of weekly and monthly magazines issues from the various publishing firms located in the city.

Sports have long been popular in Hamburg. The Hamburger Turnerschaft (1816) is Germany's oldest athletic club. The first German nowing club, founded in Hamburg in 1836, took part in 1837 in Germany's first official rowing race, against the English Rowing Club formed by members of Hamburg's then numerous English colony. The Hamburger Rennklub, for horse racing, was founded in 1852, and the North German Derby, first run in 1869, became an annual event, as the German Derby, from 1889 onward. Hamburg's first public football matches were played in 1881–82, after disputes about the rules of the game with the local Anglo-American Football Club. Another noteworthy event is the international tennis championship, which takes place every year in May.

An aspect of the city that cannot be ignored is its world-

famous red-light district, centred on the Reeperbahn, where prostitution is legally permitted and kept under control by the police. Another famous Hamburg institution is the colourful Sunday-morning market held at the Fischmarkt by the harbour, where items ranging from fish to secondhand household goods are available.

History

EARLY SETTLEMENT AND MEDIEVAL GROWTH

Hamburg's history begins with the Hammaburg, a moated castle of modest size, built in about AD 825 on a sandy promontory between the Alster and Elbe rivers. In 834, during the reign of the emperor Louis the Pious, the castle's baptistery became the seat of an archbishopric, and Archbishop Ansgar made the young city of Hamburg the base of his missions to the heathens of northern Europe. Vikings burned the city in 845, and the rebuilt Hamburg was burned down again eight times in the following 300 years. By the end of the 11th century, Hamburg's role as the spiritual metropolis of the north was over, and henceforth commerce rather than religion was to be the principal raison d'être of the city. Between 1120 and 1140 some trading businesses were installed, and the foundation of Lübeck, on the Baltic, by Adolf II, count of Holstein, further promoted the economic development of Hamburg as Lübeck's port on the North Sea. In the autumn of 1188 a group of Hamburg entrepreneurs received from their feudal overlord, Adolph III of Schauenburg (Schaumburg), count of Holstein, a charter for the building of a new town, adjacent to the old one, with a harbour on the Alster River and with facilities for the use of the Elbe River as an outer roadstead. On May 7, 1189, the emperor Frederick I Barbarossa confirmed Count Adolph's dispositions in a charter granting special trading rights, toll exemptions, and navigation privileges.

In the 13th century Hamburg grew steadily in both area and economic importance, owing to the development of the Hanse (an association of merchants trading in a particular area) into a widespread association of north German merchant cities, the great Hanseatic League, in which Hamburg's role was second only to Lübeck's. A major entrepôt for the trade between Russia and Flanders, Hamburg proceeded to safeguard the trade routes by acquiring tracts of land along the branches of the Elbe in the immediate vicinity of the town and also on the estuary farther downstream (Ritzebüttel, nucleus of the later Cuxhaven, was acquired by Hamburg in 1393). It thus came to control the use of the river and to be recognized as the protector, in the emperor's name, of navigation on its lower course. Some political complications arose with the death, in 1459, of the last Schauenburg count of Holstein, since his princely rights in Germany passed thereafter to the royal house of Denmark, but Hamburg scarcely recognized Danish suzerainty in any but a formal way.

Role in the Hanseatic League

EVOLUTION OF THE MODERN CITY

Toward the end of the Middle Ages, the Hanseatic League gradually dissolved. Hamburg then went its own way and by 1550 had surpassed even Lübeck in economic importance. A stock exchange was founded in 1558 and the Bank of Hamburg in 1619; a convoy system for shipping was inaugurated in 1662, Hamburg's merchantmen being the first to be escorted on the high seas by menof-war. About the same time marine insurance was first introduced into Germany. There were two causes for this new ascendancy: first, the wars of religion in the Low Countries in the second half of the 16th century had prompted many Dutch merchants to emigrate to the Unterelbe (Lower Elbe) region, with the result that Hamburg was henceforth to be the focus of their already established international commerce; second, the city had been so efficiently fortified in the decade 1616-25 that it could pursue its business untroubled throughout the worst crises of the Thirty Years' War (1618-48). By the end of the 17th century, Hamburg, with 70,000 inhabitants, was the largest city in Germany after Cologne.

The Treaty of Gottorp, concluded with the Danes on May 27, 1768, released Hamburg from theoretical subjec-

Sports

tion to the king of Denmark and so paved its way to being acknowledged, in 1770, as an "immediate" imperial city of Germany (that is, having no overlord other than the emperor). In addition, the treaty ceded to Hamburg the islands, from Veddel to Finkenwerder, that lay between the city and the left banks of the Elbe River and that, a century later, were to be the site of new docks. Hamburg, however, was not to enjoy its new advantage for long: the Napoleonic Wars overthrew the old order in Germany, and in 1810 the little state was annexed to Napoleon's French Empire.

After Napoleon's downfall (1814-15), Hamburg became a member state of the German Confederation, with the designation "Free and Hanseatic City of Hamburg" from 1819. Prosperity was quickly recovered, as Hamburg's trade was extended to newly opened territories in Africa. Asia, and the Americas. Even the great fire of May 1842, which devastated one-fourth of the city, did not check the booming economy, and the harbour was converted into one accessible at any time, without ships' having to depend on the state of the tides in the Elbe Estuary. Under the German Empire, founded in 1871, the political status of Hamburg was maintained, and development proceeded unchecked. The splendid Baroque houses of the densely populated Brook Island were demolished in the 1880s to make room for the warehouses of the new free port. By the end of the 19th century, in the course of which the population grew from 130,000 to 700,000, Hamburg had expanded far beyond its previous limits, absorbing such former suburbs as Sankt Pauli and Sankt Georg and spreading its tentacles into the countryside, toward Eimsbüttel, Eppendorf, Harvestehude, and Barmbek.

Hamburg entered the 20th century determined to maintain and to strengthen its position as "Germany's gateway to the world"; new docks and wharves were constructed on the left bank of the Elbe River. The outbreak of World War I in 1914 brought progress to a standstill, however, Hamburg's international trade collapsed, and its merchant fleet of 1,466 ships was virtually confined to port. After the war the victorious Allies demanded nearly all of Hamburg's ships by way of reparation from Germany.

For many years after the war, Hamburg could undertake no further development because it had already exhausted all the potentialities of its territory. The Greater Hamburg Ordinance of January 26, 1937, changed this situation by allowing Hamburg to incorporate the neighbouring cities of Altona, Wandsbek, and Harburg, which until then had belonged to Prussia. The immediate prospect of expansion, with the development of these areas on a basis of large-scale planning, was shattered by the outbreak, in 1939, of World War II, during which repeated air raids demolished 55 percent of Hamburg's residential area and 60 percent of the harbour installations and killed 55,000 people. When the war ended in 1945, only the most strenuous efforts could supply the elementary needs for Hamburg's

Reconstruction proceeded rapidly, however. Symptomatic of the city's postwar commercial efflorescence was the vast new business district City-Nord, built in the 1960s. At the same time, nightclubs on the Reeperbahn became proving grounds for British rock and roll bands-most notably the Beatles-who took advantage of a direct ship route from Liverpool, England. In 1962 the city experienced a flood, which killed more than 300 people and destroyed much of the old part of the city. In the mid-1960s, Hamburg's population exceeded 1.800,000, though it has fallen in the decades since, owing to a population shift toward the suburbs. With continued immigration of foreigners to the city, Hamburg's foreign-born population reached 10 percent by the 1980s

The unification of Germany in 1990 increased trade between the city and eastern and central Europe. During the 1990s the city underwent continued modernization. In 1993 Hamburg hosted a multimedia festival, an exhibition on the use of modern communication methods in business and the arts. The following year the city became the seat of a Roman Catholic bishopric.

Hamburg's cherished traditions, together with its thriving business and cultural life and the energy of its inhabitants, make it one of the most vibrant cities in the world.

The city between World Wars I and II

Harvey

leading English physician of the first half of the 17th century, William Harvey achieved fame by his conclusive demonstration of the true nature of the circulation of the blood and the function of the heart as a pump. Functional knowledge of the heart and the circulation had remained almost at a standstill ever since the time of the Greco-Roman physician Galen-1,400 years earlier. Harvey's courage, penetrating intelligence, and precise methods were to set the pattern for research in biology and other sciences for succeeding generations, so that he shares with William Gilbert, investigator of the magnet, the credit for initiating accurate experimental research throughout the world.

esy of Hempstead Parish Church, Essex, éhotograph, the Royal Academy of Arts, London

Harvey, marble bust by Edward Marshall. In Harvey Chapel, St. Andrews Church, Hempstead, Essex.

William Harvey was born on April 1, 1578, at Folkestone, Kent. His father, Thomas Harvey, was a prosperous businessman and a leading citizen of the small town. William, the eldest of nine children, was the only one to achieve special distinction in his career, but all his brothers were successful in business or at the royal court in London and among them amassed considerable wealth.

Career as physician and scientific innovator. Little is known of William Harvey's boyhood in the Kentish countryside. During the years 1588 to 1593 he was at the King's School attached to the cathedral at Canterbury. In his 16th year Harvey entered Gonville and Caius College, Cambridge, where he was awarded a scholarship in 1593. Although Harvey attended Caius College because of its special interest in educating doctors, his training was grossly inadequate. He was absent from the university for the greater part of his last year (1598-99) because of illness-probably malaria-but had received the B.A. degree in 1597. Determined to continue with medical training, he began a two-and-a-half-year course of study at the University of Padua, reputed to have the best medical school in Europe. His teacher was a celebrated anatomist, Hieronymus Fabricius ab Aquapendente, and it was in the now-famous oval Anatomy Theatre, still to be seen at the university, that Harvey first recognized the problems posed by the function of the beating heart and the properties of the blood passing through it.

From the time of Aristotle in the 4th century ac it had been widely believed that the blood vessels contained both blood and air. Galen, the Greco-Roman physician, in the 2nd century AD proved that the arteries contained only blood but still believed that air entered the right side of the heart from the lungs. There was a general belief that the movement of the blood was by ebb and flow, an analogy being found in the movement of the sea. Galen's views on this are difficult to assess with exactitude, but it is apparent that he, like everyone else, had no conception of a circular movement of the blood, leaving the heart by one set of vessels, the arteries, and returning to it by another set, the veins. The main propulsive force initiating this oscillatory movement was supposed to be derived from a contracting of the arterial system, rather than by a pumping action of the heart. The blood in the veins was believed to be formed in the liver, passing to the right auricle (i.e., one of the two upper chambers of the heart), and from there to the right ventricle (one of the two lower chambers), to make its way through holes in the septum, or partition, to the left side, where it met with blood from the arteries, which was mixed with air derived from the lungs. This was the extent of man's knowledge about the movement of the blood until 14 centuries later. Early in the 16th century the idea of a pulmonary circulation-that is, a circular motion of blood through heart and lungs-began to occur to some anatomists. In addition, the presence of a perforated septum was beginning to be questioned. In the middle of the 16th century a great anatomist, Andreas Vesalius, also working at Padua, first established accurate knowledge of human anatomy but was less interested in function. Several other medical investigators refined the anatomical knowledge of the heart. Realdus Columbus of Cremona, working as assistant to Vesalius, developed the idea of a pulmonary circulation, and this was made more definite by his pupil, Andreas Caesalpinus, though they still thought that the blood was distributed to the body by the great veins and their branches. Fabricius had a special interest in the anatomy of the veins and first described the system of valves found in them, but he was quite ignorant of their true function. In brief, there existed no convincing explanation of how the heart worked, and Harvey's logical mind remained unsatisfied.

His 28 months at Padua are only meagrely documented, but it is clear that he was outstanding among the students of his year. After receiving his diploma as doctor of medicine of Padua in April 1602, he returned to England. By the standards of the time he was fully trained in anatomy, the simpler functions of the human body, and in therapeutics based on the writings of Aristotle. He had had some clinical experience in the hospitals of Padua and Venice and was entitled to obtain a fellowship of the College of Physicians in London after passing through the preliminary stage of candidate for the higher qualification. At his first oral examination, in May 1603, he was given limited permission to practice medicine, but only after further examinations in April and August 1604 was he fully licensed to practice within the jurisdiction of the college-that is, in the London area.

Shortly after his return to England, Harvey married Elizabeth Browne, daughter of Lancelot Browne, physician to King James I and his queen, and a senior fellow of the college. The couple set up house in the parish of St. Martin's by Ludgate, not far from the College of Physicians; and, backed by Browne, Harvey then tried to obtain the appointment of physician to the Tower of London, where a number of distinguished men were imprisoned. Though he failed in this attempt, in 1607 he finally obtained a fellowship of the College of Physicians, which entitled him to seek an appointment as physician to one of the two great hospitals then serving London-St. Bartholomew's and

theories of the heart and circulation

Appointment to St. Bartholomew's

Scientific

research

St. Thomas's. It may have been through his brother John, who had obtained employment in the King's household, that early in 1609 the King gave Harvey a recommendation for an appointment at St. Bartholomew's, which was conveniently near his house in St. Martin's. He was given the post of assistant physician, and, when the physician died in the summer of that year, Harvey succeeded him. The hospital at that time had about 200 beds for patients in 12 wards. Harvey's duties consisted of attending in the hall of the hospital to see the patients and prescribe for their treatment; he worked at least one day a week throughout the year and at any other time when specially needed. The physician was usually expected to live within the hospital precincts, but the rule was waived for Harvey since he lived not far away. He received an annual salary of £25 with £2 extra for his livery and a further £8 since he did not use the official residence. His colleagues were three surgeons and an apothecary in charge of the dispensary.

Harvey held this office for 34 years, until 1643 when he was displaced for political reasons by Oliver Cromwell's party, then in power in London. These years saw the development and culmination of his active career as physician and scientific innovator. He developed a large private practice, attending many of the most distinguished citizens, including Sir Francis Bacon-and, about 1618, was made physician extraordinary to King James I, thus becoming a colleague of Sir Theodore Turquet de Mayerne, the senior court doctor. There can be no doubt that Harvey was for many years one of the most widely trusted doctors in England, although his unorthodox views on the circulation of the blood did injure his practice after their publication in 1628. Invariably courteous and regarded with affection and respect by his colleagues, he conducted his practice with common sense and honesty. Though advanced in his ideas of anatomy and physiology and scientific in his methods of research, he was inevitably conservative in the use of remedies. Very few potent drugs were known in his time, and accurate diagnosis was, more often than not, impossible, so that he never escaped from the influence of Aristotle, in whose principles he had been trained. He was the great protagonist of experimental biology but did not apply himself to this form of originality in therapeutics.

At the time of the King's last illness in 1625, de Mayerne was out of the country, and Harvey led the team of doctors in attendance. After the King's death it was rumoured that his favourite, the Duke of Buckingham. had contributed to the fatal outcome by applying remedies not approved by the doctors. He was actually accused of having poisoned the King, and an inquiry was ordered by Parliament in 1626. Harvey was the most important witness of several who contributed to exonerating the Duke from any direct responsibility. Charles I, the new king, continued Harvey's appointment as his personal physician and gave him a special award for the care he had given the last King. Charles's health remained good until the day of his execution, so that he rarely had need to consult his doctor. Nevertheless, Harvey became his close friend and was always in attendance on his journeys, such as his state visits to Scotland in 1633 and 1638. The King helped Harvey's scientific research by putting the deer in the royal parks at his disposal, and he delighted in showing the King anything of curiosity or scientific interest. At the same time, Harvey took his full share in the affairs of the College of Physicians, being constantly present at the meetings of the fellows and occupying all the official positions in the college hierarchy except that of president. His duties at court would not have allowed him to fill this position during his active years, and when it was offered to him in 1654 he was too old and ill to be able to accept. Yet it is clear from the college records that Harvey was always the man to whom his colleagues turned for advice. The physicians at this time had precedence over the other branches of the profession, and Harvey had a prominent part in maintaining this ascendancy over the surgeons, obstetricians, and apothecaries whenever they became restive

under the authority of the college. In spite of Harvey's activity in medical practice and college affairs, he spent much time in scientific research from the time of his return to England in 1604 until the begin-

ning of the Civil War in 1642. His interest lay primarily in elucidating the facts of the movement of the heart and its relation to the circulation of the blood. Fabricius at Padua had opened his eyes to the value of comparative anatomy, and he was tireless in dissecting every kind of living thing, from insects, earthworms, reptiles, birds, and mammals up to man himself. He seized every opportunity to increase his knowledge of pathology through postmortem examinations and was an acute clinical observer of his patients, not omitting their psychology. Most of his scientific papers were destroyed by parliamentary soldiers during the Civil War, so that there is now no direct evidence of his methods. On the other hand, his lecture notes used from 1616 onward survive. In 1615 he was appointed to a college lectureship intended to cover all parts of medical knowledge, though each lecturer modified the course to suit his own interests. Harvey's manuscript, now in the British Museum, was entitled "Lectures on the Whole of Anatomy." It is written in a very bad hand in mixed Latin and English, and it is incomplete, lacking any account of the skeleton, the sense organs, and other systems. The systematic anatomy is enlivened by many references to comparative anatomy, morbid anatomy, and clinical observations, even naming individuals whom he had treated. It is evident that he wrote these notes before he had come to any conclusions about the circulation of the blood, so that they contain nothing that seriously questioned the authority of Galen. The only reference to his novel views is on a leaf inserted some years later, probably after 1628. Harvey held this lectureship until 1656.

Discovery of circulation of the blood. It is evident from his writings that Harvey reverenced Aristotle, even though he had to dismiss some of his teachings as absurd. He also valued the views of Galen, his predecessor in experimental physiology, and enlisted his support whenever he could do so. Yet Harvey depended essentially on reasoning from his own observations and experiments for proof of his contentions. During the 12 years after 1616, Harvey may have introduced some novelties into his lectures; but, by his own assertions, he demonstrated the results of his researches to his friends privately at the college. In 1628 he finally published his book, Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus (An Anatomical Exercise Concerning the Motion of the Heart and Blood in Animals), a slender volume that established the true nature of the circulation of the blood. With Galen's help, he first disposed finally of the idea that the blood vessels contained air. He then elucidated the function of the valves in the heart in maintaining the flow of blood in one direction only when the ventricles contracted-on the right side to the lungs and on the left to the limbs and viscera. He proved that no blood passed through the septum, separating the two ventricles, and he explained the purpose of the valves in the larger veins in directing the return flow toward the heart. He showed that blood was expelled from the ventricles during contraction, or systole, and flowed into them from the auricles during expansion, or diastole. He proved that the arterial pulse was due to passive filling of the arteries by the systole of the heart and not by active contraction of their walls. He explained the purpose of the pulmonary circulation from the right ventricle through the lungs and back to the left auricle and ventricle. His only failure was in not demonstrating the connection of the arterial and venous systems in the tissues of the limbs by means of the smallest, or capillary, vessels. These he was unable to see, having no adequate form of microscope at his disposal. He was the first scientist to employ measurement of the content of the chambers of the heart and estimation of the total amount of blood in the body-that is, quantification.

Harvey's book made him famous throughout Europe, Fame and though the overthrow of so many time-hallowed beliefs attracted virulent attacks and much abuse from those who did not wish to believe the plain evidence of their senses. He refused to indulge in controversy and made no reply until 1649, when he published a small book answering the criticisms of a French anatomist, Jean Riolan. In this he reiterated some of his former arguments and utterly demolished Riolan's objections.

In 1636 King Charles dispatched a diplomatic embassy to the Holy Roman emperor Ferdinand II at Regensburg, Germany, in an attempt to establish the claim of his nephew, Prince Charles Louis, as Elector Palatine. Harvey was chosen as doctor to the mission and spent ten adventurous months of travel by land and water through territories ravaged by the Thirty Years' War, extending his journey by visits to Vienna, Prague, Venice, Rome, and Naples. At Nuremberg Harvey had a historical encounter with Caspar Hofmann, professor of medicine at the University of Altdorf, whom he attempted, at a public demonstration, to convince of the truth of his doctrine of the circulation. Though he did not succeed, Harvey behaved with great dignity and good temper in the face of obstinate blindness to demonstration of the facts.

At the start of the Civil War in 1642, Harvey was with the King and was in charge of the two princes, Charles and James, in the early stages of the Battle of Edgehill. When the King established his headquarters soon afterward at Oxford, Harvey remained with him and was given the position of warden of Merton College in 1645. Here he resumed his work on the development of the chick in hens' eggs and first met John Aubrey, antiquary and gossip, who afterward left a revealing account of Harvey in his Brief Lives. When the defeated King fled from Oxford to surrender himself to the Scots, Harvey joined him for a time at Newcastle but was forced to leave the King when he was handed over to the parliamentary army and was not allowed to go to him when he was imprisoned in the Isle of Wight. Harvey had never been much interested in politics but felt a deep personal regard for the King and after his execution in 1649 was a broken and unhappy man.

Yet two years later he published his second great book. After the publication of De Motu Cordis, the main achievement of Harvey's life, he had continued active research into the difficult subject of reproduction in animals. This led in 1651 to the publication of Exercitationes de Generatione Animalium (Anatomical Exercitations Concerning the Generation of Animals) through the persuasions of his younger friend Sir George Ent, a fellow of the college. The book contains much of historical and scientific interest. but Harvey's thought was greatly influenced by Aristotle. The book is mainly concerned with the development of the chick in hens' eggs, and Harvey insisted throughout that in all living things the origin of the embryo is to be found in the egg. He investigated also the embryology of deer, rejecting Aristotle's notion that menstrual blood played any part in the formation of the fetus; he also questioned whether or not semen had any influence. Having no microscope, he could not see the spermatozoa. which were not demonstrated until 1686 by Leeuwenhoek working in Holland with stronger lenses. Harvey remained uncertain of how fecundation of the ovum was accomplished and even suggested that it was by a kind of infection resembling the origin of infectious diseases. Aristotle had originated the theory of gradual formation of the embryo, part by part, as opposed to the idea of preformation, meaning that all the parts arose in miniature at the same time. Harvey agreed with Aristotle and crystallized the belief in the term epigenesis, though to him its meaning was extremely simple compared with all that is implied by it at the present time. Aristotle believed in the principle of spontaneous generation of primitive organisms; it is probable that Harvey did not support this belief, but his statements are equivocal, and his position remains uncertain.

Harvey's brothers had been successful merchants, and

their advice, coupled with his skill as a doctor and his naturally austere habits, enabled him to accumulate considerable wealth. But he had become old and ill. He had met with so much opposition and disbelief that his passionate desire to establish scientific truth was partially unsatisfied In his last years under Cromwell's Protectorate, he was regarded as a political "delinquent" owing to his long association with King Charles and was forced to spend most of his time lodging in one or another of his brothers' houses outside London. Though he corresponded with many distinguished foreign doctors, he was reluctant to engage in any further scientific research, saw few patients, and took little part in the affairs of the College of Physicians. He showed his regard for the fellows by giving them a new college building in 1652 with a library containing his own collection of books and presumably any remaining manuscripts. This was in use for less than 14 years, being destroyed in the Great Fire of London in 1666, so that very few of his books have survived to the present day. He suffered severe pain from gout and kidney stones and described himself to a correspondent as "not only ripe in years, but also a little weary and entitled to an honourable discharge" from further scientific argument. His last illness was brief. He awoke one morning partially paralyzed and unable to speak, probably owing to a cerebral thrombosis. He died in his 80th year on June 3, 1657, probably in his brother Eliab Harvey's house at Roehampton. He was buried in the family vault at Hempstead, an Essex village 50 miles (80 kilometres) from London. In 1883 he was reburied in a marble sarcophagus in the Harvey Chapel there, near a marble bust by Edward Marshall. This is a lifelike image of Harvey, better, probably, than any of the existing portraits of him in old age.

BIBLIOGRAPHY. SIR GEOFFREY KEYNES. The Life of William Harvey (1966, reissued 1978), is a full and definitive biography based on examination of contemporary sources, documented and illustrated, with eight appendixes; his A Bibliography of the Writings of Dr. William Harvey, 1578-1657, 2nd ed. (1953), is an account of all Harvey's books and of where they may be found; and his The Portraiture of William Harvey (1949) is a catalog of pictures, genuine and spurious, with reproductions. JOHN G. CURTIS, Harvey's Views on the Use of the Circulation of the Blood (1915), is an early study of the position of Harvey's work in the history of the knowledge of human physiology. For texts, see GWENETH WHITTERIDGE (ed.), The Anatomical Lectures: Prelectiones Anatomie Universalis, De Musculis (1964), a reliable transcription of Harvey's lecture notes, both in Latin and English, with a full discussion and interpretation, and WHITTERIDGE (trans.), An Anatomical Disputation Concerning the Movement of the Heart and Blood in Living Creatures (1976, trans. from Latin); see also whitteridge, William Harvey and the Circulation of the Blood (1970), an important study of the growth of Harvey's ideas. ARTHUR W. MEYER, An Analysis of the De Generatione Animalium of Harvey (1936), is a discussion of Harvey's second major publication, a work on animal reproduction and development; De Generatione Animalium is also treated in ELIZABETH B. GASKING, Investigations into Generation, 1651–1828 (1967). WALTER PAGEL, William Harvey's Biological Ideas: Selected Aspects and Historical Background (1967), a well-documented historical analysis of Harvey's ideas on physiology and embryology, is continued in his New Light on William Harvey (1976). A good survey of Harvey's works is KENNETH D. KEELE, William Harvey: The Man, the Physician, and the Scientist (1965). Later studies include JEROME J. BYLEBYL (ed.), William Harvey and His Age: The Professional and Social Context of the Discovery of the Circulation (1979); and ROBERT G. FRANK, Harvey and the Oxford Physiologists: A Study of Scientific Ideas (1980), an analysis based upon diaries, letters, notebooks, manuscripts, and published scientific works.

avana (Spanish: La Habana) is the capital, major port, and leading commercial centre of Cuba. It also constitutes one of Cuba's 14 provinces. Located on the island's north coast, Havana, with more than 2,000,000 people, is the largest city in the Caribbean region and one of the great treasuries of historic colonial preserves in the Western Hemisphere. Prior to 1959, when Fidel Castro came to power, it was a Mecca for tourists from the United States, who were drawn by the city's

many attractions, which included climate and nightlife in addition to history. In the next 30 years, however, despite its continued importance as the island's major economic hub. Havana lost much of its lustre as Castro's socialist government redirected the country's resources primarily toward the improvement of conditions in rural Cuba. Havana's upkeep and improvement thus lagged until the 1980s, when a major rehabilitation project began,

Physical and human geography

THE CHARACTER OF THE CITY

Havana's location along a magnificent deep-sea bay with a sheltered harbour made the city a prime location for economic development from Spanish colonial times in the early 16th century. Cuba is endowed with a number of such harbours, but Havana's on the north coast was prized above the others by the early Spanish colonizers. With land on both sides of the harbour, the port was easily defended. The early colonists erected a number of fortifications in the area that withstood most invaders. In colonial times Havana was the first landfall for Spanish fleets coming to the New World, and it became a staging area, first, for the conquest of the Americas by Spanish conquistadores and, later, for the economic and political domination of the hemisphere by Spain. The city early became a cosmopolitan centre with sprawling fortifications, cobblestone plazas, and buildings with ornamental facades and ornate iron balconies. Today's Havana mixes these structures with a variety of conventional modern buildings. Havana's rich cultural milieu included not only Spaniards

area and, in any case, was largely decimated in its early contact with the Spanish. The colonial years brought a large influx of black slaves from Africa who, after the end of slavery in the late 19th century, began flocking to Havana. Today's Havana is a mix of white Spanish stock, black ethnic groups, and significant mulatto strains. THE LANDSCAPE

from diverse regions of the Iberian Peninsula but other European peoples as well. The small native Indian popu-

lation of Cuba was not a significant factor in the Havana

The city site. The city extends mostly westward and southward from the bay, which is entered through a nar- The bay row inlet and which divides into three main harbours: Marimelena, Guasabacoa, and Atarés. The sluggish Almendares River traverses the city from south to north. entering the Straits of Florida a few miles west of the bay.

The low hills on which the city lies rise gently from the deep blue waters of the straits. A noteworthy elevation is the 200-foot- (60-metre-) high limestone ridge that slopes up from the east and culminates in the heights of La Cabaña and El Morro, the sites of colonial fortifications overlooking the bay. Another notable rise is the hill to the west that is occupied by the University of Havana and the Prince's Castle.

Climate. Havana, like much of Cuba, enjoys a pleasant year-round climate that is tempered by the island's position in the belt of the trade winds and by the warm offshore currents. Average temperatures range from 72° F (22° C) in January and February to 82° F (28° C) in August. The temperature seldom drops below 50° F (10° C). Rainfall is heaviest in October and lightest from February through April, averaging 46 inches (1,167 millimetres) annually. Hurricanes occasionally strike the island, but they ordinarily hit the south coast, and damage in Havana is normally less than elsewhere in the country.

The city layout. Walls as well as forts were built to protect the old city, but by the 19th century Havana had already grown beyond the original barriers. The city first spread to the south and west. Expansion to the east was facilitated later by the construction of a tunnel under the entrance to the bay; such suburbs as La Habana del Este were subsequently able to be developed.

Several broad avenues and boulevards stretch across the city. One of the most picturesque is the Malecón, which extends southwestward along the coast from the port en- streets

Hurricanes

City proper and Ciudad de la Habana province limits Built-up areas Parks and green areas STRAITS OF FLORIDA

Havana and surrounding area

trance to the Almendares River, under which it passes via a tunnel, emerging on the other side in Miramar as Avenida Quinta. Roughly paralleling the Malecón in the Vedado neighbourhood is Linea, another long avenue that passes under the river. Among other thoroughfares of note are Avenida del Puerto, Paseo Martí (or Prado), Avenida

Menocal (Infanta), and Avenida Italia. Contemporary Havana can essentially be described as three cities in one: Old Havana, Vedado, and the newer

suburban districts. Old Havana, with its narrow streets and overhanging balconies, is the traditional centre of much of Havana's commerce, industry, and entertainment, as well as being a residential area. It is richly endowed with historic buildings, representing architectural styles from the 16th through the 19th century. Covering some three square miles and hugging the harbour, Old Havana includes Spanish colonial structures, towering Baroque churches, and buildings in Neoclassic style, as well as commercial

property and less pretentious homes on the fringes. To the north and west a newer section, centred on the uptown area known as Vedado, has become the rival of Old Havana for commercial activity and nightlife. This part of the city, built largely in the 20th century, contains attractive homes, tall apartments, and offices along wide, tree-lined boulevards and avenues. It is also the location of many hotels that before 1959 were frequented by U.S. tourists. Central Havana, sometimes described as part of Vedado, is mainly a shopping district that lies between

Vedado and Old Havana.

A third Havana is that of the more affluent residential and industrial districts that spread out mostly to the west. Among these is Marianao, one of the newer parts of the city, dating mainly from the 1920s. Some of the suburban exclusivity was lost after the revolution, many of the suburban homes having been expropriated by the Castro government to serve as schools, hospitals, and government offices. Several private country clubs were converted to public recreational centres.

From colonial times Havana has been noted for its parks and plazas. Habaneros, as its residents are called, gather day and night under the sprawling trees of these many green areas. Through colonial times and almost to the end of the 19th century, the Plaza de Armas in Old Havana was the centre of Cuban life. Its most famous building, completed in 1793, is the Palace of the Captains General, an ornate structure that housed the Spanish colonial governors and, from 1902, three Cuban presidents. The building is now a museum.

In the 1980s many parts of Old Havana, including the Plaza de Armas, became part of a projected 35-year multimillion-dollar restoration project. The government sought to instill in Cubans an appreciation of their past and also to make Havana more enticing to tourists in accordance with the government's effort to boost tourism and thus

increase foreign exchange.

One of the first buildings to be restored was the Cathedral of Havana, the church of Havana's patron saint, San Cristóbal (St. Christopher); it was constructed in the 18th century by the Jesuit order. Located near the waterfront, its ornate facade is regarded by art historians as one of the world's finest examples of Italian Baroque design. The restoration work left the cathedral looking much as it did

when originally completed. The Plaza

The expansive Plaza de la Revolución, west of Old Havana, is the site of President Castro's major speeches, Revolución which are delivered before crowds of, it is estimated, up to 1,000,000 citizens. The plaza is distinguished by some of the city's most imposing architecture. Surrounding the towering monument to José Martí, leader of Cuban independence, are such modern structures as the National Government Centre, the headquarters of the Communist Party of Cuba and the armed forces, and various government ministries. In Central Havana are more traditional buildings, including the white-domed former National Capitol, now housing the Cuban Academy of Sciences; the Museum of the Revolution, housed in the old Presidential Palace; and the National Museum of Art.

Another restoration project was centred on the old Spanish fortifications that dominate Havana's harbour and,

for a time in the 17th and 18th centuries, made Havana the most fortified city in Spanish America. The most famous and impressive of these is Morro Castle (Castillo del Morro), completed in 1640. It became the centre of the network of forts protecting Havana, and, with La Punta Fortress (Castillo de la Punta), dominated the actual entrance to the harbour. The oldest fortification, La Fuerza (Castillo de la Fuerza), was begun in 1565 and completed in 1583. Its site at the Plaza de Armas was that of an even older fort erected by Hernando de Soto in 1538 and later destroyed by French pirates.

THE PEOPLE

Havana, like the rest of Cuba, is populated mostly by people of Spanish ancestry, with a large minority of blacks and mulattoes, whose ancestors were slaves. There are few mestizos, as in many other Latin-American countries, because the Indian population was virtually wiped out in colonial times. In the era before Fidel Castro came to power, the city was economically and ethnically divided. On the one hand, there was the minority of the wealthy, educated elite, together with a developing and expanding middle class, and on the other was the working-class majority. This division was largely based on ethnic background: whites tended to be more well-to-do, while blacks and mulattoes generally were poor. The economic structure did not provide much opportunity for blacks and mulattoes except in the more menial occupations. There was also little opportunity for them to obtain an education.

Under the Castro government that came to power in 1959, this system changed. Educational and employment opportunities were made available to Cubans of all ethnic backgrounds. In housing, the government follows an official policy of no discrimination based on ethnic background, and independent observers tend to believe this policy has been more or less faithfully carried out. Where there were few black or mulatto Cubans in middle- to toplevel national and local government posts before 1959. there are now many, although still not in the same proportion as in the population. However, many blacks and mulattoes throughout the island are still in a struggle to lift themselves out of poverty.

Habaneros, as Cubans in general, do not constitute a strongly religious community; about half do not profess a religious affiliation. A number of churches in Havana have continued to operate since the Castro revolution. Roman Catholics form the largest religious group, but the

number of parishioners worshiping on a given Sunday is relatively small. There are few priests, and services are

de la

often conducted by lay people. Protestant churches are similarly limited in activity. The Jewish community in Havana is reduced to only a few hundred from once having embraced more than 50,000 people, many of whom had fled Nazi persecution and subsequently left Cuba after Castro came to power.

One of the major phenomena of the Castro era has been the steady flow of Cubans into exile, mainly to the United States but also to Mexico, Venezuela, and elsewhere in Latin America. In the United States the largest concentration of exiles is in Florida, where they have become a significant minority in the state. It is estimated that at least Emigration a million Cubans have left the island since 1959, about 60 percent of whom were said to be Habaneros. Heavy emigrations following the revolution created a shortage of professional people in Havana. This was particularly evident in medicine, law, and economics until well into the 1970s. The Cuban government was forced to give high priority to the training of doctors, dentists, lawyers, and economists to replace these professionals.

THE ECONOMY

after

Castro

Road and

railroad

develop-

ment

Havana's economy first developed on the basis of its location, which made it one of the early great trade centres in the New World. Sugar and a flourishing slave trade first brought riches to the city, and later, after independence, it became a renowned resort. Castro, however, de-emphasized the city as a tourist Mecca.

Industry. Despite efforts by the Castro government to spread Cuba's industrial activity to all parts of the island, Havana remains the centre of much of the nation's industry. The traditional sugar industry, upon which the island's economy has been based for three centuries, is centred elsewhere on the island and controls some threefourths of the export economy. But light manufacturing facilities, meat-packing plants, and chemical and pharmaceutical operations are concentrated in Havana, Other food-processing industries are also important, along with shipbuilding, vehicle manufacturing, production of alcoholic beverages (particularly rum), textiles, and tobacco products, particularly the world-famous Havana cigars. Although the ports of Cienfuegos and Matanzas, in particular, have been developed under the Castro government, Havana remains Cuba's primary port facility; a majority of Cuban imports and exports pass through Havana. The port also supports a considerable fishing industry.

Commerce and finance. Under the Castro government Cuba's traditional free-enterprise system was replaced by a heavily socialized economic system. Most business in Cuba is in the hands of the state. In Havana the large Cubanowned department stores and U.S.-owned businesses were nationalized and today operate under state control. In Old Havana and throughout Vedado there are a few small private businesses, such as shoe-repair shops or dressmaking facilities, but their number is steadily declining.

Banking has come totally under state control, and the National Bank of Cuba, headquartered in Havana, is the control centre of the Cuban economy. Its branches in some cases occupy buildings that were in pre-Castro times the offices of Cuban or foreign banks.

Transportation. Havana has historically been the hub of Cuba's transportation system and remains so today. This position resulted from Havana's role as the seat of Spanish colonial government and the importance of the port for trade. As railroads developed and as the use of automobiles led to highway construction, the importance of Havana's focal situation increased. Havana became the key terminus for both rail and road links from the east and west. Also, Havana became the main gateway · for international air transport. The old Rancho Boyeros airport, now José Martí International Airport, is located eight miles (13 kilometres) from downtown Havana and handles domestic and international flights. A network of bus routes also centres on Havana, and buses are the main mode of inner-city transportation.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Havana is administered by a city council, with a mayor as chief administrative officer: The city is dependent upon the national government, however, for much of its budgetary and overall political direction. The national government is headquartered in Havana and plays an extremely visible role in the city's life. Moreover, the all-embracing authority of many national institutions. including the Communist Party of Cuba (Partido Comunista de Cuba; PCC), the Cuban Army, the militia and neighbourhood groups called the Committees for the Defense of the Revolution (CDRs), has led to a declining role for the city government, which, nevertheless, still provides such essential services as garbage collection and fire protection. The CDRs, which exist in virtually every street and apartment block, have two main functions: first, to actually defend the revolution against both external and internal opposition and, second, to handle routine tasks in maintaining neighbourhoods.

Havana's borders are contiguous with the province Ciudad de la Habana. Thus Havana functions as both a city and a province. There are two joint councils upon which city and provincial authorities meet-one embraces municipal and provincial leaders on a national basis, the other, a Havana city and provincial council. Havana is divided into 15 constituent municipalities. Until 1976 there were six subdivisions, but in that year the city's borders

were expanded to include the entire metropolitan area. Services. Utility services are under the control of several nationalized state enterprises that have developed since the Castro revolution. Water, electricity, and sewage service are administered in this fashion. Electricity is supplied by generators that are fueled with oil. Much of the original power plant installation, which operated before the Castro government assumed control, has become somewhat outdated. Electrical blackouts occurred, prompting the national government in 1986 to allocate the equivalent of \$25,000,000 to modernize the electrical system. It is said that any part of Havana is within five minutes of a firefighting unit; the equipment is largely new.

Health. Under the Cuban government all citizens are covered by the national health care plan. Administration of the health care system for the nation is centred largely in Havana. Hospitals in Havana are run by the national government, and citizens are assigned hospitals and clinics to which they may go for attention. During the 1980s Cuba began to attract worldwide attention for its treatment of heart diseases and eye problems, some of this treatment administered in Havana. There has long been a

high standard of health care in the city. Education. The national government assumes all responsibility for education, and there are adequate primary, secondary, and vocational training schools throughout Havana. The government claims that all children receive an education, and the claim appears to be valid. The schools are of varying quality, however, and the content of education is clearly aimed at supporting the socialist political orientation of the Castro government. Education is free and compulsory at all levels except higher learning, which is free nonetheless. The University of Havana, located in the Vedado section of Havana, was established in 1728 and was once regarded as a leading institution of higher learning in the Western Hemisphere. Soon after Castro came to power in 1959, the university lost its traditional autonomy and was placed under the control of the government. The city's only other university, the respected Catholic University in Marianao, was closed after the revolution.

CULTURAL LIFE

Havana, by far the leading cultural centre of the island, offers a wide variety of features that range from museums to ballet and from art and musical festivals to exhibitions of technology. The restoration of Old Havana offered a number of new attractions, including a museum to house relics of the Castro revolution. The government placed special emphasis on cultural activities, many of which are free or involve only a minimal charge.

The Museum of the City of Havana, formerly the Palace of the Captains General in Old Havana, contains many pieces of old furniture, pottery, jewelry, and other examples of colonial workmanship, as well as models of what

Role of the CDRs

Health quality Havana looked like in earlier centuries. The museum also houses material relating to the era of U.S. occupation and influence in Cuba. Other important museums are the National Museum of Art in Central Havana and the Museum of Decorative Arts in Vedado. The city's National Library houses Cuba's largest collection. The widest-circulating daily newspapers are published in Havana, but all of these, including the main one, Granma, represent Communist

Restaurante and cuisine

Party or government interests. (J.N.G.) Many of the city's finest restaurants are in Old Havana. The most popular is Bodeguita del Medio, once a hangout of Ernest Hemingway. La Floridita, also renowned for its Hemingway associations, claims to be the "birthplace of the daiquiri." In the kitchens of Habanero families, rice, black beans, and bananas are common staples. Although numerous food products are available at special "dollarsonly" markets and stores, Habaneros lacking supplemental income (such as tourist dollars or remittances from relatives living abroad) depend almost exclusively on the meagre quotas of food apportioned by the government.

Havana was known in pre-Castro times as the queen city of the Caribbean because of its nightlife and popular culture. Much of that has disappeared, but there is still some nightlife, particularly at the fabled Tropicana nightclub, Its present-day dancers and singers are as gaudily and scantily attired as their predecessors were in pre-Castro times,

and the stage settings are big and imaginative. At Carnival time in July, Cubans express themselves vigorously in dance and song. In Havana, Carnival is now a virtual holiday, with floats and parades officially sanctioned. These floats compete in what has become an annual parade along the waterfront Malecón. Many Cubans are avid sports fans who particularly favour baseball and association football (soccer). Habaneros support a dozen or so baseball teams. The city has several large sports stadiums. Admission to sporting events is generally free, and impromptu games are played in neighbourhoods throughout the city. Social clubs at the beaches provide facilities for water sports and include restaurants and dance halls.

History

The new

capital

FOUNDATION AND EARLY GROWTH

A port called San Cristóbal de la Habana was founded in 1515 by the Spanish conquistador Diego Velázquez de Cuéllar, possibly near the present town of Batabanó on the south coast of the island. It was not a fortuitous choice, for the climate was poor and the region was swampy. Mosquitoes abounded. The site was abandoned in favour of Havana's present location (then called Puerto Carenas) on the north coast in 1519. The natural deepwater port, together with the land protection to the harbour, made Havana a site that early attracted growing numbers of settlers. A royal decree in 1634 recognized its importance, calling it the "Llave del Nuevo Mundo y Antemural de las Indias Occidentales" ("Key to the New World and Rampart of the West Indies"). Havana's coat of arms carries this inscription. The Spaniards began building fortifications, and in 1553 they transferred the governor's residence to Havana from Santiago de Cuba on the eastern end of the island, thus making Havana the de facto capital. English, French, and Dutch sea marauders attacked the city in the 16th century.

DEVELOPMENT AS A MAJOR NEW WORLD PORT During the 17th century eastbound fleets of Spanish ships carrying treasure from the New World rendezvoused at Havana for the trip across the Atlantic to Spain. The port thus became the object of attacks by competing foreign powers and was blockaded several times during that century. By about 1700 the city walls and the major fortifications had been completed. These withstood attacks until, after a three-month siege ending in August 1762, the British under Admiral Sir George Pocock and the Earl of Albermarle took the city as a prize of war. They held it for six months until the treaty ending the Seven Years' War restored Havana to Spain.

That occupation, as onerous as it was to Habaneros, actually stimulated trade between the New World and Eu-

rone, and Hayana gained new importance as a port, thriving on the sugar and slave trades. Obstacles to commerce by foreigners were gradually removed as the 18th century ended, and all of Cuba, but Havana in particular, began attracting immigrants from countries other than Spain. This. in turn, added new strains to the ethnic mix of the city-French craftsmen, British merchants, German bankers, and others-and gave Havana a distinct international and cosmonolitan character. Wealthier Cuban colonists visited New York City and Philadelphia, A number of U.S. flagships made port calls at Havana, and there was a small but important U.S. trading community established in Havana by 1850. Nevertheless, Cuba remained a Spanish colony despite the wars of independence that raged on the continent in the early 1800s, wars that led to freedom for most of Spain's New World empire.

Growth of U.S. trade

ALLIANCE WITH THE UNITED STATES

Havana, meanwhile, continued to grow as a major world port, rivaling in population and in trade both New York City and Buenos Aires. Cuba became independent from Spain in 1898 with the aid of the United States, and for six decades thereafter Cuba was a close economic and political ally of that country. Increasing numbers of U.S. businesses and tourists were drawn to Havana, which acquired the look of a U.S. city.

Cuba's government through these years was frequently a dictatorship; at best, it was a fragile democracy, with corruption often running rampant. Many Cubans were unhappy both with the U.S. influence and with the continued dictatorship. There were a number of abortive coup attempts against the government of Fulgencio Batista, but change did not come until the revolution led by Fidel Castro, who on Jan. 1, 1959, took control of Cuba.

Castro takes power

THE CITY UNDER CASTRO

Havana's close ties with the United States were quickly ended, and Castro turned to the Soviet Union for economic and military assistance. Soviet vessels frequented the port of Havana. Soviet-made automobiles and trucks became common in the streets, and Soviet or Soviet-bloc. goods appeared in stores.

Despite these influences, Havana still retains many of its older traditions, particularly in the narrow streets of Old Havana where past and present merge. This older part of the city deteriorated somewhat after the revolution as Castro first directed resources to the hinterlands. However, in the early 1980s Old Havana was designated a UNESCO World Heritage site, and the city began a revival as sever-

al historic buildings were restored. Havana's economy was nearly crippled following the dissolution of the Soviet Union in 1991. Trade with the Soviet Bloc had effectively subsidized the Cuban economy. and the loss of this income translated into shortages of goods, power, and transportation. The government responded to the crisis by relaxing controls on private enterprise (including family restaurants and farmers' markets) and permitting U.S. dollars to circulate. It also promoted foreign investment, notably in the tourist sector, resulting in markedly increased tourist traffic by the early 21st century. Despite these changes, Habaneros remain largely focused on their families and neighbourhoods, numerous educational and cultural events are still promoted, and the government retains direct or indirect influence at nearly all levels of society, from home ownership to medical care.

(J.N.G./Ed.)

BIBLIOGRAPHY. Havana's role in Cuban national life is discussed in SUSAN EVA ECKSTEIN, Back from the Future: Cuba Under Castro (1994). Travel books include GÜNTER GRAU, Havana, trans. from German (1985); and Havana & the Best of Cuba (2001). Daily life, economic and societal changes, and architectural restoration are examined in two articles in National Geographic (June 1999) by JOHN J. PUTMAN, "Cuba," pp. 2-35; and A.R. WILLIAMS, "The Rebirth of Old Havana," pp. 36-45. Historical topics are treated in JOHN ROBERT MCNEILL, Atlantic Empires of France and Spain: Louisbourg and Havana, 1700-1763 (1985); DAVID SYRETT (compiler), The Siege and Capture of Havana, 1762 (1970); and MARÍA LOBO MONTALVO, ZOILA LAPIQUE BECALI, and ALICIA GARCÍA SANTANA, Havana. History and Architecture of a Romantic City (2000).

Hebrew Literature

iterature in Hebrew has been produced uninterruptedly from the early 12th century BC, and certain exeavated tablets may indicate a literature of even greater antiquity. From 1200 BC to C AD 200, Hebrew was a spoken language in Palestine, first as biblical Hebrew, then as Mishnaic Hebrew, a later dialect that does not derive directly from the biblical dialect and one that gained literary status as the Pharisees began to employ it in their teaching in the 2nd century BC. It was not revived as a spoken language until the late 19th century, and in the 20th century it was adopted as the official language of the new State of Israel. The latter event gave impretus to a

growing movement in Hebrew literature centred in Israel. Hebrew literature is not synonymous with Jewish literature. Some Hebrew writing was produced by the Samarians and in the 17th century by Protestant enthusiasts. Jews also produced imporant literatures in Greek, Aramaic, Arabic, Judeo-Spanish (Ladino), Yiddish, and a number of other languages, Apart from the Aramaic writings, however, such literatures always served only that part of Jewry that used the language in question. When that community ceased to exist, the literature produced in languages other than Hebrew was forgotten for, in the case of Greek Jewish literature, became part of Christian tradition! except for whatever part of it had been translated.

into Hebrew and thus became part of Hebrew literature. The Hebrew language, though not spoken between c. AD 200 and the late 19th century, has always adapted itself to the needs of changing literary tastes. In the Bible it develops from a simple and earthy idiom to a language suitable for the expression of sophisticated religious thought without losing the poetic force and rhythmic fullness that characterizes it. Mishnaic Hebrew is pedestrian, exact, and yet can reach heights of irony or of warmth. In medieval poetry Hebrew allows extravagant displays of verbal artistry but also, in northwestern Europe, a simplicity equal to that of the spoken languages of its milieu. One generation of translators in the 12th century created a scientific Hebrew that is not inferior to contemporary Arabic or Latin in precision or syntactic refinement. The 17th-19th centuries saw the formation of a stately, rigid. classical style based on biblical Hebrew, but at the same time eastern European mystics made the language serve the expression of their love of God. Literary Hebrew in the 20th century draws upon ancient literature to a marked degree, with styles often modeled upon ancient predecessors. The modern period has also evolved a new type of language for nonliterary writing, while in novels the style is often based upon the spoken language.

ANCIENT HEBREW LITERATURE

Preexilian period, c. 1200-587 BC. All that is preserved of the literature of this period is slightly more than 20 of the 39 books included in the Old Testament (the remainder being from the next period). Poetry probably preceded prose. Biblical poetry was based on the principle of parallelism; i.e., the two halves of a verse express the same idea, either by repeating it in different words or by stressing different aspects of it. Examples are found in the book of Psalms: "But they flattered him with their mouths; they lied to him with their tongues" (Ps. 78:36); "He turned their rivers to blood, so that they could not drink of their streams" (Ps. 78:44). To this form was added a simple rhythm, consisting mainly in having each half of a line divided into an equal number of stressed words. There were also folk songs, to which belonged perhaps large parts of the Song of Solomon, dirges, epic chants, and psalms. The use of various forms of poetry in the work of the prophets appears to be a later development.

The earlier prose texts were still very close to poetry in structure and language. The first real prose may well have been some of the laws recorded in the Pentateuch. In Jeremiah and Deuteronomy a high standard of prose rhetoric was achieved: some of the conversations in the historical books were attempts to reproduce in writing the style of ordinary speech. (See also BBILCAL LITERATURE.)

Period of the Second Temple, 538 BC-AD 70. The literary output of this period was large, only part of it belonging to the biblical canon. The biblical Hebrew of the writings was artificial because it had ceased to be spoken and had been replaced by Aramaic, a related Semitic language, and Mishnaie Hebrew. Works that are included among the Dead Sea Scrolls belong to this period. Some of these works provide evidence of a new kind of writing, the homilettic, or sermonizing, commentary to the Bible called Midrash. The only work of real literary merit among the scrolls is the fervent personal poetry of the Hymns of Thanksgiving.

Parts of the biblical books of Ezra and Daniel and certain works among the Dead Sea Scrolls are in an early form of Aramaic. This period also began to provide translations (called Targums) of most of the Hebrew Bible into a slightly later Aramaic.

Talmudic literature. In contrast to the works of the Bible and the Second Temple were the collections of writings concerned with Jewish civil and religious law. Whereas the former were lengthy writings bearing the imprint of their authors or editors, early rabbinic literature consisted entirely of collections of individual statements loosely strung together. The individual paragraphs exhibit the influence of Hellenistic rhetoric. Collections that follow the arrangement of biblical books are called Midrash, as opposed to works such as the Mishna, where the material is arranged according to subject. The Mishna was the main work of the period c. 100 BC-AD 200. The following period, AD 200-500, was notable for two main innovations: the appearance of an additional literary centre in Babylonia, where Jewry flourished in contrast to its subjugation under the oppressive rule of Rome and, later, Byzantium in Palestine; and the literary use of the spoken local dialects of Aramaic alongside Hebrew. The Talmuds produced by Palestine and Babylonia in this period contained a large

The Mishna and Midrash

The principle of parallelism in biblical poetry proportion of Haggada, statements dealing with theological and ethical matters and using stories, anecdotes, and parables to illustrate certain points. This material was later an influence on Hebrew fiction of the Middle Ages and of the modern period. (See also JUDAISM: The literature of Judgism)

LITERARY REVIVAL, 500-1000

In the 6th century, some Jewish groups attempted to enforce the exclusive use of Hebrew in the synagogue, this tendency being part of a Hebrew revival that began in Palestine and spread westward but did not reach Babylonia until the 10th century.

Piyyutim. Synagogues began in this period to appoint official precentors, part of whose duty it was to compose poetical additions to the liturgy on special sabbaths and festivals. The authors were called paytanim (from Greek poietes, "poet"), their poems pivvutim. The keynote was messianic fervour and religious exuberance. Besides employing the entire biblical, Mishnaic, and Aramaic vocabularies, the paytanim coined thousands of new words. Such poems, presupposing a highly educated audience, abound in recondite allusions and contain exhaustive lists of rites and laws. It is known that the most outstanding poets-Phineas the Priest, Yose ben Yose, Yannai, and Eleazar ha-Kalir, or ben Kalir-lived in that order, but when or where in Palestine any of them lived is not known. The accepted datings are 3rd century and 5th-6th century AD. Many pivyuțim are still used in the synagogue.

Adoption of Arabic metre. Biblical Hebrew was reestablished as the literary idiom about 900 by Sa'adia ben Joseph, grammarian and religious polemicist. The Arabic system of quantitative metre was adapted for Hebrew during this period (900-1000), probably by Dunash ben Labrat. At first the piyyut form was retained for religious poems, and the new metres were used only for secular poetry, which closely imitated Arabic models and, like the latter, was chiefly employed for laudatory addresses to prominent people.

THE MIDDLE AGES

The Palestinian tradition in Europe, 800-1300. From Palestine, the Hebrew renaissance soon spread into the Byzantine Empire. In Sicily and southern Italy (which belonged to Byzantium) several important paytanim were at work, and before 1000 a secular literature began to arise in Italy: a fantastic travelogue of Eldad the Danite; a historical romance, Sefer ha-vashar (1625; Eng. trans., Sefer ha-yashar, the Book of the Righteous) and Josippon, a revision of Josephus' Antiquities filled with legendary incidents-this last-named book was popular until modern times and was translated into many languages. Nathan ben Yehiel completed in 1101 at Rome a dictionary of Talmudic Aramaic and Hebrew, the 'Arukh, which is still

In the middle of the 10th century members of the north Italian family Kalonymos brought Talmudic studies and piyyuţim to Mainz, Ger., where the yeshiva (school) became a centre of studies under the direction of Gershom ben Judah, known as "the Light of the Exile." As a poet, he established a distinctive style of European piyyut in poems that read very much like early European popular poetry. The greatest alumnus of the Mainz academy was Rashi, an author of complete commentaries on the Bible and on the Babylonian Talmud, himself a poet of note.

The slaughter of Jewish peoples in western and central Europe during the Crusades drove large masses of Jews into eastern Europe. The German Jews carried with them their Yiddish speech but hardly any literary culture. In Germany accounts of the disaster were written in a new prose style permeated with poetry; liturgical poetry became henceforth mainly a chronicle of persecutions. These sufferings inspired an important mystical movement, largely propagated through stories, of which the chief collections are the Ayn Shoyn Mayse Bukh (1602; Ma'aseh Book) and the Sefer Hasidim (1538; "The Book of the Just"), the latter attributed to Judah ben Samuel, "the Hasid" of Regensburg (died 1217).

The golden age in Spain, 900-1200. Spanish Jewry be-

gan to flourish in Muslim Spain under the caliphate of Córdoba, where Hasdai ibn Shaprut, a vizier, was the first great patron of Hebrew letters. His secretary, Menahem ben Saruk (died c. 970), wrote a biblical lexicon, which was criticized by Dunash ben Labrat when the latter arrived in Spain with philological ideas from the East. Samuel ha-Nagid, vizier of Granada (990-1055), himself a poet and philologist, gathered around him a group of poets, most outstanding among whom was Ibn Gabirol. Moses ibn Ezra of Granada (died c. 1139) was the centre of a brilliant circle of poets. Moses' kinsman Abraham ibn Ezra, a poet, philosopher, grammarian, and Bible commentator, attacked the language and style of the early paytanim; he and Judah ben Samuel Halevi were the first to use Arabic metres in religious poems. Dominated by Arab standards of taste, the secular poetry dealt with themes of Arabic poetry and often reproduced Arabic phrases; it was written to be appreciated by a small circle of connoisseurs and declined with the collapse of Jewish prosperity in Muslim Spain. The last major poet in Spain was Judah ben Solomon Harizi, who translated various philosophical works into Hebrew.

The use of biblical Hebrew was made possible by the work of philologists. Of great importance was the creation of comparative linguistics by Judah ibn Kuraish (about 900) and Isaac ibn Barun (about 1100). Judah Hayyui, a disciple of Menahem ben Saruk, recast Hebrew grammar, and, in the form given to it by David Kimhi of Narbonne (died c. 1235), the new system was taken over by the Christian humanists and through them by modern scholarship. The first complete Hebrew grammar, Kitāb alluma' (1886; "The Book of the Variegated Flower Beds"), was written by Ibn Janah of Córdoba (died 1050).

Jewish medieval philosophers in Spain wrote in Arabic, not Hebrew, until the 13th century. Apart from Isaac Israeli (north Africa, died c. 940) few medieval Jews made original contributions to science, but the Spanish Jews shared the best scientific education. Abraham bar Hivva (died c. 1136) of Barcelona was an original mathematician who wrote in Hebrew works on mathematics, astronomy, and philosophy. When the Almohads expelled the Jews from Muslim Spain in 1148, many learned refugees went to Languedoc and Provence and there translated scientific and philosophical works.

THE PERIOD OF RETRENCHMENT, 1200-1750

Hebrew culture in western Europe. From 1200 to 1750 was the era of the ghetto, during which the area of western European Hebrew culture shrank to a remnant in Italy. while an entirely different culture arose in eastern Europe. The appearance in 1200 of the Hebrew version, translated from Arabic, of Moses Maimonides' Moreh Nevukhim (1851-85; The Guide of the Perplexed), which applied Neoplatonic and Aristotelian philosophy to biblical and rabbinic theology, provoked orthodox circles into opposition to all secular studies. As a result of Maimonides' work, there was a return to Neoplatonist mysticism in a form known as Kabbala. This culminated in the theosophy of the Zohar (1560; "The Book of Splendor"), which is ascribed to Moses de Leon and which exercised an influence comparable only with that of the Bible and Talmud. Hebrew culture, however, was reduced to a miniature scale in the West after the expulsion of the Jews from England (1290), from France (1306), and from Spain (1492). It continued in Italy, where it remained in contact with contemporary Christian thought. The most outstanding figure was the mystical philosopher Moshe Hayyim Luzzatto, who wrote a work on poetics and three remarkably modern plays.

Eastern Europe and the religious crisis. In the kingdom of Poland (which then extended from Lithuania to the Black Sea) refugees from German persecution mingled with earlier Byzantine émigrés to create, by the 15th century, a prosperous Jewry with extensive autonomy. Their culture was not a continuation of western European Hebrew civilization but a new creation. The Bible (except for the Pentateuch) was neglected, while the Babylonian Talmud-hitherto studied only by specialists-became the basis of all intellectual life, particularly since the so-called

The poets of Granada

Kabbala

pilpul method of Jacob Pollak had turned its study into an exciting form of mental gymnastics. The typical literature consisted of novellae (hiddushim), ingenious discussions of Talmudic minutiae written in an ungrammatical mixture of Hebrew and Aramaic. Imaginative literature existed only in Yiddish, for women and the uneducated.

The expulsion from Spain produced a wave of messianic emotion. Kabbala flourished in Safad, the new Palestinian centre, the meeting place of Spanish, European, and Oriental Jews. There, in 1570-72, Isaac Luria created a cosmic messianism. Though its formulation, in the writings of his pupil Hayyim Vital, was abstruse and esoteric, its phraseology penetrated the widest masses, as a result of the introduction of Kabbalist prayers, and coloured all later Hebrew writing. Luria's teachings were developed by the false messiah Sabbatai Zebi in the next century, for and against whom a vast literature was written.

The sufferings of Polish Jewry in the Cossack massacres of 1648-described in a long poem by the Talmudist Yom Tov Lipmann Heller-opened their country to Lurianic mysticism. Out of popular Kabbalist elements, Israel ben Eliezer, called the Ba'al Shem Tov, produced Hasidism. His teaching, like that of his successors, was oral and of course, in Yiddish; but it was noted by disciples in a simple, colloquially flavoured Hebrew. Since they taught mainly through parables, this may be considered to mark the beginning of the Hebrew short story. Indeed these narratives exercised, and still exercise, a profound influence on modern Hebrew writers.

THE 18TH AND 19TH CENTURIES

Hasidism

In the 18th century the conservative mystical movement of Hasidism spread rapidly over all eastern Europe except Lithuania. There, Elijah ben Solomon of Vilna, a writer of unusually wide scope, advocated a better graded course of Talmudic training. Shneur Zalman of Ladi created the highly systematized Habad Hasidism, which was widely accepted in Lithuania. The Musar movement of Israel Salanter encouraged the study of medieval ethical writers.

Beginnings of the Haskala movement. In the Berlin of Frederick II the Great, young intellectuals from Poland and elsewhere, brought in as teachers, met representatives of the European Enlightenment; they came under the influence of Moses Mendelssohn and also met some representatives of Italian and Dutch Hebrew cultures. One, a Dane, Naphtali Herz Wessely, who had spent some time in Amsterdam, wrote works on the Hebrew language, and another, an Italian, Samuel Aaron Romanelli, wrote and translated plays. Out of these contacts grew Haskala ("Enlightenment"), a tendency toward westernization that venerated Hebrew and medieval western Jewish literature. Among German Jews, then already in rapid process of Germanization, this Hebrew movement had no place. The Enlightenment was introduced in Galicia (Austrian Poland), a centre of Hasidism, by the Edict of Toleration (1781) of the emperor Joseph II. By supporting some of its aims, Hebrew writers incurred hatred and persecution. Their chief weapon was satire, and the imitation by Joseph Perl of the Epistolae obscurorum virorum (1515; "Letters of Obscure Men") of Crotus Rubianus and the essays of Isaac Erter were classics of the genre. One poet, Meir Letteris, and one dramatist, Nahman Isaac Fischman, wrote biblical plays.

Romanticism. Galicia's chief contribution was to the Jüdische Wissenschaft, a school of historical research with Romanticist leanings. The impact of Haskala ideas upon the humanistic Italo-Hebrew tradition produced a short literary renaissance. Its main connections were with the Jüdische Wissenschaft, to which Isaac Samuel Reggio contributed. Samuel David Luzzatto, a prolific essayist, philologist, poet, and letter writer, became prominent by his philosophy of Judaism, while a poet, Rachel Morpurgo, struck some remarkably modern chords. For the Jews of the Russian Empire, the Enlightenment proper began with Isaac Baer Levinsohn in the Ukraine and with Mordecai Aaron Ginzberg (Günzburg), in Lithuania. In the 1820s an orthodox reaction set in, coinciding with the rise of a Romanticist Hebrew school of writers. A.D. Lebensohn wrote fervent love songs to the Hebrew language, and his son Micah Joseph (Mikhal), the most gifted noet of the Haskala period, wrote biblical romances and pantheistic nature lyrics. The first Hebrew novel, Ahavat Zivvon Hebrew (1853; "The Love of Zion"), by Abraham Mapu, was a Romantic idyll, in which Mapu, like all Haskala writers, employed phrases culled from the Bible and adapted to

the thought the writer wished to express Mapu's third novel, 'Ayit tzavua' (1857-69; "The Hypocrite"), marked a departure. It dealt with contemporary life and attacked its social evils and portrayed a new type, the maskil (possessor of Haskala), in a fight against orthodox obscurantism. The new, aggressive Haskala soon came under the influence of Russian left-wing writers. such as Nikolay Gavrilovich Chernyshevsky and Dmitry Pisarev, Judah Leib Gordon, like Mapu, had started as a Romantic writer on biblical subjects. From 1871 onward he produced a series of ballads exposing the injustices of traditional Jewish life, Moses Leib Lilienblum began as a moderate religious reformer but later became absorbed by social problems, and in Mishnat Elisha ben Abuvah (1878; "The Opinions of Elisha ben Abuyah") he preached Jewish socialism. Peretz Smolenskin created in six novels a kaleidoscope of Jewish life in which he rejected the westernized Jew as much as orthodox reactionaries did.

MODERN LITERATURE IN HEBREW

Formative influences. The first formative influences on 20th-century Hebrew literature belong to the late 19th century. The middle classes of eastern European Jewry that read Hebrew books turned to Jewish nationalism, and Zionist activity, coupled with the movement for speaking Hebrew, widened the circle of Hebrew readers. Hebrew daily papers began to appear in 1886. Writers borrowed extensively from medieval translators and European languages, and the Hebrew language assumed a new character. A key figure in the transition to modern writing was Shalom Jacob Abramowitsch, who wrote under the pseudonym of Mendele Mokher Sefarim; after his first novel he became convinced that biblical Hebrew was unsuitable for modern subjects and turned to Yiddish. From 1886 onward he returned to writing mainly in Hebrew and by using Hebrew and Aramaic phrases from the Talmud was able to capture the homeliness he prized in Yiddish. His stories depicted life as it really was, and his style and support of traditional values attracted a wide readership. The popularity of his stories of ghetto life ensured that they would remain the most read and written genre of Hebrew literature until the mid-20th century. A group of writers adopted "grandfather Mendele" as their model. One of these, Asher Ginzberg (Ahad Ha'am), wrote, from 1889 onward, articles evolving a secular philosophy of Jewish nationalism. His periodical ha-Shiloah attained editorial standards previously unknown in Hebrew. From 1921, he devoted his last years to the editing of his correspondence, a valuable documentary of the period.

Hayyim Nahman Bialik, an important poet, essayist, editor, and anthologist of medieval literature, was, for a time, literary editor of ha-Shiloah and was much influenced by Ahad Ha'am. His poetry expressed the inner struggles of a generation concerned about its attitude to Jewish tradition. Saul Tchernichowsky, on the other hand, was untroubled by tradition, and his poetry dealt with love, beauty, and the three places where he had lived: the Crimea, Germany, and Palestine. Isaac Leib Peretz, who wrote both in Hebrew and in Yiddish, introduced the Hasidic, or pietistic devotional, element into literature. The emotionalism and simple joy of life of that milieu thereafter strongly influenced writers, and the language absorbed many Hasidic terms. A literary historian, Ruben Brainin, discerned the presence of a "new trend" in literature and foresaw a concentration on human problems. Bialik had already pointed to a conflict between Judaism and the natural instincts of Jews. This psychological interest dominated the work of a group of short-story writers and, in particular, that of the writer and critic David Frischmann, who, more than anyone else, imposed European standards on Hebrew literature. European literary tendencies thus became absorbed into Hebrew. Uprooted by the pogroms of 1881 and the two Russian revolutions of 1905 and 1917,

nation-

alism

conflict between Indaism natural instincts of the Jews

Jews had emigrated to western Europe and America, and Hebrew literary activity in eastern Europe was disrupted. The Soviet Union eventually banned Hebrew culture, and it also decayed in other eastern European countries and in Germany as the position of Jews deteriorated.

Émigré and Palestinian literature. The writers of this generation were known as the émigré writers. Their work was pessimistic, as the rootlessness without hope of Uri Nissan Gnessin and Joseph Hayyim Brenner exemplified. The majority of writers active in Palestine before 1939 were born in the Diaspora (Jewish communities outside Palestine) and were concerned with the past. An exception was Yehuda Burla, an Oriental Jew who wrote about Oriental Jewry. The transition from ghetto to Palestine was achieved by few writers, among them Asher Barash, who described the early struggles of Palestinian Jewry. Shmuel Yosef Agnon, the outstanding prose writer of this generation (and joint winner of the 1966 Nobel Prize for Literature), developed an original style that borrowed from the Midrash (homiletical commentaries on the Hebrew Scriptures), stories, and ethical writings of earlier centuries. Whereas his earlier stories were set in Galicia, he began in the 1940s to write about Palestine.

In contrast, poetry immediately addressed Palestinian life. Among outstanding writers were Rachel (Rachel Bluwstein), who wrote intensely personal poems; Uri Zevi Greenberg, a political poet and exponent of free verse; and Abraham Shlonsky, who led the Symbolist school.

Israeli literature. World War II and the Arab-Israeli War of 1948-49 brought to the fore Palestinian-born writers who dealt with the problems of their generation in colloquially flavoured Hebrew. In the State of Israel, where Hebrew had become the official language, literature developed on a large scale, mainly along contemporary western European and American lines. The extreme diversity in culture of parts of the population, and the problems of new immigrants, provided the main theme for fiction, Poetry flourished, but original drama at first was slow to develop. Greenberg's Rehovot HaNahar (1951; "Streets of the River") traced the process by which the humiliation of the massacred is transmuted by the pride of martyrdom into the historical impulse of messianic redemption. In a long dramatic poem, "Bein ha-Esh ve-ha-Yesha" (1957; Between the Fire and Salvation), Aaron Zeitlin envisioned the annihilation of European Jewry in mystical terms, examining the relationship of catastrophe and redemption.

Native Israeli prose writers wrote of their life in the kibbutz, the underground, and the war of 1948-49. S. Yizhar and Moshe Shamir emerged as the outstanding representatives of this generation, probing the sensibility of the individual in a group-oriented society. But the establishment of the State of Israel could not allay the anxieties of the individual. The dominant themes of writers who had no access to collective ideals were personal ones-frustration, confusion, and alienation. The poetry of this period and of following decades, represented, among others, by Yehuda Amichai and Haim Gouri, also emphasizes the dissolution of social coherence and expresses the individual devoid of a sense of historical and spiritual mission. The novelist Aharon Megged's ha-Hai 'al ha-met (1965; The Living on the Dead) casts a putative hero of the pioneer generation in an ironic light.

Memories of the Holocaust haunt the lyrical work of Aharon Appelfeld. Flight and hiding are the characteristic situations of his early stories. His Badenhaim, 'ir nofesh (Badenheim 1939), published in 1975, captures the omi-

nous atmosphere of the approaching Holocaust sensed by a group of assimilated Jews vacationing at an Austrian resort. It describes social and spiritual disintegration as does his novel Tor ha-peli 'ot (1978; The Age of Wonders). In the stories of Abraham B. Yehoshua the narrator's tone is remote, the people are drained of emotion. Occasignally an act of feeling or meaning breaks the mood of boredom and illuminates a character's humanity. In both ha-Me'ahey (1976: The Lover) and Gerushim me'uharim (1982: A Late Divorce) Yehoshua explores the confrontation between the philosophy of the present generation and the ideology of the Zionist founders. Personal frustration and religious vision are the subjects of the novelist Pinhas Sadeh, Yitzhak Orpaz's novels tend toward psychological exploration, particularly in the series beginning with Bayit le-adam ehad (1975: "One Man's House"). Yoram Kaniuk examines the alienated Israeli but, in ha-Yehudi haaharon (1981: The Last Jew), explores the Israeli experience as a response to the Holocaust, Yitzhak Ben Ner sets realistic stories in rural and urban communities (Sheki'ah kefarit [1976; "A Rustic Sunset"] and Erez rehokah [1981; "A Distant Land"]). Ya'akov Shabtai's novel Zikhron devarim (1977: Past Continuous) broke new ground in its evocation of the family in society. The world of Amos Oz is generally symbolized by a kibbutz besieged by a powerful and primitive external force always threatening to break in. His Menuhah nekhonah (1982: A Perfect Peace) considers the notion of escape from ideological and geographical confinement. Amalia Kahana-Carmon explores the subjective impressions of experience and the complexities of time and memory through a stream-ofconsciousness technique.

Hegel and Hegelianism

.W.F. Hegel was the last of the great philosophicalsystem builders of modern times. His work, following upon that of Immanuel Kant, Johann Gottlieb Fichte, and Friedrich Schelling, thus marks the pinnacle of classical German philosophy. As an absolute Idealist inspired by Christian insights and grounded in his mastery of a fantastic fund of concrete knowledge, Hegel found a place for everything-logical, natural human and divine-in a dialectical scheme that repeatedly swung from thesis to antithesis and back again to a higher and richer synthesis. His influence has been as fertile in the reactions that he precipitated-in Søren Kierkegaard, the Danish Existentialist; in the Marxists, who turned to social action; in the Vienna Positivists; and in G.E. Moore, a pioneering figure in British Analytic philosophy-as in his positive impact.

This article deals with the man and his accomplishments as well as with the philosophical movement, Hegelianism, that evolved from his thought. It is divided into the following sections:

Life and work 487 Early life 487 Emancipation from Kantianism Career as lecturer at Jena Gymnasium rector 489 University professor 489 At Heidelberg At Berlin Personage and influence 490 Hegelianism 491 General considerations 491 Problems of the Hegelian heritage Stages in the history of the interpretation of Hegel Crises in the earlier Hegelian school 491 Polemics during the life of Hegel: 1816-31 Period of controversies chiefly in religion: 1831-39 Period of atheistic and political radicalism: 1840-44 Hegelianism through the 20th century 494 Development and diffusion of Hegelianism in the later 19th century

Hegelian studies today

EARLY LIFE

Hegel-who was born in Stuttgart on August 27, 1770, the son of a revenue officer-was christened Georg Wilhelm Friedrich. He had already learned the elements of Latin from his mother by the time he entered the Stuttgart grammar school, where he remained for his education until he was 18. As a schoolboy he made a collection of extracts, alphabetically arranged, comprising annotations on classical authors, passages from newspapers, and treatises on morals and mathematics from the standard works

In 1788 Hegel went as a student to Tübingen with a view to taking orders, as his parents wished. Here he studied philosophy and classics for two years and graduated in 1790. Though he then took the theological course, he was impatient with the orthodoxy of his teachers; and the certificate given to him when he left in 1793 states that, whereas he had devoted himself vigorously to philosophy, his industry in theology was intermittent. He was also said to be poor in oral exposition, a deficiency that was to dog him throughout his life. Though his fellow students called him "the old man," he liked cheerful company and a "sacrifice to Bacchus" and enjoyed the ladies as well. His chief friends during that period were a pantheistic poet, J.C.F. Hölderlin, his contemporary, and the nature philosopher Schelling, five years his junior. Together they read the Greek tragedians and celebrated the glories of the French Revolution.

On leaving college, Hegel did not enter the ministry; instead, wishing to have leisure for the study of philosophy and Greek literature, he became a private tutor. For the next three years he lived in Berne, with time on his hands and the run of a good library, where he read Edward Gibbon on the fall of the Roman empire and De l'esprit des loix, by Charles Louis, baron de Montesquieu, as well as the Greek and Roman classics. He also studied the critical philosopher Immanuel Kant and was stimulated by his essay on religion to write certain papers that became noteworthy only when, more than a century later, they were published as a part of Hegels theologische Jugendschriften (1907). Kant had maintained that, whereas orthodoxy requires a faith in historical facts and in doctrines that reason alone cannot justify and imposes on the faithful a moral system of arbitrary commands alleged to be revealed, Jesus, on the contrary, had originally taught a rational morality, which was reconcilable with the teaching of Kant's ethical works, and a religion that, unlike Judaism, was adapted to the reason of all men. Hegel accepted this teaching; but, being more of a historian than Kant was, he put it to the test of history by writing two essays. The first of these was a life of Jesus in which Hegel attempted to reinterpret the gospel on Kantian lines. The second essay was an answer to the question of how Christianity had ever become the authoritarian religion that it was, if in fact the teaching of Jesus was not authoritarian but rationalistic.

Hegel was lonely in Berne and was glad to move, at the end of 1796, to Frankfurt am Main, where Hölderlin had gotten him a tutorship. His hopes of more companionship, however, were unfulfilled: Hölderlin was engrossed in an illicit love affair and shortly lost his reason. Hegel began to suffer from melancholia and, to cure himself, worked harder than ever, especially at Greek philosophy and modern history and politics. He read and made clippings from English newspapers, wrote about the internal affairs of his native Wurtemberg, and studied economics. Hegel was now able to free himself from the domination

of Kant's influence and to look with a fresh eye on the problem of Christian origins.

Emancipation from Kantianism. It is impossible to exaggerate the importance that this problem had for Hegel. It is true that his early theological writings contain hard savings about Christianity and the churches; but the object of his attack was orthodoxy, not theology itself. All that he wrote at this period throbs with a religious conviction of a kind that is totally absent from Kant and Hegel's other 18th-century teachers. Above all, he was inspired by a doctrine of the Holy Spirit. The spirit of man, his reason, is the candle of the Lord, he held, and therefore cannot be subject to the limitations that Kant had imposed upon it. This faith in reason, with its religious basis, henceforth animated the whole of Hegel's work

His outlook had also become that of a historian-which again distinguishes him from Kant, who was much more influenced by the concepts of physical science. Every one of Hegel's major works was a history; and, indeed, it was among historians and classical scholars rather than among philosophers that his work mainly fructified in the

19th century

of Chris-

tianity"

When in 1798 Hegel turned back to look over the essays that he had written in Berne two or three years earlier, he saw with a historian's eye that, under Kant's influence, he had misrepresented the life and teachings of Jesus and the history of the Christian Church. His newly won insight then found expression in his essay "Der Geist des Christentums und sein Schicksal" ("The "The Spirit Spirit of Christianity and Its Fate"), likewise unpublished until 1907. This is one of Hegel's most remarkable works. Its style is often difficult and the connection of thought not always plain, but it is written with passion, insight, and conviction.

> He begins by sketching the essence of Judaism, which he paints in the darkest colours. The Jews were slaves to the Mosaic Law, leading a life unlovely in comparison with that of the ancient Greeks and content with the material satisfaction of a land flowing with milk and honey, Jesus taught something entirely different. Men are not to be the slaves of objective commands; the law is made for man. They are even to rise above the tension in moral experience between inclination and reason's law of duty, for the law is to be "fulfilled" in the love of God, wherein all tension ceases and the believer does God's will wholeheartedly and single-mindedly. A community of such believers is the Kingdom of God.

This is the kingdom that Jesus came to teach. It is founded on a belief in the unity of the divine and the human. The life that flows in them both is one; and it is only because man is spirit that he can grasp and comprehend the Spirit of God. Hegel works out this conception in an exegesis of passages in the Gospel According to John. The kingdom, however, can never be realized in this world: man is not spirit alone but flesh also. "Church and state, worship and life, piety and virtue, spiritual and worldly

action can never dissolve into one.'

In this essay the leading ideas of Hegel's system of philosophy are rooted. Kant had argued that man can have knowledge only of a finite world of appearances and that, whenever his reason attempts to go beyond this sphere and grapple with the infinite or with ultimate reality, it becomes entangled in insoluble contradictions. Hegel, however, found in love, conceived as a union of opposites, a prefigurement of spirit as the unity in which contradictions, such as infinite and finite, are embraced and synthesized. His choice of the word Geist to express this his leading conception was deliberate: the word means "spirit" as well as "mind" and thus has religious overtones. Contradictions in thinking at the scientific level of Kant's 'understanding" are indeed inevitable, but thinking as an activity of spirit or "reason" can rise above them to a synthesis in which the contradictions are resolved. All of this, expressed in religious phraseology, is contained in the manuscripts written toward the end of Hegel's stay in Frankfurt. "In religion," he wrote, "finite life rises to infinite life." Kant's philosophy had to stop short of religion. But there is room for another philosophy, based on the concept of spirit, that will distill into conceptual form the insights of religion. This was the philosophy that Hegel now felt himself ready to expound.

Career as lecturer at Jena. Fortunately, his circumstances changed at this moment, and he was at last able to embark on the academic career that had long been his ambition. His father's death in 1799 had left him an inheritance, slender, indeed, but sufficient to enable him to surrender a regular income and take the risk of becoming a Privatdozent. In January of 1801 he arrived in Jena, where Schelling had been a professor since 1798. Jena, which had harboured the fantastic mysticism of the Schlegel brothers and their colleagues and the Kantianism and ethical Idealism of Fichte, had already seen its golden age, for these great scholars had all left. The precocious Schelling, who was but 26 on Hegel's arrival, already had several books to his credit. Apt to "philosophize in public," Schelling had been fighting a lone battle in the university against the rather dull followers of Kant. It was suggested that Hegel had been summoned as a new champion to aid his friend. This impression received some confirmation from the dissertation by which Hegel qualified as a university teacher, which betrays the influence of Schelling's philosophy of nature, as well as from Hegel's first publication, an essay entitled "Differenz des Fichte'schen und Schelling'schen Systems der Philosophie" (1801), in which he gave preference to the latter. Nevertheless, even in this essay and still more in its successors, Hegel's difference from Schelling was clearly marked; they had a common interest in the Greeks, they both wished to carry forward Kant's work, they were both iconoclasts; but Schelling had too many romantic enthusiasms for Hegel's liking; and all that Hegel took from him-and then only for a very short period-was a terminology.

Hegel's lectures, delivered in the winter of 1801-02, on logic and metaphysics, were attended by about 11 students. Later, in 1804, with a class of about 30, he lectured on his whole system, gradually working it out as he taught. Notice after notice of his lectures promised a textbook of philosophy-which, however, failed to appear. After the departure of Schelling from Jena (1803), Hegel was left to work out his own views untrammelled. Besides philosophical and political studies, he made extracts from books, attended lectures on physiology, and dabbled in other sciences. As a result of representations made by himself at Weimar, he was in February 1805 appointed extraordinary professor at Jena; and in July 1806, on Goethe's intervention, he drew his first stipend-100 thalers. Though some of his hearers became attached to him, Hegel was not yet

a popular lecturer.

Hegel, like Goethe, felt no patriotic shudder when Napoleon won his victory at Jena (1806): in Prussia he saw only a corrupt and conceited bureaucracy. Writing to a friend on the day before the battle, he spoke with admiration of the "world soul" and the Emperor and with satisfaction at the probable overthrow of the Prussians.

At this time Hegel published his first great work, the Phänomenologie des Geistes (1807; Eng. trans., The Phenomenology of Mind, 2nd ed., 1931). This, perhaps the most brilliant and difficult of Hegel's books, describes how the human mind has risen from mere consciousness, through self-consciousness, reason, spirit, and religion, to absolute knowledge. Though man's native attitude toward existence is reliance on the senses, a little reflection is sufficient to show that the reality attributed to the external world is due as much to intellectual conceptions as to the senses and that these conceptions elude a man when he tries to fix them. If consciousness cannot detect a permanent object outside itself, so self-consciousness cannot find a permanent subject in itself. Through aloofness, skepticism, or imperfection, self-consciousness has isolated itself from the world; it has closed its gates against the stream of life. The perception of this is reason. Reason thus abandons its efforts to mold the world and is content to let the aims of individuals work out their results independently.

The stage of Geist, however, reveals the consciousness no longer as isolated, critical, and antagonistic but as the indwelling spirit of a community. This is the lowest stage of concrete consciousness, the age of unconscious morality. But, through increasing culture, the mind gradually Relationship with Schelling

Phenomenology of Mind

emancipates itself from conventions, which prepares the way for the rule of conscience. From the moral world the next step is religion. But the idea of Godhead, too, has to pass through nature worship and art before it reaches a full utterance in Christianity. Religion thus approaches the stage of absolute knowledge, of "the spirit knowing itself as spirit." Here, according to Hegel, is the field of philosophy.

GYMNASIUM RECTOR

In spite of the Phänomenologie, however, Hegel's fortunes were now at their lowest ebb. He was, therefore, glad to become editor of the Bamberger Zeitung (1807-08). This, however, was not a suitable vocation, and he gladly accepted the rectorship of the Aegidiengymnasium in Nürnberg, a post he held from December 1808 to August 1816 and one that offered him a small but assured income. There Hegel inspired confidence in his pupils and maintained discipline without pedantic interference in their associations and sports.

In 1811 Hegel married Marie von Tucher (22 years his junior), of Nürnberg. The marriage was entirely happy. His wife bore him two sons: Karl, who became eminent as a historian; and Immanuel, whose interests were theological. The family circle was joined by Ludwig, a natural son of Hegel's from Jena. At Nürnberg in 1812 appeared Die objektive Logik, being the first part of his Wissenschaft der Logik ("Science of Logic"), which in 1816 was completed by the second part, Die subjecktive Logik.

UNIVERSITY PROFESSOR

This work, in which his system was first presented in what was essentially its ultimate shape, earned him the offer of professorships at Erlangen, at Berlin, and at Heidelberg.

At Heidelberg. He accepted the chair at Heidelberg. For use at his lectures there, he published his Encyklopädie der philosophischen Wissenschaften im Grundrisse (1817; "Encyclopaedia of the Philosophical Sciences in Outline"), an exposition of his system as a whole. Hegel's philosophy is an attempt to comprehend the entire universe as a systematic whole. The system is grounded in faith. In the Christian religion God has been revealed as truth and as spirit. As spirit, man can receive this revelation. In religion the truth is veiled in imagery; but in philosophy the veil is torn aside, so that man can know the infinite and see all things in God. Hegel's system is thus a spiritual monism but a monism in which differentiation is essential. Only through an experience of difference can the identity of thought and the object of thought be achieved-an identity in which thinking attains the through-and-through intelligibility that is its goal. Thus, truth is known only because error has been experienced and truth has triumphed; and God is infinite only because he has assumed the limitations of finitude and triumphed over them. Similarly, man's Fall was necessary if he was to attain moral goodness. Spirit, including the Infinite Spirit, knows itself as spirit only by contrast with nature. Hegel's system is monistic in having a single theme: what makes the universe intelligible is to see it as the eternal cyclical process whereby Absolute Spirit comes to knowledge of itself as spirit (1) through its own thinking; (2) through nature; and (3) through finite spirits and their self-expression in history and their self-discovery, in art, in religion, and in philosophy, as one with Absolute Spirit itself.

The compendium of Hegel's system, the "Encyclopaedia of the Philosophical Sciences," is in three parts: "Logic," "Nature," and "Mind." Hegel's method of exposition is dialectical. It often happens that in a discussion two people who at first present diametrically opposed points of . view ultimately agree to reject their own partial views and to accept a new and broader view that does justice to the substance of each. Hegel believed that thinking always proceeds according to this pattern: it begins by laying down a positive thesis that is at once negated by its antithesis; then further thought produces the synthesis. But this in turn generates an antithesis, and the same process continues once more. The process, however, is circular: ultimately, thinking reaches a synthesis that is identical with its starting point, except that all that was implicit there has now been made explicit. Thus, thinking itself, as a process, has negativity as one of its constituent moments, and the finite is, as God's self-manifestation, part and parcel of the infinite itself. This is the sort of dialectical process of which Hegel's system provides an account in three phases. "Logic." The system begins with an account of God's thinking "before the creation of nature and finite spirit"; i.e., with the categories or pure forms of thought. which are the structure of all physical and intellectual life. Throughout, Hegel is dealing with pure essentialities, with spirit thinking its own essence; and these are linked together in a dialectical process that advances from abstract to concrete. If a man tries to think the notion of pure Being (the most abstract category of all), he finds that it is simply emptiness; i.e., Nothing. Yet Nothing is. The notion of pure Being and the notion of Nothing are opposites; and yet each, as one tries to think it, passes over into the other. But the way out of the contradiction is at once to reject both notions separately and to affirm them both together; i.e., to assert the notion of becoming, since what becomes both is and is not at once. The dialectical process advances through categories of increasing complexity and culminates with the absolute idea, or with the spirit as objective to itself.

"Nature." Nature is the opposite of spirit. The categories studied in "Logic" were all internally related to one another; they grew out of one another. Nature, on the other hand, is a sphere of external relations. Parts of space and moments of time exclude one another; and everything in nature is in space and time and is thus finite. But nature is created by spirit and bears the mark of its creator. Categories appear in it as its essential structure, and it is the task of the philosophy of nature to detect that structure and its dialectic: but nature, as the realm of externality, cannot be rational through and through, though the rationality prefigured in it becomes gradually explicit when man appears. In man nature rises to self-consciousness.

"Mind." Here Hegel follows the development of the human mind through the subconscious, consciousness, and the rational will; then through human institutions and human history as the embodiment or objectification of that will; and finally to art, religion, and philosophy, in which finally man knows himself as spirit, as one with God and possessed of absolute truth. Thus, it is now open to him to think his own essence; i.e., the thoughts expounded in "Logic." He has finally returned to the starting point of the system, but en route he has made explicit all that was implicit in it and has discovered that "nothing but spirit is, and spirit is pure activity."

Hegel's system depends throughout on the results of scientific, historical, theological, and philosophical inquiry. No reader can fail to be impressed by the penetration and breadth of his mind nor by the immense range of knowledge that, in his view, had to precede the work of philosophizing. A civilization must be mature and, indeed, in its death throes before, in the philosophic thinking that has implicitly been its substance, it becomes conscious of itself and of its own significance. Thus, when philosophy comes on the scene, some form of the world has grown old

At Berlin. In 1818 Hegel accepted the renewed offer of the chair of philosophy at Berlin, which had been vacant since Fichte's death. There his influence over his pupils was immense, and there he published his Naturrecht und Staatswissenschaft im Grundrisse, alternatively entitled Philosophy Grundlinien der Philosophie des Rechts (1821; Eng. trans., The Philosophy of Right, 1942). In Hegel's works on politics and history, the human mind objectifies itself in its endeavour to find an object identical with itself. The Philosophy of Right (or of Law) falls into three main divisions. The first is concerned with law and rights as such: persons (i.e., men as men, quite independently of their individual characters) are the subject of rights, and what is required of them is mere obedience, no matter what the motives of obedience may be. Right is thus an abstract universal and therefore does justice only to the universal element in the human will. The individual, however, cannot be satisfied unless the act that he does accords not merely with law but also with his own conscientious convictions. Thus, the problem in the modern world is to construct a social

of Right

Hegel's philosophical system

and political order that satisfies the claims of both. And thus no political order can satisfy the demands of reason unless it is organized so as to avoid, on the one hand, a centralization that would make men slaves or ignore conscience and, on the other hand, an antinomianism that would allow freedom of conviction to any individual and so potted order iempossible. The state that achieves this synthesis rests on the family and on the guild. It is unlike monarby, with parliamentary government, trial by jury, and toleration for Jews and toleration for Jews and dissenters.

After his publication of The Philosophy of Right, Hegel seems to have devoted himself almost entirely to his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. It is possible to form an idea of them from the shape in which they appear in his published writings. Those on Aesthetics, on the Philosophy of Religion, on the Philosophy of History, and on the History of Philosophy have been published by his editors, mainly from the notes of his students, whereas those on logic, psychology, and the philosophy of nature have been appended in the form of illustrative and explanatory notes to the corresponding sections of his Encyklopädie. During these years hundreds of hearers from all parts of Germany and beyond came under his influence; and his fame was carried abroad by eager or intelligent disciples.

Three courses of lectures are especially the product of his Berlin period: those on aesthetics, on the philosophy of religion, and on the philosophy of history. In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert rooms, and picture galleries. At these Hegel became a frequent and appreciative visitor, and he made extracts from the art notes in the newspapers. During his holiday excursions, his interest in the fine arts more than once took him out of his way to see some old panting. This familiarity with the facts of art, though neither deep nor historical, gave a freshness to his lectures on aesthetics, which, as put together from the notes taken in different years from 1820 to 1829, are among his most successful efforts.

The lectures on the philosophy of religion are another application of his method, and shortly before his death he had prepared for the press a course of lectures on the proofs for the existence of God. On the one hand, he turned his weapons against the Rationalistic school, which reduced religion to the modicum compatible with an ordinary worldly mind. On the other hand, he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology. In his middle way, Hegel attempted to show that the dogmatic creed is the rational development of what was implicit in religious feeling. To do so, of course, philosophy must be made the interpreter and the superior discipline.

In his philosophy of history, Hegel presupposed that the whole of human history is a process through which mankind has been making spiritual and moral progress and advancing to self-knowledge. History has a plot, and the philosopher's task is to discern it. Some historians have found its key in the operation of natural laws of various kinds. Hegel's attitude, however, rested on the faith that history is the enactment of God's purpose and that man had now advanced far enough to descry what that purpose is: it is the gradual realization of human freedom.

The first step was to make the transition from a natural life of savagery to a state of order and law. States had to be founded by force and violence; there is no other way to make men law-abiding before they have advanced far enough mentally to accept the rationality of an ordered life. There will be a stage at which some men have accepted the law and become free, while others remain slaves. In the modern world man has come to appreciate that all men, as minds, are free in essence, and his task is thus to frame institutions under which they will be free in fact.

Hegel did not believe, despite the charge of some critics, that history had ended in his lifetime. In particular, he maintained against Kant that to eliminate war is impossible. Each nation-state is an individual; and, as Hobbes

had said of relations between individuals in the state of nature, pacts without the sword are but words. Clearly, Hegel's reverence for fact prevented him from accepting Kant's Idealism.

The lectures on the history of philosophy are especially remarkable for their treatment of Greek philosophy. Working without modern indexes and annotated editions, Hegel's grasp of Plato and Aristotle is astounding, and it is only just to recognize that it was from Hegel that the scholarship lavished on Greek philosophy in the century after his death received its original impetus.

At this time a Hegelian school began to gather. The flock included intelligent pupils, empty-headed imitators, and romanties who turned philosophy into lyric measures. Opposition and criticism only served to define more precisely the adherents of the new doctrine. Though he had soon resigned all direct official connection with the schools of Brandenburg, Hegel's real influence in Prussia was considerable. In 1830 he was rector of the university. In 1831 he received a decoration from Frederick William III. One of his last literary undertakings was the establishment of the Berlin Jahrbücher für wissenschaftliche Kritik ("Yearbook for Philosonbiad Criticism").

The revolution of 1830 was a great blow to Hegel, and the prospect of mob rule almost made him ill. His last literary work, the first part of which appeared in the Preussische Staatszeitung while the rest was censored, was an essay on the English Reform Bill of 1832, considering its probable effects on the character of the new members of Parliament and the measures that they might introduce. In the latter connection he enlarged on several points in which England had done less than many continental states for the abolition of monopolies and abuses.

In 1831 cholera entered Germany, Hegel and his family retired for the summer to the suburbs, and there he finished the revision of the first part of his Science of Logic. Home again for the winter session, on November 14, after one day's illness, he died of holera and was buried, as he had wished, between Fichte and Karl Solger, author of an irronic dialectic.

PERSONAGE AND INFLUENCE

In his classroom Hegel was more impressive than fascinating. His students saw a plain, old-fashioned face, without life or lustre—a figure that had never looked young and was now prematurely aged. Sitting with his snuffbox before him and his head bent down, he looked ill at ease and kept turning the folios of his notes. His utterance was interrupted by frequent coughing; every sentence came out with a struggle. The style was no less irregular sometimes in plain narrative the lecturer would be specially at wward, while in abstruse passages he seemed especially at home, rose into a natural eloquence, and carried away the hearer by the grandeur of his diction.

The early theological writings and the Phenomenology of Mind are packed with brilliant metaphors. In his later works, produced as textbooks for his lectures, the "Encyclopedia of the Philosophical Sciences" and the Philosophical Sciences" and the Philosophical Sciences" and the Philosophical Sciences" and the Philosophical Sciences and precision. The common idea that Hegel's is a philosophy of exceptional difficulty is quite mistaken. Once his terminology is understood and his main principles grasped, he presents far less difficulty than Kant, for example. One reason for this is a certain air of dogmatism: Kant's statements are often hedged around with qualifications; but Hegel had, as it were, seen a vision of absolute truth, and he expounds it with confidence.

Hegel's system is avowedly an attempt to unify opposites—spirit and nature, universal and particular, ideal and real—and to be a synthesis in which all the partial and contradictory philosophies of his predecessors are alike contained and transcended. It is thus both Idealism and Realism at once; hence, it is not surprising that his successors, emphasizing now one and now another strain in his thought, have interpreted him variously. Conservatives and revolutionaries, believers and atheists alike have professed to draw inspiration from him. In one form or Recognition and honours

Emergence of Hegelianism

centre, and

another his teaching dominated German universities for some years after his death and spread to France and to Italy. The vicissitudes of Hegelian thought to the present day are detailed below in Hegelianism. In the mid-20th century, interest in the early theological writings and in the Phanomenologie was increased by the spread of Existentialism. At the same time, the growing importance of Communism encouraged political thinkers to study Hegel's political works, as well as his "Logic," because of their influence on Karl Marx. And, by the time of his bicentennial in 1970, a Hegelian renascence was in the (T.M.K.)

Hegelianism

Hegelianism is the name given to a diversified philosophical movement that developed out of Hegel's monumental system of thought. The term is here so construed as to exclude Hegel himself and to include, therefore, only the ensuing Hegelian movements. As such, its thought is focussed upon history and logic, a history in which it sees, in various perspectives, that "the rational is the real" and a logic in which it sees that "the truth is the Whole."

GENERAL CONSIDERATIONS

Problems of the Hegelian heritage. The Hegelian system, in which German Idealism reached its fulfillment. claimed to provide a unitary solution to all of the problems of philosophy. It held that the speculative point of view, which transcends all particular and separate perspectives, must grasp the one truth, bringing back to its proper centre all of the problems of logic, of metaphysics (or the nature of Being), and of the philosophies of nature, law, history, and culture (artistic, religious, and philosophical). According to Hegel, this attitude is more than a formal method that remains extraneous to its own content; rather, it represents the actual development of the Absolute-of the all-embracing totality of reality-considered "as Subject and not merely as Substance" (i.e., as a conscious agent or Spirit and not merely as a real being). This Absolute, Hegel held, first puts forth (or posits) itself in the immediacy of its own inner consciousness and then negates this positing-expressing itself now in the particularity and determinateness of the factual elements of life and culture-and finally regains itself, through the negation of the former negation that had constituted the finite world. Such a dialectical scheme (immediateness-alienationnegation of the negation) accomplished the self-resolution of the aforementioned problem areas-of logic, of metaphysics, and so on. This panoramic system thus had the merit of engaging philosophy in the consideration of all of the problems of history and culture, none of which could any longer be deemed foreign to its competence. At the same time, however, the system deprived all of the implicated elements and problems of their autonomy and particular authenticity, reducing them to symbolic manifestations of the one process, that of the Absolute Spirit's quest for and conquest of its own self. Moreover, such a speculative mediation between opposites, when directed to the more impending problems of the time, such as those of religion and politics, led ultimately to the evasion of the most urgent and imperious ideological demands and was hardly able to escape the charge of ambiguity and opportunism.

Stages in the history of the interpretation of Hegel. The explanation of the success of Hegelianism-marked by the formation of a school that, for more than 30 years, brought together the best energies of German philosophy-lies in the fact that no other system could compete with it in the richness of its content or the rigour of its formulation or challenge its claim to express the total spirit of the culture of its time. Moreover, as Hegelianism diffused outward, it was destined to provoke increasingly lively and gripping reactions and to take on various articulations as, in its historical development, it intermingled with contrasting positions.

Four stages can be distinguished within the development of Hegelianism. The first of these was that of the immediate crisis of the Hegelian school in Germany during the period from 1827 through 1850. Always involved in polemics against its adversaries, the school soon divided into three currents: (1) the right, in which the direct disciples of Hegel participated, defended his philosophy from right, the accusation that it was liberal and pantheistic (defining God as the All). These "old Hegelians" sought to uphold the compatibility of Hegelianism with evangelical orthodoxy and with the conservative political policies of the Restoration (the new order in Europe that followed the defeat of Napoleon). (2) The left-formed of the "young Hegelians," for the most part indirect disciples of Hegelconsidered the dialectic as a "principle of movement" and viewed Hegel's identification of the rational with the real as a command to modify the cultural and political reality that reactionism was merely justifying and to make it rational. Thus the young Hegelians interpreted Hegelianism in a revolutionary sense-i.e., as pantheistic and then, consecutively, as atheistic in religion and as liberal democratic in politics. (3) The centre, which preferred to fall back upon interpretations of the Hegelian system in its genesis and significance, with special interest in logical problems.

In the second phase (1850-1904), in which Hegelianism diffused into other countries, the works of the centre played a preponderant role; thus in this phase of the history of the interpretation of Hegel, usually called Neo-Hegelian, the primary interest was in logic and a reform of the dialectic.

In the first decade of the 20th century, on the other hand, there arose still in Germany a different movement, after Wilhelm Dilthey, originator of a critical approach to history and humanistic studies, discovered unpublished papers from the period of Hegel's youth. This third phase, that of the Hegel renaissance, was characterized by an interest in philology, by the publication of texts, and by historical studies; and it stressed the reconstruction of the genesis of Hegel's thought, considering especially its cultural matrices-both Enlightenment and Romanticistand the extent to which it might present irrationalistic and so-called pre-Existentialist attitudes.

In the fourth stage, after World War II, the revival of Marxist studies in Europe finally thrust into the foreground the interest in Hegel-Marx relationships and in the value of the Hegelian heritage for Marxism, with particular regard to political and social problems. This fourth phase of the history of Hegelianism thus appropriated many of the polemical themes of the earlier years of the school.

CRISES IN THE EARLIER HEGELIAN SCHOOL

The earlier development of Hegelianism can be divided, according to predominant concerns, into three periods: (1) polemics during the life of Hegel (1816-31), (2) controversies in the religious field (1831-39), and (3) political debates (1840-44), though discussions on all of the problems continued through all three periods.

Polemics during the life of Hegel: 1816-31. While Hegel was still living, discussion was dominated by the master. It was not a matter of polemics within the school but only one of objections against the system from various quarters: from speculative theists; from Johann Herbart, a prominent student of the philosophy of mind, and his followers; and from disciples of Friedrich Schelling, an objective and aesthetic Idealist, and of Friedrich Schleiermacher, a seminal thinker of modern theology.

The substantive history of the school stems from Hegel's later teaching at Berlin and from the publication of his Naturrecht und Staatswissenschaft im Grundrisse (1821; Eng. trans., The Philosophy of Right, 1942). This book was reviewed by Herbart, who reprimanded Hegel for mixing the monism of the Rationalist Spinoza with the transcendentalism of Kant, which had explored the conditions of the possibility of knowledge in general. There were also certain critics who directed the liberal press against Hegel for attacking Jakob Fries, a psychologizing Neo-Kantian, in the introduction of The Philosophy of Right. Some of the polemical writings of Hegel made a notable impacte.g., a preface that he wrote for a book by one of his earliest disciples, Hermann Hinrichs, on the relation of faith to reason (1822). In this preface, Hegel saw the two things

Dialectical development of the Absolute

Articles in Inhrhücher

Feuerbach

as the same in content but different in form-which for faith is the representation and for reason is the concept.

Particularly significant were eight articles in the Jahrbücher für wissenschaftliche Kritik (founded 1827; "Yearbooks for Scientific Critique"), a journal of the Hegelian right. Important among these were a review by Hegel that was unexpectedly eulogistic about the thesis that philosophy and evangelical orthodoxy are compatible and another review in which Hegel responded indirectly to arguments of Herbart. Among Hegel's critics can be distinguished speculative theists such as Christian Weisse of Leipzig and Immanuel Fichte, the son of the more famous Johann Fichte, who reproached him for his panlogism and proposed to unify thought and experience in the concept of a free God, the Creator. Among the most loyal disciples of Hegel were Hermann Hinrichs, his collaborator, and Karl Rosenkranz, who defended the Hegelian solution of the faith-reason problem (which had asserted the identity of content and difference of form), thus aptly defending the free rationality of religion.

Period of controversies chiefly in religion: 1831-39. The tone of these early polemics became animated and embittered after the death of Hegel. But, inasmuch as conditions in Germany, during the Restoration, inhibited the liberalization of political discussions, the milieu of controversy shifted to the religious realm and became related to problems of immortality, Christology, and general theology.

Shortly before Hegel's death, the youthful Ludwig Feuerand Strauss bach, who later became a pioneer of naturalistic humanism, had published his Gedanken über Tod und Unsterblichkeit (1830: "Thoughts on Death and Immortality"), in which he contended that, from the Hegelian point of view, death must be necessary in order for man to be transformed from the finite to the infinite and it is thus a privilege for man preferable to empirical personal survival. This work was held to confirm the charge of pantheism that orthodox adversaries had directed at Hegel's system. On this point, at the appearance of two volumes by Johann Friedrich Richter, a pantheist and critic of religion, Hegel's disciples intervened, in an argument employing not a few dialectical artifices, to conciliate Hegelian statements with the traditional doctrine of immortality.

> The polarization of historical positions that the debate on immortality could not adequately express soon came into the open with Das Leben Jesu kritisch bearbeitet (1835-36; Eng. trans., The Life of Jesus Critically Examined, 1846), of David Friedrich Strauss, a biblical interpreter and radical theologian. This work brought the problem of the nature of Christ up to date from the point of view that had been reached by biblical criticism; i.e., Christology was no longer an issue of denominational dogma but, rather, a problem of the interpretation and evaluation of the Gospel sources and of their meaning in the historical development of civilization. In this approach, the narrowly philological outlook was overcome by a reconstruction in terms of a philosophy of history strangely suggestive of the young Hegel. The thesis of the book was that the Gospel account is interwoven with myths that are not the works of individuals but of the collective poetic activity of the first Christian community, myths that resulted in part from messianic expectations, in part from the memory of the historical figure of Jesus, and in part from a transfiguration of the real elements. The aim of the myths was to demonstrate that philosophy and religion are the same in content and to offer, in an imaginative guise (as in parables), the meaning of the one truth that Substance is unification of the divine nature and of the human, which Christ symbolized and which is realized in the spirit of all humanity

> Strauss's work provoked a lively reaction, to which he replied in his Streitschriften (1837-38; "Controversial Writings"), proposing the image of a Hegelian school split, like the French Parliament, into a right (Göschel, and several others), a centre (Rosenkranz), and a left (Strauss himself). There were responses from the right and centre and from Bruno Bauer, a philosopher, historian, and biblical critic. From the anti-Hegelian side there was, above all, Die evangelische Geschichte (1838; "The History of the Gospels"), by Weisse, who, conceding to Strauss the

necessity to rationalize the Gospel story, propounded a speculative interpretation of the Christ figure as an incarnation of the Logos (Thought-Word), in contrast to the mystic and pantheistic views.

Meanwhile, Bauer shifted toward the left in a polemic against the orthodox Ernst Hengstenberg, a vehement accuser of the Hegelians, and in his Kritik der Geschichte der Offenbarung (1838; "Critique of the History of Revelation"). In 1838 was founded the earliest journal of the left, the Hallische Jahrbücher für deutsche Wissenschaft und Kunst ("Halle Yearbooks for German Science and Art"), coedited by the activist philosopher Arnold Ruge and T. Echtermeyer. At first, the journal maintained a moderate tone, and Hegelians of the centre and right also contributed articles. In June, however, it veered to the democratic-liberal side as Ruge struck out against an accuser of the young Hegelians and as Feuerbach attacked earlier Hegelians, Hegelianism, which marks the culmination of speculative philosophy, Feurebach charged, does not demonstrate its own truth, because its contrast between sensory reality and intellectual concept comprises an irresoluble contradiction. Thus, its dialectic turns out to be a "monologue with itself," bereft of authentic mediation with the world. Hegelian philosophy, he held, is a "rational mystique," and what is needed is a return to nature, which, as objective reason, ought to become a principle of philosophy and of art. Thus an extensive examination of contemporary culture was conducted by the journal's editors in an article that depicted Romanticism as a movement degraded to a reactionary stance and extolled the spirit of reform and of liberal (yet loyalist) Prussianism. As for issues in the fields of logic and metaphysics, after

several polemical exchanges the interest of philosophers was attracted to the publicist reawakening that came to Schelling, who reactivated certain anti-Hegelian criticisms. These criticisms dealt with the impossibility of building a valid philosophy upon the pure concept assumed as a point of departure and endowed with autonomous movement, Such a philosophy would be vitiated by presuppositions of what ought to be demonstrated and by hypostatizations (i.e., the making of an idea into an entity). Schelling proposed, on the other hand, that the real itself be taken as the subject of development, to be grasped with a "lively intuition"; and that, while accepting a "negative philosophy" (such as that of Rationalism and Hegel) pointing to the conditions without which one cannot think, one must also add a "positive philosophy" delineating the conditions by means of which thought and reality can exist, premised on the existence of a free creative God.

Period of atheistic and political radicalism: 1840-44. The ensuing years marked one of the most intense periods in the cultural life of modern Europe.

Anti-Hegelian criticism. Advancing from Aristotelian presuppositions, an important critique against the Hegelian logic was presented by the classical philosopher and philologist Friedrich Adolf Trendelenburg in his Logische Untersuchungen (1840; "Logical Investigations"). In Hegel's view, the passage from Being to Nothing and to Becoming can be posited as a pure beginning "without presuppositions" of logic. In Trendelenburg's view, however, this passage is vitiated by its spurious dependence upon the surreptitious presupposition of the Empirical movement, without which support neither the passage from Being to Nothing (and vice versa) nor the recognition of Becoming as the "truth" of this primal opposition of concepts can be justified. Secondly, he charged that Hegel confused (1) the logical opposition or contradiction of A against non-A with (2) the real contradiction or contrariety of A against B. Contradiction (1) consists in the mere repetition of the first term with a negative sign; and from it no concrete movement can proceed. In contrariety (2), however, the opposition of the second term to the first is concretethus the second term cannot be deduced from the first and, instead, should be derived on its own account from empirical experience. Thus Hegel constructed his entire system, Trendelenburg charged, on an arbitrary dialectic of elements intrinsically real (contraries), which he mistakenly treated as though they were abstract opposites (contradictories) and were such by logical necessity.

Weisse. Ruge, Schelling

Meanwhile, Schelling continued to teach his "positive philosophy"-of mythology and of revelation (of a personal God). Hence the philosophy of the later Schelling became the target of all of the criticisms from the left and likewise exerted a notable influence on the speculative theists. Meanwhile, the centre, on account of the critique of Trendelenburg, oriented itself toward the future reforms of Hegelianism.

Kierkegaard and Fischer

Among those who attended Schelling's lectures was Søren Kierkegaard, the man who was destined to become one of the founding fathers of Existentialism and whose religious individualism represents the earliest major result of the diffusion of Hegelianism outside of Germany. In all of his works-but above all in his Philosophiske Smuler (1844; Eng. trans., Philosophical Fragments, 1936) and his Afsluttende uvidenskabelig Efterskrift (1846; Eng. trans., Concluding Unscientific Postscript, 1941)-Kierkegaard waged a continuous polemic against the philosophy of Hegel. He regarded Hegel as motivated by the spirit of the harmonious dialectical conciliation of every opposition and as committed to imposing universal and panlogistic resolutions upon the authentic antinomies of life. Kierkegaard saw these antinomies as emerging from the condition of the individual, as a single person, who, finding himself always stretching to attain ascendance over his existential limitations in his absorption in God and at the same time always thrust back upon himself by the incommensurability of this relationship, cannot find his salvation except through the paradoxical inversion of the rational values of speculative philosophy and through the "leap of faith" in the crucified Christ. Kierkegaard's claim that the nexus of problems characterizing man's condition as an existing being is irreducible to any other terms lay at the very roots of Existentialism. It was destined to condition the critical relationship of this current of thought to Hegelianism throughout its subsequent history. Moreover, Kierkegaard's thought, which Kierkegaard did not knowstill more than that of Strauss-seemed reminiscent of those problem areas explored in the young Hegel's religious thought-issues that were destined to appear only later when Hegel research would gain precise knowledge of the writings of Hegel's youth

At this time the attitude of the centre was oriented toward reforms of the Hegelian system in the field of logic and historiography, as reflected especially in the emergence of Kuno Fischer, one of the foremost historians of philosophy. In the fundamental triad of the dialectic, as Fischer saw it, Being and Nothing are not equally static and neutralizing. The real movement does not interpose itself into their relationship because Being is here to be understood as the Being of thought, which, to the degree that it is a thinking of Nothing, possesses that dynamic surplus that becomes manifest in the moment of Becoming. It was in making responses to this view that the forthcoming Neo-Hegelian movement in Europe found

some of its motivations.

Theological radicalism. In 1840 political conditions in Germany changed with the succession of the young Frederick William IV, whose minister began to repress the liberal press and summoned to Berlin in an anti-Hegelian capacity both Schelling and the conservative jurist F.J. Stahl, a stubborn critic of Hegel. Far from weakening the movement, however, these actions radicalized its revolutionary manifestations. Strauss, in Die christliche Glaubenslehre (1840-41; "The Christian Doctrine of Faith"), reaffirmed the opposition of philosophical pantheism to religious theism as a means of reunifying the finite and the infinite; and Feuerbach established a philosophical anthropology in his major work Das Wesen des Christentums (1841; •Eng. trans., The Essence of Christianity, new ed. 1957). in which man reappropriates his essence, which he had alienated from himself by hypostatizing it in the idea of God. The essence of man is reason, will, and love; and these three faculties comprise the consciousness of the human species as a knowledge of the infinity that man must regain. Man must thus reverse the theological propositions that express the spurious objectification of his universality in God; for this objectification had been effected through the individual consciousness in its effort to surmount its limitations. Thus Feuerbach interpreted the Christian mysteries as symbols of the alienation of human properties absolutized as divine attributes, and he criticized the contradictions of theology that are found in such concepts as God, the Trinity, the sacraments and faith. Man's reappropriation of his essence from such religious alienation is consummated in the "new religion" of humanity, of which the supreme principle is that "man is God to man."

To this period belong also the major critiques of Bruno Bauer on the Johannine (1840) and Synoptic (1841-42) Gospels. Differentiating his position from the pantheistic and mysticizing Substance of Strauss. Bauer held that the Gospels were not the unconscious product of the original community but a product of the self-consciousness of the Spirit in a given stage of its development. There followed two works specifically concerning Hegel, in which, feigning an orthodoxy from which he charged Hegel with atheism and radicalism, Bauer maintained, in the form of a parody, the revolutionary interpretation of Hegel that became customary in the current of the Hegelian left.

Sociopolitical radicalism. In the years 1841-43 the repressive measures of the government reached ever more decisive extremes: Bauer was deharred from teaching. Feuerbach did not even attempt to teach; and Ruge was enjoined to publish the Hallische in Prussia instead of Leipzig. (Actually, he transferred it to Dresden and changed its name to the Deutsche Jahrhücher.) Here also appeared one of Ruge's major writings, "Die Hegelsche Rechtsphilosophie und die Politik unserer Zeit" (1842; "The Hegelian Philosophy of Right and the Politics of our Time"), in which Ruge denounced Hegel's political conservatism, charging that his contemplative reason was reduced to the acceptance of existing conditions, to the exclusion of every effort to modify reality, and to the absolutizing of the Prussian state as the model of an ideal state. Ruge's journal was suppressed early in 1843, but in March he published in Switzerland his Anekdota zur neuesten deutschen Philosophie und Publicistik ("Anecdotes for the Latest German Philosophy and Political Journalism"), containing articles by Bauer, Ruge, Marx, Feuerbach, and others.

Feuerbach's article developed the claim that the method of speculative philosophy, which is the ultimate form of theology, is to invert the subject and predicate-i.e., to substantialize the abstract and to treat concrete determinations as attributes or "logical accidents" of hypostatized abstractions. The inversion of speculative propositions, he held, leads to the philosophical reappropriation of man's essence; the philosophy of the future will achieve mastery through the negation of the Hegelian philosophyand this is exactly what he entitled his forthcoming book: Grundsätze der Philosophie der Zukunft (1843; "Basic Principles of the Philosophy of the Future"). In place of the immediate Absolute of Hegel, he argued, there must be substituted the immediate individual existentcorporeal, sensible, and rational. Man's reappropriation of himself will be possible whenever his need to transcend his own limitations finds fulfillment in another person and in the totality of the human species: "thus man is the

measure of reason."

Meanwhile, a schism had been ripening in the left wing: (1) On the one hand, there were the "Free Berliners (initially the young Friedrich Engels, later to become Marx's theoretician, the radical anarchist Max Stirner, and the Bauer brothers), who, deeming themselves faithful to Hegel, developed a philosophy of self-consciousness (understood in a subjective and superindividualistic sense) directed toward treating social and historical problems with aristocratic intellectual detachment. (2) On the other hand, there was the group that included Ruge, the publicist Moses Hess, the scholarly poet Heinrich Heine, and Karl Marx, Influenced in their theories by Feuerbach, this group directed radicalism toward an experience deepened by the classical Enlightenment and embraced the rising Socialism. They thus involved Hegel in their critique of the political, cultural, and philosophical conditions of the time. The most widely known result of the first trend was Stirner's book Der Einzige und sein Eigentum (1845; "The

Feuerbach and Raner Individual and His Property"), in which the fundamental thesis of individualistic anarchism can be discerned. The unique entity, in Stirner's view, is the individual, who must rebel against the attempt made by every authority and social organization to impose upon him a cause not his own and must be regarded as a focus of absolutely free initiative-a goal to be reached by emancipating himself from every idea-value imposed by tradition.

The work of Marx

The years between 1840 and 1844, however, saw the emergence of a figure incomparably more representative of the crisis of German Hegelianism than any already cited, that of Karl Marx, who was destined to guide the experience of this crisis toward a revolution of world historical scope. Marx's study of Hegel dates from his university years in Berlin, the earliest result of which was his doctoral dissertation with the exceedingly important preparatory notes, in which he ventured an original application of Hegelian method to the problem of the great crises in the history of philosophy. At first a friend of Bauer, Marx clung closely, however, to the democratic wing of the left. In 1843 he completed an important critical study of Hegel's Philosophy of Right, in which he reproached Hegel for having absolutized into an ideal state the Prussian state of the time. Such absolutizing, he charged, lent itself to generalizations of broad critical scope with respect to the idealistic procedure of hypostatizing the Idea and brought about (as allegorical derivatives from it) certain concrete political and social determinations, such as family, classes, and the state powers. Not yet a Communist, Marx nonetheless completed, in his Kritik der hegelschen Staatsrechts (written in the summer of 1843, published 1929; "Critique of Hegel's Constitutional Law"), a criticism of the erroneous relationship initiated in Hegel between society and the state, which was destined to lead Marx from the criticism of the modern state to that of modern society and its alienation.

It will be recalled that Hegel had likewise proposed the concept of alienation, describing the dialectic as a movement of the Absolute that was determined by its alienating and then regaining itself (thus overcoming the self-negation). Already in the Economic and Philosophic Manuscripts of 1844 (German ed., 1932; Eng. trans., 1959), Marx had enunciated a general critique of the Hegelian dialectic that revealed its a priori nature, which, in Marx's view, was mystifying and alienated inasmuch as Hegel did nothing but sanction, by a method inverted with respect to real relationships, the alienation of all the concrete historical and human determinations.

Marx then directed himself against his former colleagues on the left-against Bauer in his Die heilige Familie (1845; Eng. trans., The Holy Family, 1956) and against Stirner in his Die deutsche Ideologie (1845-46; Eng. trans., The German Ideology, 1938), criticizing their "ideologism" (i.e., the illusion that Idealism can be carried into the revolutionary camp since it is ideas that make history). The historical Materialism that Marx counterposed against Idealism expressed the conviction that the basis comprising the relations of production, both economic and social, conditions the superstructure of political, juridical, and cultural institutions and that the interchange among these spheres of production within the totality of an historical epoch must be designed to overcome their contradictions. This Materialism, though not belonging any more to Hegelianism, was destined nonetheless to remain linked to it by continuing polemical relationships and overlapping problem areas throughout the subsequent history of the movement.

Along with Marx must, of course, be mentioned his colleague Friedrich Engels, who was more tied, however, to the Hegelian conception of the dialectic-particularly regarding the dialectic of nature-than Marx was.

HEGELIANISM THROUGH THE 20TH CENTURY

Development and diffusion of Hegelianism in the later 19th century. In Germany, the second half of the 19th century witnessed a decline in the fortunes of Hegelianism. beginning with the Hegel und seine Zeit (1857; "Hegel and His Age"), by Rudolph Haym, a historian of the modern German spirit. The decline was urged on by NeoKantianism and Positivism as well as by the political realism of Bismarck. Hegelian influences still appeared in the first representatives of historicism (which urged that all things be viewed in the perspective of historical change). The surviving Hegelians, however, such as Kuno Fischer and Johann Erdmann, devoted themselves to the history of philosophy. Strauss and the Bauer brothers were won over to conservatism, and even Ruge, returning from exile in England, became a conservative.

Political and cultural problems; East Europe and the United States. The diffusion of Hegelianism outside of Germany was oriented in two directions. With respect to its political and cultural problems, the Hegelian experience developed in east European philosophers and critics such as the Polish count Augustus Cieszkowski, a religious thinker whose philosophy of action was initially influenced by the left; and the theistic metaphysician Bronislaw Trentowski. Among the Russians can be cited the literary critic Vissarion Belinsky, the democratic revolutionary writers Aleksandr Herzen and Nikolay Chernyshevsky, and certain anarchists such as the Russian exile and revolutionist Mikhail Bakunin. And among the French there were Hegelian Socialists such as Pierre-Joseph Proudhon.

In the United States, the interest in Hegelianism was stimulated by its political aspects and its philosophy of history. Its two centres, the St. Louis and Cincinnati schools, seemed to duplicate the German schism between a conservative and a revolutionary tendency. The former was represented by the Hegelians of the St. Louis school: the German Henry Brokmeyer and the New Englander William Harris, a pedagogue and politician, and the circle that they founded called the St. Louis Philosophical Society, which published an influential organ, The Journal of Speculative Philosophy. Their legitimism, or support for legitimate sovereignty, was expressed in the quest for a foundation, dialectical as well as speculative, for American democracy and in a dialectical interpretation of the history of the United States. The Cincinnati group, on the other hand, gathered around August Willich, a former Prussian officer, and John Bernard Stallo, an organizer of the Republican Party. Willich had participated in the Revolution of 1848 as a democratic partisan in south Germany, and, as an exile, had been in lively intercourse with Marx. He founded the Cincinnati Republikaner, in which he reviewed Marx's Zur Kritik der politischen Ökonomie (1859) and endeavoured to base the principles of social democracy upon the humanistic foundations of Feuerbach, Stallo, on the other hand, tried to interpret the political philosophy of Hegel in republican terms. The democratic community became, for him, the realization of the dialectic rationality of the Spirit with a rigorous separation of church and state.

Logic and Metaphysics problems: Italy, England. The second trend in non-German Hegelianism was directed, in Italy and in England, to problems of logic and metaphysics. A vigorously speculative rethinking of the foundations of Hegel's Wissenschaft der Logik was engaged in by the major liberal Italian philosopher Bertrando Spaventa and his associates. Spaventa's Studi sull' etica di Hegel (1869) consisted of a direct liberal translation of Hegel's Philosophy of Right. Seeking to rediscover the connection between the thinking of the Italians of the 16th century and that of the German Idealists, Spaventa encountered the system of problems involved in the relationship between Kant and Hegel. He adopted from Kuno Fischer the solutions by which Fichte, Schelling, and Hegel had rendered Kant's transcendental ego consummatively veritable. He thus proposed an epistemological (idealistic theory of knowledge) interpretation of the Hegelian logic, according to which one premise of the logic is the dialectic of consciousness described in Hegel's Phenomenology of Mind, and the problems of the genesis of logic are resolved in the sense that Being is, from first to last, Becoming; i.e., it is thought in action, which negates the objective residue of thought-out Being and, for that reason, is confirmed as a creative process. From Spaventa, whose intention was to vindicate the freedom and autonomy of thought against denominational dogmatism, was derived the foundation for the subjectivistic formalization

St. Louis Cincinnati schools

Decline in Germany

of Hegelianism soon undertaken by Giovanni Gentile, an early-20th-century Idealist.

As in Italy, so also in England, interest in Hegel arose from the philoopher's need to round out his experience of classical German thought by tracing its vicissitudes since the time of Kant; and this interest was directed toward the fields of epistemology and logic and in this instance was applied to problems of religion and not of politics. The pioneer in English Hegelianism was James Hutchison Stirling, through his work The Secret of Hegel (1865). Stirling reaffirmed the lineage of thought that Fischer had traced "from Kant to Hegel," endeavouring to penetrate the dialectic-speculative relationship of unity in multiplicity as the central point of the dialectic. Toward Hegelianism as a unifying experience the ethics scholar Thomas Hill Green. the foremost representative of Hegelianism at Oxford, applied himself, though with more original attitudes; and the brothers John and Edward Caird dedicated themselves to right-wing interpretations of religious subjects-Edward in a well-known monograph entitled Hegel (1883).

Hegelianism in the first half of the 20th century. At this point, the development of Hegelianism branched out in two directions: one of which, in England and Italy, pursued the tendencies of the Neo-Hegelians of the preceding decades, while the other, in Germany and France, accomplished the philological interpretative renewal known as

the Hegel renaissance.

Bradley,

Royce,

Croce

Neo-Hegelianism in England and Italy. With respect to the first tendency, there appeared in England at the turn of the century various outstanding works on Hegel's logic by authors who were partly Hegelian in spirit. These scholars, toiling through the system of problems that they shared-which focussed on establishing a criterion for the unification of the multiplicity of experience-ended up in diverse positions; those of Bernard Bosanquet and John Ellis MacTaggart, for example, who were translators and commentators of Hegelian works; but above all that of the foremost spiritualistic philosopher then in England, F.H. Bradley, author of the renowned Appearance and Reality (1893), whose development led him to positions more and more at odds with the absolute panlogism of Hegel. His affirmation of the dualism of appearance and reality was the result of a critique of the category of relations, which, by introducing contradictions between the qualities of the thing, utterly shattered the unity of experience in which it might seem that true reality could be reached-a reality

that in Bradley's view it is not given to thought to attain. The echoes of this Idealistic system were not long in being felt in the United States by one of its most profound philosophers, an absolute Idealist, Josiah Royce, who, in The World and the Individual (1900-01), discussed the skeptical Idealism of Bradley in order to overthrow its consequences in favour of a conception of the infinite as a self-representative system and of the world (or the All) as an individualized realization of the intentional aims of the Idea copresent in a superior eternal consciousness. In Anglo-Saxon Neo-Hegelianism, the Hegelian experience has always been merely an episode-which fact serves to refine, by contrast, the methods of experimentalism that are more congenial to the Empirical tradition in England.

In Italy, on the other hand, the Neo-Hegelianism of the 20th century took the form of a spiritualistic reaction to the spread of Positivism that had followed upon the unification of Italy. This reaction developed in two directions: that of the historicism of Benedetto Croce and that of the actualism of Giovanni Gentile, two scholars who divided the realm of philosophy between themselves and occupied it-rather heavy-handedly-for four decades. The Crocean reform of Hegelianism dates from his volume Ciò che è vivo e ciò che è morto della filosofia di Hegel (1907; "What Is Living and What Is Dead in the Philosophy of Hegel") and from the systematic works of his so-called "philosophy of the spirit," Croce accepted the dialectic from Hegel as a requirement for the unification of opposites; but he rejected its system, in which Hegel would put in opposition and treat dialectically certain intellectual forms that are not really opposite but only distinctsuch as the beautiful, the true, the useful, and the good, each of which has its dialectical opposite over against itself that it has to overcome within the purview of each grade. Consequently, renouncing the possibility of a philosophy of nature or of history, Croce formulated a development of so-called "distinct grades" according to the spiritual forms of art, of philosophy, of economics, and of ethics and contended that the comprehensive meaning of the development of the Spirit is given by history "as thought and as action" and a realization of freedom.

Gentile, on the other hand, accentuated the opposition of subject and object by considering every objective factuality as surpassed by the living dialectical development of the act-i.e., the becoming of the Spirit in its own selfmaking, proceeding from an originating self-establishment, or autoktisis, of the Spirit itself. From this position he derived an absolute subjectivism that exploited all the possibilities for dialectically transforming every fixed position into its opposite, a downright sophistry of disengagement. Gentile's pro-Fascist stance, however, condemned his actualism to collapse.

Hegelian renaissance in Germany and France. Already from the beginnings of the century, however, there had been in Germany a change in Hegelian interpretation instigated by Wilhelm Dilthey's re-examination, in 1905, of the youthful manuscripts of Hegel and by the publication by one of Dilthey's principal disciples, Herman Nohl, of Hegels theologische Jugendschriften (1907; "The Theological Writings of Hegel's Youth"). Inasmuch as there had been heretofore only fragmentary notices on these unpublished literary remains, the effect of this rereading of the texts was to place them in contrast with the works of his maturity: they thus emerged as dealing, for the most part with various problem areas in ethics, religion, and history; as lacking systematic preoccupations; and as rich discourse. tending to the mystic, which invited their comparison with the severe technical uniformity of his major works. Hermeneutical interest, however, centred especially on the problem of the beginnings of the philosophy and dialectic of Hegel, of which the first formulations were investigated in order to collate their meanings with those of the major works and of the Phenomenology, which was a key work of the Hegelian evolution inasmuch as it participated both in the romanticized colouring of the youthful writings and in the systematic demands of the Encyklopädie der philosophischen Wissenschaften im Grundrisse (1817: "Encyclopaedia of the Philosophical Sciences in Outline").

Scholars were soon led to investigate the historical matrices of Hegel's intellectual culture-the late Enlightenment and dawning Romanticism-a direction of inquiry that vielded imposing contributions rich in discussions that continue to this day. These studies began with Dilthey's monograph, which pointed out the irrationalistic and vitalistic aspects of Hegel's youthful writings. In addition, a basic work by Franz Rosenzweig, Hegel und der Staat (1920), genetically reconstructed the political thought of the young Hegel in relation to its historical sources and concluded that the influence of Rousseau prevented Hegel from becoming the genuine "national philosopher of Germany," Jean Wahl, a French metaphysician and historian of philosophy, wrote on the "wretched conscience," interpreting Hegel existentially. Further, the German philosopher Richard Kroner studied the development from Kant to Hegel integrating it with the contributions of early Romanticism. And Hermann Glockner, a Bavarian aesthetic intuitionist, saw following one another in the development of Hegel a so-called "pantragistic" phase up to the Phenomenology and, subsequently, an opposing "panlogistic" phase that betrayed the most lively and concrete instances of the preceding phase-a work that approached the efforts at interpreting Hegel that were made by the Nazis.

Hegelian studies today. Today one has to speak not of the presence of Hegelianism as an operating philosophical current but only of studies on Hegel and of an experience of the Hegelian philosophy, to which, however, almost none of the present-day orientations in philosophy is foreign. The repeated encounter of Western culture with Marxist thought after World War II has brought to the fore the political, ethical, and religious implications of Hegelianism; and a marshalling into opposing camps analogous to that of the earlier crisis of the school is

Publication of the Jungendschriften

taking shape. Today there are no orthodox Hegelians, but there are denominational critics of Hegelianism, especially Catholic, whose cognizance of Hegel's painful development invokes, despite their differences, a certain fellow feeling with him.

In the centre are found scholars of a liberal and radical frame of mind but with varying orientations with respect to historical interpretations. Karl Löwith, a German philosopher of history and culture, sees Hegel as the initia-tor of the "historicist" crisis in modern thought, culminating in Marx and in Kierkegaard; and to this he contrasts the metahistorical perspective reflected in the Nietzschean motif of the "eternal return," based on the ideal of a Goethean serenity. In France, Alexandre Kojève, noteworthy for his effort to harmonize Hegel with Martin Heidegger, proposes a reinterpretation of the Phanomenologie as a manifesto of the emancipation of "man the servant" from all alienations. Jean Hyppolite, author of an outstanding commentary on the Phanomenologie, usually presents a restrained humanistic interpretation of the Hegel of Jena. This renaissance of the study of Hegel has conditioned the thought of some of the major thinkers of France. Particularly notable, however, is the Hegelian conditioning of German philosopher-sociologists such as Theodor Adorno and Herbert Marcuse. The former is sometimes regarded as the most Hegelian thinker of the mid-20th century because he sought to bring again to the fore Hegel's dialectic, understood in a new anti-intellectualistic sense, as a method for the solution of present-day social problems. Marcuse, a partisan of a Diltheian interpretation, approaches the position of the first Hegelian left, ending up in what critics see as a neoromantic anarchism. The major merit of both of these thinkers lies in their incisive analyses of aspects of modern consumer societies, especially American-though their proposed remedies remain uncertain.

The major interest, however, in the contemporary interpretation of Hegel is displayed by the Marxist camp. Marxist interpretation of Hegel had permeated the entire history of Hegelianism (notwithstanding the fact that the critical activity of young Marx against Hegel had been vehemently conducted and had led to various effects). This interpretation had settled upon the distinction made by Friedrich Engels between the method and the system of Hegel's philosophy-i.e., between the dialectic considered as a revolutionary "principle of movement" that achieves fulfillment in human culture, and the system, regarded, on the other hand, as reactionary because idealistic and conservative. With varying emphases on critical issues, this interpretation was continued in subsequent Marxist thinkers-from the Russians Georgy Plekhanov and Lenin to Mao Tse-tung and Joseph Stalin-the latter of whom affirmed the complementariness of historical and dialectical Materialism

Today many Marxist scholars, especially in the countries of eastern Europe, remain favourable to the traditional line of Engels; and above all György Lukács, a Hungarian philosopher and literary critic and author of a volume on the young Hegel, does so. With the intention of revealing the romantic and irrationalistic presuppositions of Naziism, Lukács reevaluates, in German culture, the tendency of the Enlightenment and of democracy, which he recognizes in the young Goethe, in Schiller, in Hölderlin, and in the young Hegel-in whom he sees, however, a reactionary involution.

A secondary tendency, which is drawing attention in France, with the work of Louis Althusser, draws Marx close to Structuralism, a recent school that seeks through a "human science," to probe the systematic structures evinced in cultural life. In this school Marx's humanism is viewed as a temporary, Feuerbachian phase, surpassed by commitment to the scientific observation of the structure of bourgeois society. Such Structuralistic interpretation of Marxism thus runs the risk of departing from a due emphasis on the historical substance of Marxian Materialism.

The latter motive is, on the other hand, the essential aim of a third Marxist current, in Italy, initiated by Galvano della Volpe, a critical aesthetician who discusses the relationship between bourgeois and Socialist democracy and champions, in aesthetics, a critical and antiromantic Aristotelianism. This current has been continued by Mario Rossi, who asks one to read again in full the texts of Hegel and Marx, to reconstruct the related movements, and to compare the Materialistic conception of history with more recent philosophical currents such as Structuralism. present-day sociology, and the logic of the sciences.

A conclusion of a theoretical-systematic nature concerning Hegelianism has today become not only impossible but also inopportune, because its possible interest has been effectively replaced by that of the sheer history of the movement. The latter has shown how the substantial ambiguity of the philosophy and dialectic of Hegel can be resolved only when its claim to be able to solve all problems on a theoretical level and to achieve a "circular" decisiveness in its arguments-which violates the conditioning specificity of historical facts-is refuted. It is then the scholar's task to explore the limits of Hegel's thought as well as its conditioned inadequacies-but also its merits, which are above all those of having expressed and documented the major part of the cultural problems of modern civilization. (M.R.)

RIBLIOGRAPHY

Hegel. Works: A collected edition of Hegel's published works, together with a great deal of material culled from his lectures, was published by his pupils within a few years of his death in 1831. This edition, with some rearrangement, was reissued by HERMANN GLOCKNER in 26 volumes, including a comprehensive index (1927-40). In 1905 the Philosophische Bibliothek (Leipzig, later Hamburg) began publication of a new edition with a carefully revised text edited by GEORG LASSON and later by JOHANNES HOFFMEISTER: volumes appeared for more than 50 years, but it was not completed. It has been enhanced by a comprehensive edition sponsored by the Deutsche Forschungsgemeinschaft, which is to contain about 50 volumes. The first volume appeared in 1968, English translations of most of Hegel's works were published in the late 19th and early 20th century, but, apart from those by WILLIAM WALLACE (Logic and Mind-i.e., the first and third parts of the Encyclopaedia), they are not always satisfactory and they have no notes. With a view to remedying this deficiency, new English translations have appeared of some works, including Philosophy of Right (1942, often reprinted) and Science of Logic (1969), as well as translations of writings not translated previously, such as Early Theological Writings (1948; rev. ed., 1971), and Philosophy of Nature, 3 vol. (1970), the second part of the Encyclopaedia. With the exception of Science of Logic and the Oxford translation of Philosophy of Nature, all these translations are annotated.

Life and philosophy: RAYMOND PLANT, Hegel (1973), is a study of origins of his thought; and CHARLES TAYLOR, Hegel (1975), is a study of the development of his philosophy. An excellent short account of Hegel's philosophy in English is EDWARD CAIRD, Hegel (1883, reissued 1972), but it has been updated in certain respects by G.R.G. MURE, The Philosophy of Hegel (1965); and in more detail by WALTER A. KAUFMANN, Hegel (1965, reissued 1978). An attempt to interest modern philosophers in Hegel is contained in J.N. FINDLAY, Hegel (1958, reissued 1976), but this important and lively work is for consideration only by those already acquainted with Hegel. As an introduction, G.R.G. MURE, An Introduction to Hegel (1940, reprinted 1982), is more reliable but it is not an exposition. A standard long exposition of Hegel's mature system is KUNO FISCHER, Hegels Leben, Werke und Lehre, especially the 2nd ed. (1911, reprinted 1976); while in English there is WALTER STACE, The Philosophy of Hegel (1924). In 1900 Wilhelm Dilthey maintained that Hegel could be understood only if there were a study of his early manuscripts; on the basis of these, Dilthey wrote Die Jugendgeschichte Hegels (1906, reissued 1968), a history of Hegel's development. This seminal work, hardly noticed at all by writers in English before 1965. gave rise to an immense literature in Germany, France, and Italy. An important and brilliant study of the young Hegel is GEORG LUKACS, Der junge Hegel (1948; Eng. trans. 1975). written from a Marxist point of view. An exhaustive study is that of theodor haering, Hegel: sein Wollen und sein Werk, 2 vol. (1929-38, reissued 1979). Reliable and more readable than this are the two volumes of HERMANN GLOCKNER issued (1929 and 1940) as an appendix to his edition of the collected works. Even these, however, have been outdated by the flood of material collected by the Hegel-Archiv at Bochum in West Germany, and published in a series of volumes of Hegel-Studien (1961 and subsequent years), and by the four volumes of Hegel's letters, edited by JOHANNES HOFFMEISTER (1952-60). An admirable, but now obsolete, biography is by KARL ROSENKRANZ (1824).

Three currents of Marxist interpretation

Specialized commentaries: (Mind): JUDITH N. SHKLAR, Freedom and Independence: A Study of the Political Ideas of Hegel's "Phenomenology of Mind" (1976), is a guidebook and commentary. (Phenomenology of Spirit): JEAN HYPPOLITE, Genèse et structure de la Phénoménologie de l'Esprit de Hegel (1946, reissued 1970). (Logic): G.R.G. MURE, A Study of Hegel's Logic (1950, reissued 1967); STANLEY ROSEN, G.W.F. Hegel: An Introduction to the Science of Wisdom (1974), is a study of the development and meaning of his dialectic; and HANS-GEORG GADAMER, Hegel's Dialectic: Five Hermeneutical Studies (1976), is an analysis for specialists. (Nature): The apparatus in the English translation by M.J. PETRY, 3 vol. (1970), provides a full and learned commentary. (Law, morality, and the state): WILHELM SEEBERGER, Hegel; oder, die Entwicklung des Geistes zur Freiheit (1961), is a good introduction to Hegel's thought as a whole; but HUGH A. REYBURN, The Ethical Theory of Hegel (1921, reissued 1970); and FRANZ ROSENZWEIG, Hegel und der Staat, 2 vol. (1920, reissued 1962), are excellent summaries. and the latter is a commentary as well. SHLOMO AVINERI, Hegel's Theory of the Modern State (1912), is an account of his political thought. See also George A. Kelly, Hegel's Retreat from Eleusis: Studies in Political Thought (1978). (Art): JACK KAMINSKY, Hegel on Art (1962, reissued 1970), is a fair summary of Hegel's lectures. (Religion): THOMAS M. KNOX, A Layman's Ouest (1969), deals, in chapters 5 and 6, not only with Hegel's lectures on the philosophy of religion but also with all his other writings elsewhere on religion; BERNARD M.G. REARDON, Hegel's Philosophy of Religion (1977), is a summary. (History): BURLEIGH T. WILKINS, Hegel's Philosophy of History (1974), is an introduction; and GEORGE D. O'BRIEN, Hegel on Reason and History: A Contemporary Reinterpretation (1975). questions his reputation as an anti-empirical, apriorist thinker.

Hegelianism. Critical works: Works presenting a critical consideration of Hegelianism viewed as a whole are few. See, however: STEPHAN D. CRITES, "Hegelianism," in the Encyclopedia of Philosophy, vol. 3, pp. 451–459 (1967, reissued 1972); MARIO

ROSSI, Da Hegel a Marx, 2 vol. (1970); and RENÉ SERREAU, Hegel et l'hégélianisme, 4th ed. (1971).

Historical works: JOHN E. TOEWS, Hegelianism: The Path TOWARD Dialectical Humanism, 1805–1841 (1980); JOHNNN E. RERMANN, Die Deutsche Philosophie seit Hegels Tode (1963); WILLY MOOG, Hegel und die Hegelsche Schule (1930, reissued 1973); KARL LÖWITH, From Hegel to Nietzsche The Revolution in Nineteenth-Century Thought, 1964, originally published in German. 1941); and two anthologies, on the Left and Right, respectively: KARL LÖWITH (ed.), Die Hegelsche Linke (1962); and HERMANN 108BE (ed.), Die Hegelsche (1962)

In Natious countries: (Germany): BENNICH LEVY, Die Hegel. Renaissance in der deutschen Philosophie (1927), flaby): MASSIN RENAISSANCE IN der MENDENTO (SCOCK, Saggio Sullo Hegel Sib. de (1967), (Slawic countries): Contributions of authors from Russia; Poland, the Balkans, and Czechoslovaka are presented in Hegel bei den Salven, 2nd ed., ed. by DMITRUI TSCHIZEWSKU (1961); see also BORSI JAKOWENKO. Elin Beitrag: suu Geschichte des Hegelanismiss in Russland (1934), (England): HIRK-LAL HALDAR, Neo-Hegelanism (1927). (Critied States): LOYD. D. EASTO, "Hegelanism in Nineteenhise Century Ohio," Journal of the History of Ideas. 23:355-378 (1968). (1978).

Other works: AUGUSTE CORNU, Karf Marx et Friedrich Engels, 2 vol. (1955-58), is rich in materials and citations from the Hallische and Deutsche Jahrhücher See also herbest yet. CUSE, Reason and Revolution: Hegel and the Rise of Social Theory, 2nd ed. (1954); and SIDNEY HOOK, From Hegel to Marx (1936; reissued 1959 and 1952.

(T.M.K./M.R./Ed.)

Major

influences

Heisenberg

erner Karl Heisenberg, physicist, philosopher, and public figure, helped to establish the modern science of quantum mechanics, out of which came the famous indeterminacy principle. He also made important contributions to the theories of the hydrodynamics of turbulence, the atomic nucleus, ferromagnetism, cosmic rays, and elementary particles; and he planned the first post-World War II German nuclear reactor, at Karls-

ruhe, West Germany.

In his philosophical and methodological writings, Heisenberg was much influenced by Niels Bohr and Albert Einstein. From the former he derived the concepts of the social and dialogical character of scientific invention; the principle of correspondence (pragmatic and model-theoretical continuity) between macrophysics and microphysics; the permanence, though not the universality, of classical physics; the "interactive," rather than passive, role of the scientific observer in microphysics; and, consequently, the contextualized character of microphysical theories. From Einstein he derived the concepts of simplicity as a criterion of the central order of nature; scientific realism (i.e., science describing nature itself, not merely how nature can be manipulated); and the theory-ladenness of scientific observations. He was coauthor with Bohr of the philosophy of complementarity. In his later work he conceived of a central order in nature, consisting of a set of universal symmetries expressible in a single mathematical equation for all systems of particulate matter. As a public figure, he actively promoted the peaceful use of nuclear energy after World War II and, in 1957, led other German scientists in opposing a move to equip the West German Army with nuclear weapons. He was, in 1954, one of the organizers of the Conseil Européen pour la Recherche Nucléaire (CERN; later, Organisation Européene pour la Recherche Nucléaire) in Geneva.

Early life. Heisenberg was born on December 5, 1901, in Würzburg, Germany. He studied physics, together with Wolfgang Pauli, his lifelong friend and collaborator, under Arnold Sommerfeld at the University of Munich and completed his doctoral dissertation (1923) on turbulence in fluid streams. Heisenberg followed Pauli to the University of Göttingen and studied there under Max Born; then, in the fall of 1924, he went to the Institute for Theoretical Physics in Copenhagen to study under Bohr.

Heisenberg.

Heisenberg's interest in Bohr's model of the planetary atom and his comprehension of its limitations led him to seek a theoretical basis for a new model. Bohr's conceptafter 1913 the centrepiece of what has come to be called the old quantum theory-had been based on the classical motion of electrons in well-defined orbits around the nucleus, and the quantum restrictions had been imposed arbitrarily to bring the consequences of the model into conformity with experimental results. As a summary of existing knowledge and as a stimulus to further research. the Bohr atom had succeeded admirably, but the results of new research were becoming more and more difficult to reconcile with it.

In June 1925, while recuperating from an attack of hay fever on Helgoland, an island in the North Sea. Heisenberg solved a major physical problem-how to account for the stationary (discrete) energy states of an anharmonic oscillator. His solution, because it was analogous to that of a simple planetary atom, launched the program for the development of the quantum mechanics of atomic systems. (Quantum mechanics is the science that accounts for discrete energy states-as in the light of atomic spectra-and other forms of quantized energy, and for the phenomenon of stability exhibited by atomic systems.) Heisenberg published his results some months later in the Zeitschrift für Physik under the title "Über quantentheoretische Umdeutung kinematischer und mechanischer Beziehungen" ("About the Ouantum-Theoretical Reinterpretation of Kinetic and Mechanical Relationships"). In this article he proposed a reinterpretation of the basic

concepts of mechanics. Heisenberg's treatment of the problem departed from Bohr's as much as Bohr's had from 19th-century tenets. Heisenberg was willing to sacrifice the idea of discrete particles moving in prescribed paths (neither particles nor paths could be observed) in exchange for a theory that would deal directly with experimental facts and lead to the quantum conditions as consequences of the theory rather than ad hoc stipulations. Physical variables were to be represented by arrays of numbers; under the influence of Einstein's paper on relativity (1905), he took the variables to represent not hidden, inaccessible structures but "observable" (i.e., measurable) quantities. Born saw that the arrays obeyed the rules of matrix algebra; he, Pascual Jordan, and Heisenberg were able to express the new theory in terms of this branch of mathematics. and the new quantum theory became matrix mechanics. Each (usually infinite-dimensional) matrix of the theory specified the set of possible values for a physical variable. and the individual terms of a matrix were taken to generate probabilities of occurrences of states and transitions among states. Heisenberg used the new matrix mechanics to interpret the dual spectrum of the helium atom (that is, the superposed spectra of its two forms, in which the spins of the two electrons are either parallel or antiparallel), and with it he predicted that the hydrogen molecule should have analogous dual forms. With others, he also addressed many atomic and molecular spectra, ferromagnetic phenomena, and electromagnetic behaviour. Important alternative forms of the new quantum theory were proposed in 1926 by Erwin Schrödinger (wave mechanics) and P.A.M. Dirac (transformation theory).

In 1927 Heisenberg published the indeterminacy, or uncertainty, principle. The form he derived appeared in a paper that tried to show how matrix mechanics could be interpreted in terms of the intuitively familiar concepts of classical physics. If q is the position coordinate of an electron (in some specified state), and p its momentum. assuming that q, and independently, p have been measured for many electrons (all in the particular state), then, Heisenberg proved,

Indeterprinciple where Δq is the standard deviation of measurements of a, Δp is the standard deviation of measurements of p, and h is Planck's constant (6.626176 \times 10⁻²⁷ erg-second). Indeterminacy principles are characteristic of quantum physics; they state the theoretical limitations imposed upon any pair of noncommuting (i.e., conjugate) variables, such as the matrix representations of position and momentum; in such cases, the measurement of one affects the measurement of the other. The enormous significance of the indeterminacy principle is recognized by all scientists; but how it is to be understood physically-whether it depends on using intuitive classical ("complementary") pictures of a quantum system, or whether it is a principle in (a new kind of quantum) statistics, or whether in some sense through the special properties of the mathematical model it also describes a character of individual quantum systems-has been and still is much disputed. Bohr took the principle to apply to the complementary pictures of a quantum system-as a particle or as a wave pocket in classically intuited space; Heisenberg originally took the principle to apply to the nonintuitive properties of quantum, as distinct from classical, systems.

Bohr and Heisenberg elaborated a philosophy of complementarity to take into account the new physical variables and an appropriate measurement process on which each depends. This new conception of the measurement process in physics emphasized the active role of the scientist, who, in making measurements, interacted with the observed object and thus caused it to be revealed not as it is in itself but as a function of measurement. Many physicists, including Albert Einstein, Erwin Schrödinger, and Louis de Broglie, refused to accept the philosophy of

complementarity.

Lafer life. From 1927 to 1941 Heisenberg was professor at the University of Leipzig. For the following four years, he was director of the Kaiser Wilhelm Institute for Physics in Berlin. Although he did not publicly oppose the Nazi regime, he was hostile to its policies. During World War II he worked with Otto Hahn, one of the discoveres of nuclear fassion, on the development of a nuclear reactor. He failed to develop an effective program for nuclear weapons, probably from want of technical resources and lack of will to do so. After the war he organized and became director of the Max Planck Institute for Physics and Astrophysics at Göttingen, moving with the institute, in 1958, to Munich; he was also, in 1954, the German representative for the organizing of CERN.

In the postwar period Heisenberg began working on a fundamental spinor equation (a nonlinear differential equation capable of representing with spinors—complex vector-like entities—all possible particulate states of mater). His intuitions had led him to postulate that such an equation would exhibit a basic set of universal symmetries in nature (a symmetry is a mathematic form invariant under groups of canonical space—time and other changes in the representing elements), and be capable of explaining the variety of elementary particles generated in highenergy collisions. In this work, the "Platonic" character of which he recognized, he had the support and collaboration of Hans-Peter Dirr and Caff Friedrich von Weizsäcker.

Although he early, and indirectly, came under the influence of Ernst Mach, Heisenberg, in his philosophical writings about quantum mechanics, vigorously opposed the Logical Positivism developed by philosophers of science of the Vienna Circle. According to Heisenberg, what was revealed by active observation was not an absolute datum, but a theory-laden datum; i.e., relativized by theory and contextualized by observational situations. He took classical mechanics and electromagnetics, which articulated the objective motions of bodies in space-time, to be permanently valid, though not applicable to quantum mechanical systems; he took causality to apply in general not to individual quantum mechanical systems but to mathematical representations alone, since particle behaviour could be predicted only on the basis of probability.

Heisenberg married Elisabeth Schumacher in 1937; they had seven children. He loved music in addition to physics and saw a deep affinity between these two interests. He also wrote philosophical works, believing that new insights into the ancient problems of Part and Whole and One and Many would help discovery in microphysics. Widely acknowledged as one of the seminal thinkers of the 20th century, Heisenberg was awarded the Nobel Prize for Physics for 1932 and was honoured with the Max Planck Medal, the Matteucci Medal, and the Barnard College Medal of Columbia University. He died in Munich on February I, 1976.

BIBLIOGRAPHY. Books by Heisenberg include Physical Principles of the Quantum Theory (1930, reprinted 1950; originally published in German, 1930), his most important work, containing themes of early papers amplified into a treatise; Philosophic Problems of Nuclear Science (1952, reprinted 1966; originally published in German, 1942, enlarged ed. 1948), a collection of his early essays; Physics and Philosophy: The Revolution in Modern Science (1958, reprinted 1962), his Gifford lectures; Physics and Beyond (1971, reprinted 1972; originally published in German, 1969), a memoir of his early life; and Across the Frontiers (1974; originally published in German, 1971), collected essays and occasional lectures. Biographical material is found in ARMIN HERMANN, Werner Heisenberg, 1901-1976 (1976): CARL F. VON WEIZSÄCKER. Werner Heisenberg (1977): ELISABETH HEISENBERG, Das politische Leben eines Unpolitischen: Erinnerungen an Werner Heisenberg (1980), and the works cited there. For Heisenberg's role in the German wartime atomic program, see LESLIE R. GROVES, Now It Can Be Told: Story of the Manhattan Project (1962, reprinted 1983). Collections in honour of Heisenberg include FRITZ BOPP (ed.), Werner Heisenberg und die Physik unserer Zeit (1961); HEINRICH PFEIF-FER (ed.). Denken und Umdenken: Zu Werk und Wirkung von Werner Heisenberg (1977); and PETER BREITENLOHNER and H. PETER DÜRR (eds.), Unified Theories of Elementary Particles: Proceedings of the Heisenberg Symposium, July 16-21, 1981 (1982). For the history of quantum mechanics, see THOMAS KUHN et al. (eds.), Sources for History of Quantum Physics (1967), interviews with the principal originators of the quantum theory, the transcripts and tapes of which are deposited in many places; and EDWARD M. MacKINNON, Scientific Explanation and Atomic Physics (1982), a detailed historical account, with an excellent bibliography. For studies of Heisenberg's philosophy of science, see PATRICK A. HEELAN, Quantum Mechanics and Objectivity (1965); MAX JAMMER, The Philosophy of Quantum Mechanics: The Interpretation of Quantum Mechanics in Historical Perspective (1974), and The Conceptual Development of Quantum Mechanics (1966), which provide the most complete study of Heisenberg's contribution to quantum mechanics.

Universal nonlinear spinor equation

Helmholtz

ne of the greatest scientists of the 19th century, Hermann Ludwig Ferdinand von Helmholtz made fundamental contributions to physiology, optics, electrodynamics, mathematics, and meteorology, but he is best known for his statement of the law of the conservation of energy. In addition, he brought to his laboratory research the ability to analyze the philosophical assumptions on which much of 19th-century science was based, and he did so with clarity and precision.

Early life. Helmholtz, the eldest of four children, was born at Potsdam, near Berlin, on August 31, 1821, and because of his delicate health was confined to home for his first seven years. His father was a teacher of philosophy and literature at the Potsdam Gymnasium, and his mother was descended from William Penn, the founder of Pennsylvania. From his mother came the calm and reserve that marked him all his life. From his father came a rich, but mixed, intellectual heritage. His father taught him the classical languages, as well as French, English, and Italian. He also introduced him to the philosophy of Immanuel Kant and Johann Gottlieb Fichte and to the approach to nature that flowed from their philosophical insights. This "Nature philosophy," in the hands of early 19th-century investigators, became a speculative science in which it was felt that scientific conclusions could be deduced from philosophical ideas, rather than from empirical data gathered from observations of the natural world. Much of Helmholtz' later work was devoted to refuting this point of view. His empiricism, however, was always deeply influenced by the aesthetic sensitivity passed on to him by his father, and music and painting played a large part in his science.

Helmholt

After graduating from the gymnasium, Helmholtz in 1838 entered the Friedrich Wilhelm Medical Institute in Berlin, where he received a free medical education on the condition that he serve eight years as an army doctor. At the institute he did research under the greatest German physiologist of the day, Johannes Müller. He attended physics lectures, worked his way through the standard textbooks of higher mathematics, and learned to play the piano with a skill that later helped him in his work on the sensation of tone.

On graduation from medical school in 1843, Helmholtz was assigned to a regiment at Potsdam. Because his army duttes were few, he did experiments in a makeshift laboratory he set up in the barracks. At that time he also married Olga on Velten, daughter of a military surgeon. Before long, Helmholtz' obvious scientific talents led to his release from military duties. In 1848 he was appointed assistant at the Anatomical Museum and lecturer at the Academy of Fine Arts in Berlin, moving the next year to

Königsberg, in East Prussia (now Kaliningrad), to become assistant professor and director of the Physiological Institute. But Königsberg's harsh climate was injurious to his wife's health, and in 1855 he became professor of anatomy and physiology at the University of Bonn, moving in 1858 to Heidelberg. During these years his scientific interests progressed from physiology to physics. His growing scientific stature was further recognized in 1871 by the offer of the professorship of physics at the University of Berlin; in 1882, by his elevation to the nobility, and, in 1888, by his appointment as first director of the Physico-Technical Institute at Berlin, the post that he held for the rest of his life.

The variety of positions he held reflects his interests and competence but does not reflect the way in which his mind worked. He did not start out in medicine, move to physiology, then drift into mathematics and physics. Rather, he was able to coordinate the insights he had acquired from his experience in these disciplines and to apply them to every problem he examined. His greatest work, Handbook of Physiological Optics (1867), was characterized—like all of his scientific works—by a keen philosophical insight, molded by exact physiological investigations, and illustrated with mathematical precision and sound physical principles.

The general theme that runs through most, if not all, of Helmholtz' work may be traced to his rejection of Nature philosophy, and the violence of his rejection of this seductive view of the world may well indicate the early attraction it had for him. Nature philosophy derived from Kant, who in the 1780s had suggested that the concepts of time, space, and causation were not products of sense experience but mental attributes by which it was possible to perceive the world. Therefore, the mind did not merely record order in nature, as the Empiricists insisted; rather, the mind organized the world of perceptions so that, reflecting the divine reason, it could deduce the system of the world from a few basic principles. Helmholtz opposed this view by insisting that all knowledge came through the senses. Furthermore, all science could and should be reduced to the laws of classical mechanics, which, in his view, encompassed matter, force, and, later, energy, as the whole of reality.

whole of reality. Helmholtz' approach to nature was evident in the very first scientific researches he undertook while working for his doctorate in the laboratory of Müller. Like most biologists, Müller was a vitalist who was convinced that it would be impossible ever to reduce living processes to the ordinary mechanical laws of physics and chemistry. The organism as a whole, he insisted, was greater than the sum of its physiological parts. There must be some vital force that coordinated the physiological action of organs to produce the harmonious organic behaviour that characterized the living creature. Such a vital force was not susceptible to experimental investigation, and Müller therefore concluded that a truly experimental physiology was impossible.

In Müller's laboratory Helmholtz met a group of young men, among whom were Emil Heinrich Du Bois-Reymond, the founder of experimental neurophysiology, and Ernst Wilhelm von Brücke, who later became an expert on the operations of the human eye. Du Boisa expert on the operations of the human eye. Du Boisa statement that fully expressed Helmholtz' own position. "Brücke and I." Du Bois-Reymond wrote, "we have sworn to each other to validate the basic truth that in an organism no other forces have any effect than the common physiochemical ones..."

It was with this attitude that Helmholtz began his doctoral thesis in 1842 on the connection between nerve fibres and nerve cells. This soon led him to a broader

Attack on Nature philosophy

Opposition to Müller's vitalism

Early

field of inquiry, namely, the source of animal heat. Recent publications in France had cast doubt upon the earlier confident assertion that all the heat produced in an animal body was the result of the heats of combination of the various chemical elements involved, particularly carbon, hydrogen, and oxygen. In 1842 Justus von Liebig attempted to reestablish the mechanical theory of animal heat in his book Animal Chemistry; or, Organic Chemistry in Its Application to Physiology and Pathology. Liebig tried to do this by experiments, whereas Helmholtz took a much more general path. Having mastered both physics and mathematics, Helmholtz could do what no other physiologist of the time could even attempt-subject the problem to a mathematical and physical analysis. He supposed that, if vital heat were not the sum of all the heats of the substances involved in chemical reactions within the organic body, there must be some other source of heat not subject to physical laws. This, of course, was precisely what the vitalists argued. But such a source, Helmholtz went on, would permit the creation of a perpetual motion machine if the heat could, somehow, be harnessed. Physics, however, had rejected the possibility of a perpetual motion machine as early as 1775, when the Paris Academy of Sciences had declared itself on the question. Hence, Helmholtz concluded, vital heat must be the product of mechanical forces within the organism. From there he went on to generalize his results to state that all heat was related to ordinary forces and, finally, to state that force itself could never be destroyed. His paper "On the Conservation of Force," which appeared in

principle of the conservation of energy.

In 1850 Helmholtz drove another nail into the coffin of vitalism. Müller had used the nerve impulse as an example of a vital function that would never be submitted to experimental measurement. Helmholtz found that this impulse was perfectly measurable and had the remarkably slow speed of some 90 feet (27 metres) per second. (This measurement was obtained by the invention of the myograph and illustrates Helmholtz ability to create new instruments.) The slowness of the review instruments. The slowness that it must involve the rearrangement of ponderable molecules, not the mysterious

1847, marked an epoch in both the history of physiology

and the history of physics. For physiology, it provided a

fundamental statement about organic nature that permit-

ted physiologists henceforth to perform the same kind of

material and energy balances as their colleagues in physics

and chemistry. For the physical sciences, it provided one

of the first, and certainly the clearest, statements of the

passage of a vital force.

Among Helmholtz' most valuable inventions were the ophthalmoscope and the ophthalmoscope and the ophthalmoscope and the ophthalmoscope and the ophthalmoscope in the tit was a rather imperfect piece of workmanship not at all consonant with the vitalistic idea of the divine mind at work. Helmholtz discovered that he could focus the light reflected from the retina to produce a sharp image of the tissue. The ophthalmoscope remains one of the most important instruments of the physician, who can use it to examine retinal blood vessels, from which clues to high blood pressure and to arterial disease may be observed. The ophthalmometer permits the measurement of the accommodation of the eye to changing optical circumstances, allowing, among other things, the proper prescription of evealasses.

prescription of eyeglasses.

Helmholtz 'researches on the eye were incorporated in his Handbook of Physiological Optics, the first volume of which appeared in 1856. In the second volume (1867), Helmholtz further investigated optical appearances and, more importantly, came to grips with a philosophical problem that was to occupy him for some years—Kant's insistence that such basic concepts as time and space were not learned by experience but were provided by the mind to make sense of what the mind perceived. The problem had been greatly complicated by Müller's statement of what he called the law of specific nerve energies. Müller discovered that ensory organs always "report" their own sense no matter how they are stimulated. Thus, for example, a blow to the eye, which has nothing whatsoever to

do with optical phenomena, causes the recipient to "see stars." Obviously, the eye is not reporting accurately on the external world, for the reality is the blow, not the stars. How, then, is it possible to have confidence in what the senses report about the external world? Helmholtz examined this question exhaustively in both his work on optics and in his masterly of the Sensation of Tone 4s a Physiological Basis for the Theory of Music (1863). What he tried to do, without complete success, was to trace sensations through the sensory nerves and anatomical structures (such as the inner ear) to the brain in the hope of laying bare the complete mechanism of sensation. This task, it might be noted, has not been completed, and physiologists are still engaged in solving the mystery of how the mind knows anything about the cutside world

Helmholtz' detailed investigation of vision permitted him to refute Kant's theory of space by showing exactly how the sense of vision created the idea of space. Space, according to Helmholtz, was a learned, not an inherent, concept. Moreover, Helmholtz also attacked Kant's nisstence that space was necessarily three-dimensional because that was how the mind had to conceive it. Using his considerable mathematical talents, he investigated the properties of non-Euclidean space and showed that these could be conceived and worked with as easily as the geometry of

three dimensions.

Helmholtz' mathematical talents were not restricted to such theoretical planes as non-Euclidean geometry. He attacked and solved equations that had long frustrated physicists and mathematicians. In 1858 he published the paper "On the Integrals of Hydrodynamic Equations to Which Vortex Motions Conform." This was not only a mathematical tour de force, but, for a brief time, it also seemed to provide a key to the fundamental structure of matter. One of the consequences that flowed from Helmholtz' mathematical analysis was that vortices of an ideal fluid were amazingly stable; they could collide elastically with one another, intertwine to form complex knotlike structures, and undergo tensions and compressions, all without losing their identities. In 1866 William Thomson (later Lord Kelvin) proposed that these vortices. if composed of the ether that was presumed to be the basis for optical, electrical, and magnetic phenomena, could act exactly like primeval atoms of solid matter. Thus the ether would become the only substance in the cosmos, and all physical phenomena could be accounted for in terms of its static and dynamic properties,

Later life. Helmholtz' work in electricity and magnetism revealed his conviction that classical mechanics was probably the best mode of scientific reasoning. He was one of the first German scientists to appreciate the work in electrodynamics of the British scientists Michael Faraday and James Clerk Maxwell, Faraday had appeared to strike at the foundation of Newtonian physics by his unorthodox rejection of action at a distance, that is, action between two bodies in space without alteration of the medium between them. Maxwell, however, by interpreting the mathematics of Faraday's laws, showed there was no contradiction between Newtonian physics and classical mechanics. Helmholtz further developed the mathematics of electrodynamics. He spent his last years unsuccessfully trying to reduce all of electrodynamics to a minimum set of mathematical principles, an attempt in which he had to rely increasingly on the mechanical properties of the ether

thought to pervade all space. Helmholtz was not in complete accord with Maxwell on the nature of electricity. Unlike Maxwell, Helmholtz was interested in and had studied electrochemistry, particularly the nature of the galvanic cell. Maxwell would have made the electric current solely the result of the polarization of the ether, or of whatever medium the current flowed through. Helmholtz, on the other hand, was fully conversant with Fraday's laws of electrolysis, which related the amount of current that passed through an electrochemical cell to the equivalent weights of the elements deposited at the poles. In 1881, in a lecture delivered in Faraday's honour in London, Helmholtz argued that if scientists accepted the existence of chemical atoms, as most chemists of the time did, then Faraday's laws necessarily implied

The mathematics of electrodynamics

Invention of the ophthalmoscope and ophthalmometer the particulate nature of electricity. This hypothetical particle was soon christened the electron and, ironically, the physics of its existence helped to falsify Helmholtz' theories of electrodynamics.

Though he was unsuccessful in his goal to formulate electrodynamics, Helmholtz was almost able to deduce all electromagnetic effects from the ether's supposed properties. The discovery of radio waves by his pupil Heinrich Hertz in 1888 was viewed as the experimental confirmation of the theories of Faraday, Maxwell, and Helmholtz. The special and general theories of relativity, proposed by Albert Einstein, destroyed Helmholtz' theories by eliminating the ether.

Helmholtz' early work on sound and music had led him to the study of wave motion. His work on the conservation of energy familiarized him with the problems of energy transfer. These two areas coalesced in his later years in his studies of meteorology, but the phenomena were so complex that he could do little more than point the way to future areas of research.

Helmholtz' work was the end product of the development of classical mechanics. He pushed it as far as it could go. When Helmholtz died in Berlin on September 8, 1894, the world of physics was poised on the brink of revolution. The discovery of X-rays, radioactivity, and relativity led to a new kind of physics in which Helmholtz' achievements, although impressive, had little to offer the new generation.

BIBLIOGRAPHY. There are two biographics of Helmholtz available to the reader of English. LEO KOENIGSBERGER, Hermann von Helmholtz, 3 vol. (1902-03; abridged Eng. trans., 1906, reprinted 1965), is often technical and sometimes difficult to understand. JOHN G. M'KENDRICK, Hermann Ludwig Ferdinand von Helmholtz (1899), deals only with Helmholtz' medical career. RICHARD M. and ROSLYN P. WARREN have published a collection of Helmholtz' writings on perception, entitled Helmholtz on Perception: Its Physiology and Development (1968), with critical comments, Helmholtz' Popular Lectures on Scientific Subjects, 2 vol. (1873; 2nd series, 1881), are excellent introductions to his thought.

Heraldry

eraldry is the science and art that deals with the use, display, and regulation of hereditary symbols employed to distinguish individuals, institutions, and corporations. These symbols, which probably originated as identification devices on shields, are called armorial bearings. Strictly defined, heraldry denotes that which pertains to the office and duty of a herald; that part of his work dealing with armorial bearings is properly termed armory. But in general usage, the term heraldry has come to mean the same as armory

Like all other human creations, heraldic art has reflected the changes of fashion. As heraldry advanced from its utilitarian usages, its artistic quality declined. In the 18th century, for example, heraldry described new arms in an absurdly obtuse manner and rendered them in an overly intricate style. It was not until the 20th century that heraldic art recovered and in many ways improved upon the originals. There were still, however, far too many drawings of poor quality emanating from official sources. This article is divided into the following sections:

The scope of heraldry 503 General considerations 503 The chief components of armorial bearings 505 The elements and grammar of heraldic design 507 The field or ground of the shield The "charges" on the field The nature and origins of heraldic terminology The reading of heraldry 509 Manipulation of heraldic design 510 Cadency Arms of women

The scope of heraldry

GENERAL CONSIDERATIONS

From the second quarter of the 12th century in western Europe, heraldic designs are found in general application. Elsewhere, a similar system is to be found only in Japan, in the mon, also dating from the 12th century. Other times and places are often said to have produced heraldic systems; for example, ancient Israel in the symbols of the 12 tribes, or the designs used by the Rajput princes in India. These and similar instances, however, are more properly considered incipient heraldry, since they did not develop into the complex heraldic practice known in western Europe and Japan.

From 1150 to 1500, the use of heraldry in the West was utilitarian: on armour in warfare, and on seals in peace. In the latter part of that period, it was used in peaceful ways and had much artistic value. Also, because from the beginning the use of arms had been associated with the higher feudal castes, heraldry acquired in later medieval times an identification with the concept of gentility that has persisted. To bear arms was the mark of a gentleman; therefore, to possess the desirable quality of gentility, a man needed to have armorial bearings. The great majority of those who seek to use coats of arms in the late 20th century are actuated by this motive. In the use of corporate arms, the motive of prestige rather than social distinction operates. As long as the possession of arms confers any social distinction, arms will be sought and used. At no previous time has there been so widespread an employment of heraldic devices.

The use of symbols has been universal among civilized communities, but these symbols have not assumed the character always associated with heraldry. Seals, too, which have a prominent place in heraldic practice, are of an antiquity approaching that of the most ancient civilizations. They were in use in the states that from Sumer onward flourished in Mesopotamia. Their use, for example, in the Babylonian Empire was the same as in medieval western Europe: to authenticate the documents (possibly of baked brick, later papyrus, later still parchment or vellum) on which they appeared or to which they were appended. All persons, literate and illiterate alike, were able to recognize the representation or symbol of a ruler or other potentate. In 12th-century Europe, heraldry first appeared on seals in the representations of persons. There is a clear line of

ancient devices of heraldry

Seals as heraldic prototypes. (Left) Impression of the great seal of Richard I of England, showing the mounted king bearing arms. In the British Museum, (Right) Cylinder seal impression from the Akkadian Period with a combat scene between a bearded hero and a bull-man, and beasts. In the Oriental Institute, University of Chicago.

descent from the seals of Assyria and Babylonia to the modern company seal, which is often heraldic.

Although originating in the small half continent of western Europe, heraldry has become universal, often, but not only, by way of western European colonization. Heraldry has spread to a considerable degree in both the Americas, Australia, New Zealand, and South Africa. In the former British India, the hereditary princes adopted the use of heraldry. In the numerous independent states formed in Africa from the former British colonies, official armorial bearings are generally used, and the same is true of the new states that were formerly French colonies. In Russia in the 18th century, the use of armorial bearings was adopted from the West, and state emblems are not unknown in Communist eastern Europe. In the 13th century, the Celtic princes of Wales and Ireland and the chiefs of the Scottish Highland clans took up the use of heraldic symbols from the example of the feudal lords and knights of other parts of Europe.

Other kinds of emblematic identification have some similarities with heraldry. An example is the totem system, found among the indigenous peoples of America and Australia, in which an animal, plant, or other object serves as an emblem of family or clan and is often regarded as a reminder of its ancestry. Totemism varies greatly in different countries, as do the theories that have been advanced to explain it. The totem poles used by the Indians of the northwest coast of North America contain a heraldic element in their employment of a hereditary symbol for a family or tribe. They therefore come under the heading of approaches to heraldic designs and may be termed semi-

heraldic in character.

The

Japanese

a type of

armorial

bearing

mon as

The Japanese mon is very definitely a heraldic symbol, having many parallels in its use with the armorial bearings of Europe. It was used on helmets, shields, and breastplates but never, as in Europe, large enough to identify the wearer of the armour at any considerable distance. When identification was desired, the mon was displayed on flags. The mon has usually been equated in English with "crest" and in some European languages has been translated erroneously as "coat of arms." It most closely resembles the heraldic badge (distinctive mark used by retainers), however, which in Europe often antedated armorial bearings, Further resemblances to European heraldry in the use of the mon include: the decorative use of the symbol on clothes, furniture, and houses; the use on the clothes of retainers of great lords; the legal requirement of registration of the mon (dating from the 17th century); and the reservation of the chrysanthemum mon to the emperor, with junior members of the imperial family using a different variety of the flower. This last distinction corresponds exactly to the rules of heraldic precedence that apply to the European royal families. That areas so far removed from each other as western Europe and Japan should have developed a system of hereditary symbolism independently of one another is not surprising, for in both areas feudalism was the prevailing medieval political and social system. As in Europe, Japanese heraldry survived the obsolescence of armour and has remained in widespread use in the 20th century.

Despite some uninformed opinion to the contrary, tartan has no connection with heraldry. It is simply a form of weaving cloth that is by no means restricted to the Scottish Highlands. Armorial bearings were adopted by Highland chiefs in imitation of the Lowland chivalry from the 13th

Drawing by Wm. A. Norman

The 16-petalled chrysanthemum mon of the Japanese

and 14th centuries. The badge of the chief was adopted and used extensively by the members of his clan.

Flags can be heraldic. That of the United Kingdom is certainly so; it is formed by the amalgamation of the flags of England, Scoldand, and Ireland, these showing respectively the crosses of St. George, St. Andrew, and St. Patrick, all of which are displayed heraldically. The United States flag has a quasi-heraldic character and appears to owe its principal ingredients to the armorial bearings of the first president, George Washington. The flag representing the republic of France, by contrast, is not heraldic, being merely an arraneement of the national colours.

In addition to national flags, there are banners, rectangular pieces of cloth showing the armorial bearings of the owner, and standards, strips of cloth that taper gradually to the end and usually bear heraldic devices but not the owner's full coat of arms.

An early development was the extension of heraldic design from its use by persons or families to its employment by institutions and associations of various kinds, a consequence of the concept that an assembly or body of people can be personified as an individual, much as a limited company or corporation is viewed as a legal "person." Medieval times provided numerous examples of arms borne by municipalities, churches, and colleges. The arms assumed by an individual or granted to him are regarded as being peculiarly his possession; therefore caution must be used in speaking of family arms. This question can be best dealt with in connection with the royal arms of the sovereign of the United Kingdom.

These arms are borne in their entirety only by the reigning king or queen. No other member of the royal family is permitted to bear the arms without introducing a "difference" mark that will show without doubt that the bearer is not the reigning sovereign. By analogy, the same condition holds for all so-called family arms, which belong to the head of the family; all other members should strictly bear them differenced—that is, with some mark of cadency (a sign indicating the position of the bearer with respect to the head of the family). In Scottish heraldry this rule is very rigidly enforced, but in England and elsewhere it has been allowed to fall into decay, except in the case of the royal family.

Probably the next development in the scope of heraldry was its use by ecclesiastics. The bishops and the abbots of the monasteries used arms on their seals from the 12th century onward. In this variety of heraldic usage, the arms were not those of individuals but of the body they temporarily represented-as also with arms borne by political units such as nations and cities or by educational establishments, many of which date from the Middle Ages. A great extension of medieval heraldry was connected with what came to be called the livery companies. These were guilds or associations of men in trades whose object was to uphold standards of craftsmanship. Most of them obtained charters from the crown and were granted arms. Among numerous examples in Britain are the Grocers. the Mercers, and the Glaziers companies. Membership in these still-existing companies no longer entails practice of their particular trades, but they possess property and have great charitable interests as well as considerable social esteem. Their armorial bearings are of great antiquity and are much displayed on their halls, letterheads, glass, silver, and so forth. Obviously, armorial bearings were assumed in the Middle Ages by such military bodies as the Knights Templars, the Knights of St. John of Jerusalem, the Teutonic Knights, and the great Spanish orders. Military heraldry has continued to the present: each of the three British armed forces, for example, has badges, or in some cases coats of arms, which are in the care of officers of the English College of Arms. The newest of the British armed forces, the Royal Air Force, alone makes use of more than 1,000 coats of arms or badges.

In the 20th century the development of corporate heraldry has gone far beyond anything known before. Throughout the world, banks, insurance companies, and many other great commercial concerns use arms, as do an ever-increasing number of professional, educational, and trade associations.

Institutional arms from medieval times

The arms of U.S. Pros. John F. Kennedy. The gold helmets are a variant on the three silver helmets of an ancient Kennedy cost. The borde was added as a further difference. The cilver branches and sheat was added as a further difference those of the Great Seal of the United States. The incompanion to the companion of the Great Seal of the United States. The incompanion is belazoned as argent and guiles; this is exceptional to the rule that the principal inclures of the arms (in this case or and sable) be repeated. No motive was included in the grant. The diagonal orientation of the shield is called couché and is optional in all depictions of arms.

Drawing by Wm. A. Norma

Perhaps the event most illuminative of the modern scope of heraldry was the grant, in 1961, by the government of the Republic of Ireland of armorial bearings to the president of the United States of America, John F. Kennedy. Because arms are hereditary and their owners are regarded heraldically as of noble status, the grant amounted to a bestowal of noblity by a state on the head of another state, an occurrence unique in heraldic history.

THE CHIEF COMPONENTS OF ARMORIAL BEARINGS

Heraldry originated when most men were illiterate but could easily recognize a bold, striking, and simple design. The use of heraldry in medieval warfare enabled combatants to distinguish one mail-clad knight from another and thus to know friend from foe. Thus, simplicity was the principal characteristic of medieval heraldry. In the tournament there was a more elaborate form of heraldic design. When heraldry was no longer used in war and heraldic devices had become a part of civilian life, an intricate type of design evolved with an esoteric significance utterly at variance with its original purpose. In modern times, heraldry has often been looked on as mysterious and a matter for experts only. Indeed, over the centuries its language has become intricate and pedantic. Such intricacy appears ridiculous when it is remembered that in the earlier periods swift recognition of a coat of arms or badge could mean the difference between safety and death, and in many medieval instances battles were lost through a mistake over the sameness of two devices of opposing sides.

The shield. The shield is the essential part of the armorial bearings, without it there can be no heraldic device, except for a woman, a distinction that calls for special treatment and is dealt with later. The word shield can be used to describe the coat of arms but in modern times is seldom employed in this way, except in a poetic context. Armorial bearings are generally referred to more briefly as "arms," or as a "coat of arms," a term derived from the surcoat of silk or linen worn over the armour to keep off the rays of the Sun and to prevent rust from forming on the armour. The surcoat was a waistocat-like garment on which were shown the same heraldic insignia as on the shield.

Every other object in heraldic achievement is dependent upon the shield or coat of arms. There can be, and quite often is, a coat of arms consisting solely of a shield without any other object, such as a crest surmounted. The arms of

the Churchills of Muston, a branch of the same family to which Sir Winston Churchill belonged, have no crest. The reason is that such families possessed arms before crests became fashionable.

The crest. A crest is the object placed on top of the helmet and bound onto it by what is called the wreath of the colours, which shows the two main colours of the shield (see illustration of the royal arms of the sovereign of the United Kingdom). Crests were at first made of leather, later of light wood, and, as time went on, of more valuable materials. It is supposed that they were at first borne in tournaments; they became general in families in England from the 16th century when the venal heralds of that time persuaded crestless families to acquire the addition for a payment. Nowadays, a crest is automatically included in any grant of arms made in England, Sortland, or Ireland,

When horsedrawn carriages were in use, it was the rule to show the whole heraldic insignia on the coach or carriage door. With the advent of motorcars and their smaller door space, the arms were usually left off and only the crest and motto shown. This development may be the reason for the mistake frequently encountered in which the whole coat of arms is referred to as a "crest." It should be emphasized that while a coat of arms can exist without a crest, the existence of a crest without a coat of arms can impossibility.

The helmet. On top of the shield is placed the helmet, upon which the crest is tied by the wreath. Originally, everything in heraldry was strictly utilitarian. As armorial bearings were used with the suit of armour, there had to

The crest and the age of the automobile

The chief components of armorial bearings as indicated on the royal arms of the United Kingdom of Great Britain and Northern Ireland. The royal cipher (ER) is not a part of the arms proper but identifies them as representing Queen Elizabeth II. The roman numeral II is unnecessary here, as the arms of Elizabeth I were different, apart from those of England. The shield shows England (gules three leopards or) quartered with Scotland (or a lion rampant within a double tressure flory counterflory gules) and Ireland (azure a harp or stringed argent). This is the quartering in use since the accession of Queen Victoria in 1837. The shield is encircled by the garter of the Order of the Garter bearing the motto of the order, Honi soit qui mal y pense. The dexter supporter, a royally crowned gold lion guardant, and the sinister supporter, a silver unicorn with gold horn, hooves, mane, and tufts and a gold coronet collar and chain, represent England and Scotland, respectively. Atop the full-faced helm of a sovereign with its ermine and gold mantling, or lambrequin, is the royal crown surmounted by the royal crest, a lion statant guardant crowned with the royal crown. The motto Dieu et mon droit ("God and my right"), first used by Richard I, appears on the scroll below. The ground beneath the full achievement, called the compartment, is strewn with the floral and plant badges of England (rose), Scotland (thistle), Ireland (shamrock), and Wales (leek).

The trend toward complexity and esoteric significance the helmet were elaborated to show the rank of the bearer, with some displayed in profile and some in full face, and with different metals and accourrements to indicate status. The shape of the helmet has varied greatly in heraldic representation. While the basic features of heraldry remain unchanged, the modes in which the insignia are shown are subject to change and to fashion. The barrel-shaped helmet was used in the 13th century. The tournament helmet, often shown in drawings, was of a different type altogether, its shape resembling that of a soup tureen.

Mantling. From the helmet hung the mantling or lambrequin. This was of linen or other material and performed the useful function of shielding the wearer from the Sun's rays and also served to catch or deflect sword cuts. The mantling or mantle is painted with the principal colour of the shield, while its lining is of the principal metal. More elaborately styled mantles are used for kings and princes. Crowns and coronets. These are emblems of the rank of the bearer. With the abolition of most of the great European monarchies, the study of crowns has become mainly of historical and antiquarian interest. The most famous royal crown remaining in the 20th century is that of the United Kingdom; it appears in the sovereign's arms upon the royal helmet and the crest of a golden lion crowned. Coronets (small crowns implying dignity inferior to that of the sovereign) are emblems of rank that are shown, when depicted, between shield and helmet. In Britain there are different coronets specified for the ranks of baron, viscount, earl, marquess, and duke. On the European continent, a much wider use of coronets has prevailed. Among the relics of this usage is the crest coronet, a coronet that supports the crest either instead of the wreath or in addition to it and resting upon it. Another is the chapeau or cap of maintenance, a cap with fur lining that was once worn on the helmet before the development of mantling and that is often used instead of the wreath to support the crest.

Mottoes. Many myths have grown up around mottoes. They are often said to have originated as battle cries, but very few actually did. Among those that did are the Crom a boo, of the FitzGeralds, the dukes of Leinster, meaning "Crom [one of the family's old castles] forever"; and the "furth fortune and fill the fetters" of some Scottish families, which defies explanation and must refer to some forgotten incident. In succeeding centuries large numbers of mottoes were adopted. They are not part of a coat of arms and can be varied at the user's pleasure, though they are included in a modern grant of arms. More than one motto may be used by the same family. In Scottish arms the motto is usually shown above the crest, in all other countries beneath the arms and always contained in a scroll.

The supporters. These are the figures on either side of the shield of arms and are borne (in English heraldry) by peers, and by other bearers of orders of the highest class. such as Knights of the Garter, the Thistle, St. Patrick, and by Knights Grand Cross. In former times, supporters were used more widely, and a few English families still claim the right. In Scotland their use is much more frequent.

The compartment. The ground or foundation on which the supporters stand is called the compartment. In Scottish arms it is usually a rock or piece of ground strewn with some heraldic object. In England the compartment ought to be shown in the same way, and in the 20th century often is, with the scroll of the motto beneath it; but in the debased heraldic art of the 18th and 19th centuries, the supporters were generally shown as standing on a piece of ironwork or on the scroll.

The achievement. In heraldic writing, the term achievement often carries the same meaning as "arms," but probably its better usage is to describe the whole representation showing shield, helmet, crest, mantling, and supporters. The achievement belongs to only a minority of those who possess arms, since only a few have supporters. In addition, an achievement may include representation of various knightly orders or companionships of knightly orders to which the owner of the arms is entitled. For example, Viscount Montgomery of Alamein, British field marshal and World War II military leader, could show the symbol of the Order of the Garter around his shield: persons with lesser distinctions such as the Distinguished Service Order, Military Cross, and Order of the British Empire may have the decorations shown pendent from their shields. As distinctions of this kind are not hereditary, on the death of the bearer the successor to the arms must not use representations that show these honours.

The badge. This is older than the heraldic system. Such symbols expressing a person, a body, or an impersonal idea are found from ancient times. The eagle of Rome was one of the state's symbols and was the special device of the legions. Many such symbols bring to mind the country they represent; e.g., winged bulls with human faces at once recall Assyria, On Trajan's Column in Rome, devices sometimes bear resemblances to later heraldic designs. On Etruscan vases are seen what not unfairly could be called demi-boars or bulls' heads caboshed. Nearer to heraldic times, the planta genista, or broom plant, which gave its name to the Plantagenet dynasty of England between 1154 and 1485, was a badge of the counts of Anjou before that family had armorial bearings. With the growth of heraldry, badges naturally assumed a heraldic character. They could be varied at the will of the holder, who often had more than one. Badges persist to the present and sometimes accompany a grant of arms.

Badges as symbols of persons or nations

Drawing by Wm. A. Norman Weish badge English badge French bados

Badges English badge: the red rose of Lancaster charged with the white rose of York, surmounted by the royal crown. Italian badge: the knot of the royal house of Savoy. French badge: the porcupine of Orléans, first used by Louis XII; the crow is not always included. Welsh badge: the leek; the daffodil is also a long-established badge of Wales.

Banners and standards. The users of arms in the Middle Ages often displayed them on the fork-tailed pennons of their lances. When the forked ends were cut off, the resulting flag was square, becoming a banner. Particularly valorous conduct was often indicated in this way, and the knight thus distinguished was known as a knight banneret. This last word was sometimes corrupted into baronet, a term that the English antiquary Sir Robert Cotton (1571-1631) used when he suggested to James I of England that he should revive a supposed order of baronets. The resulting Order (1611) was hereditary, however, and had no true connection with medieval knighthood. The banner bears the owner's arms, and in the 20th century anyone who possesses arms is entitled to a heraldic flag in this form. These can sometimes be seen in Great Britain flying over a house. No banner is referred to in the grant of arms made to President Kennedy, but in due course an armorial banner was made for the occasion when his brother, Sen. Robert Kennedy, carried it to the top of a mountain in the Yukon Territory named Mt. Kennedy by the Canadian government in memory of the President. The banner showed the Kennedy arms without the crest. The maker of the banner added a long white streamer on which he put the badge, the latter being part of the Kennedy crest.

On the standard, the main colours of the arms are shown with the owner's badge.

In England flags are often seen flying above churches.

The myth of battle cries as sources of mottoes

When these show the flag of St. George (England's patron saint), white with a red cross, they carry in the top right-hand corner the arms of the diocese in which the church is situated. Heraldic flags also flew in countries on the Continent in a similar manner. With the disestablishment of heraldic offices in most European countries, contemporary flags are for the most part nonheraldic.

THE ELEMENTS AND GRAMMAR OF HERALDIC DESIGN
Provided that a few elementary principles are grasped,
enough knowledge of heraldry can be acquired in a relatively short time to enable the student to understand the

Rudiments

of heraldry

about 800 terms).

in about

50 terms

tively short time to enable the student to understand the meaning of coats of arms. The multitude of terms used in heraldry need not worry him: once the rudiments are learned with some 50 of the terms, the meaning of the large remainder can be ascertained as the occasion arises. For example, when Queen Elizabeth II was crowned, some beautifully carved figures were made of the different badges that had been used by her ancestors, figures now displayed at Hampton Court Palace. They include one very rare badge—a yale. The yale is a mythical heraldic creature. Anyone unfamiliar with it could easily ascertain its meaning from the various heraldic glossares. It is therefore unnecessary to burden the memory with hundreds of terms (a heraldic glossary generally contains

The language of heraldry has a curious look. "Azure three wheat sheaves or" has been known to call forth the question, "Or what?" When it is remembered that or is the French for gold, the difficulty diminishes. Much heraldic terminology is a quasi-French, archaic language. In the Middle Ages, the French language was used by the ruling class in much of western Europe, so that it was not unnatural that heraldic terms should be French. In England, by about 1400, English words usually were used in

banner fork-tailed pennon

Heraldic flags.

Banner: the blazon of the shield is applied to the whole surface of a square or a vertically or horizontally oriented rectangular flag. This is the royal banner of Sociation, which follows the blazon of the second quarter of the royal arms of the United Kingdom. Although lits the banner of the the second quarter of the sovereign, it is widely but norrectly used today as the national symbol. Fork-tailed pennon: shown here is that of the Sovereign Military Order of Maltz, guise a cross argent. Standard: the cross of St. George at the hoist identifies this as English. The protision of badges, the diagonally placed motto, and the border of alternating inclures are typical. This is the standard of Sir Henry Stafford, c. 1475.

preference. Much modern heraldic terminology, however, is so obscure that it seems purposely designed to puzzle the uninitiated.

The terms dexter and sinister mean merely "right" and "left." A shield is understood to be as if held by a user whom the beholder is facing. Thus the side of the shield facing the beholder's left is the dexter or right hand, and that opposite his right. the sinister or left hand.

The field or ground of the shield. The field or ground of the shield is of one of three kinds: a colour, a metal, or a fur. There are five main colours (known as tinctures): azure (blue), gules (red), sable (black), vert (green). and purpure (purple). In English heraldry there are also murrey (sanguine, a tint between gules and purpure), and tenné (an orange-tawny colour). The metals are or (gold) and argent (silver, which is often shown in coloured illustrations as white). The furs are ermine (white field with black spots), ermines (black field with white spots), erminois (gold field with black spots), pean (black field with gold spots), and vair (composed originally of pieces of fur from a species of squirrel that was blue-gray on the back and white underneath, so that when several of its skins were sewn together, the result was a series of cupshaped figures, alternately blue and white, which is the way vair is shown).

It is considered bad practice to put a colour upon a colour, a metal upon a metal, or a fur upon a fur. Many examples of such bad heraldry are found in old records, but in this as in other instances, the rules now prevalent

grew up only very gradually.

The "charges" on the field. The field is said to be
"charged" with an object. Heraldic objects are of a large
and growing variety, as more and more arms are devised,
more and more objects appear as charges—telescopes, aircraft, rolls of newsprint, and so on. Charges are divisible
into two classes: the ordinantes (or honourable ordinaries
as they are often called, deriving their name from the fact
that they are so frequently used) and the others.

The ordinaries. The ordinaries comprise some 20 figures. Among them are: the chief, being a third of the shield and the top part; the pale, a third part of the shield, drawn perpendicularly; the bend, a third part of the shield, drawn from the dexter chief to sinister base; the bend, sinister, drawn from the dexter base to sinister chief; the fess, a third part and taking up the centre of the shield; and the chevron, resembling an inverted stripe in the rank badge of a noncommissioned officer. It should be noted that the bar is a diminutive of the fess, of the same shape, and can be placed in any part of the shield. The term bar sinister is often used in fiction as a synonym for bastardy. It has no such significance, bastardy being denoted heraldically in several other different ways. Since the European nations were Christian when heraldry was invented, the cross appears in many forms in heraldry. The cross in a coat of arms does not imply, however, that the original bearers were crusaders.

The border, or bordure, is used as a mark of difference sometimes, and in English heraldry since the mid-18th century it is used as a sign of bastardy. The orle is an inner border, not touching the ends of the shield; the field is seen within and around the orle, giving it the appearance of a shield with the middle cut out (voided, in heraldry). The tressure, much used in Scottish heraldry, is a diminutive of the orle. The inescutcheon, a small figure shaped like a shield in the middle of the shield, is used to denote the arms of a heraldic heiress; the quarter occupies one-fourth of the shield; the canton, less than the quarter and one-third of the chief; and checky or chequy, the field or charge divided by transverse lines horizontally or perpendicularly into equal parts. Billets are oblong figures. If their number exceeds 10 and they are irregularly placed, the field is described as billetté; the paile or pall is the upper half of a saltire (St. Andrew's Cross) and half a pale. The pile is in the shape of an inverted pyramid. The flanch, or flanque, is a segment of a circle drawn from a corner of the chief to the base point. The lozenge is a parallelogram having equal sides forming two acute and two obtuse angles, and a mascle is a lozenge voided. The roundel is circular in form. Lozengy is the field divided

The furs, from ermine to

by diagonal lines transversely, and the fret is a mascle interlaced with a saltire.

Minor charges. A field is said to be "powdered" or "semé" when strewn with minor charges; when charged with drops of liquid, it is "gutté." Partition lines divide the shield. The most common ones are straight. "Impalement" or "dimidiation" means the division of the shield into two equal parts by a straight line from the top to

gules a fess argent

Ordinaries, basic bearings that may be of any tincture and that may be combined in great variety. A combination of a cross (England) and two saltires (Scotland and Ireland) has resulted in the familiar Union Jack of the United Kingdom. Ermine and certain other textures such as ermines (black with white ermine tails) are regarded as tinctures in their own right and may bear superimposed charges. Discrete charges such as lozenges, mascles, fleurs-de-lis, etc., may be used singly, in pairs, in threes or greater numbers, sometimes in great profusion, as that of ermine tails.

bottom. This method is used to show either the arms of husband and wife, the arms of the husband being in the dexter half, or certain types of official arms, as the arms of a bishop's see impaled with his family arms, those of the see being in the dexter half. The shield is divided into four quarters when one coat of arms is quartered with another, as when the children of a heraldic heiress (the eldest daughter of a family of no sons) use their mother's arms with their father's. (Thus in the illustration A = father's arms. B = mother's arms.)

Other divisions of a shield are: party per pale or simply per pale, division of the field into two equal parts by a perpendicular line (this resembles the impalement just mentioned but does not serve the same purpose of combining arms); party per fess, division into two equal parts by a horizontal line; party per bend; party per chevron; party per saltire; gyronny of eight. When the partition lines are not straight, they can be of several varieties,

The nature and origins of heraldic terminology, Fanciful explanations have been advanced to account for heraldic charges; for example, argent to denote purity, the bend derived from the military cross belt-the cross a sign of a crusading ancestor-and so on. Since no one wrote about heraldry until it had existed for more than 200 years, these explanations of its symbolism can be discounted. With very few exceptions, the origin of the charges is unknown. The Stourton arms ("sable a bend or between six fountains") refer to the six springs in the park of their ancestral estate that are the source of the river Stour. A heraldic fountain does not resemble a real fountain but is put in the form of "roundel wavy argent and azure" (a silver and blue circlet of wavy lines), unless it is expressly stated that the fountain is "proper"; i.e., a natural fountain. The word proper is always used to denote a charge shown in its natural colours or natural form.

The derivation of heraldic charges is more easily discerned in the augmentations of honour, as they are called, when something has been added to a coat of arms by the (British) crown in recognition of services rendered. The arms of the British naval hero Admiral Horatio Nelson show fresh heraldic charges added to his ancestral arms as his victories were gained. Within the past 300 years, augmentations have generally been recorded. An example is the augmentation granted by Queen Victoria to commemorate the discovery by the English explorer John Hanning Speke of the sources of the Nile. The honour, granted posthumously, consisted of the addition to the existing arms of a chief azure upon which appeared a representation of flowing water proper superinscribed with the word Nile in gold lettering. Usually, however, the origins of the various objects used in heraldry are not known. Numerous historical instances of augmentations of honour occurred in continental Europe, especially in connection with the Holy Roman emperors. Frederick II, for example, granted to Conrad Malaspina an augmentation of a chief of the empire, thereby adding an eagle displayed sable to the Malaspina arms of per fess gules and or overall a thorn branch vert with five flowers argent in pale.

Heraldic descriptions are called blazons. The term is derived from the French blason, the etymology of which is uncertain. Originally, it denoted the shield of arms itself and still retains this meaning, but it is now generally used in a derivative sense as meaning the description of the arms. Blazon is thus a noun, and there is also the verb to blazon; i.e., to describe a coat of arms,

There are four generalizations that are useful in the deciphering of blazons. First early coats of arms are simple because they were original and there were so few of them that elaborate differentiation was not required. As time brought many more coats of arms into being, simple coats became much rarer, and the passing of warlike usage made arms much more complicated. Second, punning or canting arms are very common as, for example, trumpets for Trumpington, or a spear for Shakespeare. It is notable, however, that many armorial allusions that were formerly obvious now require research for elucidation. Other allusions have been lost entirely. Third, in grants of arms to people bearing the same name but having no relationship with each other, difference marks have had to be put in.

Augmentations of honour

Partition of the shield. The field is often divided along the lines occupied by ordinaries, just as quartering imitates a cross. "Per fess" means along the line over which a fess would be laid down The ermine tails illustrated are one type of stylization among many in use. The superior dexter segment on the gyronny shield is called a gyron and is occasionally found singly. Drawing by Wm. A N

Again, in consequence, blazons have become much more complicated. Finally, in the course of centuries and frequent intermarriages among arms bearers, many quarterly and grandquarterly coats have come about. Quarterly and grandquarterly coats are much more difficult to describe than the simple coats.
