Geomorphic Processes

comorphic processes are all those physical and chemical processes that affect the surface features of the Earth. They include tectonic activity and surficial earth movements such as rockfalls and landslides. Geomorphic processes also involve weathering and the erosion and deposition of the resultant rock debris by streams, glaciers, and wind.

This article treats the mechanics and dynamics of these various natural geomorphic agents and processes. In ad-

dition, it discusses the ways in which humans promote their performance in altering landforms and near-surface features. The direct effects of human action on the physical environment are covered as well. For further information about the origins and evolution of landforms, see the articles CONTINENTAL LANDFORMS; PLATE TECTONICS, EARTHQUAKES, RIVERS; OCEANS; and ICE AND ICE FORMATIONS; Glaceles, (E.6.1)

Physiographic effects of tectonism

It has long been known that tectonism has profoundly influenced the physiography of the Earth. The Russian scientist M.V. Lomonosov stated in 1763 that the Earth's relief is formed by shaking of the Earth (earthquakes) or long-term sinking and raising of its surface. The German geographer Alexander von Humboldt suggested that mountain ridges were formed by upwelling of molten lava (volcanism) from the Earth's interior. This idea was derived from observation of volcanic activity in Central America. The French scientist Elie de Beaumont, however, thought that the Earth's relief features were principally attributable to gradual compression or shrinking of the Earth's crust because of slow cooling since its formation. In this view, tangential pressures in the crust caused folding and general tectonic movements.

The Austrian geologist Eduard Suess noted that rock deformation was particularly intensive in mountainous areas, and he came to the conclusion that a close link existed between mountain ranges and crustal uplift and between oceanic and other basins and tectonic sinking or depression. In general, scientists today discriminate between tectonic movements that are geographically restricted and involved in mountain building (orogenic movements) and those movements that are broader, less localized, and associated with the uplift or depression of plateaus and basins (epeirogenic movements). Both types of tectonism are responsible for the Earth's present relief features or physiography. Modern investigations have led to the theory that all tectonism is produced by the movement of great blocks of the Earth's crust relative to each other (see PLATE TECTONICS).

RECENT TECTONIC MOVEMENTS

Seismic movements. Direct observations and theoretical generalizations suggest a close connection between earthquakes, which periodically occur in different parts of the globe, and recent tectonic movements. Such movements are considered to be mechanical dislocations or faults within the crust. When faulting occurs, earthquakes are generated. The detection, recording, and analysis of the resulting seismic waves provides information on the intensity of an earthquake and its location—both where it occurred on the surface of the Earth and at what depth.

Tectonic movements of a seismic character are often called rapid because the physical consequences occur swiff-ly. The reasons for these tectonic movements cannot be directly observed because they occur at depths of hundreds of kilometres, but strong earthquakes generally manifest themselves in repeated disturbances of the Earth's crust through time and thus produce discernible physiographic effects at the surface.

Rapid tectonic movements frequently occur in the Soviet Union, where intensive earthquakes of destructive character take place several times every year; less intensive earthquakes are even more common. The earthquake epicentres are geographically localized and this provides the opportunity to carry out regional seismic investigations and to forecast the locations and the intensity of possible earthquakes. The greatest frequency of intensive, rapid tectonic movements has been established as characteristic of mountain regions—from North Africa, the Alps, Balkans, and Caucasus to the Tien Shan, Pamirs, and the Himalayas and around the margins of the Pacific Ocean (Alaska, the Aleutians, Coast Ranges, Andes, mountains of New Zealand and Indonesia, and the Japanese islands.

Mountain regions of intensive seismic activity the Kurils, and Kamchatka). There are reasons to suppose that the main sources of rapid tectonic movements are the zones of deep faults that extend from the crust into the upper mantle (zone beneath the crust) of the Earth.

Slow tectonic movements. Slow tectonic movements of the Earth's surface were detected first in Scandinavia (the Baltic, or Fennoscandian, Shield, an area of ancient crystalline rocks) and subsequently in the Canadian Shield. In both regions dome-shaped, elevated, ancient shorelines and deposits of former lakes and seas were discovered. These phenomena have been explained in terms of a rather broad upward arching during the last 10,000 to 12,000 years because of constant melting of thick glacial ice cover and consequent rising caused by lightening of weight. The maximum unlift of Fennoscandia for this period was about 250-275 metres (820-900 feet) in the northern part of the Gulf of Bothnia, according to some authorities; uplift in the Hudson Bay region of Canada has attained nearly 300 metres (1,000 feet). Simple calculation shows that the average rate of such tectonic movements reaches two to three centimetres (0.8 to 1.2 inches) per year in the tops of arches, gradually decreasing toward their peripheral regions.

Slow tectonic uplift and subsidence with such characteristics are common almost everywhere. These slow tectonic movements were detected by precise geodetic measurements, and their average velocities ranged from tenths of millimetres to several millimetres per year for plains areas and 10 millimetres (0.4 inch) or more per year in mountain regions. Unfortunately, data are available for no more than 100 years. For this reason, it is not yet possible to define the general trends (or periodicity) of such movements, as is possible in regions of postglacial isostatic uplifts, where there are records or available data. Nevertheless, the main conclusion about recent tectonic mobility, supported by seismic phenomena, may at present be considered proved by numerous geodetic, oceanographic, and geomorphological investigations.

Recent horizontal movements of separate parts of the Earth's surface also have been detected with the help of precise geodetic measurements and geomorphic observations. The features of horizontal displacement along the Talass-Fergana Fault in Central Asia or more complex movements of separate points along the San Andreas Fault in California are examples. In both regions single horizontal displacements of several metres have been observed immediately after strong earthquakes.

Recent tectonic mobility must be considered proved, although not all aspects are yet understood. The evidence consists of orogenic zones that coincide with seismic phenomena, shield areas in which isostatic movements occur. and regional lines of horizontal dislocations. It is not yet possible, however, to make a precise evaluation of tectonic mobility through time and, in particular, to define the periodicity, if any, that is manifested. Further measurements and observations are needed for a full understanding of these phenomena.

EFFECTS ON THE EARTH'S SURFACE

Uplift and denudation. Modern concepts of the origins of the Earth's surface features are based on acceptance of the existence of a dynamic equilibrium between vertical tectonic movements (uplift and subsidence) and denudational processes, which encompass the erosion of rocks and accumulation of the resulting sedimentary debris.

The German geographer Albrecht Penck considered data continental on the volume of transported river sediments and concluded in 1894 that a layer 0.8 millimetre (0.03 inch) thick is annually transported to the sea by rivers. More recent calculations have shown that the solid sediment transported by rivers is alone sufficient to account for reduction of the Earth's surface by 0.09 millimetre (0.004 inch) per year. Other values, given by various scientists, range from 0.01 to 0.02 millimetre (0.0004 to 0.0008 inch) in lowlands to 0.6 to 0.8 millimetre (0.02 to 0.03 inch) per year in mountains. Values as great as 0.16 millimetre per year have been given for the United States.

It should be noted that the sediments transported by rivers make up only part of the general volume of all sed-

iments that are subject to continental denudation. Some sediment is not carried to the sea at all but is retained within the area being eroded-on terraces, hillslopes, in local closed depressions, and elsewhere (see below). This material, which is not transported to the sea, is not included in the calculations on which the foregoing data are based. Hence, values of continental denudation are greater than stated

The general correlation between recent tectonic movements and continental denudation may be considered an indication of dynamic stability of the Earth's surface. The stability is characterized by the following process: slow tectonic uplift of certain areas stimulates erosion and denudation, whereas other parts of the Earth's surface undergo tectonic subsidence, and the eroded material tends to accumulate in place, although part of it is transported to the sea in one form or another.

Data on the rate of development of a normal soil profile (sequence of vertical layers) under a natural vegetation cover are instructive in this regard. The use of radiometric measurements for defining the absolute age of humus in the recent soils has shown that a time period ranging from several hundred to 1,000 to 3,000 years (depending on the genetic type of a soil) is required for the formation of a normally developed soil. This means that the natural "growth" of soil thickness ranges from one to 10 millimetres per year. It shows that under the conditions of natural denudation, a well-regulated dynamic system exists. The three basic processes of the system-tectonic movements, soil formation, and continental denudationtend essentially toward a state of balance. The middle component of the system, the soil-vegetation cover, serves as its main regulator.

Equilibrium is lost when the natural soil-vegetation cover is disturbed, whether by human activities or natural causes. Rather widespread phenomena of natural denudation are evident in mudflows, which form in mountains during Mudflows rainstorms when there is an exceedingly high surface runoff. They are characteristic of many high mountain zones, where thick accumulations of loose sediments are present, and in arid regions, where the vegetation cover is sparse. Catastrophic displacements of ground masses on slopes (avalanches, landslides, and mudflows) are quite common in these areas. They are usually caused by earthquakes; and many interruptions of the soil-vegetation cover on mountain slopes are characteristic elements of the natural landscapes and must be considered a reflection of disturbed equilibrium.

Relief features. The state of equilibrium between tectonic movements and the processes of denudation should provide for a stable, level character of the Earth's surface; it is clear, however, that such is not the case. Aside from extraordinary disturbance of the equilibrium by catastrophic movements of sediment, more gradual tectonic movements and denudation are not balanced in the strict sense and may be progressively altered and directed over time. Consideration of this balance-or lack of balancehas led to the distinction among three main categories of elements in the structure of the Earth's surface. The largest category consists of first-order relief features, which are elements of the so-called geotecture. They include crystalline massifs, continental platforms, oceanic hollows, and large mountain systems.

Positive and negative elements of lesser magnitude make up the second-order relief features that complicate the surface of continents and ocean floors; these elements are called the morphostructure. This group includes plateaus, uplands, lowlands, ridges, and similar features. Morphostructures may be described chiefly as large forms of relief that emerge as a result of the interaction of tectonic and denudational forces. Tectonic movements play the leading role in this interaction.

Small elements of relief of the third order include such features as river valleys, lake basins, and dune or karst (cavern) forms. They are sometimes called elements of morphosculpture. The origin of these morphosculptural elements is largely dependent upon denudational processes.

It has been suggested that all tectonic movements that are expressed in present-day relief should be called neoas an example of natural denudation

Rates of denudation tectonics. In a paper delivered by a Soviet scientist in the 1940s this connotation emerged from considerations of the general amplitude and character of the most recent tectonic movements. A review map of these movements in what was then the Soviet Union served as a model for international compilations of this type. The main basis for the work was study of the thickness of Pliocene-Quaternary deposits (younger than 7,000,000 years) that accumulated in tectonic subsidence areas (depressions and basins) and of the amplitude of uplift of ancient surfaces in mountain ridges. In these instances, the obtained values of uplift and deposition amounted to hundreds of metres of relief over distances of several kilometres.

Weathering

Weathering

landforms

and

In general terms, weathering may be defined as the disintegration or alteration in situ of rocks at and near the Earth's surface, within the range of temperatures that occur there. The distinction drawn between disintegration and alteration highlights the difference between physical and chemical processes. Disintegration involves a breakdown of the rock into its constituent minerals or particles. with no decay of any of the rock-forming minerals. Chemical weathering, on the other hand, implies the alteration of one or more of these minerals. The phrase in situ is not meant to suggest that there is no translocation of material within the rock being weathered. Redistribution and reorganization of various minerals are clearly at work in many vertical soil profiles, and these processes lead to the development of distinct horizons or zones and the lateral movement of minerals. The rock mass as a whole remains in place, however. Finally, the location of weathering processes at or near the ground surface, plus the range of temperatures indicated, differentiates these processes from metamorphism, which takes place either deep in the crust or at higher temperatures than are characteristic of weathering reactions.

Weathering is an essential precursor to erosion and transportation. Weathering reduces rocks to particles and to a condition suitable for transportation. Hence, it is a key phase in the eventual production of new strata, as well as in the formation of the alluvial lowlands. Weathering also plays an important part in shaping scenery. It is not too much to say that weathering, by exploiting various weaknesses in the Earth's crust and thus preparing the way for erosional agencies such as rivers, glaciers, and winddriven waves, plays a major role in determining the form of the land surface over much of the continental area of the globe. Upland and plain, ridge and valley, hill and lowland are in large part a reflection of structural contrasts brought about by weathering. In addition, pedogenic accumulations of minerals can reduce infiltration of water, cause heavy and rapid runoff, and thus induce floods. Iron pans in the soils of Exmoor, in southwestern England, were an important factor in the flooding that partially destroyed Lynmouth in 1952. On a large scale, silcrete and laterite, for instance, form the caprock in many plateaus and mesas in arid Australia. Even travertine deposited in riverbeds may protect the landscape to such an extent that the riverbed becomes more resistant than the surrounding areas and eventually comes to stand above the rest of the land surface. An example of such inversion of relief, with a winding, travertine-capped old river course now forming a distinct ridge, has been described from Arabia. Finally, numerous minor forms, including elegant flares, caverns, pits and etchings, are a result of weathering.

PROCESSES INVOLVED IN WEATHERING

Physical processes. Weathering processes are complex, and several processes generally act together to achieve rock · disintegration and decay. The processes may for convenience be labeled physical (or mechanical), chemical, or biological, but such treatment tends to disguise the essential complexity and interconnection of weathering activities. Very few weathering processes can be observed in action; scientists must be content to see the results and try to infer from them what has taken place. Many variables affect weathering reactions, and laboratory experiments fail to

reproduce either the complexity or the immense duration of geologic time, which together provide the only correct context in which to view these processes. As a result, accounts of weathering have been dominated by speculation and theorization, much of which, though it seems logical enough, fails to accord with the evidence of nature.

Thermal expansion and contraction, for example, have Thermal long been cited as a cause of rock disintegration, particularly in the tropical deserts where great extremes of temperature are experienced. Man-made fires were used as an aid in quarrying in ancient Egypt and in India; bush or forest fires certainly cause superficial rock flaking: and some stones subjected to the intense, though local, heat of campfires are rapidly split. Reports of loud cracking noises in tropical regions have been attributed to the expansion or contraction of rocks on heating or cooling. As a consequence, numerous types of weathering, including granular disintegration, spheroidal weathering, onion (or onionskin) weathering, and sheet structure, have been explained in terms of thermal expansion and cooling as described below

Two related processes were involved. First, it was argued that, because many rocks consist of minerals that expand by differing amounts when subjected to the same temperature change, they would, on heating, expand at varied rates. As a result, daily heating and cooling would eventually loosen the cohesion between the rock-forming minerals and would thus cause the breakdown of the rock into small particles. The process described is termed granular disintegration. Second, because rocks are poor conductors of heat, those parts of a rock mass exposed at the surface would expand and contract as they are heated and cooled, while those parts below the surface should remain at a constant temperature and volume. It was supposed that stresses would be set up between the outer and inner zones, the former eventually becoming separated due to the development of fractures, and repetition of the process would cause the development of concentric layers or sheets of rock. This process resulted in spheroidal weathering, onion weathering, or sheet structure, depending on the thickness of the detached rock masses.

It now appears, however, that most field evidence points to contrary conclusions. Granular disintegration, spheroidal and onion weathering, and sheet structure have all been found deep beneath the Earth's surface, well beyond the range of the sun's heat; and even in the tropical deserts, which should be most suitable for solar heating effects, the evidence is contrary to that required by the insolation hypothesis. Observations in the Egyptian deserts indicate that rock surfaces known to have been exposed to the sun's rays for 42 centuries display no detectable sign of disintegration, whereas the same rock types buried nearby beneath the desert sand, where there is just a little moisture, show clear signs of decay. Furthermore, laboratory experiments suggest that heating and cooling alone either achieve little or work slowly, whereas heating and cooling in the presence of moisture produce almost immediate effects. Apart from the local effects of the ephemeral high temperatures achieved in bush fires, little weathering is today attributed to thermal expansion and contraction. The forms once related to this process now are generally

attributed to contact with moisture. Similar doubts relate to the interpretation of sheet structure, the massive (up to nine metres) slabs of rock that commonly are developed in crystalline rocks such as granite but that also occur in sedimentary strata. Though once considered an insolational (derived from the sun's heat) effect, they have for many years been accepted as a manifestation of offloading or pressure release. In fact, they often are called offloading joints. The pressure-release hypothesis is based on the following argument. Granites crystallize deep within the Earth's crust under conditions of high hydrostatic pressure, so that the very fact that granite is now exposed at the Earth's surface in itself proves that erosion of a considerable thickness of overlying material has occurred and that there has been a drop in vertical loading. During the erosional unloading, the granite tends to expand in response to the decreasing pressure. Such expansion is radial and upward, in the direction of least

contraction

Pressure. hypothesis

of the sheeting joints. All joints are in a sense due to pressure release. All are near-surface features and presumably all disappear at depth. Moreover, many surfaces recently exposed from beneath ice masses display numerous joints that parallel the glacially eroded surfaces, and it is difficult to look beyond pressure release in explanation of these forms, which are, however, essentially superficial, But deep-seated fractures are another matter; sheet structure extends to at least 90 metres. Considerable evidence suggests that the offloading hypothesis is not everywhere applicable and that it should not be used unquestioningly. The very residuals, frequently inselbergs (island mountains), in which sheet structure is commonly displayed, are preserved because they are under compression, not under tension as demanded by the expansive pressure-release hypothesis. In some areas the dip of the sheet structures is opposed to the slope of the land, rather than parallel to it; sheet structure affects sedimentary and volcanic sequences that have never been deeply buried, and in some areas the ages of land surfaces and the sheet structure are the reverse of that implied by offloading. Faulting and lateral compression in the crust, residual from past or continuing earth movements, appear to offer an alternative explanation of sheet structure and to account more satisfactorily for the field evidence.

Thermal expansion and contraction, and the pressurerelease hypothesis, have been considered at some length because they demonstrate how a too-ready acceptance of seemingly reasonable ideas can lead to incorrect or incomplete interpretations. Most accounts of weathering processes are similarly oversimplified, if not fallacious, Although some are more soundly based than others, none is completely understood, and it is better to work from evidence of what has taken place rather than from what presumably should happen in given circumstances

In many subarctic regions, outcrops of finely bedded thaw cycles rocks carry a veneer of platy debris. In these areas, where the vegetation blanket is thin and discontinuous, the common oscillations of temperature around the freezing point affect the superficial layers of rock. Water lodged in numerous cracks is frozen and expands, exerting a pressure sufficient to widen the fissures in which it rests. On thawing, the water rests lower in the now wider crack, until it again expands on further freezing. Such repeated expansion and contraction of contained water causes many rocks, especially those that are naturally well bedded, to break down into slabs and plates. Many close observations of strata, in regions where the temperature fluctuates about the freezing point, indicate the effectiveness of the

freeze-thaw mechanism. Crystallization of such salts as sodium chloride and gypsum is also cited as a cause of rock disintegration. particularly in arid regions. There seems little doubt that the pressures exerted by crystal growth can rupture weakly cohesive rocks. Roofing tiles on the eastern (windward) side of Port Phillip Bay (Victoria, Australia) commonly are disintegrated by the crystallization of salts blown in by spray, and clays also can be broken up and disturbed. But whether salt crystallization can shatter such strongly cohesive rocks as fresh granite is problematical. Certainly salts are a common product of granite weathering and in arid climates efflorescences of sodium chloride can be seen on sheltered rock surfaces far distant from the coast. It seems likely that such expansion may at least contribute to the total weathering process. Some writers, however, considering the problem of weathered crystalline rocks in Antarctica, where, at present, there is never any moisture because of the consistent extreme cold, suggest that salt crystallization is responsible for the shattering of the rocks. It is, however, pertinent to ask what the source from which the salts crystallize is, if no moisture is available, and to

point out that other common difficulties facing weathering studies seem to be involved: did the weathering observed occur in relation to the present climate or in a slightly different set of climatic circumstances? Is the weathering observed in Antarctica taking place now, or is it, as it were, inherited from a former, warmer and moister climate (in which case, freeze-thaw action could be invoked)

There is no doubt that tree roots can force aside considerable blocks of rock and widen pre-existing joints during growth. Even the tiny roots, or hyphae, of lichens can penetrate along crystal boundaries and cleavages and can accomplish some physical disintegration. Burrowing animals such as rabbits and termites open up avenues for other agencies, particularly moisture. The burrows of earthworms long have been recognized as a significant element in the soils; worms penetrate about 120 centimetres (four feet) below the surface and they pass about four tons of soil per hectare, on average,

Chemical processes. The understanding of physical weathering processes is beset with difficulties, but the chemical reactions at work in the regolith are even more complex. Although it is possible to set down plausible reaction formulas, the fact is that most of these are so oversimplified as to be misleading. For purposes of exposition, however, it is convenient to isolate certain processes and their results

No mineral is chemically inert, and many are to an appreciable extent soluble in water, Some, like rock salt, gypsum, and limestone, react strongly with water and either go into solution or form products that are soluble. Even quartz is to some extent soluble in water. Some minerals are more soluble in salt water than in fresh water; orthoclase, one of the feldspars and a common constituent of crystalline rocks, is 14 times more soluble. It is likely that solution is in many instances the first stage of chemical weathering. Solution also produces many distinct forms such as pits and fretting patterns, and its widespread significance is indicated by the vast quantities of material

carried in solution by rivers. Materials in solution are translocated vertically within the weathering profile (vertical section that exhibits weathering alterations) or may be carried great lateral distances and be precipitated far from their place of origin. Because of the translocation of minerals in solution (as well as of fine particles in solid state) within profiles, distinct horizons or pans rich in iron oxides, lime, silica, or gypsum may be developed. In reality, lateral accession is indistinguishable from vertical relocation, but whatever the precise source of material, salts are taken in solution from one part of the weathering profile and concentrated in another. Nodular or sporadic accumulations develop first, but these coalesce to form continuous, frequently massive, sheets. Because they tend to form tough, impermeable layers, they are called duricrusts. Bauxite is an example of such an accu-

mulation; it essentially is an alumina-rich crust. The cause of the localized precipitation of such minerals is not clear. In some instances, reaction with groundwater with contrasted chemical properties may be involved. In the case of calcrete, a lime-rich crust, it has been suggested that evaporation of groundwater may give rise to precipitation of lime at the upper fringe of the water table and near the land surface. On the other hand, plants markedly accumulate some minerals, and it has been suggested that silcrete, a silica-rich crust, for example, is fixed by plants and then added to the regolith when the plants die and decay. Whatever the mechanism involved in their formation, great sheets of laterite, calcrete, and silcrete have

accumulated in various parts of the world. Water and contained radicals and gases combine with various minerals to form new minerals, sometimes of volumes significantly different from those of the original. These processes are known as hydration (the addition of water) and hydrolysis (the addition of hydroxyl [OH-ions]). Thus, iron readily combines with water and oxygen to form various hydrated iron oxides that are responsible for the yellow and red coloration of many weathered profiles. Orthoclase, a common constituent of acid crystalline rocks, as well as of some sediments, reacts with water and carbon dioxide to produce a clay, typically kaolin, and a

The role of plant growth and organisms

Solution

Crystalgrowth pressures

Freeze-

and effects

Hydration and hydrolysis soluble salt and silica. All common rock-forming minerals except quartz are converted to clay minerals by chemical weathering, principally by hydration and hydrolysis. Thus mica is hydrated to hydrobiotite and vermiculite, and eventually to chlorite, but kaolinite and gibbsite are other common products of hydration. Hydration is important on its own account, but it also prepares mineral surfaces for oxidation and carbonation and generally enables ionic transfer to occur more readily.

Oxidation, or the formation of oxides, occurs in the aerated zone of soils, probably by interaction of the oxygen dissolved in water. Oxides are a common constituent of the regolith, and much takes place through the agency of bacteria that derive energy from the oxidation of iron and other elements. In waterlogged anaerobic sites bacteria can bring about chemical reduction (loss of oxygen). Thus, sulfates are reduced to sulfides, and organic material is reduced by fermenting bacteria.

Carbonation, or the reaction of carbonate or bicarbonate ions with minerals, is an important intermediate step in the weathering of such minerals as feldspars, and carbonic acid, though weak, is a potent solvent in nature.

Silicification and desilicification can cause the conversion of one type of clay to another. Thus, in tropical lands desilicification of micas gives rise to kaolin and iron oxide. or, if taken further, to bauxite (gibbsite) deposits.

As is the case with physical processes, considerable chemical weathering is attained with the aid of organic agencies. Humic acids, produced by the decay of organic matter. promote weathering generally. The hyphae of lichens can apparently extract certain radicals from minerals. Green algae in tidal pools raise the pH (acidity-alkalinity index) of the seawater during the day, and the emission of carbon dioxide (CO2) by algae and invertebrates at night brings about the solution of carbonate. Humus in general helps conserve moisture in soils and hence aids weathering in a number of ways.

Although numerous individual processes have been proposed, the details of many are obscure; most are complex. and many open the way for the activities of others. Hence the complex of processes embraced by the term weathering is more effective than the total of its individual components. Water, acting both directly and indirectly as a solute and as a vehicle for various radicals, is undoubtedly the most important single factor in weathering, though biological agencies have increasingly been recognized as of great significance. But however achieved in detail, weathering produces a relatively thick mantle of debris.

CONTROLS AND RATES OF WEATHERING

Several factors control the type and rate of rock weathering. Mineralogical composition. Of the common rockforming minerals, the order of susceptibility to chemical attack is the same as the order of crystallization from magma (silicate melt that yields igneous rocks on cooling): olivine is most vulnerable, followed by plagioclase, biotite, potash feldspar, muscovite, and quartz. Thus a rock like quartzite, composed overwhelmingly of quartz particles and cement, will weather only slowly, while a basalt, on the other hand, rich in ferromagnesian minerals and plagioclase, will suffer rapid alteration.

Texture. In fine-grained rocks the total surface area of the constituent minerals is very great. These surfaces are quite prone to chemical attack, but such minerals tend to be closely interlocked and do not offer avenues for physical attack. Thus the coarse-grained rocks are most susceptible to such processes.

Fracture pattern. Fractures such as joints and faults are, if open, avenues of weathering readily exploitable by various environmental agencies, but particularly by water. Thus greatly shattered and fractured rock masses are much more rapidly weathered than are essentially monolithic masses.

Climate. From what has been said so far it is clear that many weathering processes achieve their optimal activity in specific climatic zones. Thus, freeze-thaw occurs and is effective in subarctic regions, but not in arctic areas where temperatures are too consistently low. Insolational heating and cooling effects are greatest in arid tropics.

And chemical weathering is most important in the humid tropics, where moisture and humic acids are abundant and where temperatures are consistently high. Here the rate of chemical reactions is three times greater than in temperate regions, although a decrease in the viscosity of capillary water and its more rapid circulation in the regolith compensates for this to some extent.

Erosion and topography. Erosion may, by the removal of weathered debris, expose new rocks to weathering (renewal of weathering). On the other hand, stable conditions may encourage the development of deep weathering and thick regoliths. Steep slopes and high peaks are well drained, but valley floors, and particularly enclosed depressions, receive water and solubles. Hence, in poorly drained areas, waterlogging and reduction may be characteristic, or there may be marked precipitation of dissolved salts, depending on the prevailing climate.

Time. Prolonged weathering of rocks produces minerals different from those that result from brief reactions and removal of the debris. Reaction series resulting from continued hydration, silicification, or desilicification, for instance, are known and some of them have already been

Man. Ouite apart from man-induced erosion, quarrying, and excavations of various types, man has stimulated weathering by his pollution of the air. The industrial release of sulfur has produced sulfuric acids in the air, which has affected not only man-made buildings but also natural rock exposures (see also below Physiographic effects of man).

Turning to rates of weathering, various isolated estimates Rates of have been made. Limestone tombstones in northwestern England are said to require 250 to 500 years to weather to a depth of 2.5 centimetres (one inch). After 45 years the ash falls associated with the 1883 eruption of Krakatoa displayed strong leaching of alkalis and some of silica. At Soufrière in the West Indies, soil development and reforestation on volcanic ash were "normal" after only 30 years. On the banks of the Murray River, Australia, weathering of a sandy limestone has varied between one and 30 centimetres (12 inches) per century.

Such estimates, though of interest, are all meaningless in a geological sense. So many factors are involved that great variations in the rate of weathering occur in the same area; aspect, rock type, exposure to erosion, and other factors have their effect. Even deep-weathering profiles, the initiation of which can be dated (as, for example, on lava flows of known age), are of little help. Is the weathering going on now, or did the whole profile develop in the past? Was the weathering achieved during a short time span when climatic conditions were especially suitable, or has it been going on steadily over a long period? It is not possible, at present, to be confident on these points, so general and imperfect is knowledge of Earth history and weathering (C.R.T./Ed.) processes.

Slope movements

Very few landscapes are totally flat. Nearly all plains contain isolated hills rising from the main land surface, and most plateaus have valley-side slopes. The form of hillslopes, using the term for the sloping surface of both hills and valleys, consitutes a distinctive landscape feature. Of major importance in shaping hill-slopes are earth movements that occur under the influence of gravity when the stability of a slope is disturbed either by natural forces or by human interference. Earth movements of the most varied nature depend on the interaction of a number of factors, including the angle of slope, nature of materials, and time

The great diversity of slope movements can be classified according to the mode and rate of movement, form of the surface of sliding, and the type of earth material moved. The most common downhill movement, almost imperceptible because of its small rate, is called creep, a category that comprises mass movements of a very wide scale, ranging from the creep of slope debris through outward bulging to long-term gravitational slides on mountainous slopes.

weathering

Signifi-

people

cance to

Another large group of slope movements includes landslides (landslips), which are rapid movements of earth materials separated from the underlying stationary part of the slope by a definite surface. When the movements occur along a predisposed surface where there is jointing or bedding, the slide is designated as a glide. If a free fall is involved in the movement of blocks of solid rock, the phenomenon is called a rockfall. Slides along newly formed curved surfaces are called slumps, and mass movements involving high-water content are called earthflows and mudflows. On steep mountainous slopes, torrential rains may produce debris avalanches. A special case of flowage and slipping is solifluction; i.e., the movement of

a thawed surface layer on the frozen substratum. Slope movements, which may become a serious economic problem in their extent and recurrence because they often cause great damage to the property and life of people, can be an insurmountable hindrance to human activity. Many disastrous landslides and rockfalls are known to have destroyed whole towns and caused hundreds of deaths. Extensive depreciation of agricultural land, as well as of wooded areas, may also be caused by slope movements. Major slides result in the complete removal or extinction of forest growth; trees are uprooted or become dry. Highways and railways traversing areas susceptible to sliding are not infrequently interrupted by landslides, particularly when the stability of slopes is disturbed during construction. There are cases in which railway lines have had to be abandoned because of permanent danger of sliding movements and consequent high maintenance costs. Slope movements frequently produce serious difficulty during major engineering construction projects, such as tunnels and dams.

Adverse indirect effects of earth movements on slopes include clogging of valleys by landslides that impound temporary lakes that endanger the downstream reaches by flooding after the natural dam has collapsed. Sudden landslides and rockfalls along seashores also have very disastrous indirect effects. In the Norwegian fjords, for example, landslides often provoke high-water swells up to several tens of metres that are detrimental to the inhabited coast (Q.Z./Ed.)

FACTORS PRODUCING SLOPE MOVEMENTS

The variety of landslide types reflects the diversity of factors that are responsible for their origin. Such factors include the character and structure of rocks, the angle of slope, the soil or debris cover, climatic and groundwater conditions, and time.

Debris cover on slopes is prone to downslope movements. As physical and chemical weathering disturb the cohesion of newly exposed rocks, further material for sliding is supplied. The stability of rocks is also impaired by chemical changes induced by percolating water.

Slopes composed of resistant permeable beds that are underlain by weak, incompetent, impermeable rocks, such as clays, are quite prone to sliding. The underlying clays become saturated with water and are squeezed out by the weight of the hard rocks above. In stratified rocks the contributing factor is the downslope dip of beds. If this slope is undercut by river erosion, then the stability of beds is disturbed, and slipping takes place.

The vegetation cover is also important. The roots of trees maintain stability by their mechanical effects and contribute to the drying of slopes by absorbing part of the groundwater. Deforestation of slopes impairs the water regime in the surface layers and facilitates erosion. The grass mat is gradually worn away so that weathering proceeds more intensively and produces free debris.

Earth movements on slopes are frequently induced by an increase of slope angle. This may be caused by natural or artificial interference; for example, by the undermining of the foot of a slope by stream erosion or by excavation. Exceptionally, the angle of a slope becomes steeper as a consequence of processes such as subsidence or uplift of the Earth's crust. The increase in slope gradient increases the shear stress within the rock mass, and this disturbs the

Tremors produced by earthquakes also affect the equi-

librium of slopes by evoking a temporary change of Effects of stress. Some disastrous rockfalls in high-mountain areas (e.g. Peru in 1970) are known to have been caused by earthquakes. In loess (fine-grained silts) and loose sands. shocks can disturb the intergranular bond and thus lower the shear strength. In water-saturated fine sands-those in which water occupies the pore space between all sand grains-and some kinds of clays (quick clays), shocks may result in a displacement or rotation of grains leading to a

sudden liquefaction of soil. The conditions of slopes are greatly affected by groundwater. Flowing groundwater exerts pressure on soil particles that impairs the stability of slopes. In fine sand and silt, groundwater washes out fine particles, and the strength of the slope is weakened by the cavities that are formed. Moreover, soluble cement may be removed and, consequently, the cohesion of rock and the shear strength decreased. If the groundwater is under pressure it acts to uplift the overlying impermeable beds, thus decreasing the stability of slope.

The factors listed above often combine with the influence of climatic conditions, particularly the amount of precipitation and frost activity. Rain and ice meltwater, for example, penetrate into joints (rock fractures) producing hydrostatic pressure, and the increase in pore-water pressure in soils induces a decrease of shear strength.

It has been observed that, under certain climatic conditions, slope movements occur repeatedly in extremely humid years; measurements of rainfall amounts have confirmed that there is a direct relationship between precipitation and frequency of landslides. In what was once Czechoslovakia, the monthly rainfall for 70 years of record showed a striking coincidence with the recurrence of slope movements. Systematic examination of such records makes it possible to predict the renewal of slope movements in areas liable to recurrent sliding and to warn of imminent danger.

In clayey rocks, the deleterious effects of atmospheric water are heightened when the rainfall comes after a long dry period: clavey soils are desiccated and shrunken, and water easily penetrates deep into the fissures. The disturbance occurs on the lubricated layer in which the water

Among the numerous factors inducing earth movements on slopes, that of time must not be omitted. As the agents change in the course of time, several phases of development occur. These range from the first signs of disturbance of the equilibrium to general loosening of the mass, which is then propelled into motion, travels downslope, and is gradually deposited.

TYPES OF SLOPE MOVEMENTS

Rockfalls. Rockfall refers to the abrupt movement of loosened blocks or complexes of solid rocks detached from rock walls. Rockfalls are distinguished by a very high velocity resulting from the free fall. Their size ranges from isolated stones to enormous masses of rock. The stones and blocks that fall build up talus, or debris fans, at the foot of mountain slopes that in some places coalesce into extensive aprons. The slopes of these fan-shaped deposits range from 25° to 40°, depending on shape and form of stone fragments. Floods often carry away the loose material of these fans and deposit it farther downslope.

The origin of rockfalls depends on the morphology of the slopes and on the jointing and fracturing of rocks. Rockfalls are frequent in mountainous areas, particularly in valleys that have been overdeepened by glaciers. Factors contributing to the loosening of blocks are climatic conditions, chiefly weathering, wedging effects of freezing water in joints, hydrostatic pressure of water in open fissures, and pressure of growing roots. The movement can be triggered by the undercutting of steep slopes by erosion or excavation, by earthquakes, or, exceptionally, by thunderbolts.

Hundreds of rockfalls have been recorded from young mountain ranges, such as the Alps, Carpathians, Himalayas, Andes, and Rocky Mountains. One of the largest was the rockfall in the valley of Bartang River, in the Pamir Mountains in 1911. A rock mass of about 4,800,000,000

earthquakes. groundwater, and climate

Origin and occurrence of rockfalls

cubic metres (6,300,000,000 cubic yards) fell and dammed the valley, creating a lake 75 kilometres (47 miles) long and 262 metres (859 feet) deep. When large rock masses drop into a lake or fjord, dangerous huge waves flood the coast. In the Norwegian fjords numerous rockfalls have occurred, and catastrophic results were caused in part by the suddenness of the event.

If a rockfall involves an extremely large mass of rock, the freely falling body detached high from the mountain face may move downslope with a speed of up to 215 kilometres (135 miles) per hour, the blocks are shattered to rock fragments, and the mass movement takes on the character of a flow. Rock streams in the Alps and other high mountains are mostly explained in this way.

Rockfalls are also frequent on rocky shores of lakes and seas, as well as on steep concave banks of erosive river valleys. In these cases the rockfall is an important agency in modelling the cliffs and contributes to the recession of the coastline; the rocks are eroded by waves, the cliff becomes oversteepened, and the upper part of the wall collapses.

Rockfalls also can be responsible for the recession of waterfalls, particularly when hard rocks overlie less resistant beds. The existence of Niagara Falls, for instance, is threatened by large-scale rockfalls. In 1954 about 185, 000 tons of rock collapsed because of undermining by water erosion.

Creep and bulging. The simplest form of creep is the slow, almost imperceptible downslope movement of soil particles and rock debris. Creeping of loose rock fragments is the result of a number of processes, particularly those related to climatic agencies. During the winter months movement is facilitated by the loosening of rock fragments and heaving by frost. Upon thawing in spring, the particles, which have been lifted at right angles to the slope, fall back vertically under the effect of gravity, so that they move a small distance downhill. The creep of slope debris can be compared to plastic deformation occurring in a snow bed on a mountain slope. The rate of movement is greatest near the surface and decreases downward. The expansion of stones by heat and shrinkage on cooling also contribute to the downslope movements, because they are not equal at the upslope and downslope sides of stones. Subordinate effects can be produced by plowing, cattle treading, burrowing by animals, and wedging by plant roots.

Clayes surface layers move slowly downhill by the action of plastic deformation. These movements do not usually develop a discrete slide surface but occur over a wider zone. They are limited to the surface layer, which does not surpass the depth of temperature and humidity effects. Though the deformations amount to only a few millimetres, during the long intervals embraced by geological time they appear as a steady creep of slope deposits.

Creep results in the bending of beds (Figure 1). Friction that is active between the creeping debris and the surface of the bedrock produces a gradual bending of the bed faces cropping out at the surface. The dragged-out and disrupted layers of the bedrock become part of slope deposits, thus increasing their thickness.

In addition to surficial creep, a slow movement disturbing the equilibrium conditions of a slope takes place under suitable conditions at a greater depth below the surface. These earth movements are caused by the squeezing of soft rocks from beneath the more solid overlying rocks. In English literature this phenomenon is designated as buging; in some countries the result is called a valley anticline. This process involves the plastic flowage of the underlying rocks along a system of surfaces of potential sliding. The instability of the slope is perceptible only during a longer time interval, when the minute deformations have reached measurable values. In the advanced stage these creep phenomena may grade into true landslides.

In some regions the squeezing out of soft rocks in the lower parts of the valley slopes is so widespread that it causes serious economic problems. Bulging was first described from an area of iron-ore mining near Northampton (central England), where valley sides are composed of solid Jurassic limestones and shales (144,000,000 to 208,000,000 years old) that overlie soft Lias clays. Although the beds are nearly horizontal, the near-surface beds of solid

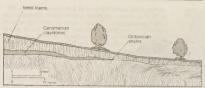

Figure 1: Creep and bending of beds in a loam pit at Prague, Czech Republic (see text).

From Quido Zaruba and Vojtech Mendi, Landstides and Their Control (1969); Elsevier Amsterdam & Academia, Prague

rocks are inclined into the slopes, whereas the clays at the fotor of the slopes are squeezed upward and contorted. In the initial stage, the bulging appears as a slight anticlinal bend of beds; with advancing deformation the clays are bent into folds, and even small faults may form at the foot of the slope. Although the disturbances extend to several tens of metres in depth, from the geological point of view they are surficial phenomena because they disappear both downward and into the slope where the beds preserve a normal subhorizontal course. This deformation can be interpreted in terms of the upward squeezing of plastic substance from the loaded medium into the unloaded one. The stress that caused the heave of clays results from the difference in the loading of clays in the bottom of the valley and under its slopes.

Figure 2 shows an example of bulging in a river valley near Ostrava (Czech Republic). The valley occurs in marly shales of Cretaceous age (66,400,000 to 144,000,000 years old) that are pierced by sills of very firm volcanic rock called teschenite. The section shows that the teschenite body is broken into several blocks by a system of faults running roughly parallel to the valley. The 50st shales that are squeezed out by the heavy rock blocks move toward the stream, which gradually carries them away. The main deformations probably occurred about 230,000 years ago, during the Pleistocene Epoch (10,000 to 2,500,000 years ago), because the steps between the blocks are filled with slope debris and loess loam.

The possible development of such deformations under present climatic conditions of the temperate zone has been the subject of much consideration. In general, squeezing of the substratum may occur whenever (1) the soft rocks within a limited area are released from the weight of the overlying rocks, and (2) this release gives rise to stresses, which, even if they do not surpass the shear resistance of plastic beds, may, in time, result in deformations.

Because the character of motion is essentially like that of creep, some long-term deformation of mountain slopes can be included in this group of earth movements. They consist of movement along planes of separation, such as planes of straitfication, schistosity, or jointing.

Many analogous phenomena have been observed in young mountain ranges such as the Alps or Carpathians and occur most frequently on the slopes formed of phyllites, mica schist, and other metamorphic rocks that can be deformed by differential movements.

Movements related to creep can grade into sliding when a slide surface develops in the course of time and the movement is accelerated.

Landslides and debris slides. Landslides include a multiplicity of downslope movements, which, in contrast to

Figure 2: Squeezing-out of marly shales on the valley bottom of the Lucina River, Czech Republic.

creep, occur along well-developed surfaces. A landslide occurs when the stability conditions of the slopes are disturbed either by the increase of shear stress imposed on the slope or by the decrease in shear strength of the rock building up the slope. The factors and processes that may provoke the change in the state of equilibrium have been mentioned previously.

The sliding movements involve bedrock or surficial deposits, but very often both bedrock and its cover are involved. The part of the slope that moves separates from the remaining mass along the plane of least resistance (Figure 3). This slip surface is commonly formed by a bedding, joint, or fault plane. The movements are generally rapid and originate when the planes of separation dip downslope and their continuity is disturbed at the foot of the slope. In stratified rocks with smooth, even bedding planes, the dip of beds is usually the maximum inclination at which the slope is permanently stable. If the beds are undercut by stream erosion, they maintain their position only by friction, which increases with the roughness and unevenness of the bedding planes. Friction can be reduced by climatic factors such as freezing and thawing of interstitial water or by hydrostatic pressure of water in the joints if the free outflow of water is obstructed. Failure can also be provoked by the increase of slope angle, as a result of uplift of the Earth's crust.

Rock sides on bedding planes or other surfaces of separation may be disastrous in mountain areas where, because of great height differences, the movement attains an acceleration nearly equal to that of a rockfall. In steep mountains the conditions are favourable for rock slides because streams with steep gradients cut readily into the bedrock, and the adjustment of the slopes cannot keep pace with erosion. The stability of slopes is particularly threatened when the dip is toward the valley.

Debris slides-movements of shallow slope debris and weathering materials above the bedrock-are categorized with landslides. Debris slides involve materials of only a few metres in thickness but may cover wide areas in some regions. On disturbed slopes, various stages of slipping are observable, from initial fissuring of the weathered layer up to advanced forms with several generations piled on top of one another. Debris slides generally occur after a heavy rainfall or spring thaw. Rainwater soaking into the soil lubricates the surface bed of the unweathered rock, on which the disrupted top layer slips down. In the other case, during the freezing of the ground the surface layers of debris are enriched by water rising by capillary action toward the surface from the lower unfrozen beds. During the spring thaw the water produces slaking of the surface layer and reduces the internal friction and the stability of slope.

Slumps, earthflows, and debris avalanches. The type of slope failure known as slump is common in homogeneous,

poorly consolidated clayey rocks, such as clays, marls, claystones, and clayey shales. Slide-promoting forces are increased by the undermining of the slope by erosion or by excayation or by the overloading of its upper part.

by excavation or by the overloading of its upper pass. Slumps have a characteristic form. The mass usually tears off along a concave head scarp and moves down a curved slip surface to accumulate at the foot of a slope, spreading laterally, Inside the sliding rock mass some minor scarps originate, so that it is broken into blocks that are tilted toward the slope. In the depressions of the hummocky surface, water accumulates into small lakelets, thus contributing to the instability of the slope. On either side, the mass is squeezed into longitudinal ridges that are often striated. The whole body is cut by cracks of different arrangement. Slumps may gradually increase by backward caving of the head scarp. The movement generally occurs along partial cylindrical surfaces, but the resulting slip surface is somewhat distorted. The depth and shape of a slump adapt to the seologic structure of the slope.

Slumps of large dimensions are frequent on river valley slopes and sea coasts. Along some river valleys deep slumps occur side by side, and the interlocking alcoves enlarge the slide area laterally. Slide material that weights the foot of the slope may help to restore the equilibrium of the slope, but tongues of the slumps are in most cases washed away during floods or by waves, and advancing crossion includes further movements. Typical examples of these slump movements are known from the coast of England near Folkestone (Figure 4) and from the valleys of various rivers (Volga, Moscow, and others) in Russia.

> From Quide Zaruba and Bojtech Menol, Landslides and Their Control (1969); Elsevier, Amsterdam & Academia, Prague

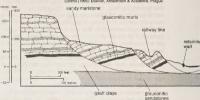

Figure 4: Landslide on the seashore near Folkestone, Kent.

On the lower parts of slopes, slumps frequently grade into flows, the shape of which is controlled by the topography. They move as sheets or streams that fill the crosion gullies or valleys. These movements—called earthflows, debris flows, or mudflows according to the material and consistency of the mass—represent a separate type of slope movement, one that differs from the slumps because of the higher water content that produces motion of flow type.

Earthflows generally originate in a large basin in the upper part of the slope, where debris and weathering material have accumulated. The movement is usually triggered by heavy rainfall. Interstitial water increases the weight of the debris cover and greatly reduces its shear strength. The loosened mass flows toward the foot of the slope, forming a loaf-shaped bulge. When it flows down a valley, it moves at a rate greater than is achieved over the slope surface, because water-saturated debris packed into a narrow tongue contacts the substratum over a smaller area; consequently, the friction is smaller. When all loose material has been emptied from the source area, the earthflow gradually becomes stabilized and overgrown with vegetation. If part of the debris remains there, heavy rainfall may provoke further movement, and the bulge at the toe will be overridden by younger material.

With increasing velocity earthflows grade into debris flows. Mountainous debris flows are sometimes called avalanches or Muren, a term currently used in the Alpine countries. As a rule, they originate above the timberline in gorges filled with rock detritus. During torrential rains, debris and larger stones travel at a tremendous speed down the stream channels. The material is unsorted, and

Form and occurrence of slumps

Role of water saturation

the ratio of solid particles to water is about 1:1. The rates of flow are so great that moving trains have been trapped and buried beneath debris avalanches. The Muren are very disastrous and often result from too great deforestation of mountain slopes. Scarcity of vegetation is also responsible · the reasons for slope instability and to determine how fast for debris and mudflows in arid and semi-arid regions. This group of slope movements also includes volcanic mudflows. Volcanic explosions are usually accompanied by torrential rains that wash ash and ejected material downward as a mushy mass. Debris flows occasionally originate on glacier-covered dormant volcanoes. When volcanism recurs, the increase in heat before and during the eruption suddenly melts the glaciers, and the waters bring much debris downhill,

Solifluction. Solifluction is a combined flow and slip movement, which involves the surface layers on slopes in the subarctic region and, to a lesser extent, high mountain regions. The deeply frozen surface layers thaw to only a small depth during a short summer. Meltwater and precipitated water saturate the soil because they cannot percolate into the frozen, impermeable substratum, and the waterlogged bed flows downslope as a dense sludge. Solifluction may occur even on a rather moderate slope because the soil moves readily on the frozen substratum.

Another somewhat special type of flow movement involves clay sediments of marine origin and is common in Scandinavia and Canada. These sensitive clays, called quick clays in Norway and Leda Clays in Canada, cover flattish areas situated about two hundred metres above sea level. The strength of these sediments progressively decreases because of the decrease of salts in the pore water. The ground and atmospheric water impoverish the salt content by osmotic processes. The decrease in salt concentration in pore water goes hand in hand with the decrease of bond between the clay particles and the bound water, and thus with the decrease in strength. Remarkably, the drop in strength is greatest toward the end of the process. The loss of strength results in a flow movement of unusually great rapidity. The failures of quick-clay slopes are treacherous because they may affect areas that are nearly flat.

Failure of

quick clays

One of the largest failures of this type occurred near Verdalen, north of Trondheim, in Norway in 1893. A layer of sensitive clay was laid bare by stream erosion. The liquefied clay, with a volume of 55,000,000 cubic metres (72,000,000 cubic yards), flowed down in 30 minutes. The dense liquid covered an area of 8.5 square kilometres (3.3 square miles) and destroyed 22 farms. The flat terrace in the broad valley of the river Veddalselva is suggestive of absolute safety today, but the monument bearing the names of 111 people who were killed in 1893 testifies to the catastrophic possibilities.

CHARACTERISTICS OF UNSTABLE SLOPES

Slopes disturbed by sliding movements show a characteristic configuration: the head scarp is arcuate with a spoonshaped depression, and the topography on the downslope side is hummocky and irregular. In active landslides the features are clear cut, whereas in the dormant, temporarily inactive landslides, the forms are effaced by rainwash and erosion or covered by vegetation. An important characteristic is the shape of the slope in cross section. Even a very ancient landslide is recognizable from its convex bulged toe made up of the accumulated slipped mass.

The growth of trees on unstable slopes reveals the presence and age of sliding movements. Trees, which on unstable ground become tilted downslope, tend to return to a vertical position during the period of rest so that the trunks are conspicuously bent. From the younger, vertically growing trunk segments, the date of the last earth movement can be inferred.

For distinguishing the slide areas, the presence of particular plants can be of help. Horsetail (especially Equisetum maximum) and coltsfoot (Tussilago farfara) are good indicators of slopes that are prone to sliding. Horsetails contain 50-60 percent silica and 19-30 percent potash in the ash. This high content suggests the presence of potassium and hydrated silicates in the soil and explains why horsetails thrive on sliding areas formed of potassium-rich (e.g., glauconite-bearing) rocks.

The earth processes and factors that cause slope movements and the characteristics noted are intensively studied because they present serious hazards. Geologists and specialists in soil and rock mechanics endeavour to decipher and how far the loosened rock mass will move. Although some slope failures will remain unpredictable for a long time, at least those disasters caused by human interference can be avoided.

Fluvial processes

Over much of the world the reduction of mountains, the building of plains, and the sculpture of the landscape is brought about to a large degree by the flow of water. As the rain falls and collects in watercourses, the process of erosion not only degrades the land but the products of erosion become themselves the tools with which the rivers carve the valleys in which they flow. The process varies over time and from place to place. Materials eroded from one location are transported and deposited in another, only to be eroded and redeposited time and again before reaching the ocean. At successive locations the riverine plain and the river channel itself are products of the interaction of the mechanics of transport by the flow and the characteristics of the sediments brought down from the drainage basin above.

The fluid in a river is not pure water. Not always visible, the load of the river may be carried in solution, in suspension, or dragged along the bed. Solutes and particulate matter are both organic and inorganic. Neither the discharge of the water nor the related rates of erosion and deposition are constant in time or in space. Steep, narrow, rock-walled canyons may be excavated by corrosion of flowing water armed with abrasive particles aided by corrosion through chemical action. Elsewhere, sediments may be deposited to form broad alluvial fans, floodplains, or river deltas in lakes along the river course.

ENTRAINMENT AND TRANSPORT OF SEDIMENTARY PARTICLES

Erosion and transport of sedimentary particles is initiated when the drag, or shear stress, exerted on the boundaries of a natural channel by the flowing water is sufficient to detach a particle from the boundary. A particle of a given size and weight will begin to move when the shear stress exceeds a component fraction of the weight of the particle under water. In general, increasing flow accompanied by increasing velocity and shear stress results in progressive entrainment of particles from the bed and higher rates of transport.

There are essentially two distinct physical modes of transport of sediment. Bed load is that portion of the material in transport that is in continuous or partial contact with other particles on the bed; thus the weight of the moving particles is supported by contact with grains in the bed. In contrast, the suspended load is born up by the fluid eddies within the flow itself. Because the turbulent eddies both near the bed and in the fluid vary in intensity from moment to moment, the motion of the individual particles is highly erratic from place to place and moment to moment. In a statistical sense, however, at any distance above the bed, an equilibrium concentration is maintained with the number of particles settling through a given level balanced by an equal number of particles thrust upward by eddies. The concentration of suspended sediment at each level above the bed is a function of the settling velocity of the particles and the intensity of shear stress or turbulent exchange in the fluid at that level. Large particles, which settle most rapidly, are found near the bed, and progressively smaller particles are carried at greater distances above the bed. Similarly, where the particles are all of the same size, larger concentrations of suspended sediment will be found closer to the bed. If the particles are very fine, they may be nearly uniformly distributed with depth. The curves in Figure 5 show the way in which sediment concentration varies with depth for particles of different sizes or settling velocities at a constant condition of flow. Settling velocity is primarily a function of the size of the

Modes of sediment transport

size and settling

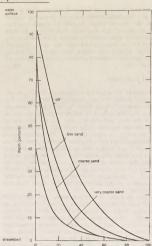

Figure 5: Distribution of suspended load with depth for particles of different sizes.

Coarse particles are concentrated closer to the bed, while finer particles, such as silt, are more uniformly distributed with

particle. Assuming the availability of a range of particle sizes in a river, as the flow fluctuates and velocity or shear stress changes, particles transported near the bed at one time may be entrained and move in suspension at a higher flow. With diminution of the flow larger particles cannot

be maintained in suspension and will settle to the bed. Where the bed of a natural channel is comprised of noncohesive particles such as sand, as velocity and depth increase with increasing flow the particles in motion no longer behave solely as discrete individuals but instead the bed itself is deformed, resulting in the formation of sand ripples, dunes, and waves. As the rate of transport increases, these bed forms change progressively with changes in depth and velocity. The sand near the bed moves in a zone close to the dune or ripple surfaces. Usually, particles are carried up the backslope of the dune and deposited usually after sliding down on the steeply dipping face producing the downstream movement of the dune. Because deformation of the mobile boundary influences the flow distribution itself, the interaction between the flow, the boundary form, and sediment transport is complex. These interactions, and the progressive changes in bed forms observed in natural channels during passage of a flood, are discussed below, under Erosion and deposition in natural channels

MATERIALS TRANSPORTED BY NATURAL RIVERS

The materials actually transported as a clastic or particulate load as well as those in solution in natural rivers are a reflection not only of physical laws governing the competence and capacity of the flow to transport material but also of the availability of materials themselves. For example, pure limestone terrain containing no insoluble materials would supply no sediment to streams draining the region. With the exception of occasional blocks broken off from limestone canyon walls, the rivers would carry only dissolved materials, and the stream beds would be devoid of sand, silt, and gravel bars. Such extremes, of course, are rare and, in general, rivers transport a mixture with coarser sediment in the bed load, finer particles in suspension, and ions in solution. Although these distinctions represent mechanisms of transport rather than sources of material, the sources are reflected in both the composition and relative abundance of each fraction.

The relative proportions of dissolved and particulate or clastic load as well as the distribution of the clastic fraction between bed load and suspended load are highly variable in nature (Table). In general, the percentage of clastic load increases as the climate becomes more arid. Less effective solution and weathering in arid regions apparently reduce the supply of dissolved solids to the stream channel system, whereas in more humid regions larger quantities of dissolved material are made available to streams. Topography, and particularly the composition of the bedrock, also can markedly influence the composition and quantity of the load. The Saline River in Kansas, for example, has a salinity of 1,000 parts per million by weight, a function of the saline deposits found in the watershed. Similarly, extreme concentrations of sediment have been measured in some rivers such as the Yellow River in China, where sediment comprised 40 percent of the total fluid, or tributaries of the Colorado River, in which 60 percent of the flow was sediment. In general, concentrations of suspended load in natural rivers vary from several hundred to 10,000 parts per million (1 percent) by weight. Some sand channels, such as the Loup River in western Nebraska. may transport 50 percent or more of the total load as bed load, but values of about 10 to 20 percent are probably more common.

EROSION AND DEPOSITION IN NATURAL CHANNELS

The supply and movement of sediment is intimately involved in the determination of the form and pattern of the river channel. A natural river flowing in sediments of its own making can maintain a stable configuration in two ways: first, by a balance of forces in which the drag of the fluid tending to erode the perimeter of the channel at any point is equalled or exceeded by the frictional or cohesive forces tending to resist the eroding force, and second, by maintenance of a rate of deposition equal to the rate of erosion. In contrast, a channel incised in rock is less free to adjust its form and pattern through deposition and erosion, but the bed of the channel will rise and fall with changes in the rate of transport of debris. The first case, in which a precise balance is maintained between the erosive force and the resistance of the boundary materials without any erosion, is relatively rare in nature. The banks of such a channel in noncohesive material are roughly parabolic and, if the flow is large, the channel cross section will consist of a wide central portion with a flat bottom and banks at each side roughly parabolic in form. Ideally, the maintenance of such an erosional equilibrium requires a

delicate balance between the opposing forces, a relatively uniform material, and a constant flow, conditions reproducible in the laboratory but only approximated in nature.

A natural river channel in which the rate of erosion is balanced by the rate of deposition and the outflow of sediment to the reach equals the inflow can maintain a stable form while moving laterally across the alluvial plain. A meandering river is the most common illustration of this process. Erosion takes place on the outside of each bend near the point of maximum shear stress as a result of the curvature of the flow. Deposition on the opposite bank is associated with transverse flow near the bed and with slack water eddies adjacent to the thread of the current. Because the locus of erosion is downstream from the point of maximum curvature, progressive erosion in the downstream direction is associated with progressive deposition as the entire channel bend moves downstream

Sand and gravel bars. Where the channel boundaries are straight, either because of the nice adjustment of discharge, gradient, and sediment, as is the case in some canals, or perhaps as a result of vegetation or channellization by man, sediment and sedimentary forms such as sand and gravel bars may move downstream in a progressive and orderly fashion. The movement of sediment and the configurations of the channel bed associated with such movement may be rather arbitrarily divided into three phases. First, channel bars may be deposited along the banks at sequential positions alternately on one side of the channel and the other. This configuration of alternating bars of gravel or sand in a straight channel is not unlike that which would be observed if the bends of a meander were "pulled out" to make a straight channel. Their spacing of roughly three to five channel widths appears to be related to the discharge and to the width of the channel, Second, sand and silt may move as dunes or ripples, a mode of transport determined by particle characteristics and the interaction of boundary form and the flow. A third mode of sedimentary deposit involves successive movement and deposition of discrete particles. Larger particles may move different distances depending upon their size, shape, and specific gravity. Boulders will move less frequently and, on the average, more slowly than smaller particles, producing a differential rate of downstream migration of particles of different sizes

Accumulation and movement of gravel and sand in bars appear to resemble the movement of what is called a kinematic wave. Discrete particles do not move independently of one another but interact or interfere with each other in much the same way as automobiles on a highway. As a result of this interaction, the particles accumulate in groups or applomerations that move downstream as "waves," The average downstream rate of movement is then represented not by the movement of the individual particles but rather by the average rate of movement of the group of particles constituting the wave. This wave phenomenon is similar to that observed on a highway crowded with automobiles, where, when the number of automobiles is low, the automobiles interact very little and each moves at its own rate. With an increase in the number of automobiles, however, interaction takes place and groups begin to form such that there are agglomerations and openings in successive positions along the highway. The celerity or rate of movement of these waves is determined then by the density of particles (or automobiles) in a given length of stream channel (or road), by the characteristics of the particles, and by the conditions of flow

Because the flow of water in natural channels is not constant, each mode of transport in a river also varies with time. The alternation of high and low flow in most of the rivers of the world not only influences the rate of transport but also the attendant forms of the channels themselves and the deposits associated with them. In the natural world the time scale of variations in flow may be matters of minutes, days, years, decades, or millennia. Peak flows from thunderstorm rainfall may occur in a matter of minutes after the start of heavy rain in streams or in urban rivers. Storms of longer duration may produce high water lasting for days or weeks. At another time scale are the seasonal or annual variations such as the cyclical rise and fall of the Nile each spring as a result of snow melt and rains in the headwaters, a variation common to many major river systems such as the Colorado, the Rio Grande, the Ganges, and the Yukon. Lastly, successions of dry years may be followed by wet ones. Such climatic variations are less periodic in occurrence and may encompass periods from decades to thousands of years in duration.

Variations in flow rate are associated with variations in transport. The dissolved load, responding to the characteristics of the source rocks as well as the flow, often decreases in concentration as a result of dilution of the salt concentration by the direct runoff from streams. In contrast, suspended load generally increases with increasing flow. Wash load (i.e., materials such as clays and fine silts) may be readily removed from the watershed, for example, when spring rains follow the melting of snow and particles of soil are detached by cycles of freezing and thawing in early spring and late winter. The first spring rains readily remove the prepared materials to the streams. The transport of bed load also increases in response to increase in velocity and shear stress accompanying the passage of higher flows or floods. As in the theoretical or laboratory condition, the change in flow in the river channel is accompanied by a change not only in the concentrations of dissolved, suspended, and bed materials but by changes in the form of the bed itself as the flow increases in depth and velocity. Changes in the form of the bed associated with the passage of a high flow in a river are shown in Figure 6, whereas Figure 7 shows concurrent changes in flow, velocity, and depth.

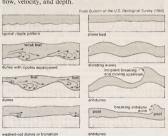

Figure 6: Forms of bed roughness in alluvial channels his sequence of forms is related to the depth and velocity of flow and to the rate of sediment transport.

Bed forms. As noted earlier, after the initiation of movement, ripples and dunes develop on the bed. With increasing depth and velocity of flow in the channel, the dunes grow in size. Experimental and field observations indicate that the amplitude or height of the dune increases until the velocity of flow over the dune prevents further accumulation on the crest. At equilibrium, dunes may cover the bed in the same way that they do the windblown surface of a sandy desert. If velocity increases more rapidly than depth, a transition occurs, dunes begin to be erased, and all or part of the bed will be planar, with dunes covering the remainder. Beyond this transition, continuing increase in velocity leads to the formation of antidunes. Dune forms on the bed move upstream as a result of the displacement of material by scour at the upstream position while net transport continues in the downstream direction. The formation of antidunes is associated with the formation of standing waves on the water surface. Unlike dunes, the crests and troughs of antidunes are in phase with the crests and troughs of the surface waves.

With declining flow in the channel and reduction in velocity and depth, the sequence is reversed. The bed is gradually transformed from the antidunes to the mixed and planar bed, to dunes, and thence to an irregular bed of sand if the flow declines to zero. A smooth bed is rarely if ever attained inasmuch as declining flow both erodes the dunes and deposits finer sediments on the channel bed.

Flow and transport variation with time

Thus the forms remaining in a sand channel are usually dissected dunes and ripples.

Each of the successive configurations of the bed is associated with a particular set of flow conditions, and with changing discharge a complex interrelationship exists between the geometry of the boundary as defined by the configuration of the channel bed, the concentration of sediment, and the flow parameters such as velocity and depth. In some cases the same discharge on the rising stage of a flood may be associated with a high velocity and a relatively low depth, while on the declining stage the depth may be higher and the velocity lower (Figure 7). Resistance to flow is greater on the falling than on the rising stage. This difference is presumed to be due primarily to

Figure 7: Sequential changes in flow (discharge), velocity, depth, and sediment transport associated with the passage of a flood in a natural channel with a sand bed Changes in bed form and the approximate Froude number at which such changes might be observed are shown in association with changes in the rate of sediment transport.

decline in flow so rapid that there is insufficient time for the transition of the bed forms. Dunes of larger amplitude associated with the higher flow remain at the lower stage and these larger forms provide a greater resistance.

The scale of dune forms may be exceedingly large. In a large river such as the Mississippi, at depths of flow from 21 to 27 metres (70 to 90 feet), dunes or dunelike forms of major proportions have been observed, with amplitudes from 5 to 12 metres and longitudinal spacing from crest to crest of 15 to 152 metres. Dunes can be seen in the beds of many rivers and creeks carrying sand, and dunes of cobbles and gravel occasionally have been observed after great floods.

Variations in flow produce variations not only in the Magnitude rate of movement of particles of different sizes but also in the distances that these move in successive intervals of time. A large boulder in a small trout stream may be moved only by rare and very large floods. In contrast, material in solution is transported continuously as long as there is flow in the stream. Between these extremes lies a continuous range. Small particles are carried more often and for greater distances during each rise in the flow than are successively larger ones. Huge boulders may be moved a matter of centimetres or perhaps hundreds of metres by a flood that occurs on the average perhaps once in a hundred years. Sand may be transported continuously in a stream where the flow never declines below the point of incipient motion of the sand particles. Thus individual particles move in steps of varying lengths that depend upon the duration of the flow in which they are transported and their size, shape, and distribution.

Flood events of large magnitude but infrequent occurrence may move very large particles as well as large quantities of material but only for short periods of time. In contrast, more frequent events will move smaller sizes but over longer periods of time. In sand bed channels of ephemeral streams, such as those in the southwestern United States, most of the movement of both suspended and bed materials may occur during relatively infrequent events, which recur perhaps four or five times per year. These few floods not only mold the channel form, but they may transport 80 to 90 percent of the total annual load carried by the river. In contrast, where flow is perennial and of relatively large magnitude, more of the dissolved and suspended load may be transported by flows of modest magnitude throughout a large part of the year. Under such circumstances, the relative contribution of the large and infrequent flood event is thus of lesser significance. To the extent that generalization is possible, existing evidence suggests that the greater the variability of stream flow and the larger the particles to be carried, the more significant are the floods of large magnitude and infrequent occurrence. Similarly, where flow is less variable, dissolved load a significant proportion of the total load, and the suspended load composed of fine particles, more frequent events assume greater importance.

Scour and fill. In a given reach of channel, fluctuations in flow, accompanied by changes in the rate of transport of both suspended and bed material, produce a scouring or filling of the channel bed. In a straight channel this may amount to a few centimetres. In bends or narrow reaches, scour may be to depths of a metre or more and in rock-walled canyons as much as six to nine metres (20 to 30 feet). The cumulative effect in any given year may result in the temporary lowering of the stream bed. The bed may be lowered in some years and raised in the next or succeeding years. Over a period of time the average elevation will remain constant. A similar process of erosion and deposition characterizes the lateral or down-valley movement of the channel. In any one year erosion may exceed deposition, but over a period of years the pattern and form of the channel remain the same. Thus, the equilibrium referred to earlier constitutes an adjustment to the quantity of water and sediment delivered to the channel, an adjustment maintained within the natural variations in flow and sediment load normally experienced in a given climate or hydrologic environment. Equilibrium of the river channel then is associated with a constancy of climate viewed as an average over a period of years.

frequency

Changes in hydrologic conditions

Rates of

deposition

erosion

and

A progressive increase in the amount of rainfall on the watershed, a change in the vegetative cover, or a combination of such factors, however, may produce a progressive change in the hydrologic conditions governing the river channel at any point. Such changes might be climatic, they might result from changes in land use or, for example, they might be brought about by construction of a dam and major reservoir. These long term or progressive changes are referred to as degradation or aggradation in contrast to the processes of scour and fill that encompass fluctuations of short duration. Changes associated with man-made works, in fact, provide a good illustration of the nature of the river response to changes in climate. A reservoir, by impounding flood flows for release during periods of low natural flows, alters the frequency distribution or pattern of river flows. In addition, the reservoir becomes a sediment trap, which reduces the quantity of sediment delivered to a channel below, A river previously in equilibrium with the natural flow and sediment supply is thus subjected to a new set of controls that, in turn, result in a succession of changes in the river channel itself. Thus, where scour took place in one year to be followed by deposition in succeeding years prior to construction of the dam, after construction the elimination of floods and sediment supply produces progressive lowering of the channel bed, or degradation, rather than an alternation of scour and fill (see also below Physiographic effects of man).

In contrast, progressive accumulation, or aggradation of material in channels, also results from changes in climate. from man-made works, or at the interface of land and water where sediments accumulate in deltas. In some locations, such as on the Yellow River, the river bed has risen to well above the surrounding countryside in the delta because successive floods deposited coarse sediment along the river banks and on the bed. Elsewhere, changes in climate have resulted in the delivery of large quantities of sediment to river channels, producing alluviation or filling for great distances over entire channel systems.

Rates of accumulation or degradation are highly variable. For over a thousand years the Nile has risen at an average rate of about one metre (more than three feet) per hundred years. In contrast, during the period of hydraulic gold mining in the Sierra Nevada the Sacramento River rose as much as three metres (10 feet) in 35 years. Valley fills or terraces along major rivers in the great plains of the western United States indicate that some rivers may have cut through the alluvial materials in their valleys at rates on the order of three metres or more in 100 years. although these estimates are crude at best. Below Hoover Dam on the Colorado River, the bed of the channel was lowered ten feet in five years after closure of the dam.

FLUVIAL PROCESSES IN DIFFERENT ENVIRONMENTS

The characteristics of a river and the processes associated with it are determined by a combination of the geology of a region and the climatic conditions responsible for providing the flow in the river. The term geology includes the underlying structure of the region, such as the presence or absence of mountains, as well as the composition and distribution of the bedrock. The latter, in turn, determine the quantity and often the size fractions of the materials delivered to the stream system. In contrast, although the climate may be influenced by the elevation of the region, major aspects of the atmospheric circulation will determine the amount of precipitation and seasonal variations in temperature. Indirectly these will affect the vegetation, characteristics of the soils, and the distribution of runoff or flow to the river system.

Clearly, innumerable combinations of geologic and climatic controls must exist in nature. Each segment or reach of a river will be dominated by a set of conditions of local origin as well as by a set determined from the larger area of the drainage basin upstream. Despite these obvious variations, however, some combinations of controls are sufficiently common to allow rather rough characterization of rivers in different regions. It must be emphasized, however, that the key to understanding why rivers look and behave as they do lies in a knowledge of the mutual interaction of the controlling factors such as

discharge, sediment, and rock type. What might be called characteristic regional types simply represent particular combinations of these factors as well as the existence of a control in some regions or environment. Many complex factors are involved in developing a certain type of river or stream; each stream is classified according to the factors affecting it.

Trout stream. The so-called trout stream, or brook, for example, is indeed a recognizable type of river. It is usually characterized by a vigorous flow (of cool water), high gradient, and a bed of cobbles and boulders bordered by mossy banks and trees. Climate and elevation determine

Figure 8: A boulder-bed high mountain stream, Crandall

the availability of the flow, whereas the coarse bed material is a function of the steep gradient determined by the geologic structure. A high gradient permits the flow periodically to move some of the larger cobbles producing in time a series of pools and riffles. In some brooks, particularly those in coarse sand or cobbles, the spacing of the riffles or shallows appears to be proportional to channel width.

Arroyo. A second rather distinctive river in an opposing climatic regime is the arroyo of the Spanish-speaking world, the wadi of the Middle East and Mediterranean region. These dry washes, which experience periodic torrential flows, are otherwise dry sand channels comprised primarily of sands, perhaps dissected dune forms, some gravel, and occasional cobbles, depending on the local geology and topography. Because of the aridity and high temperature of the bed, vegetation is usually sparse. The combination of dry bed, absence of vegetation, and rapid changes in flow permit large variations in the configuration of the sand bed and in the amount of scour and fill. In addition, because such channels are often on relatively steep slopes and in noncohesive materials, they tend to be wide and shallow and subject to high velocities at shallow depths, a condition promoting the formation not only of dunes but of antidunes along with rapid rates of sand transport.

Channels in humid-temperate regions. In contrast to these rivers in semi-arid regions, the well-defined channels of the humid region are a response not only to the regularity of the flow but to the presence of fine sediments and vegetation that stabilize the river banks, emerging point bars, and other deposits laid down by the river. These channels, composed of silt banks stabilized with vegetation, are narrower and less mobile. Not infrequently floods that overtop the banks deposit on the adjacent plain varying amounts of silt, sand, and mud, thus creating a floodplain composed of channel and bar deposits overlain by finer "overbank" deposits. Where the channel is confined or maintains itself within a relatively narrow belt within which it meanders, the fine-grained deposits of floods may predominate in the floodplain.

The preceding descriptions suggest that in alluvial river channels flowing in sediments of their own making, there is a range of channel or river types, from the wandering channel that deposits bars over a vast shallow plain to the

Dry washes

Waterfalls

well-fixed, stabilized, narrow channel bordered by vegetation. In the former the ability of the channel to alter its course at will by erosion and deposition, a condition common to large rivers flowing on an apron of debris deposited at the front of a glacier, creates a broad flat plain composed of sand and gravel bars deposited within the channel and in rapidly migrating bends, coupled with the overbank materials that are deposited from rapid

At the opposite extreme, the established channel in cohesive material bordered by vegetation will move laterally at a modest rate accompanied by deposition of sediments upon which vegetation will become established. With each flood above the normal bank height (a level attained on the order of once each year or two) sediments may be deposited over nearly the entire width of the valley. Where the river channel traverses the valley with rapidity, the bottomland is virtually all in channel deposits, while in the less mobile environment overbank or nonchannel deposits predominate.

Between the extremes, the wandering and stabilized channels, lies a spectrum of processes and resultant alluvial landforms, each dependent upon the relative rates of lateral migration of the river and of overbank deposition; that is, upon relative rates of erosion and sediment transport and upon the frequency distribution of river flow. A given channel then may fall anywhere within this spectrum. The channel of the Missouri River along the boundary between northern Iowa and Nebraska, for example, contains many bars that may shift with each flood. At the same time. the river moves laterally in a broad meandering pattern experiencing progressive erosion as well as deposition over broad areas

Rivers in canyons. Rivers in canyons such as the Colorado in the Grand Canyon, the Yangtze Gorge, or the limestone valleys on a smaller scale in Kentucky and Tennessee in the United States are confined by bedrock walls and valley floors. No longer free to alter either form or pattern save over long periods of time, the characteristics of the river are determined primarily by the rock itself and by slow erosional processes of abrasion and scour of rock material. Falls may occur where resistant beds are in contact with less resistant ones such as at Niagara, or long

Figure 9: Arroyo trenching an alluvial valley in the Carrizo

smooth stretches may be encountered where, unbroken by changes in lithology or by joints or faults, abrasion by the river has produced smooth polished surfaces. Elsewhere, as in the bottom of the Colorado River, deep pools scoured by the flow may be separated by rocky rapids. In some places lateral abrasion excavates sheltered coves where rockwalls overhang the river itself. Rock canyon sections may occur in any climatic region where water has been or is currently available to scour the bedrock.

Cold region rivers. In extreme climates, such as in Arctic, Antarctic, or periglacial (cold, frozen ground) regions,

the river may be frozen throughout much of the year. Here the river processes will be determined by the configuration of the bedrock geology and by the annual climatic regime, which determines both the way in which the river freezes with the onset of winter and the way in which the ice breaks up in the spring. Some rivers, such as the Yukon, break up throughout the length of the river in a relatively short period of time. The resultant breakup and the rising spring flood with which it is associated produce enormous forces that not only shatter the ice but cause it to accumulate in ice jams, to override the river banks, and to erode

the channel banks as the high flow moves down the river. This type of river presents quite a different pattern from that observed on other kinds of cold region rivers such as the Nelson River in Canada, which flows from Lake Winnipeg to Hudson Bay. The Nelson consists of a series of lakes and open water sections linked by bedrock falls or rapids. Freeze-up and breakup are discontinuous, beginning in the lakelike sections and controlled by the backing up of water above the controls at the rapids. The breakup of the ice is sequential and does not occur over the entire river, but instead the ice melts in the lakes and intervening backwater sections and, as the water rises, it begins to flow through and over the ice covering the falls. The flow scours areas adjacent to the falls themselves and gradually erodes through the ice capping the falls. The presence of ice and the movement of large ice blocks from the bedrock falls provide additional force to scour and to move boulders along the bed of the river. (M.G.W./Ed.)

Processes of glaciation

As a glacier moves over the land surface it modifies the terrain by removing material or by depositing debris carried within the ice mass or on the glacier surface. Each of these major glacial processes produces distinctive landforms that remain long after the glacier has disappeared (see CONTINENTAL LANDFORMS: Glacial landforms). In addition to direct glacial erosion and deposition, closely related geological events occur in nonglaciated regions as a direct consequence of the glacial ice, or the climatic conditions that caused the glaciers to grow and expand. These events include the depression of the Earth's crust resulting from the superimposed weight of glacier ice, the creation of lakes at the edge of the glacier during its retreat, the distribution of wind-transported sand dunes and silt blankets, emerged and submerged shorelines resulting from sea-level fluctuations in response to waxing and waning of the ice sheets, and the development of characteristic features produced by frost action in cold-dominated regions that were not covered by glacier ice.

GLACIAL EROSION

Glaciers are made up of interlocked grains of ice crystals. Laboratory experiments on single ice crystals and on samples of glacier ice show that ice deforms plastically when stress is applied. In nature the stress is gravity, the basic cause of ice movement. Two kinds of glacier movement have been identified: internal deformation of the ice by slippage or shear along certain planes in the individual ice crystals, and sliding of the base of the glacier on its bed. The velocity of the glacier thus consists of two components, an internal one resulting from deformation or creep of the glacier, and a basal one resulting from the sliding of the glacier on its bed.

The basal ice in many glaciers is at or near the pressuremelting point of ice, so that freezing and thawing occur at various times at the plane of contact between the glacier and the rock or soil beneath it. This permits loose debris such as silt, sand, cobbles, and larger rock fragments to be incorporated as part of the moving glacier mass. These basal, non-ice constituents of the glacier are abrasive tools that scratch, polish, or groove the rock or frozen ground over which the glacier moves.

The melting and refreezing of basal ice is a process that is Glacial capable of removing very large blocks of bedrock and incorporating them in the moving glacier mass. Many rocks of the Earth's crust characteristically contain intersecting fractures or cracks, called joints, which define incipient

quarrying

angular blocks that can be incorporated into the base of a glacier through the melting-freezing process. Large-scale excavation of many blocks (the individual dimensions of which may range from about a metre to more than three metres) is another form of glacial erosion known as glacial quarrying, or plucking

The exact mechanism of glacial quarrying is not known because conditions at the base of a glacier cannot be directly observed. Tunnels, driven into glaciers along the ice-rock basal contact, have yielded very little information about quarrying. Generally, the excavation of rock by glacial quarrying seems to be restricted to rocks that are well-jointed. Massive, unjointed rocks, such as quartzite and others with few joints, are smoothed and polished by overriding glaciers. Glacially quarried surfaces, on the other hand, are rough and jagged because blocks were lifted out by the poorly understood quarrying process.

A good deal of controversy exists about the efficacy of glacial erosion. Some geologists admit that glaciers are capable of abrading rock surfaces but deny that glaciers produce any major landforms comparable to the large canyons cut by rivers. It is suggested instead that such features were produced by preglacial erosion and that glacial modification of them was insufficient to obliterate their preglacial forms.

The real question is not whether glaciers are capable of eroding the land surface but, rather, the magnitude of glacier erosion.

GLACIAL TRANSPORT

Ablation

cumulation

of glaciers

and ac-

Material incorporated in a glacier by abrasion or plucking is transported by glacier flow until it is deposited directly by the ice, or until the glacier melts and leaves its load as a mantle over the landscape. Valley glaciers receive material from the valley walls confining them. Individual boulders and rock fragments, loosened by frost action from cliffs above the glacier surface, fall onto the glacier and are carried in conveyor-belt fashion as the ice stream flows down-valley. In some instances large landslides and debris flows may descend to the surface of a valley glacier. which then transports the rock and soil debris in a downglacier direction.

A glacier consists of two parts, the zone of accumulation and the zone of ablation. The former occurs in the upper reaches of the glacier where more snow falls each winter than is melted in the following summer. The latter is found at lower elevations on a glacier where, in addition to melting of the annual snowfall during the summer months, part of the glacier ice is destroyed by melting. If a glacier ends in a lake or the ocean, large masses of glacier ice become detached from the glacier terminus to become icebergs. Ablation thus is any process that removes ice from the glacier mass.

Rock debris that falls on a glacier in the zone of accumulation becomes buried by the snowfall of successive winters. A boulder that comes to rest on the glacier surface in the zone of accumulation has two components of movement as it is carried by the glacier. One component is down-valley, parallel to the general surface of the glacier. The other component is vertically downward as the boulder becomes covered by successive snow layers. Snow in the accumulation zone is transformed to glacier ice by a process of recrystallization as it is buried deeper and deeper each year. Debris falling on the glacier surface as airborne dust or boulders from a rockfall ultimately becomes imbedded in the glacier ice.

The flow lines of a glacier in the zone of accumulation are thus inclined downward toward the base of the glacier, whereas in the ablation zone, the flow lines have an upward component toward the glacier surface. Because of this pattern of flow, debris falling on the uppermost reaches of a glacier will be carried to the base of the glacier and then move upward until it reappears at the surface of the ice in the ablation zone.

The boundary between the ablation zone and the accumulation zone is called the snowline. It is best observed in late summer at the end of the ablation season. At that time the accumulation zone still has a residual layer of snow from the previous winter, whereas the ablation zone is strewn with debris released from the melting glacier ice If the amount of annual accumulation exceeds annual ablation over a period of years, then mass is added to the glacier. The glacier responds in two ways: it thickens, and it expands over a larger area. Valley glaciers expand in a down-valley direction and ice sheets expand by spreading outward in all directions. In both cases the glacier is said to be advancing.

If, on the other hand, ablation exceeds accumulation over a period of time, the glacier responds by thinning and by reducing its total area. The terminus of a valley glacier retreats in an up-valley direction while the edge of an ice sheet withdraws along the entire margin. During advance and retreat, the glacier continues to transport material in the direction of glacier flow.

From the foregoing it can be deduced that a vigorously advancing glacier may transport debris lying at its terminus by a "snowplow" action, thereby pushing material forward as the snout or margin advances. The snout is also the site of transportation of debris along thrust planes within the glacier itself. Thrust planes in some glaciers are exposed in crevasses near the glacier terminus or on the ablation surface, where the edges of the thrust planes occur as a series of parallel or subparallel bands emphasized by a concentration of dirt and stones that have been carried to the glacier surface by thrusting.

GLACIAL DEPOSITION

Material transported by glacier ice eventually comes to rest on the land surface. Glaciers that terminate in the ocean (tidewater glaciers), such as those discharging from Greenland, Alaska, or Antarctica, deposit material on the sea floor. If the terminus of a tidewater glacier is grounded on the sea floor, deposition is concentrated around the edges of the grounded portion as debris frozen in the glacier is released by melting. If the terminus is afloat, sediment released from the underside of the glacier will fall to the sea floor as melting progresses. These glacio-marine sediments are distinguished from other marine deposits by their heterogeneous detrital content.

During the height of the ablation season, the terminus of Fluvioa glacier on land is a chaotic mixture of melting ice, running water, and mounds of rock and soil debris recently released from the ice by ablation. These conditions change hourly; in late afternoon the discharge of glacial meltwater reaches a maximum, and large volumes of water can be seen flowing on the glacier surface in ice channels or debouching from tunnels in the ice. The flow of meltwater slackens after sunset, and by the early morning hours of the following day, the volume of meltwater being discharged from the glacier may be only a small fraction of the maximum flow of the preceding day.

These conditions give rise to a great variety of glacially

ioure 10: Bedrock channel near the head of Søndre Strømfjord, West Greenland, carved by silt-lader glacial meltwaters. The rock surface was smoothed by glacial erosion.

glacial processes at the ice margin

derived sediments ranging from ablation debris blanketed over stagnant ice masses to sands and gravels deposited by glacial meltwaters a few miles down-valley from the glacier terminus. The extremely variable conditions of transportation in space and time give rise to extremely varied deposition of sediments. Ablation boulders and unsorted rock rubble may slump onto a deposit of well-sorted gravels, or boulders may fall from the ice front into a quiet meltwater pool where fine sand and silt are accumulating on the bottom.

If a glacier margin retreats year after year, these chaotic ice-marginal deposits will persist over a wide expanse of recently deglaciated terrain. Pauses in the retreat may result in a concentration of the ice-marginal deposits in the terminal zone. If the ice front advances, it may override the older debris-covered areas or push some of it into ridges and mounds that remain for centuries after the glacier has retreated or disappeared entirely.

Meltwater issuing from the ice front in rivulets on the ice, or torrential discharges from ice tunnels, generally converges to form a single channel or series of channels that divide and recombine in an anastomosing (braided) pattern. These braided rivers are choked with glacially derived sediment called outwash or glaciofluvial sediments. If a glaciofluvial river empties into a lake, the coarser fraction of the suspended load is deposited at the river mouth while the silt and clay, called rock flour, are deposited on the lake floor. Glacial meltwaters heavily charged with rock flour are distinctively gravish-white in colour and are referred to as Gletschermilch in the Alpine regions of Europe.

GLACIAL LOADING AND UNLOADING

The Earth's crust tends toward a condition of balance or isostatic equilibrium. If the crust is considered to be a series of large blocks extending to a constant depth, approximately 20 to 50 kilometres (12 to 30 miles), each of the blocks will stand at a different elevation above sea level because of its difference in density. This condition of crustal balance is constantly changing because material from the higher-standing blocks (the continents) is being eroded and transported to the lower blocks (the ocean basins)

If glacier ice accumulates to some appreciable thickness over a large part of the Earth, the crust will be depressed about 300 metres (1,000 feet) for every 900 metres (3,000 feet) of ice. Crustal downwarping increases in magnitude from the marginal areas of a large ice sheet toward the zone of greatest thickness. Where the ice is thin, the crustal downwarping is zero, and where the ice is thickest, the depression of the crust is greatest.

Deformation of the crust because of glacial loading is not a permanent condition. After an ice sheet has melted away, the crust restores itself to a new condition of isostatic balance by rising in response to the glacial unloading.

Crustal downwarping from glacial loading, and crustal uplift from glacial unloading are operative on the Earth today. The crust beneath Greenland and the Antarctic ice sheets is downwarped several thousand feet because of the load of glacier ice on each. In contrast, crustal upwarping is going on in Scandinavia, North America, and the British Isles as a result of the disappearance of the ice sheets from those areas somewhat less than 10,000 years ago. The rate of uplift is determined by the change in the elevation of tide gauges with respect to mean sea level during historical time. The Scandinavian Peninsula, for example, is currently rising at differential rates: north of the Gulf of Bothnia the rate is about 88 centimetres (35 inches) per century, near Stockholm it is around 40 centimetres (16 inches) per century, and at Copenhagen it is zero. These rates are undoubtedly less than they were in the earlier stages of deglaciation, but it appears from other evidence that the land around the Baltic Sea may rise another 180 metres (600 feet) in the centre of the area of uplift before isostatic equilibrium is regained. The maximum uplift in Fennoscandia at that time will have been as great as 760 metres (2,500 feet). If it is assumed that the postglacial rebound equals the total amount of downwarping, and that the ratio of downwarping to ice

thickness is about one to three, then the maximum ice thickness for the Fennoscandian region was about 2,300 metres (7,500 feet). This is comparable to the measured ice thickness of the Greenland Ice Sheet, which covers about the same area today as did the Scandinavian Ice Sheet during the Pleistocene.

The depression of the Earth's crust by glacier ice produces some side effects in the nearby nonglaciated areas. Coastal regions are submerged, causing invasion of the land by the sea. River mouths are inundated by seawater and river gradients are reduced, giving rise to deposition of river sediments.

The postglacial rise of a previously glaciated land area is recognized in coastal regions such as Scandinavia, the eastern United States, and the Great Lakes region of southern Canada (Figure 11). The evidence comes from differen-

Figure 11: Upper Great Lakes region during Port Huron maximum, about 13,000 years ago

tially uplifted or warped strandlines, which marked the shorelines of water bodies marginal to the retreating Pleistocene ice sheets. These strandlines, represented by beach ridge deposits, were horizontal when formed, but because of glacial rebound since deglaciation these linear features now rise toward the direction of greatest ice thickness. Accurate dating of successively younger strandlines provides the basis for determining postglacial rates of uplift. Crustal recovery patterns are depicted in maps showing isobases, lines connecting points of equal uplift in a given region, as around the Great Lakes or the Gulf of Bothnia and the Baltic Sea. The limit of uplift is defined by the zero isobase (no uplift) or "hinge line." In the Great Lakes region the hinge line has an east-west trend roughly from Milwaukee through Cleveland to New York City. South of that line, all strandlines of the ancestral Great Lakes are horizontal, a fact that implies no uplift. Northward from the zero isobase of the Great Lakes region, uplift is still in progress, but the rate appears to be declining. It has

Postglacial uplift in progress today

been shown that the maximum uplift north of the Great Lakes occurred at Golfe de Richmond at about latitude 56° N on the east coast of Hudson Bay. There, at least 300 metres of uplift has occurred since the load of the ice sheet was reduced by thinning at the end of Pleistocene time. Assuming that complete uplift represents one-third of the ice thickness, the uplift at Golfe de Richmond reflects only about 900 metres of ice. This value is too small in relation to maximum Pleistocene ice thickness for the Greenland and Antarctic ice sheets, at comparable distances from their margins. It must therefore be assumed that uplift in the Hudson Bay region is still in progress. and that as much as 600 metres of additional uplift can be expected to occur.

PERIGLACIAL PROCESSES

Periglacial

environ-

ment

As originally used, the term periglacial was an adjective used to describe the climatic conditions prevailing in a nonglacial zone marginal to a large ice sheet. As used today, the term is synonymous with "cold-dominated" and is applicable to a rigorous climate in which the freezethaw process predominates. Generally speaking, the periglacial environment is characterized by perennially frozen ground (permafrost), low precipitation, strong winds, and vegetation ranging from the boreal forests (central Alaska), through taiga (northern Canada) and tundra (Arctic Alaska and Siberia), to vegetation-free areas (northern coast of Greenland and glacier-free areas of Antarctica).

The periglacial environment was undoubtedly more widespread during the Pleistocene than now, and many effects of this environment are preserved in various landforms that resulted from periglacial processes that are no longer active. The landforms resulting from these processes are discussed in CONTINENTAL LANDFORMS. Whereas such features are not, in the strictest sense, landforms produced by glaciation, they are closely related to glacial climates and are commonly superimposed on terrains that originated through glaciation. Moreover, the presence of underground ice, and its thawing and refreezing are basic requirements for many of the landforms associated with the periglacial environment. (IHZ)

Wind action

The term wind action embraces all aspects of the interaction between wind and rock and mineral materials on the Earth's surface. Wind is geologically most effective in areas where it acts with the greatest force for the longest time upon materials of greatest susceptibility. These conditions are attained more fully in dry than in humid regions. Consequently, the magnitude, abundance, and diversity of geological products of wind action are greatest in the principal desert areas of the world; the Arabian Peninsula, South West Africa, the Sahara, northwest China, Australia, the west coast of South America, and southwestern North America. Many of the large-scale patterns in arid regions visible from the air are the product of geological work of the wind. Local enclaves also exist within humid regions, where wind action can be a significant or even dominant geological process. Examples are sea- and lakeshores and the alluvial plains of rivers with variable flow. Many areas peripheral to glaciers are not arid in the usual sense, yet some of the most intense and effective wind action on geological record has occurred in such settings.

Wind displays unusual diversity as a transporting agent. It is one of the few agents that carries material uphill, and sometimes it works in opposition to other transporting processes. Streams of water, for example, carry sand from the land to the sea, where it is redistributed along shore in the form of beaches; in places wind picks up this beach sand and carries it back inland toward the source from which it came. In total weight of material transported, wind cannot match running water, but in terms of distance of transport it surpasses all other agents for materials as fine as dust. No part of the planetary surface escapes the influence of wind action; even deep-sea oozes contain wind-borne particles, and bits of snow are widely drifted by wind across the heart of the Antarctic Ice Sheet, where liquid water is unknown.

Geological activities of wind impinge upon the affairs and concerns of man. Deposits of windblown sand encroach upon railroads, highways, canals, airports, settlements, and other man-made works to the extent that sand control becomes necessary. Dust- and sandstorms temporarily close down major arteries of travel. Drought and man's disturbance of the ground permit wind to render areas of settlement and cultivation untenable. On the other hand, some of the richest croplands of the world occur on soils derived from deposits of windblown dust (loess), and wind has created aesthetically pleasing features such as the graceful form of lines and features of sand dunes.

TRANSPORTATION OF ROCK DEBRIS BY WIND

The flow of air. Because air has a very low viscosity. about one-sixtieth that of water, any movement or airflow at velocities greater than three or four kilometres (two to three miles) per hour is predominantly turbulent. A. breeze of that velocity is barely perceptible to a standing observer. In turbulent flow, individual parcels of air within the flowing mass move in all directions, up, down, and sidewise, as the air moves forward. The other mode of movement is laminar flow, in which adjacent sheets of air slip past each other like playing cards in a deck, in essentially parallel paths without mixing. Because air is a perfectly viscous fluid, a thin zone of laminar flow always exists adjacent to any fixed surface, and an additional very thin film of dead air (air with no movement at all) lies in

Turbulent flow and boundary

immediate contact with the surface. Within air moving across a surface there is a contact zone in which the velocity of translation changes from zero at the surface to the prevailing value at some distance therefrom. This is called the boundary layer, and above a natural ground surface its thickness is usually between one and 10 centimetres (0.4 and four inches). The boundary layer is a zone of great velocity change (gradient), strong shearing action owing to large differences in velocity at different levels, and unusually high turbulence. Its dimension and character are strongly influenced by the roughness of the ground. Wind velocity refers to the rate of movement parallel to the ground, and the prevailing velocity is that value measured at one to several metres above the surface. Significant geological work (that is, wind action on rock materials) does not occur at prevailing velocities below about 16 kilometres per hour (10 miles per hour). Winds above this velocity are termed effective, and their capacity for doing work varies roughly as the cube of the velocity. If the velocity doubles, the capacity to do work increases eightfold. Strong storm winds, even though short-lived,

by much more frequent but gentler winds. Particle size and wind velocity. Wind-tunnel experiments show that different wind velocities are required to initiate movement of particles of different size, but of similar shape and density. The relationship is not linear, however. The highest velocities are required for the largest and for the smallest particles. A particle of some

therefore, can produce major effects, and not infrequently

they cancel out the work of transportation accomplished

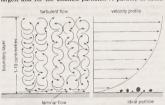

Figure 12: Diagrammatic view of the laminar and turbulent flow fields and the velocity distribution of the wind above the ground surface. The smallest particles are not lifted because they do not project above the laminar flow zone. The largest particles are subject to turbulent lifting forces but are too heavy to be moved. The "ideal particle," as shown, is that which will be transported by wind action

Saltation

of grains

intermediate size is the one that can be moved with the lowest wind velocity. This is the so-called ideal particle. On Earth it has a diameter of 0.08-0.1 millimetre (0.004 inch), and it starts to move at a wind velocity of about 16 kilometres per hour. On a planet such as Mars, however, where atmospheric density is less than 0.01 and gravity is about 0.4 that of Earth, the ideal particle size is about 0.7 millimetre (0.03 inch), and the required wind velocity is in the neighbourhood of 320 kilometres per hour (200 miles per hour). The reason small particles are hard to move is illustrated by Figure 12; they simply do not project high enough into the boundary layer for the wind to get hold of them.

Mechanics of movement, Wind moves particles by rolling or sliding (traction), by hopping (saltation), by suspension, and by a process of impact creep wherein the impacted grains slide or roll across the ground. Unless disturbed by other means, the initial movement as the wind attains an effective velocity is by rolling. As wind velocity and particle movement increase, the rolling grain may hit an irregularity and make a little hop. This gives the wind a better grip, and it accelerates the grain's movement. If the grain hits the surface in a favourable spot and fashion at the end of its leap, it rebounds to greater heights, the wind accelerates it even more, and the hopping process is magnified. This is saltation (Figure 13). Creeping grains travel at a rate of several millimetres per second but saltating grains cover many metres per second; the effects in terms of transport and of wear and tear upon themselves and other objects are multifold.

The height attained by a saltating grain depends upon its velocity, the rate and direction of its spin, its size, and the orientation and physical properties of the surface upon which it impacts. At high wind velocities (50 kilometres, or 30 miles, per hour), over resilient surfaces, individual saltating grains rebound to heights as great as three to six metres (10 to 20 feet). Most grains travel at much lower heights, about seven to 50 centimetres (three to 20 inches), however.

The distance covered in a single hop is governed by the above considerations controlling the height of rebound, and it ranges from a few centimetres to 10 metres or more. The mean distance over sand-mantled surfaces is on the order of 10 to 15 centimetres (four to six inches). Slow-motion photography and laboratory experiments show that most saltating grains moving under winds of 30-50 kilometres (20-30 miles) per hour approach the ground at angles between 10 and 16 degrees. For a grain rebounding to a height of one metre this means a hopping distance of three to five metres. Slow-motion photographs also record many midair collisions among grains. Such impacts produce abrupt changes of path, and some grains are returned to the ground at abnormally steep angles.

One saltating grain tends to produce others, particularly if the ground is abundantly supplied with sand. Unless the incoming grain scores a direct hit on another particle, it splashes down among other grains creating a small crater and blasting a half dozen particles into the air. Saltating grains quickly multiply by this means, and shortly after a wind attains an effective velocity a curtain of saltating

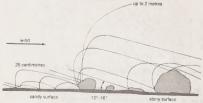

Figure 13: Trajectories and general distribution of particles transported by wind over (left) sandy surface and (right) stony surface. Note the much higher paths of particles on the stony surface, which result from impact with larger particles.

grains becomes visible over surfaces supplied with loose sand. Over nonresilient surfaces, such as dunes, this curtain attains a height of only 30 to 45 centimetres (12 to 18 inches). Over resilient surfaces, such as stony plains or concrete highways, it easily attains heights of two metres (six feet) and more (Figure 13). Saltating sand grains seldom rise above knee height on the windward side of a sand dune, even in strong winds of 50-80 kilometres (30-50 miles) per hour. Under corresponding conditions over a paved highway, humans and vehicles both suffer.

Within all saltating curtains, the vast bulk of material travels close to the ground. Samples taken over a bouldermantled surface show that about 50 percent of the grains travelled at levels less than 15 centimetres (six inches) and 90 percent at levels less than 63 centimetres (25 inches), even though a few grains rebounded as high as three to six metres (10-20 feet). Over cultivated fields or loose sand surfaces lower heights are recorded.

Particles of moderate size resting on the ground experience an abrupt forward movement if hit by a saltating grain. This is impact creep. Because a saltating grain can move particles six times its diameter and 200 times its weight by impact, this becomes an important mechanism for transport of small pebbles, one to two centimetres (0.4-0.8 inch) in diameter, which are too large to be moved directly by most winds. It also affects smaller particles. and the little jerks and spurts of grains on sand-mantled surfaces that are subject to a rain of saltating particles are of this origin.

Very fine or unusually light materials can be carried in suspension by wind when the sum of the upward-directed forces of turbulence equals or exceeds the settling velocity of the particles. Settling velocity is determined by size and density of the particle, the viscosity of air, and the force of gravity. Because most natural wind velocities are such as to produce turbulence, the problem is more one of a mechanism for getting fine particles up into the air in the first place than of keeping them there. For reasons already given, wind experiences difficulty in grasping small particles on the ground. The saltating grains unquestionably play a major role in initiating transport by suspension by blasting small particles off the ground. The first phase of most major duststorms involves saltation of grains to raise the dust that is carried away in suspension. Material that travels in suspension is most conveniently termed dust (mean diameter about 0.01 millimetre, or 0.0004 inch). and the grains that travel primarily by saltation (mean diameter about 0.25 millimetre, or 0.01 inch) may be designated as sand.

Surprisingly large rock fragments are occasionally transported by wind in unusual ways and circumstances. If material composing the ground surface is loose to a depth of an inch or two, surface stones can become perched on low pedestals owing to wind scour around their base. In time, these stones fall from the pedestals, usually in a downwind direction. They may roll or slide many centimetres in the process. In particularly loose material and with underloaded wind, scouring on the upwind side can be so excessive that a perched stone becomes tilted upwind. Eventually, it may slide off in that direction, and repeated perching and sliding can result in measurable upwind movement of such a stone. This is an anomalous behaviour and a further demonstration of the eccentricity of wind transport.

Movement of unusually large fragments, some weighing hundreds of kilograms, by wind occasionally occurs in the instance of stones resting on the surface of normally dry lake flats (playas) in arid regions. When the surface of such flats becomes wet and muddy, high winds blowing under just the right conditions can cause the stones to slide across the slippery surface leaving distinct tracks. During the winter of 1968-69, a stone weighing 6.4 kilograms (14 pounds) moved 64 metres (210 feet) across the surface of Racetrack Playa in Death Valley, California, in this fashion.

Distance of transport. The distances materials are moved by wind depend largely upon the mode of transport, terrain configuration, and wind regime and pattern. Large fragments shifted by undermining move centimetres

Impact creep

Movement of large particles

to perhaps a few metres at most. Particles travelling by traction, including impact creep, can cover hundreds to possibly thousands of metres under favourable conditions. Particles transported by saltation can travel tens to hundreds of kilometres, provided they are not constricted by terrain or captured by dunes, vegetation, or water bodies. There is probably an upper limit to the distance a grain can travel by saltation before it becomes completely reduced to smaller pieces by impact. This distance is not actually known but may be on the order of 160 to 325 kilometres (100-200 miles).

Materials carried in suspension cover thousands of kilometres. Dust derived from North Africa falls in England and northern Germany, 3,200 kilometres (2,000 miles) away. Ships a thousand or more kilometres at sea expedistribution rience dust falls on their decks. Australian dust travels 3,000-4,000 kilometres (2,500 miles) to New Zealand. Dust thrown high into the atmosphere by volcanic explosions can circle the globe several times. Circumglobal transport of very fine particles is probably more common than realized. Very fine dust is distributed throughout the entire atmosphere. The particles provide nuclei upon which snowflakes crystallize and raindrops condense, and they are eventually removed from the atmosphere by this means

> The amount of material carried by different modes of wind transport varies with local situations, but some generalizations are possible. Traction and impact creep account for 20 to 25 percent of all sand transport; saltation provides the remainder. The mean amount of debris moved in suspension is perhaps in the neighbourhood of 20-25 weight percent of the wind-borne total. It varies widely with the local situation, and being highly visible, it is usually overestimated. Even so, individual storms have transported as much as an estimated 100,000,000 tons of dust.

EFFECTS OF WIND TRANSPORT

Inter-

dust

continental

Modification of particles. Materials subjected to wind transport undergo modification. Wind is an excellent sorting agent, and deposits of windblown material are inevitably well-sorted; that is, the grains are of closely similar size. It is an unformulated law of nature that the sorting power of a transporting medium is the inverse of its viscosity. Glacier ice has very high viscosity, and its deposits are very poorly sorted. Air, having very low viscosity, is an excellent sorting agent.

Wind blowing over an alluvial deposit consisting of gravel, sand, and dust produces an initial sorting by removing small particles and leaving the large ones. Of the particles removed, sand is carried moderate distances and dust is carried greater distances, thus separating (sorting) these materials. The sands are further sorted by the differences in mode of transport, traction or saltation, with traction debris being the coarser. Within traction debris, larger particles travel more slowly and cover shorter distances, resulting in further sorting.

The sharp corners and edges of angular sand grains partaking of saltation are knocked off and worn away by the constant impacting. In time, these grains become rounded and smooth. Several tens of kilometres of travel by saltation is required, at least in some settings, to produce well-rounded grains. Most accumulations of dune sand, however, consist of well-rounded grains, and this is one means of identifying ancient deposits of windblown sand preserved in the geological column. By contrast, particles in deposits of dust (loess) are mostly angular and show minimal wear. This is so because they are so small and light that they are cushioned from impacts by the air itself. Glass bottles left on the ground in areas of saltating sand quickly become frosted because of little pits made by the impacting particles. Grains of vitreous (glassy) minerals, such as quartz, become frosted for the same reason.

Thus, deposits of sand grains transported by wind are distinguished by being unusually well-sorted, well-rounded, and frosted. Investigations have shown that another type of frosting can be caused by chemical processes, so frosting alone is not proof of wind transport. Investigators working at huge magnifications under electron microscopes, however, feel that they can distinguish the type of pits and cracks made by impact during wind transport from frosting produced by other means.

Deflation of surfaces. Removal of material by wind is deflation. If the mantle of loose rock debris underlying a deflating surface is a mixture of particle sizes, removal of the fine material results in residual accumulation of larger fragments. Eventually, a surface armour of coarse fragments results, and further removal of fine particles is prevented. Such residual concentrations are known as Production lag gravels or, in arid regions, as desert pavement. Desert of desert pavements are smooth, firm, compact, relatively impervious, and without vegetation.

pavement

In desert pavements the fragments, particularly if platy, are fitted together in a crude mosaic nearly completely covering the ground surface. The topsides of these stones commonly develop a dark brown to black weathering coat, rich in iron and manganese, known as desert varnish. The bottoms of these same stones, where seated in the underlying soil, usually have a brilliant orange coating rich in iron oxide.

Desert pavements form mostly on gently sloping alluvial surfaces. The pebbles are usually seated in a fine gray silt that more often than not overlies a well-developed desert soil. Desert pavements are resistant to erosion and relatively long-lived. Where well developed, they indicate an extended period of stability, with respect to processes of deposition and erosion. It is not yet a matter of full agreement that desert pavements are solely the product of wind action, some investigators preferring to believe that the stones are concentrated on the surface by a heaving process and subsurface movement of fine materials. In the classical view, however, wind is regarded as a significant genetic agent in the development of many desert pavements.

In places where the material subject to deflation is wholly fine grained no lag gravel develops, and large quantities of material can be removed. As much as 15-30 centimetres (6-12 inches) of soil have been deflated in a single season. Spots where removal is inhibited by cementation, vegetation, or by other obstructions develop positive relief; and areas where exceptional removal occurs become depressions.

Closed depressions called blowouts are generally considered to be a product of localized deflation. They can be small and shallow, involving areas of only a few square metres and depths measured in centimetres or metres, or they can be huge. Big Hollow, west of Laramie, Wyoming. is over 14 kilometres (nine miles) long, 45 metres (150 feet) deep, and nearly 10,000,000,000 tons of sand and dust had to be removed to create it. Deflation is a favoured mode of origin.

Most oases of the Sahara lie on the floors of great shallow depressions, the largest of which is 80 kilometres (50 miles) long by 30 kilometres (20 miles) wide, with depths of 100-160 metres (330-525 feet). The floors of many lie below sea level, and a number have large sand sheets and dune fields on their downwind sides. Although deflation has probably not been the only factor or process involved in shaping these depressions, they are generally regarded as largely the product of wind excavation. In Mongolia, great, shallow, closed depressions with gently sloping sides, known as P'ang Kiang Hollows, are also attributed to deflation.

Satellite photographs covering wide areas of the North African and Arabian deserts indicate the presence of extensive and prevailing topographic patterns, strongly suggesting that scour by wind plays a major role in determining the configuration of these regions. Surface travellers in these areas have long been aware of the local manifestations of wind erosion. Although wind deposition has been recognized as a major process in this area, it may be that the total effect of widespread, pervasive wind erosion has been underestimated, even though deposition at any site implies a corresponding erosion elsewhere.

Abrasion by sandblasting. Artificial sandblasting has long been employed as an efficient means of cleaning dirty buildings or etching decorative concrete, and objects impacted by natural saltating sand grains suffer similar

abrasion. Power and telephone companies operating in areas of strong eolian saltation know that the lower parts of wooden poles must be protected to keep them from being cut away by wind-driven sand. The wires of a lowstrung Trans-Caspian phone line are reported to have lost half their diameter within a decade. Other artificial articles such as bricks, bottles, cans, or pieces of wood left in such environments show strong modification by sandblasting within just a few years.

The larger, harder, more angular, and faster travelling the saltation grains, the more effective is the sandblasting. It is also favoured by a ready but not too copious supply of sand, by strong prevailing winds, extended expanses of gentle terrain, and sparse vegetation. Too much sand results in accumulations that bury the objects that might he abraded.

The maximum rate of wear by sandblasting in natural situations occurs at a discrete height above ground level. This probably reflects the greater impact energy of saltating grains travelling at that height. The shape of most sandblasted faces and specific field experiments suggest that maximum wear occurs mostly between five and 25

Figure 14: Common red brick after six years of natural sandblasting.

centimetres (two and 10 inches) above the ground. At one site, subject to frequent sand saltation over a bouldery surface, maximum wear over an 11-year interval occurred at a height of 22 centimetres (nine inches).

One distinctive geological result of sandblasting is the modification it produces in the shape and surface character of stones resting on the ground. These are given the special name ventifacts. Extended sandblasting can produce one or more relatively smooth, planed facets on such stones, and multiple facets intersecting in sharp edges are usual. Ventifacts are thus described as ridge-shaped (two facets), pyramidal (three or more facets coming to a peak), or irregularly polygonal (many facets). One special type of ventifact has three wind-cut faces that comprise the entire surface of the stone. This is a Brazil-nut shape and goes by the German term dreikanter ("three edges").

Not all facets are plane, some are concave or convex, especially on larger stones. On stones smaller than 15-25 centimetres (6-10 inches) facets often are cut without great regard for the stone's original shape, but this is less true of larger stones. Sandblasted faces display distinctive lustre, some are polished, others look like cellophane, and a few are greasy or dull. Additionally, they are usually pitted, fluted, or grooved in a highly characteristic manner. Surfaces that faced into the wind at angles exceeding 55°. 60° are commonly pitted. Pits range from a millimetre to two or three centimetres (0.05 to about one inch) in width and depth, depending upon grain size and structure of the rock. Pits form principally in soft particles or minerals, and the associated projecting points are capped by hard grains, such as quartz or garnet. Flutes are scoopshaped depressions, elongated parallel to the wind and of a size range similar to that of pits. Shallow, barely perceptible flutes 1-2 millimetres (0.05-0.1 inch) wide and 1-2 centimetres (0.5-1 inch) long are highly characteristic of wind-cut surfaces inclined at less than 55° to the wind.

On still more gently inclined surfaces grooves are formed. They differ from flutes in being open at both ends and commonly have dimensions approaching two or three centimetres in width and depth and lengths of many centimetres. Both grooves and flutes develop independently of structural layering in the stone, unless such structure parallels the wind. Then etching of softer layers occurs. The pattern of grooves and flutes on the upwind faces of sandblasted boulders a few metres feet in diameter shows graphically how stones of that size affect the direction of wind currents. These markings display a hemiradial pattern like shoots of water within a fire-hose stream directed against the boulder's face.

Sandblasting occurs without regard to rock type. Most well shaped, smooth surfaced ventifacts, however, are formed in relatively hard, fine-grained, homogeneous rocks, even those composed of pure quartz. Soft rocks such as limestone or marble are easily cut, but they do not long preserve the evidences of sandblasting because of subsequent weathering by solution. Friable rocks disintegrate under the impact of saltating grains and do not develop good wind-cut surfaces.

In areas of unidirectional wind, large stones show cutting only on one side, but stones smaller than 25 centimetres (10 inches) in diameter commonly display cutting on several sides. These smaller stones have clearly shifted position and changed orientation. This can happen through one of several possible mechanisms, including, among others, perching and falling from pedestals. In areas with strong winds from several directions, multiple facets should be formed without the shifting of stones, but such situations are relatively rare. Differences in the age of facets can often be recognized because of deterioration of the older wind-cut faces through weathering.

Estimates of the time required to produce a well-shaped facet on hard stones by natural sandblasting range from a decade to centuries. Laboratory tests and field observations suggest that even in areas of intense sandblasting the time is probably more on the order of a century than of a decade. Evidence of sandblasting in the form of shallow etching can be produced in a year or two on stones com-

posed of a variety of minerals, however.

Sandblasting currently occurs mostly in dry, barren areas and in regions peripheral to existing glaciers, as the dry valleys of Antarctica or the margins of the Greenland Ice Sheet. Most of the world's deserts display ventifacts in local abundance. During the Great Ice Age (the last 2,500,000 to 10,000 years ago), when continental ice sheets pushed south into central Europe and central North America, conditions in areas around their margins were nearly ideal for sandblasting. Adequate quantities of loose, angular sand grains were available, strong winds blew outward from the ice sheets, and vegetation was scanty. Consequently, "fossil" ventifacts are abundant in spots throughout central Europe and North America where wind cutting is unknown today. The same is true for areas peripheral to former mountain glaciers in the Alps. Himalayas, and other glaciated ranges. Wind has generally been given more than its just share of credit for creating niches, hollows, alcoves, pits, and fretted rock surfaces as well as natural bridges, windows, and pedestal rocks. These forms are actually more the product of differential weathering, with wind helping mostly by removal of rock particles that have been loosened by weathering.

Wind scouring of modestly coherent soily materials, however, has locally created parallel U-shaped chutes separated by narrow ridges. These features, elongated in the direction of the wind and usually a metre or two wide and deep and a few tens of metres long, are named yardangs. Similar forms are developed by wind scouring, accompanied by some deposition, in the hard-packed snow that mantles large glaciers such as the ice sheets of Greenland and Antarctica. These ridges and furrows, called sastrugi, are the bane of travellers traversing such surfaces.

DEPOSITION BY WIND

Geological materials transported by wind must eventually come to rest, and eolian handling frequently results in accumulation rather than dispersal. In the immediate past, windblown dust (loess) has accumulated to thicknesses of a good many metres (10-30 feet) in numerous regions and locally to thicknesses as great as 100 metres (330 feet) in Conditions favourable sandblasting

Ventifacts. flutes, and grooves

some. Mongolia, central Europe (especially Hungary, Belarus, and Ukraine), Argentina, Uruguay, New Zealand, central Alaska, and central North America are examples of regions with extensive loess cover.

Loess forms a blanket of even-grained, homogeneous, unbedded material on the land surface. It is typically coherent enough to stand in vertical bluffs vet loose enough to cultivate easily. In Mongolia, people live in caves hollowed out of loess bluffs. Sources of dust for such deposits include desert areas such as North Africa, dust bowls such as that of the southwestern United States, raw detrital plains peripheral to glaciers, and wide river bottoms subjected to frequent flooding. Once deposited, the dust is not easily picked up again, and eventually it is fixed in place by moisture and vegetation, mostly grass,

Sand dune formation and migration. Because wind moves more sand than dust, accumulations of windblown sand are more widespread and voluminous. They occur in the lee of bushes, rocks, hills, and cliffs, in major mountain wind shadows, and in places where opposing wind regimes cancel each other. The most obvious products are the hillocks of sand known as dunes.

If a heavily laden curtain of saltating sand traveling across a stony surface encounters a sandy patch, it loses velocity and deposits some of its load because of the drag effected by the loose sand surface. Thus, sand begets sand, and the patch grows in area and height. In the early stages, a gently rounded, nearly symmetrical, streamlined mound develops, and over this the wind moves smoothly without separation of the boundary layer.

Growth

structure

of dunes

and

As the mound gets higher, it develops a slight asymmetry with a gentler windward slope and a somewhat steeper leeward slope. Under unusually strong winds, separation of the boundary layer occurs at the dune crest, resulting in exceptional deposition of traction and saltation sand just downwind. This creates a steep lee face inclined at the angle of repose for loose sand, about 30°; at greater angles material will slide. The mound now becomes an efficient sand trap; it is truly a dune. The more sand it traps, the higher the lee face grows and the more efficient is the trapping mechanism. Sand traveling by traction and creep is dumped over the brink of the lee face, and saltating grains rain down upon it from the separated boundary layer (Figure 15). Deposition is greater on the upper reach of the lee face, causing it to become increasingly steeper. Under such conditions the slope steepens to an inclination of about 34° before it gives way by avalanching to establish a more normal angle of repose (30°-33°). For this reason, the lee slope has been called the slip face. The lee slope of an active dune is constantly being scarred by little sand avalanches all along its face. Similar avalanches can be initiated artificially by a person walking along the brink of a freshly built lee slope. The flowing sand generates a very low-pitched noise, often heard in dune areas when strong winds are blowing and active deposition is under way.

The sand composing dunes exists in two recognized and distinctive physical states well known to experienced dune travelers as accretion sand and avalanche sand. Layers of sand that accumulate under a saltating curtain, as on the windward side of a dune, become firm through the beating of the passing saltating grains. Avalanche sand of the lee slope is, by contrast, loose and poorly packed. The larger part of most migrating dunes consists of avalanche sand covered by a veneer of accretion sand. In places where the accretion is missing or unusually thin, travelers sink deeply into the loose avalanche sand.

Migrating dunes advance by deposition of material on the lee face. In time, therefore, under ideal circumstances

Figure 15: Distribution of sand on and within a dune due to wind action. Sand is shown raining down onto the lee or slip face; this general process leads to dune migration.

Figure 16: Sand avalanche tongues on lee face of a recently active dune. By courtesy of Robert P. Sharp

they must consist primarily of layers of sand laid down near the angle of repose (30°-33°) inclined in the direction of dune advance. In many dunes the internal bedded structure departs from this simple model, but it has proved a useful concept in determining paleo-wind directions indicated by ancient deposits of dune sand.

Surfaces of loose sand across which wind is transporting sand usually develop a rippled configuration. The ripples are small, essentially parallel, asymmetrical ridges composed largely of sand moving by traction and impact creep, although some exchange with the saltating curtain also occurs. The windward slopes of the ridges are gentle (8°-10°), and the leeward slopes are steeper (20°-30°). At any single site, the ripples are regularly spaced at distances commonly ranging between seven and 18 centimetres (three and seven inches). The distance from crest to crest is usually referred to as wavelength, and the difference in elevation from crest to trough is height or amplitude. The height is usually less than a centimetre (0.4 inch). In cross section, most wind ripples are seen to be an accumulation of relatively coarse sand resting on a smooth surface composed of finer sand. The size of ripples-that is, their wavelength and height-is influenced by the coarseness of the grains and wind velocity, increasing with both. In some situations, giant ripples, composed largely of small pebbles, are built by impact creep. They may have wave-

Figure 17: Wind ripples formed in sand (foreground) and in sand and fine gravel (midground).

In strong winds, it is easy to measure the rate of sandripple movement from reference points established by sticking small twigs into the ground and timing ripples as they move by. They move as rapidly as five to seven centimetres (two to three inches) per minute. At very high wind velocities, around 80 kilometres (50 miles) per hour, ripples disappear and the sand surface becomes smooth. Role of vegetation. Windblown sand and vegetation display some significant interrelationships. Vegetation of almost any type inhibits transport by traction, creep, and saltation. The resulting deposition can overwhelm and

kill the vegetation, although some vegetation can survive

Wind

partial or even complete burial by a migrating dune and continue to flourish after it has passed. This is likely to be particularly true of sand-tolerant plants. Some plants, known as sand-loving, thrive on active sand deposition; indeed, it seems to be required for their continued growth. These are primarily grasses with complex crawling root systems and nodes on stems from which new roots sprout in case of burial. The marram grass of Europe and North American dune grass are common examples.

Deposition of coastal dunes

Along some seashores, sand-loving vegetation captures sand blown inland from the beach and forms a long narrow dune parallel to the shoreline, known as a foredune ridge. If the beach is receiving additional sand from longshore currents (those parallel to the shore) so that it is building out into the sea, the result is a succession of foredune ridges parallel to the shore. The newest foredune ridge deprives its predecessors from the continuous supply of new sand required by sand-loving plants. Consequently, they do not thrive and are replaced by plants that are only sand-tolerant, which eventually cover the entire dune and stabilize it. Finally, these, too, are replaced by more advanced vegetative complexes, including trees. Successions of such stabilized foredune ridges occur along the North Sea and Baltic coasts of several European countries.

Not all wind deposition of sand along shorelines occurs as foredunes. Where sand supply is copious and vegetation is not able to keep pace, great sheets of sand dunes are built for miles inland. If the sand supply is later reduced or cut off, dunes commonly become overgrown and stabilized by vegetation. This sequence has been repeated more than once along some coasts because of the rise and fall of sea level related to water withdrawal during glacial periods and its return during interglacial periods. Such sea-level shifts cause major changes in shoreline position, especially on gently shelving sea floors, thereby affecting the sand supply.

The supply of sand for localized inland dune masses is often cut off for a variety of reasons involving geologic accidents or climatic changes. When this happens in humid areas, the dunes become overgrown by vegetation, rapidly assuming a "fossil" status. Subsequently, the vegetative cover may deteriorate because of climatic changes, lowering of groundwater levels, or other causes. When this happens, the sand becomes reactivated, creating local clusters of new dunes downwind from blowouts. The middle parts of Europe and North America harbour examples of such fossil dune areas created during earlier glacial episodes.

The ecological role of dune sand in desert areas merits note. Being composed of well-sorted, well-rounded grains. deposits of dune sand are highly pervious. They soak up water like a sponge, and even during the heaviest rains runoff does not occur. Furthermore, they conserve the percolated subsurface moisture efficiently. As the surface sand dries out, it forms a protective blanket for the moist sand beneath. This happens because the well-sorted and rounded grains touch each other at points, and there is much dead airspace between grains. Thus, no continuous capillary passages extend to the surface by which moisture can move up and evaporate. Further, the dead air in the dry layer provides good thermal insulation. A surface layer of dry sand only 10 centimetres (four inches) thick appears adequate to prevent significant moisture loss according to data obtained by investigation in mainland China.

Consequently, moist sand can usually be found in dune areas at depths of a few to 50 centimetres (20 inches) many months after precipitation has occurred and when the surrounding desert floor is bone dry to depths of many metres. Animals and plants are fully aware of this, and the fauna and flora associated with some desert dune masses is more varied and rich than in the surroundings. Little burrowing animals and insects live in temperaturecontrolled comfort. Predators come to the dunes in search of such animals, and, judging from artifacts, aboriginal people also found the dunes attractive. (R.P.Sp.)

Physiographic effects of man

Man accomplishes some physiographic changes directlyfor instance, by quarrying rock or digging canals-and

also contributes to the development of the Earth's surface features by influencing the performance of other agencies, as when he promotes soil erosion by clearing vegetation or initiates channel incision by building a dam. Such indirect effects are often unforeseen and may be far more powerful and long-lived than the force by which they were set in motion or directed.

In many cases, no clear distinction can be drawn between artificial and natural landforms; indeed, the direct physiographic effects of man have invited comparison with the work of glaciers, volcanoes, and termites. Though not wholly felicitous, these parallels are collectively instructive in bringing out the variety of man's handiwork. In terms of scale, the features he constructs or excavates are dwarfed by comparable landforms fashioned by other agencies; and, when viewed against the geologic time scale, the cumulative effect of man's activities appears insignificant. On the other hand, the indirect agency of man is outstanding in its pervasiveness, no physiographic process being wholly immune from its influence.

The role of man in fashioning the landscape has attracted interest since antiquity. Detailed investigation began in the late 18th century and advanced concurrently with the marked acceleration in the growth of man's power to intervene. In the course of these two centuries, man has come to dominate the physical environment of restricted areas and to affect the general environment to some degree over the entire globe. The combined pressure of technological advance and population increase has tended to enhance and accelerate the influence of man through time.

RISE OF HUMAN AGENCY

Man became an important influence on physiographic Importance change with the help of fire. Repeated burning of the vegetation cover alters its composition and hence its contribution to soil development; it can also lead to erosion by wind and water. To judge from the archaeological record, man's control of fire spans an estimated 300,000 years in Europe and Asia, more than 50,000 years in southern Africa, and at least 12,000 years in North America. The firing of vegetation in driving game and improving the yield of edible plants has been practiced by hunting and collecting communities in many parts of the world and presumably played a part in Paleolithic economics. Its cumulative effects can only be conjectured. Nevertheless, there is botanical evidence to suggest that the world's principal grasslands and prairies, as well as some major woodlands (among them the pinewoods of the southeastern United States and the teak forests of Myanmar [formerly Burma]), are the product of repeated burning over millennia. Lightning fires are too infrequent to furnish an adequate explanation. Should the agency of man be confirmed, the soils associated with the tropical and temperate grasslands would rank among the most prominent incidental effects of human agency now in evidence.

The transition from hunting and gathering to stockraising and cultivation was slow and piecemeal; extensive territories long remained subject to temporary exploitation. The outcome was mainly to concentrate and intensify the effects of man and the animals he needed on the vegetation cover: permanent clearings spread, grazing was increasingly controlled, and preferred plant species were introduced. The trend was accentuated by the rise of farming settlements such as those to be found in many parts of Southwest Asia by 6000 BC, for they made heavy demands on timber and fuel as well as the products of plant and animal husbandry. The introduction of tillage practices enabled man to modify soil structure directly; once animal power was diverted to this purpose, areas subject to prolonged cultivation were gradually sculptured into a stepped or furrowed configuration.

Although clearing, overgrazing, and cultivation were locally accompanied by soil erosion, many of the areas thus affected had undergone much more severe erosion during Paleolithic occupation. It is not clear how far burning contributed to a primarily climatic phenomenon, but there is little justification for assuming that, until the advent of farming, man invariably respected the equilibrium between soil-forming and erosive processes.

Ancient irrigation works

Materials

pyramids

and other

for the

works

Where irrigation was called for and favoured by social and physical conditions, the manipulation of soil and water left a clear imprint on the landscape. Cultivation terraces, some of them more than 3,000 years old, occupy thousands of square kilometres in Asia, Europe, Africa, and the Andes area of South America. The dikes, canals, and embankments on which the earliest urban societies depended can be traced on the great alluvial plains of the Old World, Ridged fields created in pre-Columbian times to exploit land subject to seasonal flooding have recently been identified in many parts of tropical South America. In North Africa the control of ephemeral floods in the coastal uplands awaited Carthaginian settlement and reached its apogee in Roman times; elsewhere, it was not until the Middle Ages or later that the action of running water was significantly modifed by engineering works.

Such devices had implications for landscape development that went beyond their immediate purpose. Terracing reduced the sediment yield of river basins, and the soils they held developed distinctive characteristics, especially when subject to waterlogging. In parts of Mesopotamia irrigation was not matched by adequate drainage and soon led to the accumulation of noxious salts at the surface. The embanking of streams promoted silt deposition within their channels, which, in turn, rendered them unstable and increased the incidence of flooding; the Huang Ho is a case in point. In the Tafilalt oasis of Morocco, medieval stream diversion provoked the accumulation of alluvium, reaching a maximum depth of five metres (16 feet).

Where runoff had been brought under control by damming, as in Roman Libya, or by underground drainage, as in Etruscan Italy, valley erosion was checked, and the topography now contrasts sharply with that of river basins not thus protected. Conversely, irrigation made it possible to cultivate marginal areas where the role of vegetation in shielding the soil from water and wind action was especially important; the Romans, at other times hailed as supreme practitioners of conservation, have on these grounds been held responsible for the decay that ultimately overtook large parts of their empire.

The building of cities, engineering works, harbours, monuments, and defenses had as its counterpart the extraction of large volumes of rock and clay. The Sadd-el-Kafara, a dam built south of Cairo between 2950 and 2750 BC, alone embodied 100,000 tons of material; the Great Pyramid of Khufu at Giza consists of 2,300,000 blocks with an average weight of 2.5 tons. Most of the material used in construction was obtained from quarries and floodplains. Shafts had been employed in Neolithic flint mines throughout western Europe, notably at Spiennes, Belgium, where the resulting pitted landscape extends over two hectares (five acres). By the early 4th millennium BC, shafts were in use in the copper mines of Armenia and the Caucasus. Shafts also made possible the digging of tunnels called qanāts or foggara that were as long as 20 kilometres (12 miles) in order to tap the underground water held by alluvial deposits; the aligned craterlike depressions by which they are marked are a prominent feature of the Iranian desert, where the technique has been known for 3,000 years. The scars of mining and of other forms of excavation spread with the adoption of new minerals and fuels and the dispersion of technical knowledge; qanāts are to be found in other parts of Asia and in Europe, North Africa, and the Americas.

Aerial photography has played an important part in filling in the details of the ancient man-made landscape. It has revealed the grid laid out by Roman surveyors in Tunisia and other parts of the Mediterranean, the puzzling Nazca designs of the Peruvian desert, and many mounds and dikes that fulfilled military and religious functions. The picture that emerges is one of gradation between areas subject to long-standing, though varied, direct and indirect modification and others where man's handiwork betrays short-lived, opportunist use of the land.

EFFECTS OF MODERN MAN

In reviewing the effects of modern man on the landscape, it is convenient to classify human activities in terms of the geologic processes to which they most closely correspond.

The issue of motives, and any assessment of the outcome in economic or aesthetic terms, is not central to the present discussion.

Direct effects. The technological and demographic upsurge that characterized the 18th and 19th centuries was marked by a rapid increase in the power of direct human intervention; by 1922 it was possible to claim that, in the densely populated British Isles, man's capacity for removing and comminuting rock exceeded that of all the atmospheric forces combined.

Land cultivation and mining. The uneven spread of this power is illustrated by the distribution of cultivation methods. About 11 percent of the world's land area is under cultivation, of which one-tenth is irrigated. The technology employed ranges from digging sticks to mechanical devices that wholly transform the existing soil structure and from the occasional diversion of spates to the application of specified volumes of water at controlled rates. Soil chemistry may be modified by the abstraction of nutrients by plants until their exhaustion, or it may be manipulated by rotation and chemical fertilization. Other weathering agents are influenced: frost action may be encouraged to improve tilth or may be checked if injurious to the crop.

The boundaries of the sown areas continue to fluctuate. In New England, large areas have reverted to forest in the course of the last century; conversely, drainage has added more than 600,000 hectares (1,500,000 acres) to the cultivable territory of Finland since 1941. The margins of arid areas are rendered especially unstable by rainfall variability.

The relief produced by plowing and by the excavation of drainage and irrigation canals is limited by the stability of the soil material as well as by the available power and equipment. In this respect it conforms in vertical scale to the products of water erosion, however much it may depart from the fluvial landscape in its geometric pattern. In contrast, the depths attained by open-pit mining are Quarries determined primarily by the economics of mining. The copper pit at Bingham, Utah, is more than 800 metres (2,600 feet) deep and has not yet reached the limits of rewarding excavation. Laterally, the scope is technically unlimited, although the largest quarries, such as the Hull-Rush-Mahoning iron ore pit in Minnesota, remain far smaller than the Aso caldera of Japan and other volcanic features

excavations

Open-pit mining accounts for 70 percent of the world's output of minerals and rocks. The excavations range from small borrow pits, such as the 300,000 marl pits that dot East Anglia, England, to vast stepped amphitheatres. The strip-mining of coal produces its own distinctive topography, as does the working of placer deposits by hydraulic methods or by dredging. The terrain thus affected is rapidly expanding; in the United States, for example, the production of natural aggregates increases by 5 percent each year. Because sand, gravel, and rock suitable for crushing are low in value, their extraction tends to be concentrated near urban and industrial sites. This tendency is countered, however, by the needs of highway and aqueduct construction, and it may be largely ignored where more precious minerals are involved, as in the case of the great copper open-pit mine of Chuquicamata in the Atacama Desert of Chile. Military and scientific activities. such as the explosion of atomic devices and the creation of craters by bombing, have further dispersed man's erosional activities.

Man-made pits are often bordered by waste tips and mounds. The proportion of usable to unusable solids ranges from less than 20 percent of the output in sands and gravels to as much as 14,000 percent in the case of slate. Contributing to the process are such underground workings as the gold mines of the Witwatersrand, South Africa, which yield some 60,000 tons of waste each year. The potential instability of some of these features has been borne out by the collapse of tips at Espenhain in what was East Germany in 1959 and in Aberfan, Wales, in 1966. The unconsolidated material of which they are composed has constructional value, and, together with urban and industrial waste, it is employed to level and create building land in response to economic and social pressures.

Harbours.

break.

waters.

and dikes

Geomorphic Processes

Artificial channels and coastal works. Surface waters are more widely affected. The density of the drainage network is increased by canals, ditches, and other artificial channels. Surface drains may triple the length of channel that would otherwise characterize a particular area; in parts of Scotland the increase has been 20-fold, Conversely, subsurface drainage can lead to the local elimination of organized runoff, Canals, including the Panama cut, exploit existing watercourses and also disregard watersheds; the channel that links Abidjan, Ivory Coast, with the sea bears little relationship to the natural drainage. The geometry of the channels and their floodplains is often modified to improve the efficiency of drainage; dikes, embankments, and auxiliary canals remain a prominent feature of the fertile alluvial valleys of the Old World and have transformed the valley of the Mississippi River. Lake Kariba, over 280 kilometres (170 miles) long, on the Zimbabwe-Zambia border, is the outstanding example of further diversification produced by artificial lakes and reservoirs.

Coastal modification similarly ranges from the minor adjustment of existing features to the creation of novel landforms. Most of the major harbours of the present day, including those of Sydney, San Francisco, and New York, occupy propitious sites; a few are largely artificial, such as those of Takoradi, Ghana; Sète, France; and Algiers, Algeria. The port of Ischia, Italy, lies on a crater lake that has been opened to the sea. Offshore islands are also exploited in the building of breakwaters; artificial islandsfor instance, Rincon Island in the Gulf of Mexico-may be the solution to the problems posed by offshore drilling.

Protective works range from those designed to preserve the existing situation, such as sea walls, to groins and other devices that work in conjunction with the transport by waves and currents. The creation of land at the expense of the sea has been most successfully pursued in areas already subject to coastal sedimentation. In England, the area around the Wash has gained 16,000 hectares (40,000 acres) of land since the 18th century. In the Netherlands, over 740,000 hectares (1,800,000 acres) have been won in this way since the early 13th century; the dike that blocks the IJsselmeer lies at a maximum distance of 85 kilometres (53 miles) from the former coast and has reduced the length of the coastline by about 300 kilometres (200 miles). The material yielded by the dredging of existing facilities is sometimes used for reclamation rather than being dumped at sea: a combination of dredging and filling was employed in developing San Juan Bay, Puerto Rico.

Man's direct intervention is seen to differ from other physiographic processes chiefly in its versatility. It is not unique in effecting both chemical and physical changes and transcending the distinction between the organic and inorganic worlds. Tree roots, for example, break up rocks by mechanical means and also influence microbial activity. But human agency is not confined to a specified range of environments or sources of energy. Glaciers and rivers are creatures of topography and climate; volcanoes are restricted to well-defined zones; and even the action of wind is strongly localized. Man, however, is potentially free of such constraints.

Indirect effects. The incidental effects of man's activities on the landscape have long attracted attention. Plato. for instance, ascribed the barrenness of Attica to soil erosion consequent upon deforestation; Pausanias pointed out that silting at the mouths of the Achelous and Maeander rivers was accelerated by cultivation within their catchments. Later writers came to regard such phenomena as indicative of the tendency by modern man to disturb the equilibrium attained by nature, a viewpoint that was powerfully endorsed by the soil erosion that afflicted the U.S. Midwest in the 1930s.

The difficulties to be faced in measuring such unforeseen and often undesirable developments have long been emphasized. The need remains to rely on historical evidence and on deduction based on present-day parallels, and many of the effects are still poorly understood. Nonetheless, advances in the study of soil mechanics, meteorology, geophysics, and allied fields have thrown light on some of the mechanisms by which indirect human agency operates and have demonstrated that the consequences are

sometimes out of all proportion to the energy involved in man's intervention.

Land subsidence and slope failure. In many cases the role of man is self-evident and easily evaluated. The underground extraction of solids and fluids, for example, can lead to subsidence, and its prediction presents few problems. The salt fields of Cheshire, England, are widely affected by such activity, and flooding of the depressions has formed lakes known locally as meres or flashes. The coal-mining areas of Pennsylvania provide instances both of subsidence and of collapse. Where water, oil, or gas is withdrawn from an underground stratum that is poorly consolidated, the loss of supporting pressure provided by the fluid can result in compaction. Mexico City has been subject to subsidence since pre-Columbian times because of drainage by surface channels; the process was greatly accelerated by pumping to supply urban needs, and sinking at the rate of 15 centimetres (six inches) per year was observed in places. Despite restrictions placed on pumping. parts of the city are still settling by about three centimetres each year. In the Wilmington, California, oil field, the abstraction of petroleum and gas has produced depression of the surface over an area of about 56 square kilometres (22 square miles), to a maximum depth of nine metres (30 feet). The application of large surface loads also leads to depression; at the site occupied by Lake Mead, Nevada, for example, a maximum of 175 millimetres (seven inches) of subsidence has occurred in the course of 15 years, a figure that comes close to the predicted elastic yield of the Earth's crust.

Analogous topographic changes can arise through drainage or irrigation of the soil. The drainage of organic soils promotes their shrinkage through the decomposition and oxidation of organic matter. Where the superficial deposits consist of loose, dry material of low density, such as windlain particles, the application of water sometimes produces the phenomenon of hydrocompaction. Over 500 square kilometres (200 square miles) have been thus affected in the San Joaquin Valley of California, and in places depression amounts to more than five metres.

Slope failure, like subsidence, occurs when gravitational stresses overcome the resistance of the rock material (see above Slope movements). Man may bring this about by undercutting and steepening slopes, or by changing the moisture content and hence the cohesion of deposits in which they are developed. The former is illustrated by the extensive landslides that took place during construction of the Panama Canal, one of which involved 400,000 cubic metres (14,000,000 cubic feet) of material. Infiltration from gardens and cesspools allegedly triggered an extensive landslide in the Palos Verdes Hills of Los Angeles in 1956; in three years movement exceeded 20 metres (70 feet). The Vaiont Dam in Italy was destroyed when a landslide comprising over 240,000,000 cubic metres (8,500,000,000 cubic feet) slid into the reservoir; by raising the water table, the dam itself had contributed to slope instability. In areas with a permanently frozen subsoil (permafrost), thawing may be encouraged by the disturbance or removal of vegetation or superficial sediments and soils, since these act as insulators. Highway and railroad construction in Alaska has been accompanied by landslides, slumps, and rock flows, and road surfaces are distorted by frost heaving. The vibration produced by passing traffic may also trigger movement in unstable slopes.

Techniques have been developed to preserve or restore slope stability, for example by creating an insulating layer over frozen ground or by controlled drainage of terrain weakened by seepage. The Folkestone and Warren landslips of Kent, England, have been controlled by drainage combined with coastal protection, because undercutting by wave action is an important contributory factor. In California, waterlogged clay slopes have been dried by circulating warm air through tunnels. The use of vegetation to bind the surface of cuttings and embankments is commonplace.

Erosion and sedimentation. Any change in the geometry, water discharge, or sediment load of a stream will disturb existing equilibrium conditions, and is followed by readjustment that may involve erosion, deposition, or

Underground fluide

both. The silt that accumulates behind a dam often forms a delta; in the case of the Furnish Dam, Oregon, the entire basin was filled in 16 years. By trapping sediment and altering the pattern of flow, dams often lower the river bed in the valley below the dam. The channel of the Red River of Oklahoma and Texas has in this way become both wider and deeper for a distance of 160 kilometres (100 miles) below the Denison Dam. River straightening and dredging sometimes lead to further incision by accelerating the velocity of flow, as in the Rhine, which has deepened its bed at Duisburg by two metres (seven feet) since 1900. On the other hand, man may promote deposition by introducing surplus sediment, as in the Sierra Nevada of California and other areas subject to hydraulic mining.

The incidental effects of stream modification extend to lakes and coasts, whether as changes in the water balance or in terms of the sediment supplied. The progressive fall that has characterized the Artal and Caspina seas in recent years is attributed largely to dam construction on their adlhents (inflowing streams); it has exposed 38,000 square kilometres (15,000 square miles) of land in the former and 25,000 square kilometres (10,000 square miles) in the latter. The area of San Francisco Bay has contracted by over 700 hectares (1,700 acres) since 1850, largely because of the import of sediment by rivers affected by hydraulic mining of placer gold; in contrast, Ventura Beach, California, has been deprived of much of its sand supply by

the damming of the Ventura River.

Urbanization is a further source of hydrologic change. By paving the Earth, man armours it against weathering and erosion; he also renders it impermeable and thus produces a far higher proportion of runoff (as opposed to infiltration) than would otherwise prevail. A little less than 1 percent of the world is occupied by buildings, roads, and kindred structures, but their distribution is uneven. Measurements taken in the United States have shown that, during construction, building sites release sediment at rates up to 40,000 times greater than those of corresponding rural areas under grass or woodland; for urbanized and developing zones as a whole, the factor ranges between 10 and 100. Channel flow gains little from groundwater and is therefore closely related to the incidence of precipitation; runoff is rapid, and the proportion lost to sewers is quickly restored to surface drainage. Hence, discharges are relatively higher and more short-lived than in areas where infiltration plays a prominent role in the hydrologic cycle and, in turn, contribute to stream load by producing channel enlargement. In brief, the progress of urbanization enhances stream activity, always providing that some erodible material has been left exposed to the action of water.

Like river basins, stretches of shoreline operate as physiographic units that adjust to man-made modification by changes in geometry or in process. Where breakwaters, jetties, or groins are erected to trap material, further erosion may take place along the coast if the beach depends for its equilibrium on the supply of sand or shingle by longshore movement of sediment. Much agricultural land has been lost in this way near Durban and Madras, and a breakwater erected to form a harbour at Santa Barbara, California, caused silting in the harbour and erosion along more than 15 kilometres (nine miles) of coast. The extraction of shingle can be equally deleterious by robbing the beach of its protection against wave action; it has aggravated erosion along the Holderness coast of England, indicated by the loss since Roman times of a strip averaging four kilometres (two miles) in width.

At times man intervenes to restrain erosion, as when he fixes coastal dunes with the help of vegetation, or seeks to establish or restore a balance between coastal erosion, and deposition. In England, trucks have been employed to earry shingle from the beaches of Rye to those from which it had been derived at Winchelsea, and a similar function is fulfilled by pumping sand across the erosive channel that leads to Palm Beach, Florida. To maintain or create a deep navigable channel, however, submarine erosive processes are turned to advantage by means of training walls or by judicious dredging. Liverpool Docks and the New York Harbor both benefit from this stratagem.

Man's indirect influence is displayed most prominently in the varied physiographic changes that are grouped under the heading of soil erosion and that affect two-thirds of the Earth's land surface. In the United States, for example, 5 percent of the land suitable for cultivation or forestry has been entirely ruined, 15 percent has lost three-quarters of its topsoil, and 41 percent is subject to moderate erosion. In addition to its local implications, soil erosion affects other landscape elements and the performance of allied processes. The incidence of violence of flooding is increased by rapid runoff and low inflitration; stream channels are choked by silt; and material removed by wind erosion accumulates in drifts.

Many factors help to determine the stability of soils, and the scope for human intervention is correspondingly large. Differences in the character and density of the vegetation cover generally account in large measure for areal variations in the severity of soil erosion; hence, the importance of fire and burning, as previously discussed. In the United States it has been found that land used for row cropping may erode at rates that are 100 times greater than for woodland or pasture; in Cyprus, the sediment yields from vineyards are more than six times those on comparable terrain under forest cover. In either case, slight modification of the vegetation cover will produce disproportionate

changes in the rate of soil loss.

Soil structure provides further opportunities for inadvertent triggering or acceleration of erosional activity. Vegatation and plant litter protect the soil against the impact of raindrops and the action of running water and wind. A soil structure that is resistant to these forces may be destroyed by compaction, whether by hooves or vehicle tires. In many badly eroded areas, gullies are fed by runoff from roads that have not been provided with adequate gutters. Once linear erosion is initiated, soil moisture is locally depleted; the benefits of good soil structure are overridden by downcutting and bank collapse.

Unlike vegetative cover and soil structure, whose reinstatement is hampered and ultimately precluded by erosion, the factor of topography is amenable to correction; hence the emphasis on terracing and contour plowing in

many soil conservation schemes.

Climate and air pollution. Rainfall intensity and the duration of individual storms are important factors influencing flood flow and the protective value of the vegetative mat, particularly in semiarid areas. Although large-scale weather modification by man is still in its exploratory stages, there is little doubt about man's capacity to stimulate precipitation by seeding suitable clouds with condensation nuclei. Hail suppression by this means is already practiced, and the mitigation of destructive downpours appears feasible. The climatic changes associated with urbanization are not wholly irrelevant to erosion, because they may involve increases in the total annual precipitation of up to 18 percent, a value that will be enhanced by the impermeability of the terrain on which it falls.

Air pollution, which is an important element of urban climates, may be influential in rural areas if it is virulent enough to weaken the vegetation cover. The emission of sulfur dioxide by the copper smelters of Ducktown, Tennessee, has had this effect and thereby led to severe gullying; a similar chain of events has been reconstructed for the Swansea Valley of Wales in the 18th and 19th centuries. It is also suggested that overgrazing in parts of the Rajasthan desert of India has increased the local dust cover and that this, in turn, leads to desert formation.

Air pollution is suspected of influencing world climate as a whole. The carbon dioxide content of the atmosphere has increased by an estimated 11 percent over its value in 1850, and the associated warming (greenhouse effect) sput at 0.6 percent between 1880 and 1940, It has long been held that the combustion of fossif fuels is a primary source of the additional carbon dioxide; the oxidation of humus, peat, and other organic material is also regarded as a major contributor, but even here man retains some responsibility because the process is encouraged by forest clearing, cultivation, and the drainage of bogs. Overall, the extent of human influence on long-term temperature changes has not yet been precisely determined.

Urbanization and hydrologic change

Earthquakes. Forces acting within the Earth are not immune from the influence of man. It has been observed that the incidence of earthquake shocks has increased near the sites of large reservoirs, among them lakes Mead, U.S.; Kariba, Zimbabwe; Koyna, India; and the Arapuni River, New Zealand. On the other hand, there is some evidence to suggest that Lake Mead has reduced earthquake activity, as the seasonal variations in its level during 1939-51 show some correlation with the number of shocks within a given radius. Underground nuclear explosions are followed by aftershocks, and some believe that they may trigger impending earthquakes in the vicinity. This has given rise to proposals for the controlled release of strains within the crust by means of explosions, in order to avert major earthquakes. The finding that the leakage of fluids into fault zones appears to affect their activity has similarly encouraged attempts to lubricate lines of crustal fracture subject to intermittent but large-scale displacement.

Interaction of human and natural forces. Other environmental changes that have been attributed wholly or in part to human agency can be explained in other ways. Many of the erosional features that are regarded as characteristic of accelerated erosion are duplicated in the geological record for periods apparently immune from human depredation. The sediment yields and erosional rhythms they represent are in some cases found greatly to exceed those now prevalent. In New Mexico, for example, ancient arroyos appear to have formed at a rate that is more than nine times greater than those of the immediate prehistoric and historic period; and in some valleys in Iowa the deposition of alluvium in prehistoric times took place at over twice the modern rate. These findings challenge the view that a placid physiographic regime was disrupted by abuse of the land, although the possibility that abuse of the land is a long-standing attribute of man has already been raised. An alternative approach is to postulate changes in the climatic conditions governing physiographic processes. In the Mediterranean area, for example, erosional features often attributed to medieval deforestation and overgrazing can be interpreted in terms of a slight change in the seasonal incidence of rainfall. The onset of gullying in the southwestern United States is attributed by some to the arrival of white settlers armed with herds of cattle and metal plows, and by others to a climatic change that led to a weakening of the protective grass cover and perhaps also to a higher incidence of erosive floods.

In many such cases the answer probably lies in the combined effect of human and climatic influences. Man's potential for influencing other physiographic processes is understood; the difficulty lies in isolating his contribution to the landscape, which is a prerequisite for effective control of deleterious physiographic change.

RIBI IOGRAPHY

Comprehensive works: R.W. FAIRBRIDGE (ed.), The Encyclope-dia of Geomorphology (1968), a many-authored, international, one-volume encyclopaedia of geomorphic terms, processes, and studies, with precise definitions and relevant source literature: and L.C. KING, The Morphology of the Earth, 2nd ed. (1967), provides a detailed discussion of the Earth's surface features and the fundamental forces affecting their development.

Tectonism: The following books give general but moderately technical treatment to the physiographic effects of tectonism. The Encyclopedia of Geomorphology, ed. by R.W. FAIRBRIDGE (1968), includes articles on all major aspects of the physiographic effects of tectonism. For a more modern but somewhat technical account of all physical attributes of the Earth that are related to tectonism, see P.J. HART (ed.), The Earth's Crust and Mantle (1969).

Weathering: Weathering is discussed in some detail in several general geomorphological and geological texts. B.W. SPARKS, Geomorphology, ch. 3 (1960), is notable for its critical approach. A. HOLMES, Principles of Physical Geology, 2nd ed. (1965); and W.D. THORNBURY, Principles of Geomorphology, 2nd ed., ch. 4 (1968), are quite comprehensive. Several aspects of weathering and its results are illustrated in C.R. TWIDALE, Geomorphology with Special Reference to Australia, ch. 4 and 5 (1968), and

with M.R. FOALE, Landforms Illustrated (1969).

Slope movements: LAURITS BJERRUM, Mechanism of Progressive Failure in Slopes of Overconsolidated Plastic Clays and Clay Shales (1966), a modern theoretical analysis of slope stability in overconsolidated clays; EDWIN B. ECKEL (ed.), Land-slides and Engineering Practice (1958), a summary of research on the origin and correction of landslides in the United States with respect to highway construction; ALBERT HEIM, Bergsturz und Menschenleben (1932), a report on rock falls and mountain slides in the Alps, demonstrated by many examples; S.E. HOLLINGWORTH, J.H. TAYLOR, and G.A. KELLAWAY, Large-Scale Superficial Structures in the Northampton Ironstone Field (1944), the first description of slope deformations originated by bulging in valley bottoms; C.F.s. SHARPE, Landslides and Related Phenomena (1938), a survey of slope movements. their classification, and relationship to geomorphological cycles; KARL TERZAGHI, Mechanics of Landslides (1950), a classic work on processes leading to landslides and considerations on modern preventive measures; QUIDO ZARUBA and VOJTECH MENCL, Landslides and Their Control (Eng. trans. 1969), a book summarizing the economic importance of landslides, their relation to geological conditions, and controlling measures-includes a comprehensive list of literature.

(O.Z./Ed.) Fluvial processes: B.R. COLBY, "Fluvial Sediments: A Summary of Source, Transportation, Deposition, and Measurement of Sediment Discharge," Bull. U.S. Geol. Surv. 181-A (Nov. 1963), a brief review of the range of river sediment relations. ships; F.M. HENDERSON, Open Channel Flow (1966), a modern text in the hydraulics of flow in all kinds of open channels. includes several excellent chapters on sediment transport and the behaviour of natural rivers not found in any other text, for the advanced student; s. LELIAVSKY, An Introduction to Fluvial Hydraulics (1955), contains varied treatment of specific topics related to natural channels and canals, includes information from river control works in Europe: L.B. LEOPOLD, M.G. WOLMAN, and J.P. MILLER. Fluvial Processes in Geomorphology (1964), a textbook in analysis of landforms with primary emphasis upon rivers, contains much empirical information on rivers, as well as brief treatment of related hydraulic phenomena; H. ROUSE (ed.), Engineering Hydraulics (1950), a treatise containing separate chapters on a variety of topics in hydraulics ranging from hydraulic machinery to sediment transport, for the advanced student.

Processes of glaciation: C. EMBLETON and C.A.M. KING, Glacial and Periglacial Geomorphology (1968), a scholarly, compre-hensive treatment of the origin of glacial and periglacial landforms, written for the student with some previous knowledge of geomorphology or physical geography, and including many references to original works, organized on a chapter-by-chapter basis; R.F. FLINT, Glacial and Quaternary Geology (1971), encyclopaedic and world coverage of all aspects of Pleistocene glaciation, Quaternary climatic changes, the fossil record, and geomorphic history of nonglaciated regions, including a bibliography of more than 1,300 entries covering the relevant literature of the world.

Wind action: R.A. BAGNOLD, The Physics of Blown Sand and Desert Dunes (1941), the scientist's bible for the mechanics of wind action, based on extended field observations and labo ratory experiments; E.E. FREE, The Movement of Soil Material by the Wind (1911), the most comprehensive and best documented description of wind work in the English language; w.F. HUME, Geology of Egypt, vol. 1, ch. 3 (1925), a comprehensive review of wind effects and action in a part of the Sahara, a classic locality; w.s. COOPER, Coastal Sand Dunes of Oregon and Washington, pt. 2, pp. 25-76 (1958), an excellent digest of basic principles bearing on wind, sand, dunes, and relationships with vegetation; E. IRVING, Sand Control Research in Communist China (1962), a translation of reports on 23 papers given at a symposium in Peking in 1960, provides excellent insight into research on sand control and sand mechanics by a large number of Chinese scholars.

Physiographic effects of man: R.L. SHERLOCK, Man As a Geological Agent (1922), deals with the British Isles in unusual detail. Physiographic change is one of the many topics treated in an international symposium on Man's Role in Changing the Face of the Earth, ed. by WILLIAM L. THOMAS, JR. (1956). ROBERT F. LEGGETT, Geology and Engineering, 2nd ed. (1962), considers many of the problems that confront the civil engineer. The use of air photographs in tracing prehistoric, classical, and medieval man-made features is illustrated in JOHN BRADFORD, Ancient Landscapes (1957). GEORGE PERKINS MARSH, Man and Nature (1864), is the first general study on the subject.

German Literature

erman literature consists of the literary works of the German-speaking peoples of central Europe. Its development having transcended oft-changing political boundaries, it includes not only the writings from what are now the two republics of Germany but also those from Austria and Switzerland

This article provides a concise historical survey of Ger-

man literature. Its major periods and movements are discussed in relation to broader cultural developments throughout Europe and its ties with or indebtedness to other literatures are noted.

For coverage of related topics in the Macropædia and Micropædia, see the Propædia, section 621, and the Index. The article is divided into the following sections:

Old High German period

Although Gothic was the earliest recorded Germanic language and the only east Germanic language on which there is trustworthy information, only a translation of the Bible by Ulfilas (c. 311-c. 383), a Gothic bishop, has survived

in fragments. The first written records of the western German tribes dated from the second half of the 8th century. There is, however, evidence of an earlier, orally transmitted literature, consisting of short Heldenlieder (songs celebrating the exploits of famous heroes), hymns connected with pagan religious rites, battle songs, and laments for the dead. Although none of these was recorded, their substance formed the basis of later popular heroic epics. As in other areas, the first significant texts were a product of the efforts to spread Christianity. Many were translations from Latin, as, for example, the Alemannic version (c. 800) by an unknown author of De fide catholica ("Concerning the Catholic Faith") by the Spanish churchman and scholar Isidore of Seville (c. 560-636) and the translation of Boethius' Consolation of Philosophy made about 1000 by Notker Labeo of the Swiss monastery of St. Gall.

The few extant verse works were more original, albeit religious and didactic in subject. The largest, the Evangelienbuch (c. 870; "Book of the Gospels") by Otfrid of Weissenburg, presented the life of Christ in a form rivaling that of the Heldenlieder. The poem is noteworthy as the · first German work to replace the alliteration of Germanic tradition with the end rhyme of Medieval Latin verse.

Despite the church's opposition to interest in anything pagan, there survived a few pagan works, such as the Zaubersprüche-magic spells used to protect domestic animals and for various other everyday concerns. The fragmentary Hildebrandslied (c. 800; "Song of Hildebrand")-a grim account of a duel between father and son-is more interesting and is important as the sole relic of heroic verse in Old High German. Throughout the period the vernacular was sporadically used as a literary medium, but scholars continued to prefer Latin. The movement for ascetic reform, which spread from the monastery of Cluny in France all over western Europe in the first half of the 10th century, discouraged churchmen from writing for the laity, and hence there was even less recorded literature in the vernacular for about a century. By the time the vernacular was written again, important changes had occurred in the language and the old ecclesiastical didacticism had been replaced by courtly feudalism.

Middle High German period

CHARACTERISTICS OF THE PERIOD

The changes accompanying these events marked the transition from Old to Middle High German, one important point being that the knight replaced the cleric as a poet. Early works still reflected the clerical tradition, but already in Heinrich von Melk's Von des tôdes gehugede (c. 1160; "Remembrance of Death") the feudal knight's love of combat was used to illustrate the transient nature of life. The main literary forms at this time were Minnesang (love lyric) and epic. Poets, mainly noblemen, expressed their love according to courtly convention or told traditional tales of combat and romance.

It was long believed that the epic of local tradition was created by the Spielmann (wandering minstrel), who collected and recited heroic songs on popular legends and began to link together the Heldenlieder to form longer epic narratives. Many scholars have abandoned this view, however; the minstrels are believed to have been illiterate and poorly educated, and there is no evidence that they composed these works. Probably the earliest such composition was König Rother (c. 1160), a repetitive tale of violent bride abduction. The poets often provided interesting, sometimes amusing, commentaries on the life

Holden. lieder

Pagan works of their times. Salman und Morolf treated the conflict between Christian and pagan communities, reflecting an interest aroused by the Crusades also evident in Orendel and Sankt Oswald. With the Alexanderlied (c. 1130), a free rendering of the Roman d'Alexandre, German poets began drawing on successful French epics.

began drawing on successful Frenci epics.

The anonymous Austrian poet who wrote the Nibelungenlied (c. 1200–10; "Song of the Nibelungs") displayed great dramatic skill and poetic ability in recounting a well-integrated story of the hero Siegfried that combined songs of heroic legends about historical events and an epic concerning the destruction of the Burgundians, or Nibelungs, in 437. Gudrun, composed around 1210, centred on the heroine Gudrun's steadfastness in the face of abduction, while a collection, Das Heldenbuch ("The Book of Heroes"), includes romances about Theodoric the Great.

PRINCIPAL LITERARY FORMS

Court epics. The nationalistic epics, popular principally in the south, were counterbalanced in the west by court epics based on French models. The first notable work, by Eilhart von Oberg, dealt with the Arthurian subject of Tristrant und Isalde (c. 1170). Although Dutch, Heinrich von Veldeke (Henric van Veldeke) established himself as the father of the German court epic with his Aeneid (c. 1175-86), which was based on a French source. The three most famous poets of the court epic were Hartmann von Aue, Wolfram von Eschenbach, and Gottfried von Strassburg. Their work, dated largely between 1190 and 1210, was concerned with the knightly virtues of moderation, constancy, loyalty, and the duty of service to superiors and to God. Hartmann was an artistic and lucid storyteller. In Erec and Iwein, based on the French romances by Chrétien de Troyes, he handled the conflict between private inclination and public responsibility that existed for the medieval knight, and in Gregorius and Der Arme Heinrich ("Poor Heinrich") he illustrated man's relationship with God. Wolfram von Eschenbach's Parzival employed highly original imagery in a subtle and ambitious treatment of man's search for truth in his relationship with God, its hero Parzival progressing in maturity to become keeper of the Holy Grail. Gottfried von Strassburg took Thomas of Brittany as his source for his Tristan: a careful master of form and artistry, he was less concerned with otherworldly considerations and concentrated on an ideal primacy of love in this life.

Later epic poets could not equal these three. Heinrich von Türlin's epic Die Krome ("The Crown") followed Hartmann but was hadly written. Despite the prolific writing of Rudolf von Ems and Konrad von Würzburg, the epic tradition gradually weakened. Although Meier Heinbrecht (c. 1250), by Wernhert the Gardener, movingly described the lawlessness and violence of decadent feudal society, the social level of its subject and its realistic approach announced the end of courtly titerature.

Courtly lyric. The other important literary form, Minnesang, the courtly love lyric, like the court epic, borrowed its content and stanza form from French or Provençal models. Its poets were minor noblemen who often became court poets to the higher nobility or traveled as minstrels throughout Germany, Austria, and Switzerland. Many of the poems representative of Minnesangs-frühling ("springtime of Minnesang") were recorded in an early 14th-century manuscript collection, the Codex Manesse, attributed to Swiss-born Rudiger Manesse (1224–1304).

About 1190 Reinmar von Hagenau became court poet to the dukes of Austria, shortly after he had tutored Walther von der Vogelweide. Walther's love lyries, which united the courtly style for which Reinmar became famous with popular, natural love poetry, were the finest produced in medieval Germany, and he influenced later poets throughout Austria and Tirol. His Sprüche—moral and political poems—dealt with his relationship with patrons, the struggle between empire and papacy, and the spiritual value of crusade and pilgrimage. This interest in worldly wisdom was continued by the Bavarian Neidhart von Reuenhal and again reflected by the popularity of Freidank's Bescheidenheit (c. 1230; "Modesty" or "Moderation") and Hugo von Trimberg's Rener (c. 1300; "The Runner" with the strugger of the properties of the properties of the structure of the properties of the properties of the structure of the properties of the properties of the properties of the structure of the properties o

Prose and drama. Medieval German prose literature was less substantial than that in verse. Berthold von Regensburg's sermons were eloquent vernacular works, and the writing of Mechthild von Magdeburg served as an early example of the mysticism that became important in the 14th century. The Ackerman aus Böhmen (c. 1400; Death and the Ploughman) by Johannes von Tepl marked the beginning of the humanistic tradition in Germany. The quality of Tepl's prose was unrivaled until the Reformation. Notable nonreligious works in Middle Low German were the Sāchsische Weltchronik (c. 1235; "Saxon World Chronicle"), a history of the world compiled from Latin sources, and Sachsenspiegel (c. 1225; "Mirror of Saxon,"), a compendium of medieval law written by Eike von Repsau.

Early works in drama—the fragmentary Easter play of Muri and the St. Gall Passion play (c. 1330)—led to a growing volume of popular morality and miracle plays, which were part of the church's campaign to instruct and inspire the lower orders. By the beginning of the 15th century, popular drama for secular entertainment appeared in the form of Fastnacht, or carnival, plays. These farcical comedies became increasingly popular, finally gaining ressectability in the 1500s with the works of Hans Sachs.

Morality and miracle plays

From Middle High German to Baroque

The fall of Constantinople to the Turks (1453) created a fear of the Turk in western Europe that was often reflected in literature of the 16th and 17th centuries, while territorial rulers in Germany grew more independent at the expense of the empire. The invention of printing with movable type around 1440 revolutionized printing and literature. The old art forms continued, however, beyond 1440medieval allegory, folk songs, songs of love and nature. and ballads survived in profusion. Hans Folz introduced more liberal rules to revive the art of the Meistersinger (members of guilds for cultivating singing and poetry). In the south, Fastnachtsspiele ("Shrovetide plays") became a vehicle of satire and broad humour, while in the north they were more restrained. Collections of comic anecdotes (Schwänke) evolved, often grouped around a single hero; anecdotes connected with Till Eulenspiegel, a 14thcentury peasant jester, acquired a European reputation. From about 1450 a new bourgeois realism evolved.

THE COURTLY REVIVAL AND THE HUMANIST MOVEMENT
The Burgundian "renaissance." At some princely courts
the Burgundian "renaissance." Notered a revived interest
in medieval chivalry. At Innsbruck, Duchess Eleonore of
Austria wrote a prose version of a French chivalrous romance, Pontus und Sidonia (1456); at Rottenburg, Jakob
Potterich von Reichershausen's work fostered a cult of
Wolfram von Eschenbach. Medieval poems were printed,
either in their original verse form or in prose versions of little literary merit. The allegorical works of the Holy Roman
emperor Maximilian I, Weiskunig ("The White King")
and Theuerdank ("Noble-Mind"), represented probably
the last attempt to revive medieval chivalrous ideals.

Humanism. In sharp contrast to this courtly renaissance stood the new element in German literature after 1450; the humanist movement. The humanists between 1450 and 1480 drew their inspiration from Italy. Albrecht von Eyb, Heinrich Steinhöwel, Niklas von Wyle, "Arigo" (probably the pseudonym of Heinrich Schlüsselfelder), and Antonius von Pforr were chiefly translators who produced versions of many Latin classics, some Greek and Indian ones, and Italian works, including Boccaccio's Decameron.

German humanism took a different turn after 1480. Conradus Celtis, Eobanus Hessus, and others were closely associated with university circles and wrote almost entirely in Latin. A strong patriotic and political strain was evinced in the Germania (1501) of Jakob Wimpfeling. A lively interest in German history appeared in the work of Beatus Rhenanus, in the Chronik der Abbebte von St. Gallen (1533; "Chronicle of the Abbots of St. Gall") of Joachim Vadianus (Joachim von Watt), and in the Bayerische Chronik (1533; "Bayarian Chronicle") of Aventinus.

The humanist impact was more direct in the drama.

The love lyrics of Walther von der Vogelweide Revitalization of drama by humanism

A lively dramatic tradition was established as part of university courses. Roman comedies and Latin plays by modern authors were performed for moral instruction and to teach eloquence. These plays contrasted sharply with the medieval dramatic types, and from them 16th-century German drama developed. Later this Latin drama was turned to the service of the Reformation.

The concentration on Latin by the most gifted writers of the age goes far to explain why vernacular literature between 1490 and 1520 was so scarce. Satiric or didactic works predominated; the most famous work of the 15th century, Das Narrenschiff (1494; "The Ship of Fools") by Sebastian Brant, reviewed all the vices of the age. In the Low German Reinke de Vos (1498; "Reynard the Fox"), verse was accompanied by a prose commentary applying the satirical episodes to contemporary evils.

Austrian literature under the Habsburgs. In Austria the vast expansion of the Habsburg empire brought the imperial chancellery from the Prague of the Luxembourg dynasty to the Vienna of the Habsburgs, carrying with it a double heritage: the German literary language and a humanist disposition and care for style. The emperor Maximilian I, himself a writer, made Vienna, through its chancellery and university, the leading humanist city in Germany with the aid of the scholars Conradus Celtis. Johannes Spiessheimer (Cuspinian), and Joachim Vadianus (von Watt).

Vienna acquired a theatre in the early years of the 16th century with the court plays of Celtis and the monastery plays of the abbot of the Schottenkloster ("Scottish," i.e., Irish, monastery), Benedictus Chelidonicus. The German plays of the schoolmaster Wolfgang Schmeltzl were first performed in the Schottenkloster. From 1554 onward the Jesuits created out of the dynastic alliance of Austria and Spain a community of religious conviction and mental inclination. They began to perform a considerable repertoire of plays, and at the same time the Italian opera developed and was patronized especially by the emperors. The Viennese Baroque theatre became one of the artistic triumphs of Europe.

The individual regions flourished too. Tirol had its own courts from time to time. From 1430 there was an abundance of sacred and secular drama. A century later, in Sterzing, Vigil Raber was collecting and rewriting the plays of the people. About 1570 Archduke Ferdinand of Tirol led a poets' court, whose preacher was Johannes Nas, while the monk Laurentius von Schnüffis, from being theatrical producer to a duke, became a mystical lyricist. Salzburg had a life of its own, shining through a humanist, Paul von Hofhaimer, who set its tone, through the theatre of the archbishop's court and through the Benedictine university founded in 1620. Styria had a wide range of artistic interest in the great monasteries such as Kremsmünster, where Simon Rettenbacher wrote religious plays. Christoph van Schallenberg, Wolfgang Helmhard von Hohberg, and Katharina von Greiffenberg, poets who belonged to the nobility, were Protestants. It was the emperor Ferdinand II, sometime ruler of Styria, who decided the battle against the Reformation, first in Styria and then in his other lands. The voice of the triumphing church was uplifted in Vienna by Abraham a Sancta Clara, Habsburg

THE REFORMATION

The Reformation and the vigorous protest of Martin Luther against ecclesiastical abuses affected life in Germany; it left little room for purely aesthetic considerations. The Humanists, who favoured reform without doctrinal changes, mostly held aloof, though with certain notable exceptions: Ulrich von Hutten, hoping for a political reformation too, supported Luther's cause in a series of pamphlets; Philipp Melanchthon, a Greek scholar, introduced the Humanist tradition into Protestant schools. But apart from the Humanists, almost every writer of note was preoccupied with the Reformation.

court preacher and master of Baroque German prose.

From the torrent of printed works that swept over Germany a few had literary merit: Luther's various writings, his eloquent Reformation pamphlets of 1520, for example, or his terrible condemnation of the peasants' revolt; Die 15 Bundsgenossen (1521-23; "Fifteen Comrades"), in which Johann Eberlin von Günzburg attacked religious abuses: Thomas Murner's satires in defense of the old religion; the fierce anti-Catholic satire in the Fastnachtsspiele of Niklaus Manuel of Bern; and the writings of Sebastian Franck, an independent radical thinker.

Luther's influence. In three respects the Reformation had a lasting effect on German literature. First, Luther's Bible translation (New Testament, 1522; Old Testament, 1534) was not only based for the first time on Hebrew and Greek texts but also achieved a vigorous, popular German style. It exercised an incalculable influence on the style and ideas of later German writers. Second, Luther established congregational hymn singing as an essential part of the Protestant service and wrote several hymns. His example established a tradition of hymn writing that has been a major contribution to the Christian world. Third, Luther had commended certain biblical subjects as suitable for plays, encouraging many dramatists-of whom Sixtus Birck, Paul Rebhuhn, Joachim Greff, Burkhard Waldis, and Jörg Wickram were the most outstandingto write plays in German as vehicles of Lutheran teaching. Modeled on the Latin school drama, these plays marked

a break with medieval types of drama. Swiss-German literature of the Reformation. The activities of the religious reformer Huldrych Zwingli had an indirect influence on literature. Zwingli himself wrote mainly in Latin. The so-called Zürich Bible of 1529 was gradually adapted to conform with the Luther Bible, which tightened the connection between Swiss and German writings. As a result of Zwingli's work, the Protestant majority of German-speaking Switzerland established a permanent connection with Protestant parts of western Switzerland and with Protestant countries abroad. The anonymous play about William Tell from the canton of Uri was a forceful and popular expression of Swiss patriotism. Gilg Tschudi's Chronicon Helvetikum (1734-36 "Swiss Chron-

icle"), covering the years 1000-1470 in Swiss history,

Other writings of the time. The Reformation did not

endured as literature.

account for all the vernacular literature after 1520. In scholarly works, such as the treatises of the Swiss doctor. alchemist, and scientist Paracelsus (Theophrastus von Hohenheim), German was beginning to replace Latin. But satirical or didactic works remained predominant, as, for example, the proverbs by Johann Agricola. The fable enjoyed a revival: Luther's translations from Aesop had no special merit, but Erasmus Alberus in his Fabeln (1534) and Burkhard Waldis in his Esopus (1548) turned the fable into a lively minor genre. Grobianus (1549) by Friedrich Dedekind, a satirical Latin guide to table manners, was translated into German by Kaspar Scheidt in 1551.

Apart from Luther, the most prolific and characteristic writer of the century was Hans Sachs of Nürnberg. His works, didactic in aim but entirely unpolemical, reflected ideals of the devout, upright, industrious Lutheran townsman and artisan. The greatest of the Meistersinger, he brought the form to perfection and virtually to an end, despite attempts at revivals by later poets. Sachs was at his best in comic verse anecdote and Fastnachtsspiel.

As the tide of Reformation polemics receded, works of pure entertainment came into greater prominence. The popular chapbooks were often prose versions of medieval verse romances or were adapted from foreign sources. The stories of Fortunatus, Magelone, and Melusine were favourite reading far beyond the 16th century. The public also found distraction in collections of anecdotes. The Schimpf und Ernst (1522; "Jest and Earnestness") of Johannes Pauli had didactic aims, but entertainment was the sole aim of Jörg Wickram's Rollwagenbüchlein (1555; "Coach Book") and of similar collections by others. The modern novel began in Wickram's more substantial prose narrative-for example, Der Goldfaden (1557; "The Gold Thread")-and in the German translation (1569-95) of the Spanish chivalrous romance Amadis de Gaula.

THE CLOSE OF THE 16TH CENTURY

The Council of Trent (1545-63), which attempted to reform the Roman church, and the advent of the Catholic

Drama as a vehicle for Lutheran teaching

The works of Hans

Literature of the Reformation

Society of Jesus gave religious controversy a new turn. The Jesuits adapted the Latin school drama for educational purposes. Meanwhile, the Protestant academy in Strassburg, especially under the humanist Johannes Sturm, developed a rich educational and dramatic tradition.

In the last quarter of the century the most outstanding author was Johann Fischart, many of whose works were directed against the Jesuits, the Counter-Reformation, and notably a brilliant preacher, Johannes Nas. In all Fischart's writings, the didactic aims of the age were combined with an interest in literary form. Das glückhafft Schiff (1576; "The Ship of Good Fortune") was, formally and stylistically, one of the most distinguished poems of the century. Fischart's contemporary Philipp Nikodemus Frischlin was the last notable Latin dramatist of the century. On the other hand, the versions of Psalms by Paul Schede Melissus and Ambrosius Lobwasser, on the Calvinist model of Clément Marot, added a new element to the rich tradition of Protestant hymn writing, while an anonymous chapbook, Historia von Dr. Johann Fausten (1587), gave rise to the whole European Faust tradition. A noteworthy feature in the last years of the century was the arrival in Germany of troupes of English actors whose repertoire included versions of contemporary English plays. They influenced Jakob Avrer and Heinrich Julius, duke of Brunswick,

The 17th century

THE CHARACTER OF THE PERIOD

German 17th-century literature, widely known as Baroque literature, was a product of the times and of the social situation in Germany. Ushered in against a background of religious fervour and strife and political uncertainty, the early period was dominated by the Thirty Years' War and the shadow it cast over life. The local context was one of princely absolutism, each ruler emulating Louis XIV's court of Versailles and supporters of the Reformation struggling against those of the Counter-Reformation, New scientific discoveries were set in a society overshadowed by the influence of Luther, Machiavelli, Petrarch, and the Renaissance figures of the preceding century.

Baroque literature was dominated by writers who were guided by a sense of occasion rather than by the value of experience. They did not express themselves subjectively but used a medium of conventional images and strict formal patterns that heightened the emotional tensions of their themes. The themes were those common to European literature of the period and appeared in the lyric, epic, and drama: "fickle fortune" presides over the world, worldly pleasures are illusory, and man's duty is to fulfill his actor's role on the stage of life. Baroque literature presented these roles as examples of how man may escape the toils of fortune and cheat time: the martyr scorns the world and aspires to eternity, the statesman uses the present to his advantage, the stoic endures steadfastly, the hermit flees, while the pastoral figures escape to makebelieve and the mystic seeks union with God.

MAJOR WORKS OF THE PERIOD

Lyric poetry. Lyric poetry quickly reached a high standard. In the Buch von der deutschen Poeterev (1624: "Book on German Poetry"), Martin Opitz demonstrated an elevated literary style in German, formulated rules such as the observance of stress in lines, and made other introductions and suggestions that he further demonstrated in his own poetry. His ideas were widely adopted and had a formative influence on later poets, including Georg Weckherlin and Paul Fleming.

Given the basic similarity of many of its themes, the variety of Baroque verse is surprising. Paul Fleming's love poems and sonnets revealed emotional depth and lyric power, Andreas Gryphius was simultaneously pessimistic and religious, while formal dexterity in the patriotic poet and novelist Philipp von Zesen and verbal exuberance in the nature poetry of Johann Klaj illustrated an urge to experiment. Baroque poets wear masks: Gryphius regally expressed the existential problems of the day; Christian von Hofmannswaldau was a virtuoso of form who was intellectually flamboyant or soberly sincere according to

his theme. In an age concerned with ultimate values, poets wrote both secular and religious verse, and in both this variety was present. The outstanding Lutheran poet Paul Gerhardt wrote hymns of quiet simplicity and warmth, the Jesuit Friedrich von Spee wrote religious pastoral lyrics, while Ouirinus Kuhlmann was a mystic visionary.

The intellectual temper of the age found admirable expression in the epigram, which was developed to a fine art by Angelus Silesius and Friedrich von Logau. The variety of Baroque lyric poetry was matched by its volume.

Drama. In the first half of the century, vernacular drama was relatively uninspired. Later, with Daniel Caspar you Lohenstein, a dichotomy between excess of feeling and acuteness of intellectual perception was expressed in full-blown rhetoric. The most notable works of the period were those of Jakob Bidermann and Gryphius. Bidermann's Jesuit dramas dealt with themes of mutability. worldly vanity, and the urgency of salvation with great effectiveness. Gryphius' tragedies and comedies focused on stoicism and personal integrity. His work was literary rather than popular and so had little permanent influence, despite its artistic merit. The increasingly popular masques, ballets, and operas were to lay the foundations of the later, very different drama of Germany.

Prose narrative. The development of the novel was considerably influenced by Spanish, French, and neo-Latin sources. A host of foreign translations followed that of Mateo Alemán's Guzmán de Alfarache in 1615. Many were large, diffuse works, amalgams of moral and didactic elements with fantasy and amusement designed to satisfy the thirst for knowledge of the times. Some read like formal exercises in a particular form, but two writers stood out: the Austrian storyteller Johann Beer, who foreshadowed 18th-century realism, and Hans Jacob Christoph von Grimmelshausen, whose Abenteuerlicher Simplicissimus (1669; The Adventurous Simplicissimus) was one of the great novels of German literature, incorporating the principal themes of the age with metaphysical depth and religious insight.

Philosophy and criticism. The Silesian mystic Jakob Böhme was outstanding as an original and influential philosopher whose doctrines inspired several religious separatist movements. Gottfried Leibniz' achievements in philosophy (see below) summed up the age and pointed toward the literature of the 18th century, when Baroque was to be rejected until its rediscovery in the 20th century.

The 18th century

THE AGE OF ENLIGHTENMENT

Rationalism. If religion was the dominant factor in German intellectual and spiritual affairs in the 17th century, the Enlightenment of the 18th brought about a reaction. Man now claimed to be able to understand the universe by virtue of his possession of the divine gift of reason. Empirical and idealist thinkers alike were united in rejecting traditional authority. In a rational universe, governed by the law of cause and effect, there was room neither for mystery nor for the doctrines of original sin and predestination. Evil was the result of irrational conditions of life, and man had it in his power to improve his lot by the pursuit of science and education. An optimistic belief in human perfectibility was generally held; it lay in the cultivation of reason and tireless effort in the service of human improvement. The man of the world being more highly regarded than the devout Christian, good taste and common sense came to be demanded, and literature assumed a markedly didactic character

The foundations of rationalism had been laid by Leibniz. With him, the relationship of God and man to each other ceased to be considered within the limits of Christian dogma. German religious life was marked by a revival of Pietism, which left its traces in the sphere of religious poetry. The main emphasis lay not on conformity but on the individual's spiritual experience.

In literature the new ideas soon began to emerge. One of the most marked features of German literature in the 18th century was the progressive influence of English literature: first, of Joseph Addison, Jonathan Swift, Daniel Defoe, translations

Martin

Opitz'

influence

The influence of English

influence

of Herder

and Alexander Pope; later of James Thomson, John Milton, and Edward Voung. Translations and imitations of the English Spectator, Tatler, and Guardian helped to regenerate literary taste. Samuel Richardson had much effect upon the growth of the moral novel, while Young's Con-Jectures on Original Composition heralded a new epoch in German literature that was to be profoundly affected by the Scottish poet James Macpherson's Ossian, Bishop Thomas Percy's Reliques of Ancient English Poetry, and Shakespeare—the epoch of the Sturm und Drang ("Storm and Stress") movement.

The reaction against rationalism. Between 1724 and 1740 the critic Johann Christoph Gottsched succeeded in establishing in Leipzig literary reforms in accord with French 17th-century Classicism. He purified the stage and laid down principles according to which good literature was to be produced and judged. The limitations of Gottsched soon drew resistance from two Swiss scholars, Johann Jakob Bodmer and Johann Jakob Breitinger. Basing their arguments on John Milton's poem Paradise Lost, they insisted that imagination should not be dominated by reason. The effects of the controversy appeared toward midcentury in a group of Leipzig writers of Gottsched's own school, the Bremer Beiträger (Bremen Contributors), as they are usually called after the paper in which they published their work. In this-the Neue Beiträge zum Vergnügen des Verstandes und Witzes-there appeared in 1748 the first installment of an epic by Friedrich Gottlieb Klopstock, Der Messias (completed 1773), whose theme created a sensation when the first cantos appeared. Klopstock's genius was, however, more suited to the lyric, and his odes, in which sentimental and patriotic themes were prominent, were much admired. Friedrich von Hagedorn showed to what perfection occasional verse could be brought, while Ewald Christian von Kleist excelled in sentimental nature poetry. Meanwhile, a rising interest in Germanic antiquity aided the growth of the "bardic' movement led by Heinrich Wilhelm von Gerstenberg, Karl Friedrich Kretschmann, and Michael Denis, the translator of Macpherson's Ossian. A notable group of poets was the Göttinger Hain (Göttingen Grove) founded in 1772. Johann Heinrich Voss, the group's leader, was author of the famous idvll Luise (1795). The influence of Lessing. As Klopstock had been the

first of modern Germany's inspired poets, so Gotthold Ephraim Lessing was the first critic who brought credit to the German name throughout Europe. Like Gottsched, he had unwavering faith in Neoclassicism, but classic meant for him, as for his contemporary Johann Joachim Winckelmann, Greek art and literature rather than French pseudo-Classicism, though it is true that Lessing's own exposition of Aristotle's theory of tragedy was full of the moral preoccupations of the Enlightenment. He looked to England rather than to France for the regeneration of the German theatre. His own dramas were pioneer works in this direction. Miss Sara Sampson (first performed 1755) was a bourgeois tragedy on the English model; Minna von Barnhelm (1767), a comedy in the spirit of George Farquhar; in Emilia Galotti (1772) Lessing remodeled the "tragedy of common life" in a form that came to be acceptable to the Sturm und Drang; and finally in Nathan der Weise (1779; Nathan the Wise) he won acceptance for iambic blank verse as a medium for elevated drama

Because of Lessing, German literature made a great leap forward beyond the feeble achievements of the first half of the century. The domestic tragedy, its plot centred on the problem of class distinction, foreshadowed plays involving marked political and social criticism in the Sturm und Drang period, while Nathan was a forerunner of the "drama of ideas" of Weimar Neoclassicism. Lessing's theoretical work placed criticism in the forefront of affairs in literary Germany. His sharp rejection of descriptive poetry had a great effect on the writing of the next generation, and his attack on French literary authority prepared the way both for a greater attention to English examples and for the search for native originality.

Christoph Martin Wieland contributed to the widening of the German imagination by introducing remote and exotic settings. With the exception of his verse-romance

Oberon (1780), his work fell into neglect; he did excellent service, however, to the development of German prose fiction with his psychological novel Agathon (1766–67; The History of Agathon) and his satire Die Abderiten (1774; "The Abderites"; Eng. trans., The Republic of Fools...). The German novel owed much to the example of Agathon, but its groundwork and form were borrowed from English models.

THE AGE OF GOETHE

Sturm und Drang. The period of Neoclassicism and Romanticism, the greatest epoch in German literature, fell within the lifetime of Johann Wolfgang von Goethe. The age of Goethe went beyond the Enlightenment's substitution of science for religion, inasmuch as it ascribed to science only a peripheral position in relation to the ultimate questions of life. It insisted upon the value of feeling in face of the limitations of reason. Impulse, instinct, emotion, fancy, and intuition acquired a quasireligious significance as being the links that connect man with divine nature. The ideal of the classical age, soon to be called Humanität ("humanness"), was that of the fully developed personality in which intellect and feeling should be harmoniously balanced. Three phases may be distinguished in the evolution of this new outlook: Sturm und Drang, Classicism, and Romanticism,

Goethe belonged to and profoundly affected the Sturm und Drang movement, which aimed at overthrowing rationalism. Seeds of the new growth were to be found in Klopstock, in the spiritual force of Pietism, and in the rising resistance to French Classical taste, while the influence of Rousseau, Young, Macpherson, and the recently translated Shakespeare was of prime importance. Nature, genius, and originality were the slogans of the new movement, and an increasingly oppressive sense of dissatisfaction with the civilization of the day assailed its exponents. The cult of nature replaced orthodox religion. No law was recognized as being above the individual conscience. The standard outlook thus demanded unceasing effort, like that of Faust. Strain, protest, revolt, yearning, disillusion were obvious on all sides, and egotism became a dominating feature in literature and thought.

The critical writings of Heinrich Wilhelm von Gerstenberg stressed personal feeling in matters of taste, but the chief impetus came from Johann Georg Hamann, who emphasized the inspirational and symbolical function of language. His pupil was Johann Gottfried von Herder, who grasped, as no thinker before him had done, the idea of historical evolution and engendered the main current of the Sturm und Drang. He stressed the value of historical continuity in literature and pointed to the folk songs, ballads, and romances of the Middle Ages as sources of inspiration to which Bishop Thomas Percy's Reliques of Amspiration to which Bishop Thomas Percy's Reliques of Am-

cient English Poetry (1765) had recently drawn attention. It was, moreover, Herder who aroused in Goethe an interest in Gothic architecture, the Volkslied, and Shakespeare. A pamphlet, "Von deutscher Art und Kunst" (1773; "Concerning German Nature and Art"), was a kind of manifesto of the Sturm und Drang. The new ideas seemed at once to set Goethe's genius free. His Götz von Berlichingen (1773), the first important drama of the Sturm und Drang, was followed by the first novel of the movement, Die Leiden des jungen Werthers (1774; The Sorrows of Young Werther), which made the author famous throughout Europe. In all forms of literature he set the fashion for his time. The Shakespearean restlessness of Götz found imitators in Jakob Michael Reinhold Lenz, Friedrich Maximilian von Klinger, Johann Anton Leisewitz. Heinrich Leopold Wagner, and Friedrich Müller. The dramatic literature of the Sturm und Drang was its most characteristic product; it was inspired by a desire to present upon the stage figures of Shakespearean grandeur impelled by gigantic passions, all considerations of plot, construction, and form being subordinated to character, and all accepted authority-literary, social, political, or moral-being rejected.

With the production of *Die Räuber* (1781; *The Robbers*) by Friedrich Schiller, the drama of the Sturm und Drang entered a new phase. Schiller's tragedy was more skillfully

The dramas of young Schiller

Moral

idealism

adapted to the exigencies of the theatre than those of his predecessors had been; it and the succeeding dramas, Die Verschwörung des Fiesko zu Genua (1783; Fiesco; or the Genoese Conspiracy) and Kabale und Liebe (1784; Cabal and Love), were fine pieces of high promise. Germany owed its national theatre to the Sturm und Drang period; permanent theatres were established in these years at Hamburg, Mannheim, and Gotha, and the Burgtheater (now the Hofburgtheater) was founded at Vienna in 1776 by the emperor Joseph II.

Neoclassidsm. Herder's doctrine of Humanităt, in which intellect and feeling are reconciled, became fundamental to German Neoclassicism. This harmonious balance and self-discipline was lacking in the Sturm und Drang, and the movement soon exhausted itself. A more positive form of moral idealism appeared in the poetry of Goethe and Schiller, as well as in the philosophy of Immanuel Kant. The problem of freedom was rendered acute by the impact of the French Revolution, which German literature generally regarded as a warning. Schiller believed the antagonism between duty and inclination could be resolved once morality became "second nature," and this could be achieved only through the contemplation and

production of beauty. Art thus acquired an educational function, and aesthetic education was one of the major

objectives of Neoclassicism.

Goethe's Weimar period. For Goethe a new phase in his development began with his departure for Weimar in 1775, while after Don Carlos (1787) Schiller turned from poetry to study history and philosophy. The first 10 years of Goethe's life in Weimar were marked by his renewed friendship with Herder, by his public service as a minister of state, and by his emotional attachment to Charlotte von Stein. He did not achieve greater clarity in his ideas until after his sojourn in Italy (1786-88). In Italy he turned his attention to three dramatic works: he gave Iphigenie auf Tauris (Iphigenia in Tauris) its final form (1787), completed Egmont (1788), and replanned Torquato Tasso (1790). Wilhelm Meisters Lehriahre (Wilhelm Meister's Apprenticeship), Goethe's most important novel, had become, by the time it appeared in 1795-96, a book on the conduct of life. It is an outstanding example of the bildungsroman ("educational" novel), a characteristic German novel form, and profoundly affected future practitioners of the genre.

Before Wilhelm Meister appeared, however, German philosophical thought and literature had arrived at that degree of stability in form and ideas essential to a great literary period. In the year of Lessing's death (1781), Kant had published his Kritik der reinen Vermuff (Critique of Purg Reason), Under the influence of Kant, Schiller turned to the study of aesthetics, the first finits of which were his philosophical lyrics and his treatises "Über Anmut und Würde" (1793; "On Grace and Dignity") and, between 1795 and 1796, Briefe über die ästhetische Erziehung des Menschen (Letters on the Aesthetic Education of Man) and "Über nawe und sentimentalische Dichtung" ("On Naive

and Sentimental Poetry").

Goethe and Schiller. The years 1794 to 1805, when Goethe and Schiller were united in close friendship in Jena and Weimar, mark the culmination of literary Neo-classicism. Schiller provided the theoretical basis; Goethe, as director of the ducal theatre, influenced the whole practice of dramatic production in Germany. Under his encouragement Schiller turned from philosophy to poetry and between 1798 and his death in 1805 wrote a series of Classical dramas that are Germany's greatest: the Wallenstein trilogy, Maria Stuart, Die Jungfrau von Ordeans (The Maid of Ordeans), Die Braut von Messina (The Bride of Messina), and Wilhelm Tell, closing with the fragment Demertius.

The universality of the greatest writers is also reflected in others: Karl Philipp Moritz wrote on aesthetics and mythology and produced the novel Anton Reiser (1785–90); the physicist Georg Christoph Lichtenberg wrote on the English artist William Hogarth and was Germany's greatest master of the aphorism.

The supreme work of Goethe's later years is Faust, Germany's greatest contribution to world literature. Part I

(1808) sets out Faust's despair, his pact with Mephistopheles, and his love for Gretchen; Part II (1832) covers the magician's life at court, the winning of Helen of Troy, and Faust's purification and salvation. The doctrine of the fulfillment of life by striving and selfless activity revealed in Faust was fundamental to Goethe's nature works. The tragic novel Die Wahiverwandschaften (1809; Kindred by Choice) insisted on the theme of renunciation. Wilhelm Mesters Wanderjahre (1821–29; Wilhelm Meisters' Kravels), with its social utopianism and teaching of restraint, offered a criticism of the rise of industrialism. The autobiographical Dichtung und Wahrheit (1811–33; Poetry and Truth: From My Own Life), containing dramatic pieces, scientific writings, and lyrics, indicates the many-sidedness of Goeth's achievement (see GoETHE).

THE ROMANTIC MOVEMENT

First phase. The Romantic Movement began less as a protest against the Neoclassicism of Weimar than as a radical extension of some of its beliefs and interests. especially, at first, in its emphasis upon Greek antiquity, longed for like some lost paradise. The Romantic poet could create his own world from reality or from fancy and could turn whatever he liked into poetry. There was to be no end to the innovations made in content and style by the great wealth of literary talents who now emerged all over Germany and from various strata of society. The rising generation felt free and able to revise all accepted representative values, not only in art and literature but in other spheres as well. Among the topics then in vogue were nature and the spirit in all their manifestations, particularly the supernatural, the subconscious, and the mystical. In the evolution of German Romanticism no small part was played by the philosopher Johann Gottlieb Fichte and the theologian Friedrich Schleiermacher.

Two major writers fall between Neoclassicism and Romanticism proper. Friedrich Hölderlin and Jean Paul (Johann Paul Friedrich Richter). Hölderlin was one of Germany's greatest poets. He was a friend of the philosophers Friedrich Schelling and G.W.F. Hegel and was influenced by Klopstock and Schiller. His lyrical novel Hyperion (1797–99) sums up his major concerns: his yearning for antiquity, for union with the divine, and for a political renewal of Germany. His poems in Neoclassical metres and free rhythms convey a vision of sublime nobility. Jean Paul's once immensely popular novels introduced a new focus on ordinary life. They lack shape but sustain interest by their display of humour, warmth, sentiment, and whimsy. His main novels include Hesperus (1795). Stebenská (1796–97; Hower, Frutt and Thorn Pieces), Titan (1800–03), and Die Fleeglahre (1804–05; Walt and

Vult).

The first Romantic school originated in Jena about 1798. It was partly inspired by the subjective idealism of Fichte. but its principal philosopher was Schelling, whose Naturphilosophie asserted the unity of nature and the human spirit. The major literary theorists were the brothers August Wilhelm and Friedrich von Schlegel, who held that the first duty of criticism was to understand and appreciate, while Romantic literature was to encompass all forms of writing in "progressive universal poetry." Their main literary model was Goethe's Wilhelm Meister. The chief creative writers of the Jena school were Wilhelm Heinrich Wackenroder, Ludwig Tieck, and Novalis (Friedrich von Hardenberg). Wackenroder's collection of anecdotal accounts and sketches, Herzensergiessungen eines kunstliebenden Klosterbruders (1797; "Effusions of an Art-Loving Friar"), was the school's first major literary production, and it gave to art a religious significance. Tieck was a skillful and prolific prose writer and a tireless publicist. The finest imaginative achievement of early Romanticism, however, was found in Novalis' lyrics and aphorisms and in his unfinished novels, notably Heinrich von Ofterdingen (1802; Henry of Ofterdingen). These works combined abstract ideas with symbols of beauty and innocence. Romanticism's universal sympathies were also exemplified by many superb translations, of which the greatest were the translations of Shakespeare's plays by August Wilhelm von Schlegel and Tieck.

Hölderlin and Jean Paul

Wackenroder, Tieck, and Novalis

Goethe's

Interest in folk heritage

Kleist and

Hoffmann

The second Romantic school. The first Romantic school had dispersed by 1804. After 1805, however, a second school developed in Heidelberg around Achim von Arnim, Clemens Brentano, and Johann Joseph von Görres. Unlike the members of the earlier school, the Heidelberg writers produced historical works and also collected folk songs and popular prose romances. From this period dates the scholarly study of German philology and medieval literature. The most characteristic production was the folksong collection published by Arnim and Brentano under the title Des Knaben Wunderhorn ("The Youth's Cornucopia") in 1805-08. The same impulse later led the brothers Wilhelm and Jacob Grimm to compile their famous collection of fairy tales, Kinder- und Hausmärchen (1812-15; "Children's and Household Stories"; Eng. trans. Fairy Tales).

The folk song had a profound influence on Romantic poetry and not least on its greatest exponents, Brentano and Joseph von Eichendorff. Brentano's poetry, collected posthumously in 1852-55, is characterized by intense musicality. Eichendorff's lyrics, collected in 1837, nostalgically describe man, God, and nature in simple but highly

evocative imagery.

The concept of universal poetry encouraged a fashion for short poetic fiction that combined the realism of the Novelle form with fairy-tale fantasy, often interspersed with lyrics. Illustrative examples include Tieck's Der blonde Eckbert (1797), Friedrich de la Motte Fouqué's Undine (1811), Adelbert von Chamisso's Peter Schlemihls wundersame Geschichte (1814; The Wonderful History of Peter Schlemihl), and Eichendorff's Aus dem Leben eines Taugenichts (1826; Memoirs of a Good-for-Nothing).

The Heidelberg school broke up about 1809, and Berlin and Dresden became the main centres of Romanticism. Two major writers are associated with this phase, Heinrich von Kleist and E.T.A. Hoffmann, Both explored the darker aspects of life that had always interested the Romantics. Kleist was a master of the Novelle form (Erzählungen [1810-11; "Tales"; Eng. trans. The Marquise of O. and Other Stories]) and the greatest dramatist of his day. His plays include Amphitryon (1807), Penthesilea (1808), and Prinz Friedrich von Homburg (posthumously published, 1821). In such works, Kleist depicted the tragic impossibility of understanding a world riddled with ambiguities. Hoffmann, a storyteller of genius, gave European currency to German Romanticism in countless works of fantasy and the grotesque. Among his tales are Der goldne Topf (1814: The Golden Pot) and Das Fräulein von Scudéri (1819; Madame de Scudéri). Other figures of note in this phase were the dramatist Zacharias Werner and the poet Wilhelm Müller, whose song cycles such as Die Winterreise (1824; "The Winter Journey") were set to music by Franz Schubert.

Romanticism entered its final phase with the Swabian school, whose more talented members included Ludwig Uhland, Justinus Kerner, and Gustav Schwab. By this time Romanticism had become stereotyped and lacked its original vigour.

The 19th century

The death of Goethe in 1832 marked the end of the cosmopolitan humanism typical of the 18th century. Although some leading Romantics outlived Goethe by a decade, the movement had lost its impact. In conservative, nonliterary fields, Romanticism was more tenacious, and in politics its alliance with rising nationalism coloured German thinking for more than a century. In literature, Goethe himself was of more lasting significance; few writers were unaffected by his work, though the effect sometimes took the form of rebellion against his Olympian predominance.

Rule by conservative governments repressed liberty of thought, and writers' efforts to prescribe solutions for social ills were foiled by censorship. Literature was dominated by disillusionment with man's capacity to achieve lofty ends, and pessimistic appraisal of man's role replaced once optimistic or constructive attitudes. In keeping with this change in attitude, writers sought to free themselves from the bondage of Neoclassical and Romantic thought. not always by rejection but often by adaptation.

GRILLPARZER, BÜCHNER, AND THE DRAMA

The post-Napoleonic era produced several fine dramatists. notably the Austrian Franz Grillparzer and the German Georg Büchner. Grillparzer consciously formed his dramas in the mold of Neoclassicism but filled them out with a new vein of realism and a theatricality that he derived from the Viennese popular theatre. His tragedies on Classical and historical subjects had as their theme the conflict between active life and contemplative life. Sappho (1818) was modeled on Goethe's Tasso, and Das goldene Vliess (1820: The Golden Fleece) was a tragedy of stark psychological realism. The historical plays mirrored contemporary events: König Ottokars Glück und Ende (1823: King Ottocar, His Rise and Fall) reflects Napoleon's fate, while Ein Bruderzwist in Habsburg (c. 1848: Family Strife in Hapsburg) conveys Grillparzer's pessimism about the possibility of right action in mid-19th-century politics.

parzer's historical

Whereas Grillparzer was politically and poetically a conservative, Büchner was in every respect the opposite. He turned to literature after failing to start a revolution in his native Hessen. His plays were rooted in the achievements of the Sturm und Drang but anticipated 20th-century dramatic forms. In Dantons Tod (1835; Danton's Death), Büchner portraved the failures of the French Revolution. and in Woyzeck (posthumously published in 1879) he created the first major tragedy with a lower-class hero. Büchner viewed man pessimistically but with compassion as a victim of social, historical, and other forces: mere existence causes pain, and the cosmos is a spiritual void.

Significance of Büchner's Wovzeck

Büchner and Grillparzer each wrote one comedy, but the most successful comic dramatists were Ferdinand Raimund and Johann Nepomuk Nestroy, who gave lasting currency to the Viennese popular stage. The ambitious tragedies of Christian Dietrich Grabbe, such as Napoleon (1831), have not stood the test of time, but he also produced one memorable comedy in Scherz, Satire, Ironie und tiefere Bedeutung (1827; Satire, Irony, and Deeper Meaning). The heritage of Neoclassicism and Romanticism had been discredited, but no new faith emerged from the resulting disillusionment.

LYRIC POETRY

The great tradition of Neoclassical and Romantic poetry made it possible to achieve formal excellence but difficult to be original. Friedrich Rückert and August von Platen-Hallermünde, two consummate formal lyricists, illustrated this amply. A greater depth of feeling, however, was achieved in the melancholy lyrics of Nikolaus Lenau.

For Eduard Mörike, too, classical poetry was a model; Mörike's formal excellence was matched by an idyllic and melodious portrayal of nature and country life. In Mozart auf der Reise nach Prag (1856; Mozart on the Way to Prague), he humorously examined the problems of artists in a world uncongenial to art. Nature was also a source of inspiration for Annette von Droste-Hülshoff, whose powerful rhythm and sombre language expressed apprehension of the irrational forces of life, as in Das geistliche Jahr (1851; "The Spiritual Year"). Religious feeling helped balance her vision and gave her poetry greater maturity

Heine. No one attacked Romanticism more ruthlessly than Heinrich Heine. In Germany, Heine was, and still is, a controversial figure, mainly because he subjected German national susceptibilities and Romantic nationalism to scathing criticism, but his Buch der Lieder (1827; "Book of Songs") became one of the best known anthologies of love poetry. Heine described dreams and yearnings, and his realism showed that they were only make-believe. In Romanzero (1851) and the posthumously published poems, his poetry conveyed the hopes and anguish that were so real during his last long, drawn-out illness, and his early Saint-Simonian belief in the "rehabilitation of the senses" that had given way to a belief in God. His lesserknown prose, Reisebilder (1826-31; "Travel Sketches"); Lutezia (1854), a collection of reports on life in France; his analysis of German intellectual life and history in Zur Geschichte der Philosophie und Religion in Deutschland

Heine's attack on Romanti(1834; "On the History of Religion and Philosophy in Germany"), reveal him as a master of ironic prose, dissatisfied with solemnity and pretension. His most effective political satire is a verse epic, Deutschland: Ein Winternärchen (1844; "Germany: A Winter's Tale"), a savage attack on personal enemies and political conditions of his time.

"Young Germany." In 1835 an edict of the federal Diet banned Heine's writings, together with those of Ludolf Wienbarg, Karl Gutzkow, Heinrich Laube, and Theodor Mundt. Wienbarg's Ästhetische Feldzüge (1834; "Aesthetic Campaigns") had been dedicated to "Young Germany," and this name was then given to the writers who were in tune with the radicalism of the Young Hegelians and political liberals, frustrated by severe censorship and authoritarian government. Wienbarg advocated a literature to deal with political and social problems. Karl Gutzkow criticized conventional morality and orthodoxy in a novel, Wally, die Zweiflerin (1835; "Wally the Doubter"), and a drama, Uriel Acosta (performed 1846). Exile was often the fate of those who dared to criticize the established political and social order. Ludwig Börne, a highly talented prose writer, went into self-imposed exile in Paris, and his Briefe aus Paris (1830-33; "Letters from Paris") were valuable social documents. Two important lyric poets, Georg Herwegh and Ferdinand Freiligrath, had to flee, one to Switzerland, the other to London,

More conservative was Emanuel Geibel, whose collections, such as Zeitstimmen [1841] "Voices of the Age"), contain patriotic verse. He was the leader of the popular Munich school of poetry, whose patron was Maximilian II of Bavaria. Of these poets only Heinrich Leuthold struck a deeper note. Paul von Heyse's novellas rarely roused the reader, and Victor von Schelfel's verse tale Der Trompeter von Säckingen (1854) and novel Ekkehard (1857), though popular at the time, came to sound unconvincing.

REALISM AND REGIONALISM

Realism, often of regional inspiration, was a source of originality at this time. Its finest exponents were Adalbert Stifter, Gottfried Keller, and Theodor Fontane. Poetic Realism, a term coined by Otto Ludwig, aimed at portraying life but only insofar as life was artistically significant and appeared to possess intrinsic value. Attention focused on social reality but not, as in later naturalism, on its ugly, pathological side. The main objective of a realist writer was to discover positive values in everyday life without reference to transcendental ideas. Changes in the social order had caused a host of social critics to question developments that accompanied the beginning of urbanization. Of them Karl Marx is the best known, but Arthur Schopenhauer's pessimistic philosophy and Ludwig Feuerbach's materialistic thought also amounted to a more sober appraisal of man's capacity. There also developed a positivism that, by way of analogy, sought to apply to the study of literature and society methods that were mistakenly believed to be those of natural science. This, in turn, led to the study of sources and texts, formalized by the first important organized school of literary history in Germany, that of Wilhelm Scherer. Together with his successors, Erich Schmidt and Jakob Minor, Scherer established criticism of modern literature as an academic discipline; the Grimms and Karl Lachmann had already given academic respectability to German medieval studies.

In fiction, writers concentrated on subjects that they could, through familiarity, accurately describe. Karl Immermann, whose work was still greatly influenced by Neoclassicism, in Der Oberhof (1839; "The Manor") portrayed peasants rooted in their work and their countryside. The Low German novels Ut de Franzosentid (1859; "During the Time of the French Conquest"; Eng. trans. When the French Were Here) and Ut mine Stromtid (1862-64; "During My Apprenticeship"; Eng. trans. Seed-time and Harvest) by Fritz Reuter contained a wealth of individual character made more convincing by a lively dialect style. With Quickborn (1853), a collection of lyrical poetry, Klaus Groth became a prototype of the regional poet; his dialect clearly linked his work to colloquial speech and recalled the folk song. A major dialect writer was the Swiss novelist Jeremias Gotthelf (Albert Bitzius). A close

knowledge of the life of the Swiss peasants and their problems is reflected in his novels, of which Ult der Knecht (1846; Ulric the Farm Servani) and Ult der Pächter (1849; "Ulric the Tenant-Farmer") are the best known. Concerned for the moral welfare of the peasants, he preaches against liberalism in politics and against the loosening of moral sanctions and seeks to advocate a life of probity based on communal responsibility. His works convince the reader because of his shrewd insight into the mind of the peasants, his realistic assessment of their motives, and his faithful description of the peasant community. In Due schwarze Spinne (1842; The Black Spider) the events and persons, though realistically described, assume almost symbolical importance.

Adalbert Stifter, too, drew strength from his native Bohemian forest; some of his tales, collected in Studien (1844-50) and Bunte Steine (1853; "Colourful Stones"), are set there, but his language is Classical, reflecting his quest for stylistic perfection. For Stifter the world of everyday events is a symbol of emotional significance; he carefully portrays it and can thus be called a Poetic Realist. In Nachsommer (1857; "Indian Summer"), a bildungsroman influenced by Goethe's Wilhelm Meister. Stifter stresses the power of art to educate; he seeks to show how the gentle law of humane action, based on justice, simplicity, selfcontrol, restricted activity, and admiration of the beautiful, is effective in bringing about an exemplary life true to nature. Renunciation of violence is the major theme of Witiko (1865-67), a historical novel about the growth of culture in the 12th century; humane restraint is also the message of his story Die Mappe meines Urgrossvaters (1841-67; "The Portfolio of My Great Grandfather").

The realism of Otto Ludwig had a psychological flavour. "Die Heiterethei" ("The Cheerful Ones") and "Aus dem Regen in die Traufe" ("From the Frying-Pan into the Fire"), the two tales making up his collection Thuringer Naturen (1857), are a humorous exploration of life in his native land, while in his novel Zwischen Himmel und Erdel (1856; Bewwen Heaven and Earth) a conflict within an artisan family is explored with striking objectivity and careful characterization. His play Erbförster (1849; The Forest Warden) is a domestic tragedy of a forester obsessed by a sense of justice who finally shoots his own daughter in mistake for the son of his enemy. While Ludwig's Shakespeare-Studien (1871) reveals a fine understanding of dramatic art, his own Die Makkabäer (1854; "The Maccabees") is a failure.

With Gottfried Keller a pinnacle of Poetic Realism in prose narrative is reached. The scene of his works is his native Switzerland. All his writings reveal his attempts to differentiate between those characters whose thought and conduct allow their personalities to mature and those who. ignoring the voice of nature, fail to develop their inner potentialities. Der grüne Heinrich (1854-74; Green Henry), a semiautobiographical bildungsroman, is the story of the lively struggle and development of a Swiss painter. Keller portrays a romantic personality seeking to come to terms with life and shows how youthful dreams may become mutilated and how the artist's vision has to be readjusted to the demands of everyday life. Die Leute von Seldwyla (1856-74; "The People of Seldwyla"), a collection of Novellen, reveals his humour at its best. He resists the flights of a romantic imagination and cautiously consolidates his appraisal of everyday life. Martin Salander (1886) is political in tone, and its strictures on the liberalism of the day do not enhance its artistic value.

Another important realist was Theodor Storm, whose works a famely the teamosphere of his native Schleswig-Hokistin. In his work romantic elements were gradually subordinated to realistic description. The elegiac, often sentimental, tone of his cartier writing prevailed less and less, though both his prose tales and his lyric poetry were permeated by his sense of the ephemerality of life. Romantic preoccupation with the past had stimulated historical thought and writing. Some of Storm's and Keler's Novellen had dealt with the past, but other writers, such as Willibald Alexis, Corrad Ferdinand Meyer, Wilhelm Hauff, Gustav Freytag, and Wilhelm Heinrich Riehl, made history their main theme. The stories of Alexis are

Literature

of socio-

political

ment

imbued by a delicate sense of humour and a feeling for the landscape of Brandenburg. Freytag was less successful in his historical novel Die Ahnen (1872-81; "The Ancestors") than in portrayal of social and economic changes of his age in Soll und Haben (1855; Debit and Credit) and in his comedy Die Journalisten (1854). Friedrich von Spielhagen described social conditions more amply in a series of novels written after 1861. Though such works contain

political criticism, they are spoiled by their sentimentality. Wilhelm Raabe's analysis of social life is more profound. His writings appear complex; he anticipates 20th-century methods of storytelling in focusing attention not only on the story but on the way in which the story is told. He attacked the narrowness of the bourgeois philistinism and the nationalism of Otto von Bismarck's German empire. His humour helped him to overcome the pessimism of his early work, of which Der Hungerpastor (1864; The Hunger Pastor), Abu Telfan, oder Die Heimkehr vom Mondgebirge (1868; Abu Telfan, Return from the Mountains of the Moon), and Der Schüderump (1870; "The Rickety Cart") are striking examples. In his later work-e.g., Alte Nester (1880; "Old Nests") and Stopfkuchen (1891; "Cake Fater")-he depicted eccentric characters with a rich inner life who achieve spiritual freedom. His pessimism and humour are paralleled by Wilhelm Busch, whose laughter over human imperfection savagely exposes hypocrisy and illusion.

In Austria gentler moods prevailed during the late 1800s. Ferdinand von Saar and Marie Ebner von Eschenbach provided realistic accounts of both bourgeois and peasant Austrian society. Peter Rosegger and Ludwig Anzengruber also wrote about peasant life.

Conrad Ferdinand Meyer, a Swiss, through his understanding of history, achieved a rare fusion of poetry and realism. He described in chiseled prose the downfall of great men through the lust for power. The best of his Novellen, such as Jürg Jenatsch (1874), were inspired by an insight into the life of the Renaissance that had been stimulated by the work of the Basel historian Jacob Burckhardt. His lyrical poetry, like his prose, showed a rare sense of form. It is symbolical poetry that subordinates his personal feeling to imagery

The plays of Friedrich Hebbel revealed Poetic Realism at its most powerful. His work was a synthesis of psychological analysis and metaphysical beliefs. Deep inner impulses drove his characters to doom: his dramas, Judith (1841), Herodes und Mariamne (1849), and Gyges und sein Ring (1856; Gyges and His Ring), depicted the tragedy of those who suffered defeat because their outraged individuality did not allow them to compromise. In his last play, Die Nibelungen (performed 1861), he interpreted an old legend in terms of his own psychological and metaphysical ideas. Theodor Fontane produced the first true social novels in German. His realism was subtle and impressive for its humour and irony, but it also contained a strong poetic vein. In such novels as L'adultera (1882), Irrungen Wirrungen (1888; "Trials and Tribulations"), Frau Jenny Treibel (1892), and Effi Briest (1895) he combined psychological insight with an understanding of social conditions: human relationships clashed with society and survived or broke down according to their innate strength. Traditional social codes proved inadequate, but new ones had yet to be forged.

Friedrich Nietzsche was a harbinger of 20th-century literature. His distinction, in Die Geburt der Tragödie aus dem Geiste der Musik (1872; The Birth of Tragedy), between the Apollonian and Dionysian elements of art was of considerable consequence. The view spread that Classical art could not only be serene but also could be ecstatic, and that the origins of Greek drama sprang from * the orgiastic intoxication of Dionysian religious mysteries. Nietzsche's emphasis on a need to liberate personality from the shackles of conventional Christian morality (he denounced Richard Wagner after the composer had turned to Christianity), his skepticism as to the validity of the artist's statements and his place in society, and his prophecy of the nihilism to come provided an arsenal of ideas and intellectual ferment for the next generation of writers (see NIETZSCHE).

NATURALISM

The keynote of naturalism in Germany was scientific objectivity, and the principal model was the work of Émile Zola in France. An anthology of lyric verse, Dichtercharaktere, appeared in 1884, in which urban life was the theme. but the real revolution was made by Arno Holz, who, in Buch der Zeit (1886; "Book of the Times"), revealed himself as the first important poet of naturalism. Together with Johannes Schlaf, he wrote three tales published as Papa Hamlet (1889), in which they attempted faithfully to depict the minutiae of life, even its pathological and sordid aspects. Gerhart Hauptmann was the chief naturalist playwright. His play Vor Sonnenaufgang (1889; Before Dawn) was memorable for its novel technique: it was a drama without hero or proper plot. Die Weber (1892; The Weavers) was an indictment of dire poverty caused by industrialization, while Der Biberpelz (1893; The Beaver Coat), one of the few successful German comedies, was a satire on Prussian officialdom. In Hanneles Himmelfahrt (1893; "The Assumption of Hannele"), Hauptmann began to experiment with Symbolist drama, and Der Narr in Christo, Emanuel Ouint (1910: The Fool in Christ) revealed his force as a prose narrator.

In Hauptmann's wake several writers wrote in a straightforward naturalist manner. The best known among them were Hermann Sudermann, notable for Ehre (1889: "Honour"; Eng. trans. What Money Cannot Buy) and Heimat (1893; "Home"; Eng. trans. Magda), plays criticizing middle-class morality; and Max Halbe, whose Jugend (1893; "Adolescence") was a drama of young love.

In the course of the 19th century, German literature had increasingly abandoned an idealistic conception of man and turned to a more down-to-earth and deprecating appraisal of reality, reflecting the rise of positivist and materialist thought in science. This proved too narrow; and in consonance with the new relativist scientific cosmology of the 20th century, artistic imagination began to portray a more complex vision of the world.

The 20th century

Through the 20th century, German literature has reflected the social, political, and spiritual uncertainty of its surroundings. Early dissatisfaction with conventional literary forms led to experiments with new ones in an attempt to avoid sterility and to revitalize the language-aims that have emerged as dominant forces in modern literature.

MAJOR LITERARY TRENDS AND CONDITIONS

Impressionism. Impressionism evokes a mood or state of mind by emphasizing the impression made by an object on its observer. The poet Detlev von Liliencron provided an early example of this, as did Richard Dehmel. Writers influenced by Symbolism also had elements of Impressionism in their work. A successor of French Symbolism who had considerable effect on other writers was Stefan George, whose solemn, carefully composed verse aimed at asserting the lofty stature of poetry, which, for him, had a religious character. George founded the journal Blätter für die Kunst (1892; "Journal for Art") to publish his followers' poetry. Among those attracted by his work were

the critic Friedrich Gundolf and the poet Karl Wolfskehl. Hugo von Hofmannsthal, an Austrian whose Impressionistic elements had their roots in Romanticism, declined to join George's circle. In his melodious poetry he delicately analyzed his sensibilities and was haunted by his obsession with the inadequacy of language completely to convey feeling. An essay, the "Chandos-Brief" (1902; "Letter by Lord Chandos"), records this sense of the inadequacy of words. The plays of the 1890s concerned the aesthete faced with the reality of this inadequacy. Later dramas, such as Jedermann (published 1911), an adaptation of Everyman, and Das Salzburger grosse Welttheater (1922; The Great Salzburg Theatre of the World), were religious in tone and borrowed from Baroque and medieval drama; a comedy, Der Schwierige (1921; The Difficult Man), analyzed a sophisticated mind inhibited by the weight of social tradition. His greatest public successes were his librettos, such as Der Rosenkavalier (1911), which Richard Strauss set to

music. Conscious of the heritage of European culture and of ethical responsibility, Hofmannsthal conveyed a strong awareness of moral issues in his work.

The endof-thecentury analyses of decadence Vienna was now a major cultural centre. Arthur Schnitzter depirted is pre-1914 decadence. Karl Krusu relentiesly exposed the Viennese press and morals in his one-man satiric newspaper. Die Fackel ("The Torch") and attacked World War I in his monumental drama Die letzten Tage der Menschheit (1915–17; "The Last Days of Mankind"). A cooler analyst was Robert Musil. His novel Der Mann ohne Eigenschaften (1930–43; The Mann Without Qualities), one of the masterpieces of the age, ironically dissects modern incertitude, sham values, and political folly. Hermann Broch, too, gave a profound historical analysis in his trilogy Die Schlafwandler (1931–32; The Steepwalkers). Joseph Roth was still another who depicted the decline of Austria-Hungary, as, for example, in the novel Radetzkymarsch (1932; Radetzky March).

Prague had also become a centre of writing. Franz Kaßka, Rainer Maria Rilke, Franz Werfel, Max Brod, and Gustav Meyrink wrote and lived in Prague. Their work inclined toward the esoteric and was strongly influenced by Symbolism. One last generation of Prague writers, which included Hermann Grab, Johannes Urzddi, and Franz Wurm, became active in exile during and after World War II.

Symbolism. Like most poets of the time, Rilke was indebted to Symbolism. His melodious verse, which made him one of Germany's great lyric poets, gave his vision of reality compelling power. This was clearly evident in Das Stunden-Buch (1905; "The Book of Hours"), which described a search for spiritual health in a hostile urban civilization. Rilke's conception of the universe. God. and death was determined by a quest for artistic fulfillment. In Neue Gedichte (1907-08; "New Poems") he ceased to depict his subjective response to spiritual isolation and instead attempted to give a more objective view of life, art, and nature. In Die Aufzeichnungen des Malte Laurids Brigge (1910; The Notebooks of Malte Laurids Brigge) he studied the disintegration of an artistic sensibility alienated by the modern world. The Duineser Elegien (1923; Duino Elegies) summed up his spiritual struggles in complicated severe verse, while Die Sonette an Orpheus (1923; Sonnets to Orpheus) sought to show poetry's power to transmute problems of existence and to justify reality.

Symbolism also influenced prose writers, not least Thomas Mann, who attempted to use symbol and myth in narratives that started from a clinical analysis of modern man's mental and physical state. Mann's characterization was Impressionist, but impressions became leitmotivs conveying the power of the subconscious. His work was influenced by the philosophers Schopenhauer and Nietzsche; yet his portrayal of social change, of the impact of ideology, was an organic part of the story, and he was occupied, as always, with the status of the artist in society. In his early works art was symbolic of decadence, an overrefinement no longer acceptable; but with Der Zauberberg (1924; The Magic Mountain), Mann, like Rilke, emphasized the constructive qualities of art. His great novels examined different facets of his age: Buddenbrooks (1900) explored bourgeois society; Der Zauberberg dealt with intellectual corruption; Doktor Faustus (1947) examined the German mind and character during the Third Reich. His novellas-e.g., Tonio Kröger and Tristan (both 1903) and Der Tod in Venedig (1912; Death in Venice)depicted the same themes. Irony and resultant ambiguity were characteristic of Mann. His increasingly complex style reflected the complexity of his mind and his study of the history of ideas. Mann's last work, Bekenntnisse des Hochstaplers Felix Krull (1922 and revised 1954; The Confessions of Felix Krull, Confidence Man), humorously stated the doubt that ran through all his work-whether the pursuit of beauty and, hence, pursuit of culture and art were not in the end a great deception.

Hermann Hesse was influenced by Neoromanticism and concentrated on man's spiritual conflict. His novels, from his first success, Peter Camentind (1904), portrayed the struggle of individuals in a world hostile to sensitivity or explored the subconscious and the balance between sensuality and the spirit. In Der Steppenwoff (1927), he

examined the conflict between the bourgeois world and the sensitive outsider, here resolved by self-abandonment to fantasy; in Das Glasperlenspiel (1943; "The Glass-bead Game"; Eng. trans. Magister Ludi) he questions the whole purpose of civilization.

Ricarda Huch's novels, like those of Thomas Mann and his brother Heinrich, emphasized the individual's independence and dignity. Heinrich Mann savagely attacked social and political abuses in novels such as Professor Unrat (1905; Small Town Tyrant, or The Blue Angel) and Der Untertan (1918. The Patrioteer).

Expressionism. Expressionism was the key movement in German literature, as it was in painting, during and immediately after World War I. Expressionism emphasized the inner significance of things and not their external forms. Actually anticipating the war, it depicted the disintegration of the world and proclaimed a quest for the "New Man."

Frank Wedekind's dramas were forerunners of this style. For example, the plays constituting what is commonly known as the Lulu Tragedy, Erdgeist (1895; Earth Spirit) and Die Büchse des Pandora (1895; Pandora's Box), had pilloried bourgeois morality and broken with dramatic convention. The first fully Expressionist drama, however, was Johannes Reinhard Sorge's Bettler (1912; "The Beggar"), in which characters appeared as abstract functions in each other's lives. This play, like those of Walter Hasenclever, Paul Kornfeld, Fritz von Unruh, Ernst Barlach the sculptor, and Oskar Kokoschka the painter, was characterized by a quest for the essence of things, for the ideas behind personality and spiritual meaning in life. Ernst Toller wrote political plays employing an Expressionist technique in Die Maschinenstürmer (published 1922; The Machine-Wreckers). Georg Kaiser, the leading Expressionist playwright, moved from naturalism through Expressionism to a mature traditional style, while Carl Sternheim unmasked bourgeois pretensions by means of a shrill satire of contemporary language.

Expressionist poetry was equally nonreferential, attaining coherence through its associative power. The chief poets were Ernst Stadler, Georg Heym, Georg Trakl, August Stramm, Gottfried Benn, and Else Lasker-Schüler. The mainspring of Expressionist verse was a horror over urban life and over the collapse of civilization. Portrayals of this apocalyptic vision range from Trakl's moving lamentation to a macabre, cynical detachment in Benn's early verse. The vision of meaninglessness was extended in the so-called Dadaism of poets such as Jean (Hans) Arp and Yvan Goll. An absurd view of life was also featured in the nonsense verse of Christian Morgenstern (Galgenlieder, 1905; Gallows Sones).

Franz Kafka shared this negative vision. His parables, stories, and novels seem to epitomize the problems of modern life. With the stark clarity of a nightmare, he depicted the horror and uncertainty of human existence. In Das Urteil (1913; The Sentence, or The Judgment), a father condemns his son to death; in Die Verwandlung (1915; The Transformation, or Metamorphosis), a man turns into a beetle; and in In der Strafkolonie (1919; In the Penal Settlement), a torture machine runs wild. In his posthumously published novels, notably Der Prozess (1925; The Trial) and Das Schloss (1926; The Castle), the individual is trapped in a labyrinth of anxiety and guilt and crushed by unfathomable forces. There is also humour in Kafka, sometimes grotesque and at others sublime. The terror of his art, however, is only alleviated by its moral strength.

Kafka's themes recall Expressionism, but his classically balanced style echoes the prose of the Swiss Robert Walser, author of Jakob von Grunen (1929). The Expressionist novel is best exemplified by Alfred Döblin's Berlin Alexanderplatz (1929; "Alexander Square, Berlin"; Eng. trans. The Story of Franz Biberkonf).

Post-Expressionism and Social Realism. After 1918 Expressionism gave way to Social Realism through which writers hoped to gain objectivity. The first subjects chosen were World War I and its aftermath: Arnold Zweig's Streit um den Sergeanten Grischa (1927; The Case of Sergeant Grischa), Erich Maria Remarque's Im Westen The nightmare vision of Franz Kafka

Mann's analyses of his age

Rilke's

of God

view

Nichts Neues (1929; All Quiet on the Western Front), and Hans Fallada's (Rudolf Ditzen's) and Erich Kästner's works documented the war and postwar society

This new objectivity continued in the work of Anna Seghers and in Carl Zuckmayer's Hauptmann von Köpenick (1931; The Captain of Köpenick) and Des Teufels General (produced 1946; "The Devil's General"). Ernst Jünger explored the philosophical implications of technology and modern civilization; Auf den Marmorklippen (1939; On the Marble Cliffs), a criticism of the Third Reich, revealed his inability to conceive imaginatively individual character. The poetry and prose of Jünger's brother Friedrich exhibited greater lyrical and narrative skill.

The Third Reich disrupted the continuity of German literary life. Under the Nazis, talented writers either left Germany, were driven out, were forced into silence, or were exterminated, and good writing did not come to the surface until after World War II.

LITERATURE AFTER WORLD WAR II

Böll's

writings

Grass's

portrayal

German

history

of modern

The Nazi era, the war, and its aftermath profoundly affected the course of German literature after 1945, Writers felt impelled to come to terms with their historical and political situation. In the West the Group 47 brought together almost all important writers from Heinrich Böll to Günter Grass, and for more than 20 years it helped to shape the literary climate. In the East a new literature emerged from the dialogue with Marxism, but an increasing number of writers moved to the West,

The atmosphere after 1945, known as Zero Hour, was

captured in the stories of Wolfgang Borchert, in Ilse Aichinger's novel Die grössere Hoffnung (1948; "The Greater Hope"), and in the early fiction of Heinrich Böll. Böll's humane analysis of postwar problems in such novels as Haus ohne Hüter (1954; The Unguarded House) made him the most representative German writer of the period. He was awarded the Nobel Prize for Literature for 1972. In his comic short stories and the novel Ansichten eines Clowns (1963; The Clown), Böll looked critically at modern life, and he did so increasingly in later works such as Die verlorene Ehre der Katharina Blum (1974; The Lost Honor of Katharina Blum) and Fürsorgliche Belagerung (1979; The Safety Net).

Günter Grass provided a more exuberant, amoral, and grotesque picture of German history in his Danzig trilogy: Die Blechtrommel (1959; The Tin Drum), Katz und Maus (1961; Cat and Mouse), and Hundejahre (1963; Dog Years). In Das Treffen in Telgte (1979; The Meeting at Telgte), he wrote a satiric epitaph on Group 47. Another work on an ambitious scale was Uwe Johnson's tetralogy Jahrestage (1970-83; Anniversaries), which gives a minute analysis of the German situation. Other notable contemporary German novelists include Wolfgang Koeppen, Alfred Andersch, Siegfried Lenz, and Martin Walser. Among women writers who established major reputations were the Austrian Ingeborg Bachmann, author of the novel Malina (1971), and the East German Christa Wolf, who wrote several stories and the novels Der geteilte Himmel (1963: Divided Heaven) and Nachdenken über Christa T.

(1968; The Quest for Christa T.). Several novelists continued the prewar Viennese tradition. George Saiko's Auf dem Floss (1948; "On the Raft" and Albert Paris Gütersloh's Sonne und Mond (1962; "Sun and Moon") provided brilliant symbols of the vanished Austrian world. Heimito von Doderer's complex but absorbing novels Die Strudlhofstiege (1951; "The Strudlhof Steps") and Die Dämonen (1956; The Demons) achieved a sustained and vivid panorama of prewar society. Elias Canetti's inspired novel about a world gone mad, Die Blendung (1935; "The Deception"; Eng. trans. Auto-da-Fé), won international recognition. His plays revolved around related themes, as did his sociological study Masse und Macht (1960; Crowds and Power). Canetti was awarded the Nobel Prize for Literature for 1981. His other publications include aphorisms, criticism, and a remarkable two-volume autobiography. Other novelists in the Austrian tradition include H.G. Adler, Peter von Tramin, Wolfgang Georg Fischer, and the comic writer Fritz von Hertzmannovsky-Orlando.

German poetry of the post-World War II period has been rich and varied. Two opposing trends, however, have dominated the scene; one toward difficult, esoteric verse, and the other toward a simple, plain style. Hans Carossa and other poets of the older generation continued to publish, and the war's victims such as Jesse Thoor Gertrud Kolmar, and Albrecht Haushofer were discovered. Poets. like authors of prose fiction, caught the mood of Zero Hour, Later, Paul Celan developed increasingly intricate hermetic verses; Johannes Bobrowski recreated myth; and Christine Lavant wrote symbolic yet folklike poems. The poet Nelly Sachs was awarded the Nobel Prize for Literature for 1966. Hans Magnus Enzensberger manufactured what is often called consumer poetry, and Wolf Biermann and Erich Fried popularized political verse. Later poets were more subjective.

The giant of European theatre was Bertolt Brecht, much of whose work had been completed almost 30 years before he received international acclaim. His first successful play. Trommeln in der Nacht (performed 1922; Drums in the Night), and the satiric opera Die Dreigroschenoper (1928. music by Kurt Weill; The Threepenny Opera' dated from the 1920s, when he was developing his theory of "epic theatre" and his social criticism, which led him to Marxism. During the Third Reich he went into exile, where he wrote his most mature plays: Mutter Courage und ihre Kinder (1941; Mother Courage and Her Children), Leben des Galilei (1943; The Life of Galileo), and Der kaukasische Kreidekreis (1948; The Caucasian Chalk Circle). Besides being a gifted playwright, Brecht was a highly influential

theorist and a poet of considerable talent.

Other significant contributions to modern German drama during the postwar years have come from Switzerland. The two best-known contemporary Swiss writers, Max Frisch and Friedrich Dürrenmatt, both have made hold experiments with dramatic form. Dürrenmatt's Besuch der alten Dame (1955; The Visit) and Die Physiker (1961; The Physicists) and Frisch's Nun singen sie wieder (1946; "Now Sing Again") and Andorra (1961) are modern morality plays. The latter's novels, Stiller (1954), Homo Faber (1957), and Der Mensch erscheint im Holozan (1979: Man

in the Holocene), are investigations into the place of the

intellectual in the modern world. Both writers criticize the emotional sterility of modern life.

Several German dramatists received international attention, notably the politically oriented so-called documentary school represented by Rolf Hochhuth's Der Stellvertreter (1963; The Deputy) and Die Soldaten (1967; The Soldiers") and Peter Weiss's Die Ermittlung (1965; The Investigation). Weiss's Die Verfolgung und Ermordung des Jean-Paul Marats . . . (1964; The Persecution and Assassination of Jean-Paul Marat . . .; often referred to simply as Marat/Sade) was a political dramatic spectacle. His Hölderlin (1971) reinterpreted the poet's life. Other German dramatists were Tankred Dorst, Botho Strauss, and Franz Xaver Kroetz. The Austrian dramatists Wolfgang Bauer and Peter Handke excelled at provoking their audiences. Handke's plays were Publikumsbeschimpfung (1966; "Abusing the Audience"), Kaspar (1968), and Der Ritt über den Bodensee (1971; The Ride Across Lake Constance). Handke turned increasingly to prose, as in Die Angst des Tormanns beim Elfmeter (1970; The Goalie's Anxiety at the Penalty Kick), the semiautobiographical Wunschloses Unglück (1972; A Sorrow Beyond Dreams), and Die linkshändige Frau (1976; The Lefthanded Woman), and he popularized the techniques of experimental writing.

Much of the writing produced since the late 1940s has been decidedly innovative and experimental. The poet Günther Eich perfected the then new genre of the radio play in Träume (1951; "Dreams"). Many others, including Bachmann, Böll, and Dürrenmatt, tried their hand at the genre as well. It was followed by the New German Radio Play, in which meaning gave way to experimentation with form and sound, as in Franz Mon's ich bin der ich bin die (broadcast 1971; "i am he i am she"). This genre emerged from concrete poetry, a verse style developed by Eugen Gomringer and the Vienna Group of Hans Carl Artmann, Gerhard Rühm, and Konrad Bayer, as well as by Ernst

The plays of Bertolt

Documentary school of drama

The New German Radio Play Jandl and Friederike Mayröcker. Such poets treated language as a physical object, both visually and acoustically. Bayer, and Helmut Heissenbüttel in D'Alembert's Ende (1970; "D'Alembert's Death"), extended the style into the genre of the novel, as did Jürgen Becker. The doyen of experimental prose, however, was Arno Schmidt, whose works include Die Gelehrtenerpublik (1975; "The Republic of Letters"; Eng. trans. The Egghead Republic or Republica Intelligentisia; his magnum opus, Zettels Traum (1970; "Zettel's Dream"), developed complex linguistic play within a visual structure.

Trends in literary criticism

Literary criticism also became more complex during the 20th century. It increasingly supplanted 19th-century positivism with a variety of approaches that treated literature in the light of the history of ideas as defined by Wilhelm Dilthey. Two very different exponents of this method were Fritz Strich and Hermann August Korff. After World War II stylistic analysis, which made the work of literature rather than the writer the focus of inquiry, emerged as the most popular tendency. Its leading critic was for many years Emil Staiger. This text-oriented school, however, underwent a crisis in the 1960s, which coincided with the discovery of the prewar esoteric Marxist criticism of Walter Benjamin. Two new trends emerged: a sociopolitical approach and a more self-conscious, theoretical one. The ensuing debate over method stimulated a wide variety of critical styles, reflecting the prevailing relativism of the age.

Günter Grass and Christa Wolf continued at the forefront of German writers. Grass, influenced by the multiple-text bias of what has come to be called postmodernism, produced Der Butt (1977; The Flounder) and Die Rättin (1986; The Rat), two works composed of varying types of narrative. Among his later novels was Ein weites Feld (1995; Too Far Afield), a novel set in Berlin that deals in part with the subject of Germany's reunification. Reunification also influenced Wolf's Was bleibt (1990; What Remains), about the author's surveillance by East German police, and the narrator in Thomas Hettche's Nox (1995; [Latin: "At Night"]) has his throat slit the night the Berlin Wall comes down, East Germany itself is targeted in Reiner Kunze's Deckname "Lyrik" (1990; "Code Name 'Lyric'"). Kunze, like Wolf, had been under the surveillance of the East German secret police, who are also featured in Thomas Brussig's satiric novel Helden wie wir (1995; Heroes Like Us).

The country's Nazi past remained an important topic. Monika Maron's Stille Zeile Sechs (1991; Silent Close No. Six) deals with postwar guilt and also with East Germany's communist experience. Marcel Beyer's Flughunde (1995: "Flying Foxes," Eng. trans. Flughunde) centres on the death of Nazi propagandist Joseph Goebbels' children. In Thomas Lehr's Frühling (2001; "Spring"), the suicidal narrator has a father who had served as a doctor in a concentration camp. Vati (1987; "Daddy"), by Peter Schneider, presents another Nazi father, based on the infamous doctor Josef Mengele. Thomas Bernhard's Ein Zerfall (1986; Extinction) deals in part with Austria's collaboration with the Nazis. W.G. Sebald's important novel Austerlitz (2001: Eng. trans. Austerlitz) features a character who explores the past he had escaped by being adopted by an English couple. Another significant work along these lines is Christoph Ransmayr's Morbus Kitahara (1995; The Dog King), set in an imaginary Germany returned to preindustrialization as a punishment.

At the turn of the century, then, Germany's writers con-

tinued to be haunted by the country's recent past, on the one hand, and exercised by the possibilities and the problems of reunification, on the other. The residual sense of crime and guilt for the Nazi years, together with a more general Western trend toward exploring the outer limits of individual behaviour, is epitomized in works such as Patrick Süskind's Das Parlim: Die Geschichte eines Mörders (1985; Perfinne: The Story of a Murderer) and in his Kafkaesque Die Taube (1987; The Pigeon); and the profusion of voices resulting from the complicated state of German life is well represented by Günter Grass's Mein Jahrhundert (1999; My Century), with its various texts—history, memoir, and, to encompass the tragic and fantastic aspects of Germany's past, fliction.

The end of the century

he core area of the German-speaking peoples. the Federal Republic of Germany (Bundesrepublik Deutschland) occupies a section of north-central Europe traversing the continent's main physical divisions, from the outer ranges of the Alps, northward across the varied country of the Central German Uplands, and then across the North German Plain, or Lowlands. It is bounded at its extreme north on the Jutland Peninsula by Denmark. East and west of the peninsula, the Baltic Sea (Ostsee) and North Sea coasts, respectively, complete the northern border. To the west, Germany borders on The Netherlands, Belgium, and Luxembourg; to the southwest, on France. It shares its entire southern boundary with Switzerland and Austria. In the southeast, the border with the Czech Republic corresponds to an earlier boundary of 1918, renewed by treaty in 1945. The easternmost frontier adjoins Poland along the northward course of the Neisse River and subsequently the Oder to the Baltic Sea, with a westward deviation in the north to exclude the former German port city of Stettin (Polish: Szczecin) and the Oder mouth. This border reflects the loss of Germany's eastern territories mandated in the Potsdam agreement among the victorious World War II Allies and reaffirmed by subsequent governments.

Of historical, if no longer political, importance is the long internal boundary that for 40 years partitioned Germany into two nations. It was based on the lines of demarcation agreed upon at the Yalta Conference of 1945, separating the then-Soviet occupation zone of Germany from the zones occupied by the Western allies, on which territory West Germany subsequently emerged. On the East German side, this boundary was, until the fall of the communist government in 1989, marked by defenses in depth designed to prevent the escape of the population. The 185 square miles (480 square kilometres) of the "island" of West Berlin were similarly ringed from 1961 to 1989 by the Berlin Wall running through the city and a heavily guarded wire-mesh fence in the areas abutting the East German countryside. The city declined in national and international significance until the events of 1989-90 restored a united Berlin as the capital of a united Germany. In June 1991 the Bundestag voted to move the seat of government from Bonn to Berlin.

The republic has a maximum north-south extent of about 520 miles (840 kilometres), between latitudes 47° and 55° N, and an east-west maximum (across the middle of the country) of about 385 miles (620 kilometres), between longitudes 6° and 15° E. It has an area of 137,735 square miles (356,733 square kilometres).

The constitution of the republic, adopted in 1949, gives most government powers to its constituent Linduer (states), which at the time of unification numbered 11 (including West Berlin, which, however, had the special status of a Land without voting rights) but which grew to 16 (including the reunited Berlin) upon the accession of East Germany; only matters of undoubted importance for the nation as a whole, such as defense and foreign affairs, are reserved to the federal government. At both the state and federal levels, parliamentary democracy prevails. The Federal Republic has been a member of the North Atlantic Treaty Organization (NATO) since 1955 and was a founding member of the European Economic Community in 1957. During the four decades of partition, the Federal Republic concluded a number of agreements with

the U.S.S.R. and East Germany, which it supported to some extent economically in return for various concessions with regard to access to Berlin and humanitarian matters. West Germany's rapid economic recovery in the 1950s (Wirtschaftswunder, or "economic minatel") brought it into a leading position among the world's economic powers, a position that it has subsequently maintained. Reunion with the eastern territories, while constituting a huge financial burden at the outset, was expected eventually to strengthen this standing.

The constituent states, including those delineated in the former eastern sector in 1990, follow the historic lines of the political divisions of the former Reich. They enjoy considerable political autonomy within the federative structure, especially in such areas as education, finance, and law enforcement. Each has its own equivalent of a prime minister, a parliament or diet, and provincial ministries. Their strong voice in the upper levels of the federal government is unique among Western republics.

The largest of the states is Bavaria (Bavern), the richest is Baden-Württemberg, and the most populous is North Rhine-Westphalia (Nordrhein-Westfalen). In the extreme north lies Schleswig-Holstein, south of which is Lower Saxony (Niedersachsen). The ancient free Hanseatic cities of Hamburg and Bremen rank as states in their own right, Rhineland-Palatinate (Rheinland-Pfalz) and Hesse (Hessen) cover the central area of the republic; the Saarland is a pocket in the southwestern corner of the Pfälzer Mountains (Pfälzerwald). Five states, in addition to that of Berlin, were formed in 1990 from the territory of the former Democratic Republic: Mecklenburg-West Pomerania (Mecklenburg-Vorpommern) in the north; Brandenburg (surrounding Berlin) in the east; Saxony (Sachsen) south of Brandenburg and bordering on the northwestern Czech Republic; Thuringia (Thüringen) between Saxony and Hesse; and Saxony-Anhalt (Sachsen-Anhalt) between Brandenburg and Lower Saxony. They are small in comparison with most of the states of the original Federal Republic

Historically, the German peoples have been characterized by almost perpetual political disunity and fluctuating boundaries in their central European position. The Treaty of Versailles, at the end of World War I, established a string of states, notably Poland and Czechoslovakia, at the expense of former Reich or Austrian territory, containing substantial German-speaking minorities. Germany's defeat in 1945 was even more devastating for the Germanspeaking peoples. The Soviet Union and Poland occupied nearly a quarter of Germany's former territory, and they proceeded to expel most of the German-speaking populations. At the same time, German minorities were expelled from some of the post-Versailles successor states, notably Czechoslovakia. In a brutal fashion, therefore, the frontiers of post-1945 Germany came to be largely coincident with the distribution of German-speaking people; only Austria, Liechtenstein, and German-speaking Switzerland remained outside. (T.H.El./G.H.K.)

This article first discusses the physical and human geography of Germany. Following that section is a discussion of the history of the Germans from ancient times to the present, including the reunification of the German state. For detailed coverage of the city of Berlin, see the article BERLIN.

PHYSICAL AND HUMAN GEOGRAPHY

The land

The major lineaments of Germany's physical geography are not unique. The country spans the great east-west morphological zones that are characteristic of the western part of central Europe. In the south, Germany impinges on the outermost ranges of the Alps. From there it extends across the Alpine Foreland (Alpenvorland), the plain on the northern edge of the Alps. Forming the core of the country is the large zone of the Central German Uplands, which is part of a wider European arc of territory stretching from the Massif Central of France in the west into the Czech Republic, Slovakia, and Poland in the east. In Germany it manifests itself as a landscape with a complex mixture of forested block mountains, intermediate plateaus with scarped edges, and lowland basins. In the northern part of the country, the North German Plain, or Lowland, forms part of the greater North European Plain, which broadens from the Low Countries eastward across Germany and Poland into Belarus, the Baltic States, and Russia and extends northward through Schleswig-Holstein into the Jutland peninsula of Denmark. The North German Plain is fringed by marshes, mud flats, and the islands of the North and Baltic seas. In general, Germany has a south-to-north drop in elevation, from a maximum 9,718 feet (2,962 metres) in the Zugspitze of the Bavarian Alps to a few areas slightly below sea level in the north.

It is a common assumption that surface configuration reflects the underlying rock type; a hard resistant rock such as granite will stand out, whereas a softer rock such as clay will be weathered away. However, this assumption is not always borne out. The Zugspitze, for example, is Germany's highest summit not because it is composed of particularly resistant rocks but because it was raised by the mighty earth movements that began in the Tertiary Period, some 37 to 24 million years ago and created the Alps, Europe's highest and youngest fold mountains. Another powerful force determining surface configuration is erosion, mainly by rivers. In the Late Carboniferous Epoch. (360 to 286 million years ago), an earlier mountain chain, the Hercynian, or Variscan, mountains, had crossed Europe in the area of the Central German Uplands. Yet the forces of erosion were sufficient to reduce these mountains to almost level surfaces, on which a series of secondary sedimentary rocks (those of Permian to Jurassic age [286 to 144 million years old]) were deposited. The entire formation was subsequently fractured and warped under the impact of the Alpine orogeny. This process was accompanied by some volcanic activity, which left behind not only peaks but also a substantial number of hot and mineral springs. Torrential erosion occurred as the Alpine chains were rising, filling the furrow that now constitutes the Alpine Foreland. The pattern of valleys eroded by streams and rivers has largely given rise to the details of the present landscape. Valley glaciers emerging from the Alps and ice sheets from Scandinavia had some erosive effect, but they mainly contributed sheets of glacial deposits. Slopes outside the area of the actual ice sheets-those under tundra conditions and unprotected by vegetation-were rendered less steep by the periglacial slumping of surface deposits under the influence of gravitation. Winds blowing over unprotected surfaces fringing the ice sheets picked up fine material known as loess; once deposited, it became one of Germany's outstanding soil-parent materials. Coarser weathered material was carried into alluvial cones and gravel-covered river terraces, as in the Rhine Rift Valley (Rhine Graben).

The detailed morphology of Germany is significant in providing local modifications to climate, hydrology, and soils.

RELIEF

The Central German Uplands. Geographically the Central German Uplands form a region of great complexity. Under the impact of the Alpine orogeny, the planed-off remnants of the former Hercynian mountains were shattered and portions thrust upward to form block mountains, with sedimentary rocks preserved between them in lowlands and plateaus. The Central German Uplands may be divided into three main parts: a predominantly lowland country in the south, an arc of massifs and plateaus running from the Rhenish Uplands to Bohemia, and a fairly narrow northern fringe, composed of folded secondary rocks

Southern Germany. In southern Germany, Hercynian massifs are of restricted extent. The Black Forest (Schwarzwald) must once have been continuous with the Vosges Mountains in what is now France, but they were broken apart through the sinking of a central strip to form the Rhine Rift Valley, which extends 185 miles (300 kilometres) in length. The Black Forest reaches its greatest elevation in the south (Mount Feld, 4,898 feet [1,493 metres]) and declines northward beneath secondary sedi-

ments, before rising to the smaller Oden Forest. For the most part, however, southern Germany consists of scarplands, mainly of Triassic age (208 to 245 million years old). The work of erosion on eastward-dipping strata has left the sandstones standing out as west- or northwestfacing scarps, overlooking valleys or low plateaus of clays or Muschelkalk (Triassic limestone formed from shells). The sequence of Triassic rocks ends south and east against the great Jurassic scarp of the Swabian Alp (Schwäbische Alb), rising to more than 3,300 feet (1,000 metres), and its continuation, the lower Franconian Alp (Frankische Alb). Large parts of the plateaus and lowlands in the eastern region are covered with loess, but the massive Bunter Sandstone fringing the Black Forest and the Keuper scarp are mainly wooded. West of the Rhine there are again wide stretches of forested Bunter Sandstone, with more open country in the Saar region and along the foot of the Hunsrück Upland.

The barrier arc. The open land of southern Germany ends against a great barrier arc of Hercynian massifs

and forested sandstone plateaus. In the west the Rhenish Uplands (Rheinisches Schiefergebrige) consist mainly of resistant slates and shales. The complex block is filted generally northwestward, with a steep fault-line scarp in the south. The intensely folded rocks are planed off by crosion surfaces that give the massif a rather monotonous appearance, broken only by quartize indges, especially in the south, where the Hunsrück rises to 2,684 feet (818 metres) and the Taunus to 2,887 feet (879 metres).

The valleys are a different world. They range from narrow forested slots—a great hindrance to passage—to the spectacular gorge of the Rhine, the most important natural routeway through the barrier arc. The most dramatic section of the gorge runs from Bingen to the vicinity of Koblenz; hilltop castles look down over vineyards to picturesque valley towns. In this section is the Lordei rock, from which a legendary siren is supposed to have lured fishermen to their death on the rocks.

Until highways were constructed over the plateau tops, access to the uplands was difficult. The landscape gained

The valleys

some variety from past volcanic activity responsible for the eroded volcanic necks of the Seven Hills (Siebengebirge), across from Bonn, the flooded craters and cinder cones of the Eifel Upland, and the sombre basalt flows of the Westerwald, Westward the Rhenish Uplands continue into Belgium as the Ardennes. In the Carboniferous Period (from 360 to 286 million years ago) when the Hercynian Uplands were still young folded mountains, great deltaic swamps developed to the north and south; these were the basis of the great Ruhr coalfield and the smaller Aachen and Saar fields.

Bohemian Massif

The eastern end of the barrier arc is buttressed by the great and complex Bohemian Massif, which Germany shares only marginally. On the southwestern fringe of the massif, German territory includes the remote and thinly populated Bohemian Forest and the Bavarian Forest. Across from Czechoslovakia are the Ore Mountains (Erzgebirge), where the centuries-old mining tradition was still continued in the period of the German Democratic Republic. The Bohemian Massif is prolonged northwestward by the long spur of the Thuringian Forest (Thuringer Wald), which separates the scarplands of northern Bavaria from the Thuringian Lowland. The barrier arc is completed by the great eroded cone of the Vogelberg (2,536. feet [773 metres]), the volcanic Rhon, and the forested Bunter Sandstone plateaus of northern Hesse. The Rhine Rift Valley continues northward through Hesse, with a series of discontinuous basins filled with Tertiary sediments that allow a slightly difficult traverse to the North German Plain.

The northern fringe of the Central Uplands. North of the upland barrier there are a number of regions, generally of folded limestones, sandstones, and clays, that mark the transition to the expanse of the North German Plain. Balanced on either side of the plateau of Hesse are two basins of subdued scarpland relief, the Westphalian Basin to the northwest and the Thuringian Basin to the southeast, both of them partially invaded by glacial outwash from the North German Plain. Hesse and the Westphalian Basin are succeeded northward by the hills of Lower Saxony. The breakthrough of the Weser River into the North German Plain at the Porta Westfalica, south of Minden, is overlooked by the giant monument of the emperor William I (built in 1896), North of the Thuringian Basin is one of the smaller Hercynian massifs, the Harz, which reaches an elevation of 3,747 feet (1,142 metres) in the Brocken Peak

The North German Plain, or Lowland. Less than 90 miles broad in the west, the North German Plain widens

eastward across the whole of northern Germany. Although relief is everywhere subdued, there is considerable variety of landscape in terms of detail and much natural beauty. Unconsolidated Tertiary deposits, gravels, sands, and clays with overlying glacial drift, have buried the previous landscape of secondary rocks. These make only two brief appearances, in the chalk cliffs of the island of Rügen in the Baltic Sea and in the cliffs of Triassic Bunter Sandstone of the island of Helgoland, located some 40 miles northwest of Cuxhaven in the North Sea. In Tertiary times large swamps developed, and the underlying deposits of lignite (brown coal) are presently mined in Saxony, in Lower Lusatia (Niederlausitz), and west of the city of Cologne.

The North German Plain is divided into contrasting eastern and western portions, the division marked approximately by the Elbe valley. The northern and eastern regions were molded by southward-moving ice sheets in the last (Weichsel, or Vistula) glaciation. The advancing ice sheets pushed up material that remains today as terminal moraines, stretching across the country in a generally southeast to northwest direction and rising to some 500 feet above the general level. Within the terminal moraines the decay of the ice sheets typically left behind sheets of till (ground moraine), which have mainly been cleared of their heavy soils for agriculture. They are studded with ponds, often resulting from the decay of buried "dead ice," littered with boulders of all sizes brought by the ice from Scandinavia. In a region lacking in stone these boulders were used as building material and are to be found forming the walls of the oldest churches. Outside the moraines. meltwater laid down sheets of outwash sands, which, offering poorer soils, are frequently forested. A feature of the present-day moraine country is the existence of large, long, and branching lake systems, usually believed to have been formed by water moving under the ice sheets.

The unique character of the region east of the Elbe is further enhanced by the fact that the ice sheets of the last glaciation coming from the north blocked the river's natural flow to the Baltic, forcing it to escape laterally around the margin of the ice toward the North Sea; the river cut a deep trench as it did so. The landscape in the western portion of the plain tends to be monotonous. Much of it was formerly heath; the few patches that have escaped afforestation, agricultural improvements, or damage caused by military training have a wistful beauty, especially when the heather is in bloom. Wilseder Berg (554 feet [169 metres]), a fragment of a former moraine, is the highest elevation in the Lüneburg Heath, a plateau extending on

Barge on the Rhine River, with vineyards in the background, at the town of Kaub, Rhineland-Westphalia, Ger

terminal moraines a morainic belt between Hamburg and Hannover. Toward the maritime northwest, large areas of peat bogs have been reclaimed for agriculture. The southern edge of the plain extending to the Thuringian Basin is marked by a belt of mainly windblown loess.

The coasts. The western and eastern coastlines vary considerably in their forms. The coast of the North Sea continues the type familiar in the northern Netherlands; an offshore bar, crowned with sand dunes, has been shattered and left as the chain of the East Frisian Islands off the coast of Lower Saxony and the North Frisian Islands off the Schleswig-Holstein portion of the Jutland Peninsula. These islands form a favourite vacation area in summer, even if it is often necessary to seek shelter from the wind in high-backed wicker beach chairs. The sea has encroached upon the land behind the islands, forming tidal flats (known as Wattenmeer), which become exposed at low tide. The coast is broken by the estuaries of the Elbe, Weser, and Ems rivers and by drowned inlets such as the Jade and Dollart bays.

Along the Baltic coast, the boulder-clay plains shelve rather tamely beneath the sea. However, the typically varied relief of minor moraines, depressions, and other glacial features gives sufficient diversity to the coastline. In Schleswig-Holstein long inlets (fjords), carved by water moving beneath the ice sheets, extend to the sea. Farther east the coast gains in complexity; there are peninsulas and sea inlets known as Bodden, and sandy beach bars dominate the landscape. Several islands line the shore, including Usedom, Hiddensee, Poel, and Rügen, Germany's

largest island.

The Wat-

tenmeer

The Alps and the Alpine Foreland, Very small portions of the outer limestone (or calcareous) Alps extend from Austria into Germany. From west to east these are the Allgauer Alps, the Wetterstein Alps-with Germany's highest mountain, the Zugspitze (9,718 feet)-and the Berchtesgadener Alps. Like the North German Plain, the Alpine Foreland is fundamentally a depression filled with Tertiary gravels, sands, and clays, which are derived from the Alpine orogeny. But, in contrast to the North German Plain, the Tertiary deposits are more visible on the surface. Along the foot of the limestone Alps, but particularly in the Allgauer Alps in the west, the older Tertiary deposits (flysch, molasse) were caught up in the later stages of the Alpine folding, forming a pre-Alpine belt of hills and low mountains consisting mainly of sandstone. The Tertiary sands and clavs also emerge at a much lower elevation in the northeast, forming a subdued landscape.

Glaciers emerging from the main Alpine valleys formed lobes stretching some 20 to 35 miles into the plain. Crescentic moraines mark the points where the lobes came to rest: within the moraines are irregular deposits of till and many lakes. Outside the moraines, floodwaters deposited sheets of outwash gravel, which extend as river terraces along the courses of tributaries flowing north to the Danube. The Alps and the Bavarian lakes are among

Germany's most favoured tourist areas.

DRAINAGE AND SOILS

Drainage. Most German rivers follow the general northto-northwest inclination of the land, eventually entering the North Sea. The major exception to the rule is the Danube; it rises in the Black Forest and flows eastward, marking approximately the boundary between the Central German Uplands and the Alpine Foreland. It draws upon a series of right-bank Alpine tributaries, which, through reliance on spring and summer snowmelt, make its regime notably uneven. Further exceptions are the Altmühl and the Naab, which follow a southerly direction until becoming north-bank tributaries of the Danube, and the Havel, which flows south, west, and north before emptying into the Elbe River. River flow relates mainly to climate, albeit not in a simple way; for example, in all but Alpine Germany, maximum river flow occurs in winter when evaporation is low, although in the lowlands the peak rainfall is in summer.

The most majestic of the rivers flowing through Germany is the Rhine. It has its source in east-central Switzerland, flows west through Lake Constance (Bodensee), skirting the Black Forest to turn northward to flow across the Central German Uplands. Below Bonn the Rhine emerges into a broad plain, and west of Emmerich it enters The Netherlands to issue into the North Sea. It is of great advantage that the Rhine belongs to two types of river regime. Rising in the Alps, the Rhine profits first from the extremely torrential Alpine regime, which causes streams to be swollen by snowmelt in late spring and summer. Then, by means of its tributaries, the Neckar, Main, and Moselle (German: Mosel), the Rhine receives the drainage of the Central German Uplands and the eastern part of France, which contributes to a maximum flow during the winter. As a result, the river has a remarkably powerful and even flow, a physical endowment that caused it to become the busiest waterway in Europe. Only in occasional dry autumns are barges unable to load to full canacity to pass the Rhine gorge

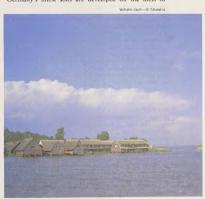

The Weser and Elbe rise in the Central German Urlands, crossing the North German Plain to enter the North Sea. The northward-flowing Oder (with its tributary, the Neisse) passes through the northeastern part of the country and a small section of Poland before emptying into the Baltic Sea. The navigation of these rivers is often adversely affected by low water in the summer and by ice in the

winter, which increases eastward.

River courses in the northern lowlands have a notably trellised pattern-rivers follow the ice-margin stream trenches (Urstromtäler) carved outside the fringes of the retreating ice sheets before breaking through the next moraine ridge to the north. This pattern greatly facilitated the cutting of canals linking the Rhine River with Berlin

and the Elbe and Oder rivers. Germany has relatively few lakes. The greatest concentration comprises the shallow lakes of the postglacial lowland of the northeast. The largest natural lake of the region is Lake Müritz (44 square miles [114 square kilometres]) in the Weichsel glacial drift of Mecklenburg-West Pomerania. In addition to Lakes Dümmer and Steinhude in Lower Saxony, a few small lakes of glacial origin dot Schleswig-Holstein. The remainder of Germany's lakes are concentrated at the extreme southeastern corner of Upper Bayaria, many of these in outstandingly beautiful surroundings. Germany shares Lake Constance, its largest lake (having the proportions of an inland sea), with Switzerland and Austria.

Soils. Most of Germany has temperate brown and deep brown soils. Their formation is dependent on relief, hydrologic conditions, vegetation, and human intervention. Germany's finest soils are developed on the loess of

Fishermen's huts (Fischerhäuser) on the west coast of Lake Müritz near Röbel, Mecklenburg-West Pomerania

the northern flank of the Central German Uplands, the Magdeburg Plain, the Thuringian Basin and adjoining areas, the Rhine valley, and the Alpine Foreland. They range from black to extremely fertile brown soil types, and most of them are arable land under cultivation. The till (ground moraine) of the North German Plain and Alpine Foreland has heavy but fertile soil. Brown soil covers much of the Central German Uplands and is used for agriculture and grazing. With increasing elevation, soils are suitable only for grazing or forestation. In the northern plains the soil types are sand, loam, and brown podzols, which are heavily leached of mineral matter and humus by deforestation and grazing. Along the North Sea littoral in the northwest there are some extensive areas of sand, marsh, and mud flats that are covered with rich soil suitable for grazing and growing crops.

The remainder of German soil types, because of the preponderance of mountainous and forested areas, range from sand to loam, from loam to clay, and from clay to rocky outcrops. Timber production thrives where the land is all but unarable, and viticulture in the southern regions flourishes in an otherwise inhospitable type of soil.

(THEL)

CLIMATE

Germany is favoured with a generally temperate climate, especially in view of its northerly latitudes and the distance of the larger portions of its territory from the warming influence of the North Atlantic Current. Extremely high temperatures in the summer and deep, prolonged frost in the winter are rare. These conditions, together with a more than abundant and well-distributed amount of rainfall, afford ideal conditions for raising crops. As throughout western Europe in general, however, Germany's climate is subject to quick variations when the warm westerly winds from the Atlantic Ocean collide with the cold air masses moving in from northeastern Europe. Whereas in the open coastlands near the North and Baltic seas the maritime component prevails, continental elements gain in importance moving toward the east and southeast.

The seasons, year by year, are subject to great variations: winters may be unusually cold or prolonged, particularly in the higher elevations in the south, or mild, with the temperatures hovering only two or three degrees above or below the freezing point. Spring may arrive early and extend through a hot, rainless summer to a warm, dry autumn with the threat of drought. In other years, springinvariably interrupted by a frosty lapse in May, popularly known as die drei Eisheiligen ("the three ice saints")may arrive so late as to be imperceptible and be followed by a cool, rainy summer. One less agreeable feature of the German climate is an almost permanent overcast in the cool seasons, only infrequently accompanied by precipitation; it sets in toward the latter part of autumn and lifts as late as March or April. Thus, for months on end, virtually no sunshine may appear.

Despite the generally temperate climate for the country as a whole, specific regional patterns associated with temperature, frequency of sunshine, humidity, and precipitation exist. The northwestern and lowland portions of the republic are affected chiefly by the uniformly moist air, moderate in temperature, that is carried inland from the North Sea by the prevailing westerly winds. While this influence, on the whole, affords moderately warm summers and mild winters, it is accompanied by the disadvantages of high humidities, extended stretches of rainfall, and, in the cooler seasons, fog. Precipitation diminishes eastward as the plains open toward the Eurasian interior, and the average temperatures for the warmest and coldest months become more extreme. The hilly areas of the central and southwestern regions and, to an even greater degree, the upland and plateau areas of the southeast are subject to the more pronounced ranges of hot and cold from the countervailing continental climate. The mountains have a wetter and cooler climate, with westward-facing slopes receiving the highest rainfall from maritime air masses. At a station on the Brocken in the Harz Mountains, annual precipitation reaches 63 inches (160 centimetres) at an altitude of 3,747 feet. The sheltered lee slopes and basins

have by contrast, rainfall that is extremely low (Alsleben receives 17 inches annually) and hot summers (July mean temperatures above 64° F [18° C]), necessitating crop irrigation. Southeastern Germany may intermittently be the coldest area of the country in the winter; but the valleys of the Rhine, Main, Neckar, and Moselle rivers may also be the hottest in the summer. Winters in the North German Plain tend to be consistently colder, if only by a few degrees, than in the south, largely because of winds from Scandinavia. There is also a general decrease of winter temperature from west to east, with Berlin having an average temperature in January of 31.5° F (-0.3° C).

One anomaly of the climate of Upper Bavaria is the occasional appearance of warm, dry air passing over the northern Alps to the Bayarian Plateau. These mild winds. known as foehns (Föhn), can create an optical phenomenon that makes the Alps visible from points where they normally would be out of sight, and they also are responsible for the abrupt melting of the snow.

The foehns

Annual mean precipitation varies according to region. It is lowest in the North German Plain, where it ranges from 20 to 29 inches: in the Central German Unlands it ranges from 28 to 59 inches; and in the Alpine regions, up to and exceeding 78 inches.

PLANT AND ANIMAL LIFE

Since Germany is a somewhat arbitrary south-north slice across central Europe, it does not have vegetation and animal life greatly different from that of neighbouring countries. Before being settled, Germany was almost totally forested, except for a few areas of marsh. At present it would be hard to find any truly natural vegetation; not only the cultivated areas but the forests, which cover 20 percent of the land area, are man-made.

Plants. After the Ice Age the loess areas were covered by oak and hornbeam forests, which, however, have largely disappeared. The sand spreads of the North German Plain were originally covered by a predominantly mixed oak-birch woodland. They were cleared and replaced by heather (Calluna vulgaris) for sheep grazing, with associated soil erosion. In the 19th century artificial fertilizer was introduced to improve some of this land for agriculture. and large stretches were forested, mainly with Scotch pine (Pinus sylvestris). The Central Uplands are traditionally the domain of the beech (Fagus sylvatica), a tree with a leaf canopy so dense that few plants can survive beneath it. Although beech trees survive well on the poor soils covering the limestones and the Bunter Sandstone, they have been increasingly replaced by pine in the lowlands and spruce in the uplands. Other conifers, such as the Douglas and Sitka spruce, Weymouth pine, and Japanese larch, were introduced in recent years. In the highest elevations of the Alps, mixed forests and pasture provide grazing for cattle. German forests have suffered greatly from acid rain pollution, generally blamed on emissions (of sulfur dioxide and nitrogen oxide) from power plants and industrial operations. Damage has also been severe in southeastern Germany, near the Ore Mountains, which border on the Czechoslovakian lignite-burning industries.

Animals. The vast tracts of forest and mountainous terrain, with only scattered habitation, contribute to a surprising variety of wildlife in so densely populated and highly developed a country. Game animals abound in most regions-several varieties of deer, quail, and pheasant and, in the Alpine regions, the chamois and ibex-and their numbers are protected by stringent game laws. The wild boar population, which soared after World War II because of restrictions on hunting, has now been reduced so that it no longer represents a danger to people and crops. The hare, a favoured game animal, is ubiquitous. Although in the wild the bear and the wolf are now extinct in the republic, the wildcat has had a resurgence in the postwar years, especially in the Eifel and Hunsrück regions and in the Harz Mountains. The lynx has reappeared in the areas near the Czechoslovakian border, and the elk and wolf are occasional intruders from the east. The polecat, marten, weasel, beaver, and badger are found in the central and southern uplands, and the otter and wildcat are among the rarer animals of the Elbe basin. Common reptiles include

in seasons

Develop-

World

War II

salamanders, slowworms, and various lizards and snakes, of which only the adder is poisonous.

Germany has several internationally recognized bird reserves. The tidal flats of Lower Saxony (Niedersächsisches Wattenmeer) and the Schleswig-Holstein national parks along the North Sea coast, the lakes of the Mecklenburg plains, and glacially formed lakes of the North German Plain are vital areas for the European migration of ducks, geese, and waders. The Lüneburg Heath, an excellent nature reserve, is a haven for various species of plants, birds, insects, and reptiles. The rare white-tailed eagle can be found in the lakes of the North German Plain, whereas the golden eagle can be seen in the Alps. White storks have decreased in number, but they can still be seen, perched on enormous piles of sticks on chimneys or church towers in areas where unpolluted and undrained marsh is still to be found.

SETTLEMENT PATTERNS

Rural settlement. The most striking feature of the rural settlement pattern in western Germany is probably the concentration of farmyards into extremely large villages, known as Haufendörfer. These villages are surrounded by unenclosed fields divided into often hundreds of striplike units. The Haufendorf is particularly characteristic of Hesse and southwestern Germany, areas that have a tradition of partible inheritance. During periods of population pressure, land holdings-as well as farmhouses and farmyards-were repeatedly divided on inheritance. becoming smaller and more fragmented all the time. As a result, villages became increasingly huddled and chaotic. In areas with a tradition of undivided inheritance, such as Bavaria and Lower Saxony, the holdings-the individual field parcels and the farmhouses-remained larger.

During the period of high medieval prosperity in the 11th to 13th centuries, population pressure brought about two further developments: the advance of peasant settlements into the forests, where isolated farms and hamlets were the usual settlement form, and the colonization of the predominantly Slav lands beyond the line of the Elbe and Saale rivers. Since this was an organized colonization, under the control of the lords and their agents, the haphazard structure of the western Haufendorf could be streamlined into a few well-planned forms. Thus farmhouses in the eastern regions were customarily arranged along either a single village street (Strassendorf) or an elongated green, on which stood the church (Angerdorf): long unfenced strips of land were alotted at right angles to the road or green.

The evolution of rural settlement has not been uniform: there have been phases of advance and retreat. In particular, the decline of medieval prosperity, accompanied by the Black Death, led to a stage of retreat, in which many hundreds of villages-the so-called "lost villages"were abandoned in western Germany. In eastern Germany, lords often appropriated deserted farms and added them to their own land, thus initiating that characteristic feature of the area beyond the Elbe, the large Junker estate farm (Gut).

After World War II the organization of agriculture and settlement in the two Germanys diverged considerably. The western direction was one of evolution, with federal and state governments giving large subsidies to improve the existing structure. Land consolidation was one method: scattered strips were regrouped to form larger holdings, and in some places farmers were moved to new farmsteads dispersed outside the villages. An increased average size of holding was associated with a massive movement of people out of agriculture. But instead of leaving for the cities, as happened in the 19th century, people mostly remained in their existing homes and commuted to work; the manure tank in front of the house became a rose bed, and the barn a garage. Part-time "Sunday" farming remained, but on a reduced scale. Land was actually left uncultivated by the new urban workers (social fallow); some of it was taken up by the few remaining full-time farmers, but marginal areas were abandoned, being either afforested or reverting to rough grass and scrub.

In the former East Germany, the Junker estates were confiscated and either divided among peasants or turned into state farms. This development was only the first stage in a process of collectivization; from 1958 to 1960 private holdings were regrouped under heavy political pressure into vast "cooperative" farms. New buildings marked the introduction of mechanized cultivation or large-scale animal husbandry, and multistory apartments and community centres reflected a politically inspired attempt to create a new concept of rural life. Now all is once more in transformation.

Urban settlement. From medieval times onward Germany was politically fragmented, with numerous states competing with one another to develop lucrative market

Village built along a single street (Strassendorf); Stolberg, Saxony-Anhait.

Village forms

centres and to create capitals, large and small; as a result, the country inherited a profusion of towns and cities. Most of these remained frozen within their circuit of walls until the 19th century; only the larger princely capitals, such as Berlin or Munich, developed distinctive government quarters in the early modern period. The great urban explosion came late in the 19th century. Because industrialization was largely linked to the development of the railways, urban expansion was not confined to areas near the coalfields, such as the Ruhr region, but was distributed among many cities. Typically the new urban workers were herded into dismal five-story apartment blocks built on a monotonous grid of straight-line streets. Today, especially in eastern Berlin and cities such as Halle and Leipzig, these blocks present an urgent problem of urban renewal.

World War II was followed by a period of rapid urban growth as evacuees returned to the bombed cities. After 1949 contrasting government policies of the two Germanys, however, led to divergent development. In the West many people abandoned the old city cores in favour of widespread suburbs and urbanized villages within commuting range. Thus, in many agglomerations, notably in the Ruhr region, population loss has been associated with peripheral gain. By contrast, the East German government pursued a policy of population concentration, whereby people were moved into concentrated peripheral settlements of 50,000 to 100,000, consisting of uniform prefabricated high-rise housing blocks.

The people

The German-speaking peoples-to whom must be accounted not only the inhabitants of Germany but also those of Austria, Liechtenstein, the major parts of Switzerland and Luxembourg, small portions of France and Italy. and the remnants of German communities in eastern Europe-are extremely heterogeneous in their ethnic origins, in their dialectal divisions, and in their political and cultural heritage, in which the split between Protestant and Roman Catholic has played a significant role since the Protestant Reformation and Catholic Counter-Reforma-

tion in the 16th century.

Origins

German

people

of the

A characteristic of Germany, throughout its history, has been the lack of clearly defined geographic boundaries, particularly on the great lowland of northern Europe; both the area occupied by the German peoples and the boundaries of the German state (at such times as it existed) have fluctuated constantly. The German people appear to have originated on the coastal region of the Baltic Sea and in the Baltic islands in the Bronze and early Iron ages. From about 500 BC they began to move southward, crushing and absorbing the existing Celtic kingdoms; from 58 BC onward they clashed along the line of the Rhine and Danube rivers with the power of Rome. With the fall of the Roman Empire, German peoples, predominantly under Frankish tribal leadership, closely settled a large area west of the Rhine River in what is still German territory; they also penetrated deeply into Belgium and areas that later became France. The Merovingian and Carolingian empires knew no distinction between what are now France and western Germany; it is understandable that Charlemagne (Karl der Grosse) is recognized as an important figure in the history of both countries.

The weakness of Charlemagne's successors was revealed in their inability to deal with the waves of savage invaders that poured into the empire at the end of the 9th century. In despair, people turned to local leaders able to offer protection. In the German heartland, the old tribal divisions still retained their validity, and the tribes looked for defense to an army of their own people, led by a duke. (The names of these dukedoms are still in use for some of the states [Länder] of Germany today, notably Bavaria, Thuringia, and [Lower] Saxony.) In the 10th and 11th centuries they were brought under the power of a single monarch, but this precocious centralization did not survive. The dukedoms were progressively subdivided until Germany became notorious for its Kleinstaatereiits swarm of frequently tiny states, each with its court borne on the backs of the peasantry. The states, and particularly their boundaries, were of considerable social and economic significance, introducing contrasts that are in part still perceptible today.

The rise of France as a centralized power extinguished most of Germanic control west of the Rhine, a process facilitated by German divisions; dialects of German remain in use in France only in Alsace and parts of Lorraine. However, driven by population pressure during the Middle Ages, Germans not only cleared large areas of forest for the expansion of cultivation but extended their settled area far to the east. From about 800 in the south, and about two centuries later in the centre and north, the Germans moved east in an advance that divided into three prongs: down the Danube through Austria, north of the Central German Uplands through Silesia, and along the Baltic shore. Between the prongs were the partially isolated Slav areas of Bohemia and Poland: this development held the potential for conflict that lasted until the 20th century. Islands of German people were at various times established beyond the continuously settled area as far as the Volga. The tenacity of these groups in retaining their German language and culture through the centuries was remarkable.

The German Empire created in 1871 had not included all German-speaking peoples; in particular, the Germans of the Austro-Hungarian Empire were excluded from the new Reich, while Switzerland, with its majority of German speakers, has maintained its independence to this day. After World War I large numbers of Germans who had lived under German or Austrian rule found themselves either in France-Alsace and Lorraine, German since 1871, having been returned to French control-or in the states created by the Treaty of Versailles in 1919, notably Poland and Czechoslovakia. The presence of German ethnic minorities in these countries was later used by Adolf Hitler as an excuse for military occupation. After World War II the German populations were largely expelled from Czechoslovakia and Poland; in this way the distribution of German-speaking people came more nearly to coincide with the boundaries of the German state, although Austria and German-speaking Switzerland still remained outside.

ETHNIC STRUCTURES

The Germans, in their various changes of territory, inevitably intermingled with other peoples. In the south and west they overran Celtic peoples, and there must at least have been sufficient communication for them to adopt the names of such continuing features as rivers and hills: the names Rhine, Danube, and Neckar, for example, are thought to be of Celtic origin. Similarly, in occupying the Slav lands to the east, they seem to have taken over and reorganized the Slav people along with their established framework of rural and urban settlements, many of which, including numerous physical features, still bear names of Slavic origin. The same is true of family names. In addition, large numbers of immigrants have added to the mixture: French Huguenots at the end of the 16th century, Polish mineworkers of the Ruhr at the end of the 19th, White Russians in Berlin after the revolution of 1917, and stateless "displaced persons" left behind by World War II. Prior to the 1950s there were few ethnic minorities in Germany. A population of Slavic-speaking Sorbs (Wends), variously estimated at between 30,000 and an improbable 100,000, have survived in the Lusatia (Lausitz) area, between Dresden and Cottbus, while a small number of Danish speakers are still to be found in Schleswig-Holstein, even after the Versailles boundary changes there. Of the "guest workers" (Gastarbeiter) and their families, introduced from the mid-1950s onward, the largest group are the Turks; they are distinct in culture and religion, but they do not occupy a contiguous region, being spread throughout German cities. Even more culturally distinct groups have been added by asylum seekers from countries such as Sri Lanka and Vietnam, and the opening of the eastern frontiers has brought many more (see below).

LINGUISTIC DIVERSITY

The dialectal divisions of Germany, once of conspicuous significance for the ethnic and cultural distinctions they

expansion

Ethnic minorities implied, persist despite leveling and standardizing influences such as mass education and communication and despite internal migration and the trend among the younger, better-educated, and more-mobile ranks of society to speak a standard, "accentless" German. The repository of differences in dialect now lies more with the rural populace and the longtime native inhabitants of the cities.

Standard German itself is something of a hybrid language in origin, drawn from elements of the dialects spoken in the central and southern districts but with the phonetic characteristics of the north predominating. Indeed, the pronunciation of standard German is an arbitrary compromise that gained universal currency only in the late 19th century. Even today the most "accent-conscious" of the well-educated speak with the coloration of their native district's dialect, especially if they are from the southern re-

The dialects of German

The three major dialectal divisions of Germany coincide almost identically with the major topographic regions: the North German Plain (Low German), the Central German Uplands (Central German), and the southern Jura, Danube basin, and Alpine districts (Upper German). Of the Upper German dialects, the Alemannic branch in the southwest is subdivided into Swabian, Low Alemannic, and High Alemannic. Swabian, the most widespread and still-ascending form, is spoken to the west and south of Stuttgart and as far east as Augsburg. Low Alemannic is spoken in Baden-Württemberg and Alsace, and High Alemannic is the dialect of German-speaking Switzerland. The Bavarian dialect, with its many local variations, is spoken in the areas south of the Danube River and east of the Lech River and throughout all of Austria, except in the state of Vorarlberg, which is Swabian in origin.

The Central German, or Franconian, dialect and the Thuringian dialect helped to form the basis of modern standard German. The present-day influence of Thuringian is of greatest significance in Thuringia, Saxony, and Saxony-Anhalt states. East Franconian is spoken in northern Bavaria, South Franconian in northern Baden-Württemberg. The Rhenish Franconian dialect extends northwest from approximately Metz, in French Lorraine, through the states of Rhineland-Palatinate and Hessen. Moselle Franconian extends from Luxembourg through the Moselle valley districts and across the Rhine into the Westerwald. Ripuarian Franconian begins roughly near Aachen, at the Dutch-Belgian border, and spreads across the Rhine between Düsseldorf and Bonn into the Sauer-

The dialect known as Low German, or Plattdeutsch, historically was spoken in all regions occupied by the Saxons and spread across the whole of the North German Plain. Although it has been largely displaced by standard German, it is still widely spoken, especially among elderly and rural inhabitants in the areas near the North and Baltic seas, and is used in some radio broadcasts, newspapers, and educational programs. Tiny pockets of Frisian, the German dialect most closely related to English, persist. Foreign immigration, more widespread education, the influence of the United States, and globalization also have helped create a polyglot of languages in major German

RELIGIONS

The Reformation initiated by Martin Luther in 1517 divided German Christians between Roman Catholicism and Protestantism. The Peace of Augsburg (1555) introduced the principle that (with some exceptions) the inhabitants of each of Germany's numerous territories should follow the religion of the ruler; thus, the south and west became mainly Roman Catholic, the north and east Protestant. Religious affiliation had great effect not only on subjective factors such as culture and personal attitudes but also on social and economic developments. For example, the willingness of Berlin to receive Calvinist religious refugees (Huguenots) from Louis XIV's France meant that by the end of the 17th century one-fifth of the city's inhabitants were of French extraction. The Huguenots introduced numerous new branches of manufacture to the city and strongly influenced administration, the army, the ad-

vancement of science, education, and fashion. The Berlin dialect still employs many terms of French derivation.

Population movements during and after World War II brought many Protestants into western Germany, evening the numbers of adherents of the two religions. In the former West Germany most people, whether or not they attended church, agreed to pay the church tax levied with their income tax; the revenue from this tax has been used to support community centres, hospitals, senior citizens' centres and group homes, and the construction of church buildings in the former East Germany. The centrality of religion in Germany has meant that religious leaders, especially the Roman Catholic hierarchy, sometimes exercise considerable influence on political decisions on social issues such as abortion.

In East Germany Protestants outnumbered Roman Catholics about seven to one. Although the constitution nominally guaranteed religious freedom, religious affiliation was discouraged. Church membership, especially for individuals who were not members of the ruling Socialist Unity Party (SED), was a barrier to career advancement, Similarly, youth who on religious grounds did not join the Free German Youth (Freie Deutsche Jugend) lost access to recreational facilities and organized holidays and found it difficult, if not impossible, to secure admission to universities. Not surprisingly, formal church affiliation was relatively low, amounting to only about half the population, compared with nearly seven-eighths in West Germany. However, Protestant (Lutheran) churches did act as rallying points for supporters of unofficial protest groups, leading ultimately to the demonstrations that toppled the communist government in 1989.

Lutherans and Roman Catholics in Germany now are about equal in number. Small percentages of Germans are members of what are known as the free churches, such as Evangelical Methodists, Calvinists, Old Catholics, Jehovah's Witnesses, and (by far the largest) Eastern Orthodox. The number of people professing no religion (Konfessionslose) has sharply increased and now represents about onefifth of all Germans, Because of large-scale Turkish immigration, Muslims now account for some 5 percent of the total population. Only a few thousand German Jews survived the Holocaust, During the 1990s, however, Germany's Jewish population quadrupled, the result of significant immigration from eastern Europe (especially Russia). There are now some 100,000 Jews in the country, and Berlin, with Germany's largest concentration of Jews, has experienced a modest rebirth of its once thriving Jewish community.

DEMOGRAPHIC TRENDS

"Internal" migration. After World War II Germany received more than 12 million refugees and expellees from former German territory east of the Oder and from areas with substantial German ethnic populations in central and eastern Europe. These numbers were swollen by the ranks of "displaced persons"-non-Germans unwilling to return to their former homelands. After Germany was partitioned in 1949, the demographic histories of the two parts of the country diverged, with West Germany becoming the prime target of continuing migration flows. Although immigrants, principally ethnic Germans, continued to drift in from the east, their numbers were overshadowed by a mass desertion of some two million people from East Germany. Because these immigrants from East Germany were mostly young and highly skilled, their arrival was a major gain for the booming West German economy but a grievous loss for the much smaller East Germany. In 1961 the East German government blocked further flight by its people by building strong defenses along the inner-German border and around West Berlin (including the Berlin Wall). East Germany enjoyed relative demographic tranquillity for most of the following three decades. After the disintegration of communist regimes throughout central and eastern Europe, however, the population of West Germany began to surge again, because of flows first from newly liberalized Hungary and Czechoslovakia and then from East Germany after the inner-German boundary was opened and the Berlin Wall fell in November 1989. In 1989-90 alone Konfession-

nearly 700,000 East Germans poured into West Germany; thereafter the stream continued, though from 1994 to 1997 net immigration occurred at a sharply reduced rate before increasing again because of ongoing economic problems in eastern Germany.

The arrival of these new migrants caused some resentment among western Germans because of the pressures placed on an already overburdened housing market and on social services. Because the new arrivals were mainly young and skilled, they fueled a postunification boom in western Germany but continued to drain the economy and society in the east, which still faces economic and social problems. Several hundred thousand eastern Germans also

"Guest workers'

commuted to jobs in western Germany. Immigration. To spur economic growth, West Germany began as early as the mid-1950s to encourage workers to migrate from other countries. At first these migrants were to be "guest workers," coming to work for a limited period of time only, but increasingly they sent for their families; thus, even when economic recession occurred in 1973 and the further immigration of workers was discouraged, the number of foreign residents continued to grow, reaching more than seven million people-nearly one-tenth of the total-by the beginning of the 21st century. Because of higher birth rates among the foreign-born population, non-Germans have accounted for a majority of natural population growth since the 1950s. Turks represent the largest group of foreign residents, followed by Serbs and Montenegrins, Italians, Greeks, Poles, Croats, Austrians, and Bosnians. Immigrants typically were employed in the heaviest, dirtiest, and least-remunerative jobs, and in times of economic difficulty they generally were the first to lose their jobs and the last to be reemployed. Their childrenof whom more than four-fifths have been born in Germany-are among the last to be considered for an apprenticeship or training place. Immigrants also inhabit the least-desirable housing. Turks, in particular, have formed distinctive quarters in the poorest "inner city" areas. Although the East German state prided itself on its nonreliance on guest workers, some Poles, Vietnamese, Angolans, Cubans, and Mozambicans were imported, ostensibly for "education and training,"

With the opening of the eastern frontiers and a more liberal attitude of the Soviet Union toward emigration, the influx of ethnic Germans from former Soviet-bloc countries other than East Germany became a veritable flood. Nearly 400,000 came in 1989, followed by more than 200,000 annually between 1991 and 1995; subsequently the number of immigrants fell but remained substantial. These new immigrants were less easily assimilated into western German culture than those from eastern Germany; many had difficulties with the German language and lacked marketable skills. With some apprehension, united Germany realized that an additional one million ethnic Germans could arrive from eastern Europe in the future, and there was a further fear that the freedom to travel and political or economic problems might produce a flow of untold millions of non-German residents of the former Soviet Union. Partially in response to these concerns, Germany's relations with Russia focused on attempting to improve the lot of ethnic Germans living in Russia, thereby diminishing the likelihood of mass emigration to Germany.

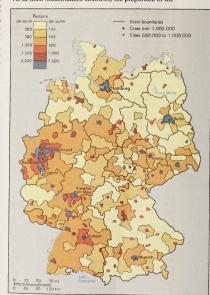

The right of asylum

West Germany's constitution guaranteed the right of asylum to those forced to flee their native countries because of political oppression. This privilege was regarded as compensation for the asylum granted to 800,000 German victims of political and ethnic persecution during World War II. Criticism of this constitutional provision mounted in the 1980s with the arrival of asylum seekers from non-European countries such as Sri Lanka, Iran, Lebanon, Ghana, and India, together with stateless Palestinians; it was diffi cult to distinguish those hoping to better themselves economically or to avoid compulsory military service from genuine victims of oppression. The issue of asylum became even more pressing when the eastern borders were opened, admitting a flood of foreigners-most prominently Poles, Romanian Roma (Gypsies), and Bosniacs (Bosnian Muslims). Between 1990 and 1993, one million people sought asylum in Germany, and, as antagonism toward immigrants increased, there was a surge of violent attacks against foreigners. Although the government and citizen groups condemned such xenophobic sentiment and behaviour, foreigners continued to be subjected to discrimination and sporadic violence. Beginning in 1991, legislation brought Germany in line with the more restrictive policies practiced by other members of the European Community (EC; since 1993 embedded within the European Union) regarding immigration from outside the EC. But while cooperation with neighbouring states reduced the flow of illegal immigrants and somewhat abated the problem. Germany nevertheless became embroiled in a domestic debate over the rights of noncitizen residents, including the right to naturalization, which had become somewhat easier for long-term residents in the late 1990s.

POPULATION STRUCTURE

General characteristics. Germany is the most populous European country west of Russia. Its population density is high in comparison with most other European countries. though it is exceeded by those of Belgium and The Netherlands. Germany has one of the world's lowest birth rates, and its life expectancy-some 75 years for males and 80 for females-is among the world's highest. Over the last several decades Germany has witnessed years of both positive and negative population growth. From the mid-1970s to the mid-1980s the country's population dropped; however, Germany experienced significant population growth-largely because of immigration-over the following decade. Thereafter the country's population growth was slight. To stem long-term population decline, governments at all levels have attempted to develop policies aimed at encouraging an increase in the birth rate, in particular by subsidizing child care and providing benefits and other tax incentives to families.

As in most industrialized countries, the proportion of the

Population density of Germany.

population under age 15 is quite low, accounting for about one-sixth of the total; in contrast, the proportion of those over age 60 has increased dramatically, representing more than one-sixth of the population. That women predominate in the older population is largely a reflection of their higher life expectancy and of the significant losses of men during World War II, but the discrepancy has become less pronounced with time. In eastern Germany the disproportion of elderly citizens increased significantly after the desertion of the young before the erection of the Berlin Wall and after its destruction in 1989.

Population distribution. Because Germany has for centuries had a profusion of states (each with towns and cities), its population is more widely dispersed than that of countries, such as France, in which centralization occurred early. It is possible, however, to discern two major population axes. The main axis runs from the Rhine-Ruhr region southward through the Rhine-Main (Frankfurt) and Rhine-Neckar (Heidelberg-Mannheim-Ludwigshafen) agglomerations, the great cities of southern Germany, and to Basel (Switzerland) and the Alpine passes. This is the main axis not only for Germany but also the European Union (EU). The second axis runs from the Rhine-Ruhr region eastward north of the Central German Uplands through Hannover, Braunschweig, and Magdeburg to the great urban concentration of Saxony. Some major cities stand in isolation outside the two axes, notably Augsburg and Nürnberg to the south and Bremen, Hamburg, and the capital city of Berlin, forming islands in the thinly populated North German Plain. Before unification, population redistribution from the agglomeration cores in western Germany was accompanied by a marked drift of population from the north to the booming cities and attractive environment of southern Germany. In eastern Germany, early gains by migration were experienced in areas of planned industrial development (Eisenhüttenstadt, Rostock, Schwedt, Hoyerswerda). After initial postwar recovery, the cities of the south lost population, reflecting industrial decline, rationalization of production, and unattractive environments. East Berlin and its satellite towns were the principal targets of migration until western Germany became accessible in 1989.

The economy

The German constitution, the Basic Law, guarantees the right to own property, freedom of movement, free choice of occupation, freedom of association, and equality before the law, However, the constitution modified the operation of the unfettered free market by means of its "social market economy" (Soziale Marktwirtschaft). With a "safety net" of benefits-including health care, unemployment and disability compensation, maternity and child-care provisions, job retraining, pensions, and many others-paid for by contributions from individuals, employers, and public funds. Germany has an economic order supported by most workers and businesses.

In the social market economy, the government attempts to foster fair play between management and labour and to regulate the relationship between the capitalist participants in the market, particularly with regard to competition and monopolies. Works councils have been established, and workers have representation on the boards of businesses. The social market economy was created by policy makers with a vivid memory of market distortions and social tensions caused by the giant industrial trusts before 1939. Legislation against monopolies appeared in 1958 and has been criticized as ineffective. For example, it has proved impossible to restrict the indirect coordination, through which individuals, banks, and other financial institutions build , up "diagonal" share holdings linking a range of firms that are nominally independent. Moreover, where a whole branch of industry has experienced difficulties (e.g., the Ruhr coal industry), even the federal government has encouraged concentration. The emergence of very large monopolistic firms has been unavoidable because, in an increasingly international economy, large firms that enjoy economies of scale are better positioned to survive. With globalization, governments are less able to regulate businesses at the national level or even at the transnational level of the EU.

The social market economy is regulated and administrated not exclusively by the federal government but by a plurality of agencies. For example, there are numerous insurance institutions that deliver social benefits. The most important institution in post-World War II Germany is the Frankfurt-based Deutsche Bundesbank (German Federal Bank). With memories of the runaway inflation of 1922-23, the West German government decided that it should never again have a license to print money and that the central bank should be independent of political control. Consequently, Germany's adoption of the euro, the EU's single currency, in 1999 raised some concerns in the country that the European Central Bank would be subject to political influence and manipulation. The Chambers of Trade, at every level of the administrative hierarchy, are also influential, and the state governments play a significant economic role (e.g., the government of North Rhine-Westphalia is intimately concerned with the survival of the Ruhr coal industry). Federal and state governments also participate in the ownership of some enterprises, notably public utilities. The Basic Law, however, prevents the arbitrary intervention of the central government.

Because Germany has numerous economic actors, a high degree of coordination has been required to achieve adequate growth, balanced foreign trade, stable prices, and low unemployment. A variety of consultative bodies unite federal and state governments, the Deutsche Bundesbank, representatives of business and of the municipalities, and trade unions. The Board of Experts for the Assessment of Overall Economic Trends, established in 1963 and known as the "five wise men," produces an evaluation of overall economic developments each year to assist in national economic decision making. Moreover, the federal government submits an annual economic report to the legislature that contains a response to the annual evaluation of the Board of Experts and an outline of the economic and financial policies it is pursuing.

Although the free market operates in Germany, the federal government plays an important role in the economy. It is accepted as self-evident that it should underwrite the capital and operating costs of the economic and social infrastructure, such as the autobahn network, waterways, the postal system and telecommunications, and the rail system. The federal government, the states, and the cities also contribute to the regional and local rapid transit systems. Government collaborates with industry in bearing the costs of research and development, as, for example, in the nuclear power industry. Federal intervention is particularly strong in the defense industry. The coal industry is perhaps the most notable example of subsidization, and agriculture has traditionally been massively protected by the state, though the sector is now governed by EU institutions. Regional planning is another significant field of government intervention; the federal government fosters economic developments in rural and industrial "problem" regions. States and cities also intervene with schemes to foster regional or local development.

Germany has a varied tax system, with taxes imposed at the national, state, and local levels. Because of the generous system of social services, tax rates on corporations, individuals, and goods and services are all relatively high in comparison with those of other countries. Germany employs a system of tax equalization, through which tax revenues are distributed from wealthier regions to less-prosperous ones. After unification these transfers were resented among many western Germans.

FROM PARTITION TO REUNIFICATION

The West German system. After the devastation of World War II, West Germany rebounded with a so-called "economic miracle" that began in 1948. The subsequent combination of growth and stability made West Germany's economic system one of the most respected in the world, though it began to suffer strains beginning in the 1990s, exacerbated by the costs of unification. Germany's remarkable economic performance was largely a result of

Social market economy

axes

Postwar economic miracle

"Vitamin

effective economic management, but temporary factors were especially important in spurring economic growth in the immediate post-World War II era. In particular, a large force of unemployed workers—returned servicemen and displaced persons—were available and eager to rebuild their own lives and willing to work hard at a rate of remuneration that left a considerable investment surplus in their employers' hands. In addition, the country reaped benefits from the joint economic planning for the American, British, and French zones of occupation that culminated in the vital and essential currency reform that introduced the deutsche mark in June 1948 and the U.S.-financed Marshall Plan (1948–52), which helped to rebuild war-torn Europe.

From 1951 to 1961 West Germany's gross national product (GNP) rose by 8 percent per year—double the rate for Britain and the United States and nearly double that of France—and exports trebled. Despite some occasional economic downturns (e.g., during the oil crisis of 1973-749, West Germany's economy followed an upward trend. Indeed, when East and West Germany reunited in 1990, West Germany's economy was enjoying a cycle of business expansion that had begun in the early 1980s and continued into 1992. By that time Germany had one of the largest economies in the world and was a leader in world rade. All this was achieved while maintaining low infla-

The East German system. East Germany also had experienced an economic miracle of sorts. Unlike the other Soviet-style states of eastern Europe, East Germany had been part of an advanced capitalist economy before the war, which gave it a considerable advantage in reconstruction. Even though it had emerged from World War II and the postwar Soviet demolitions economically ravaged, its surviving industrial infrastructure, inherited skills, and high level of scientific and technical education enabled it to develop the economy and to advance the standard of living to a level markedly higher than those of most other socialist countries, though living standards were still well below those of western Europe. East Germany became the principal supplier of advanced industrial equipment to the communist countries, though it became apparent after unification that it produced poor quality goods and caused environmental devastation.

East Germany had a command economy, in which virtually all decisions were made by the governing communist party, the Socialist Unity Party (SED). The system of planning was inflexible and eventually caused ruinous economic conditions. Power, influence, and personal connections (Beziehungen, or "vitamin B") drove economic decisions, and all groups, including trade unions, were expected to collaborate to achieve the SED's economic obiectives.

East Germany's industrial sector lacked quality controls and technological innovation. The cynicism, apathy, and inertia that were common among workers and enterprise managers contributed to low rates of East German technological development. Despite excellent training, workers were not rewarded with increased earnings for ingenuity; the result was a general malaise.

Supply and distribution were controlled by state-owned companies, and the centralized provision of services through nationalized concerns and local administrations was a generally recognized weakness. This was partially addressed by a "gray market" for goods and services in short supply (e.g., automobiles and automobile and house repairs), particularly when payment was made in hard currency; for example, repairmen offered much faster service for an extra fee or favours, and sales clerks also kept certain goods "under the counter." By the 1970s and "80s, particularly as contacts with the West increased, this gray market grew in significance.

ECONOMIC UNIFICATION AND BEYOND

The implementation of Mikhaii Gorbachev's glasnost (political liberalization) and perestrolika (economic restructuring) policies in the Soviet Union fueled sentiment of Germany that reunification could become a reality, and the basic steps toward German economic unity were accomplished with astonishing speed. The unexpected opening of the frontier between East and West Germany and the breaching of the Berlin Wall on Nov. 9, 1989, were a heavy blow to the East German economy, as the relatively small numbers of migrants, who in previous years had left the country by way of Hungary or Czechoslovakia, rose dramatically. Exacerbating the problem was the fact that most of those who left were the younger, more active members of the population and those with marketable skills. The economic unification, achieved by July 1, 1990, swept away all customs barriers and introduced the deutsche mark as the sole currency in Germany.

Following Germany's official reunification on Oct. 3, 1990 the western German economy continued to grow rapidly until 1992, after which it began to experience an economic slowdown before growth resumed in the mid-1990s. During the decade following 1992, the German economy grew at an average annual rate of 1.4 percentamong the lowest rates in western Europe. Many economists attributed the slowdown to rigid labour policies, high taxes, marginal incentives for investment, and generous incentives for workers to retire, miss work, or be unemployed. The slowdown was also related to unification. which wholly revealed the economic deficiencies of East Germany-the extent of its technological backwardness, its low productivity, and the faltering state of its manufacturing plants. Disillusionment in eastern Germany rose sharply as manufacturing output and employment declined rapidly. The federal government's insistence that eastern German firms compete immediately in the free market led to economic devastation in the east. By spring 1991, mass demonstrations against unemployment occurred regularly in Leipzig, and there was concern that economic despair would cultivate the rise of political extremism. Indeed, the Berlin office of the Treuhandanstalt (a government-owned but independent trust agency for the privatization of eastern German industry with wide powers of disposal) was firebombed, and in April 1991 its head was murdered by the West German Red Army Faction.

The Deutsche Bundesbank believed that the government had introduced the deutsche mark into eastern Germany too precipitately, with practically no preparation or possibility of adjustment, and at too favourable a rate. The effect of currency conversion and subsequent wage pressure deprived industry in the east of one of its few advantages. low labour costs. The favourable exchange rate and relatively high wages and salaries did, on the other hand, help achieve a sociopolitical goal-encouraging eastern Germans to remain in the east rather than migrating to the west, where people feared being overwhelmed by migrants. There were commercial bankruptcies in eastern Germany, and the eastern economy was further decimated by the tendency of easterners to buy the better-presented and technically superior consumer goods from western Germany or abroad rather than the generally drab products of eastern German industry; by the end of the decade, however, highquality goods produced in eastern Germany holstered the economy, and there was a wave of regional consciousness

that favoured the patronage of local products. Economic unification caused particularly severe hardships for eastern German workers; unemployment rose sharply and industrial output fell by two-thirds in the years after unification. Decline was greatest in the food-processing sector, metallurgy, building materials, machinery and vehicles, electronics and related equipment, and textiles. Eastern German agriculture also was devastated, with employment dropping by some three-fourths. Although the eastern economy later rebounded, at the beginning of the 21st century more than one-sixth of its labour force was unemployed-more than double the rate for western Germany. Unemployment also rose disproportionately for women. As a result of job losses, migration from east to west continued throughout the 1990s and into the early 21st century.

The slowness of economic recovery in eastern Germany was the result of a variety of factors. The haste of change, especially regarding the currency conversion and the breakup of the great industrial combines, and the fact that East Germany had no effective government for a period of

Low growth

Unemployment in eastern Germany three months following the economic union in July 1990 hampered economic reconstruction efforts. Even after political unification, progress was disappointing. Firms removed from ministerial control and transformed into limited companies found themselves unable to compete in the free market, burdened not only with outdated plants but with debt, because the East German government had appropriated their profits while requiring them to borrow their capital. The federal government had assumed that the reconstruction of eastern German industry would essentially come about by the takeover of plants by Western, predominantly western German, firms. In reality, however, the Treuhandanstalt set up to dispose of some 10,000 formerly nationalized firms made extremely slow progress partly as a result of an excessively legalistic approach and partly because of the shortage of experienced administrators afflicting the reconstituted public service in the east, Western German firms were under no great financial pressure to move in, and, with the help of the additional labour available from eastern German migrants, they expanded production at their existing plants without having to become involved in the difficulties of actually setting up a branch in the east. Protesters warned that eastern Germany was turning into an internal colony; however, this overly pessimistic outlook was exaggerated, and about 1992 some economic revival began to occur.

Land ownership was a significant barrier to establishing plants in eastern Germany. Following the principles of the German constitution, after unification, former owners were assured that they could reposess their property or at least be compensated for their losses. However, this did not apply to property expropriated by the Soviet military administration (1945–47), including many large estates that not everybody would be happy to see returned to their original aristocratic owners. Where a plant had originally been owned by a family or firm in western Germany but had received additional investment from the East German government and had perhaps expanded over land originally in a number of hands, western German firms were deterred from moving in, there being a lack of clear title to ownership.

The production-focused East German communist system had ignored environmental considerations. Firms seeking to take over electrical generation based on brown coal, any part of the chemical industry, or any other plant where dangerous chemicals had been used in processing faced enormous costs in attempting to meet federal government standards. Firms were also discouraged from taking over plants, because the inevitable reductions in surplus labour would involve the payment of unemployment compensation. As a result, the few western German firms setting up in the east preferred to establish a completely new plant on a green-field site, allowing them to avoid these excessive costs.

The federal government initially believed that the costs of unification could be borne by borrowing and without increases in taxation. Despite these assurances by Chancellor Helmut Kohl during the 1990 all-German election campaign, by 1991 additional taxation was required. If people in the east were disillusioned by the economic results of union, those in the west grew increasingly resentful of the cost of paving for it.

During the 1990s Germany made a number of dramatic changes in its energy sector (e.g., higher taxes, lower subsidies for coal mining, and privatization of huge eastern German energy firms), and in 2000 the government announced a plan to phase out the nuclear power industry by about 2025. Massive reconstruction projects in the east (Aubbau Ost), funded largely by higher taxes in the west, helped to improve infrastructure in the eastern regions. Telecommunications systems were upgraded, and there were generous subsidies to encourage capital investment.

Quite apart from the costs and problems associated with unification, Germany and its economy faced a number of interrelated problems at the beginning of the 21st century. High unemployment—which regularly exceeded four million people—became the chief political issue. Extremely high wages—among the world's highest—generous social services, and high taxation also dampened the economy. Unification caused the public debt to grow dramatically, and at the beginning of the 21st century some one-fifth of the annual federal budget went toward interest payments on the accrued national debt.

Although unification was more than a decade old, at the beginning of the 21st century its effects still weighed heavily on the German economy and its political institutions. However, in large measure unification gave way to other issues, such as globalization, the introduction of the euro as the single currency of the EU in 2002, and the enlargement of the EU to include central and eastern European countries. Germany's domestic economic problems and opportunities are complexly bound up with global and regional processes over which it has only varying levels of influence and control—a somewhat unsettling situation for a society that became very prosperous by following accustomed patterns and having firm control of the major levers of its own economy.

AGRICULTURE, FORESTRY, AND FISHING

Agriculture. As in other sectors of the economy, the division of Germany was reflected in a dramatic divergence of agricultural development. West Germany remained essentially a country of small family farms; in the 1980s only about 5 percent of holdings had more than 124 acres (50 hectares), though they accounted for nearly one-fourth of the total agricultural area. By the beginning of the 21st century, however, large farms represented about half of the total agricultural area in western Germany and some twothirds in eastern Germany. The change in western Germany is reflective of a rationalization of agriculture, with many small landholders leaving farming and the remaining farms often increasing in size. The larger farms in the west are mainly concentrated in Schleswig-Holstein and eastern Lower Saxony, with smaller groupings in Westphalia, the lowland west of Cologne, and southern Bavaria. Small farms predominated in the central and southern parts of West Germany. The process of steady enlargement decreased the total number of holdings by more than threefourths from 1950 to the end of the 20th century. The number of people employed in agriculture also declined substantially, from about one-fifth of the total workforce in 1950 to less than 3 percent by the end of the 20th century. Wage labourers virtually disappeared from all but the largest farms, and smaller farms were cultivated on a parttime basis.

By contrast, in the east, following conquest by the Soviet army at the end of World War II, many large estates were split up or retained as state farms. From 1952 to 1960 virtually all the small farms in East Germany were united, under strong political pressure, to form agricultural cooperatives. Agricultural production was increasingly concentrated into extremely large specialized units; by the mid-1980s state-run or cooperative crop-producing enterprises averaged more than 11,000 acres (4,450 hectares). Despite a marked decrease in agricultural workers, modern machinery and technological innovation led to increased production. After unification agricultural employment in eastern Germany plunged by about three-fourths.

In areas of high natural fertility, wheat, barley, corn (maize), and sugar beets are the principal crops. The poorer soils of the North German Plain and of the Central German Uplands are traditionally used for growing rye, oats, potatoes, and fodder beets. Technological changes have altered much of the traditional spatial pattern of German agriculture. Sugar beets, formerly confined to deep fertile soils such as the loess lands on the northern fringe of the Central German Uplands, are now much more widespread. With the availability of chemical fertilizers, light soils have become more highly valued because of their suitability for machine cultivation; for example, fodder corn is now widely grown on the North German Plain, replacing potatoes. The two most widespread forms of agricultural land use are cereal cultivation (including corn for its grains) and permanent pasture; both are important sources of animal feed. Dairying formerly was concentrated in the area of mild climate in the northern coastal lowlands and in the Alpine foothills, but it is now widespread in all areas where small farms predominate. East Germany concen-

The agricultural cooperatives

Costs of unification Vineyards

trated milk production into vast specialist holdings in arable areas where food was available and urban markets accessible. In both the western and eastern sectors, chickens, eggs, pigs, and veal calves are concentrated into large battery units, divorced from immediate contact with the soil. Besides concern for the plight of the animals under this system of concentrated production, Germans are distressed by the groundwater pollution associated with it.

In the areas surrounding western German cities, crops such as fruits, vegetables, and flowers are grown. The warm lowlands of the southwest favour tobacco and seed corn. They also support vegetables, as do the Elbe marshes south of Hamburg and the marshy Spreewald south of Berlin. Fruit grows abundantly in southern Germany: other important areas of specialization include the "Altes Land" on the Elbe south of Hamburg, the Havel lake country near Potsdam, and the Halle area. Vineyards are located in the west, especially in or near the valleys of the Rhine, Moselle, Saar, Main, and Neckar rivers, although the slopes of the Elbe valley near Dresden also produce wine grapes.

At the time of reunification, western Germany produced some four-fifths of its food requirements, and increased productivity and guaranteed prices resulted in vast surpluses (especially of butter, meat, wheat, and wine). At the beginning of the 21st century, Germany's production of major agricultural products (e.g., grains, sugar, oils, milk and meat) exceeded domestic consumption, resulting in

both exports and continued surpluses. Forestry. Some three-tenths of Germany's total land area is covered with forest. In the Central German Uplands and the Alps, forests are particularly plentiful, but they are notably absent from the best agricultural land, such as the loess areas of the North German Plain. The western part of the North German Plain also has little forest cover, but there are substantial wooded stretches farther east. Conifers predominate in the forest area; spruce now accounts for much of the plantings because of its rapid growth and suitability for building purposes and for the production of paper and chipboard. Domestic production covers about half of the demand for wood from temperate forests, but producers face severe competition from Austria, Scandinavia, and eastern Europe. The federal government, states, and municipalities own about half the forest in western Germany, with the remainder in private hands; eastern German forests are primarily publicly owned.

Fishing. Fishing in western Germany began to decline markedly from the 1970s because of overutilization of traditional fishing grounds and the extension of the exclusive economic zone to 200 miles (320 kilometres) offshore. The greatly reduced deep-sea fleet now uses freezer vessels and accompanying catchers; Bremerhaven, Cuxhaven, and Hamburg are the home ports and processing centres. During the 1990s, high-seas catches by German fishermen declined by about half. The North Sea herring fishery has almost disappeared, and now the German appetite for pickled herring is satisfied mainly by imports. There are well over 100 fishing ports on the North Sea and Baltic coasts. Fishing for shrimp and mussels is important on the mud flats fringing the North Sea. Prior to unification East Germany had a substantial deep-sea fishing fleet, but most of it has since been scrapped; its shore base for fish processing was at Sassnitz on the island of Rügen.

RESOURCES AND POWER

Germany, which has relatively few domestic natural resources, imports most of its raw materials. It is a major producer of bituminous coal and brown coal (lignite), the principal fields of the latter being west of Cologne, east of Halle, south and southwest of Leipzig, and in Lower Lusatia in Brandenburg. Other minerals found in abundance are salt and potash, mined at the periphery of the Harz mountains. The mining of most metallic minerals ceased for economic reasons in western Germany before unification; in the 1990s the centuries-old mining and processing of copper ores in the Mansfeld area of eastern Germany and the mining and processing of uranium ores for the benefit of the Soviet Union in the Ore Mountains also stopped. There are small reserves of oil and natural gas in northern Germany.

As in all industrialized countries, water supply is a constant problem. The filtration of water on riverbanks (e.g., those of the Rhine) is one source. It is supplemented by reservoirs in the uplands. For example, the Harz mountain range provides water to much of the North German Plain as far as Bremen, and the Ore Mountains supply the central German industrial region.

Oil is Germany's principal source of energy. As domestic production is quite limited, most crude oil is imported. Many petroleum products also are imported, transported from Rotterdam by product lines, barges, and rail. Until the mid-1950s the refining of oil took place at the coast, notably at Hamburg and Rotterdam; however, refineries have been developed at inland locations close to markets. mostly on rivers such as the Rhine and Danube, which are served by pipelines from Wilhelmshaven, Rotterdam (Netherlands), Lavéra (near Marseille, France), Genoa (Italy), and Trieste (Italy). Eastern Germany receives oil delivered by pipeline from Russia to a refinery at Schwedt on the Oder, which supplies the central German industrial region; there is also a pipeline from Rostock that provides industry with oil. German supplies of natural gas are significant, but most gas is imported. Principal sources are the Friesian and North Sea fields of The Netherlands and the Norwegian North Sea. Gas is imported from Russia via a pipeline from the Czech Republic, with a branch serving eastern Germany and Berlin.

Bituminous coal, Germany's second most important source of energy, is available in profusion from the Ruhr field and from the smaller Saar, Aachen, and Ibbenbüren fields, though extraction is costly and often subsidized. In the last half of the 20th century, however, output shrank by some two-thirds. Coal now has two major uses: the generation of electricity and the production of metallurgical coke. A striking feature of the German economy is the significance of brown coal (lignite). This low-grade, waterlogged fuel can be worked economically in vast open pits, which are mined with massive machines. About seveneighths of all the coal is fed straight to electric-power generating stations that are situated on the field itself. A relatively small quantity of the coal is pressed into briquettes for domestic heating. Electricity generation is also the principal use of the main fields in eastern Germany: however, during partition lignite was a major basis of the chemical industry as well as a source of gas and briquettes for urban consumption. After unification many eastern German pits closed, particularly those producing the most sulfurous coal. The shortfall in energy output led the federal government to subsidize additional imports of gas from Russia.

The largest producers of electric energy are the thermal plants that are located primarily in the Ruhr and the Rhenish brown-coal fields and in the brown-coal fields of the east, especially in Lower Lusatia. During partition all western German plants were required to significantly reduce the emissions of the dust, sulfur dioxide, and nitrogen oxide formerly emitted into the atmosphere. Plants in the east were not similarly regulated and thus contributed to general atmospheric pollution; after unification a number of them were closed and others were upgraded.

Nuclear power plants rival thermal plants in significance; in western Germany they are typically located on the coast or on rivers far from the coalfields. Plants in eastern Germany, built on the Soviet (Chernobyl) model, were closed for safety reasons. In 2000 the German government committed to phasing out all of the country's nuclear power plants within about 20 years, though the future of nuclear power, as well as the number of years that existing plants would function, was unclear.

The canalization of such rivers as the Main, Neckar, and Moselle, together with hydroelectric power plants in the Alps, produce relatively minor amounts of electric power; pumped storage schemes in mountain areas are important in meeting peak electricity demands. Before unification, East and West Germany had distinct transmission grids without interconnection. The West German network was linked to that of neighbouring countries, allowing it to import surplus power from the French nuclear system and, during the Alpine snow melt, especially from Austria. West Nuclear power

Coal

Brown coal (lignite) pit in Eschweiler in the Rhenish field between Cologne and Aachen, North Rhine-Westphalia.

Berlin formerly was forced to generate its own power, adding to urban pollution. The eastern and western German grids were connected in the 1990s, and West Berlin was connected to the network in 1994.

MANUFACTURING

Industrial employment in western Germany declined steadily from a postwar peak. However, deindustrialization was not as precipitous in Germany as it was in some other European countries. Western German industry benefited from the willingness of banks to take a long-term view on investment and of the federal government to underwrite research and development. German industrial products are viewed with great prestige on world markets and are in strong demand overseas. By contrast, unification revealed that most of eastern German industry was incapable of competing in a free market.

Germany is one of the world's leading manufacturers of steel, with production concentrated in the Ruhr region; however, since the peak output of the early 1970s, a number of plants have closed. (The steel industry in eastern Germany was largely abandoned after unification, though some production was reestablished at a renovated plant at Eisenhuettenstadt.) Germany's principal industries include machine building, automobiles, electrical engineering and electronics, chemicals, and food processing. Automobile manufacturing is concentrated in Baden-Württemberg, Lower Saxony, Hessen, North Rhine-Westphalia, Bavaria, the Saarland, and Thuringia. Leading automobile manufacturers in Germany include Audi, BMW, Daimler-Chrysler (formerly Daimler-Benz), Ford, Opel, and Volkswagen. Following unification, production of the environmentally unfriendly Trabant and Wartburg cars in eastern Germany ceased. Volkswagen, Opel, and Daimler-Benz were quick to establish assembly or parts production in the east. Shipbuilding, once a major industry, has de-

clined significantly.

Since the late 19th century Germany has been a world leader in the manufacture of electrical equipment. As the home of internationally known firms such as Siemens, AEG, Telefunken, and Osram, Berlin was the industry's principal centre until World War II, after which production was largely transferred to Nürnberg-Erlangen, Munich, Stuttgart, and other cities in southern Germany. The output of these centres made Germany one of the world's leading exporters of electrical and electronic equipment.

• In East Germany electrical and electronic production was concentrated in East Berlin, with Dresden forming a second important centre. The country was a major supplier of electronic equipment (e.g., computer-controlled robots) to the communist world. Although eastern German plants were outdated in comparison with those in the west, both Dresden and Erfurt achieved some success in developing microelectronics production following unification.

With the discovery of synthetic dyestuffs in the late 19th

century, Germany became a world leader in the chemical industry. Most of the western German chemical industry is concentrated along the Rhine or its tributaries, notably in Ludwigshafen, Hoechst (near Frankfurt), and Leverkusen (together with a row of other plants along the Rhine in North Rhine-Westphalia). Chemical plants also operate in the Ruhr region. The majority of East German chemical plants were on the two brown-coal fields of Lower Lusatia and Halle-Leipzig; after unification some plants were closed because of environmental reasons, and others were unperaded.

Germany is also particularly strong in the field of optical and precision industries. The once-mighty textile industry has suffered from overseas competition but is still significant. Principal centres are in North Rhine-Westphalia (Mönchen-Gladbach, Wuppertal) and southern Germany. After unification many textile plants were closed in eastern Germany, where employment in the sector plunged by some nine-tenths.

EINIANIC

The central banking system. Germany's central bank, the Deutsche Bundesbank, is headquartered in Frankfurt am Main, which is the country's main financial centre and also the base of the European Central Bank, the EU's chief financial institution. Before the circulation of the euro, the common currency of the EU, in 2002, the Bundesbank issued the deutsche mark (the country's former currency) and oversaw its circulation. As the EU's most powerful national central bank, the Bundesbank played a pivotal role in the planning of and preparation for the euro. One of its primary roles now is to implement the monetary policies of the European System of Central Banks to help maintain the euro's stability.

ts of the
es Bundesin bank

iint
ne-

The role

Upon the establishment of the Bundesbank, its preeminent characteristic was its independence from government control, instituted to prevent a recurrence of the severe inflation experienced in 1922-23, when the government resorted to the printing press for finance. The federal bank maintained a policy of careful control of credit and concern for the international exchange rate of the deutsche mark, which had made West Germany the leading financial power in post-World War II Europe. The Bundesbank demonstrated its genuine independence in 1991 when it insisted that additional government expenditure for the eastern sector be covered by unwelcome tax increases rather than by borrowing. Individual Land (state) central banks are the Bundesbank's representatives at state level

The private banking sector. There are hundreds of commercial banks, of which the most important are the Deutsche Bank, the HypoVereinsbank, the Dresdner Bank, and the Commerzbank, though mergers have tended to shrink the number of major banks. Apart from conducting normal banking business, German banks provide financing for private businesses. As a result, the stock exchanges in Frankfurt, Düsseldorf, and other cities are less influential in providing finance for industry than parallel institutions in other countries.

Public and cooperative institutions. Germany has several types of public ifnancial institutions, including credit and personal checking institutions and cooperative banks. Under public law, credit institutions operate as savings banks, and the state banks act as central banks and clearinghouses for the savings banks and focus on regional financing. The state-owned Kreditanstalt für Wiederaufbau ("Development Loan Corporation") channels public aid to developing countries.

The cooperative banks are headed by the DZ Bank (Deutsche Zentral-Genossenschaftsbank, or "German Central Cooperative Bank"), which serves as a central bank for some 1,500 industrial and agricultural credit cooperatives. There are also public and private mortgage banks, installment credit institutions, and the now-privatized postal check and postal savings systems, which were once operated by the federal postal services.

In East Germany the state bank was subordinate to the Ministry of Finance and designed to be a tool of central planning. It was part of a unified system that embraced not

Steel manufacture only central and local government but also banks, insurance companies, and industries, all of which were directed in their use of funds.

With economic union on July 1, 1990, East Germany came under the central banking system of the Deutsche Bundeshank, which effected the conversion of the eastern system to the West German mark. Progressively, the western German commercial banks, insurance companies, and all the other financial institutions moved in. The ruined East German economy, the unemployment assistance fund, and the bankrupt state and local administrations all required massive financial transfusions from the federal government and the West German states. In stages, consumer subsidies have been removed, while wages, social insurance payments, and taxes have been progressively raised toward western levels.

Principal trading partners

One of the world's leading exporters, Germany has consistently maintained a surplus with its trading partners. More than half of its trade is with members of the EU. Germany's principal export markets are France, the United States, the United Kingdom, Italy, and The Netherlands. Trade with eastern and central Europe has increased, and Germany has replaced the former Soviet Union and Russia as the primary trading partner for most countries in the region. Major exports include transport equipment (including automobiles), electrical machinery, and chemicals, as well as some food products and wine. Imports fall into remarkably similar categories, but in addition they include raw materials and semifinished products for industry. Germany's major sources of imports include France, The Netherlands, Italy, the United States, the United Kingdom, and Belgium.

Before unification East Germany specialized as a supplier of advanced industrial equipment, electronics, ships, and rail rolling stock to the communist bloc countries. Following economic unification, the countries of the former communist bloc were virtually unable to pay for equipment in hard currency, with disastrous consequences for eastern German industry. However, unlike the other former communist countries, eastern Germany, as part of united Germany, automatically received the benefits of full EC membership, though its factories also immediately faced overwhelming competition from western producers.

As is the case in many other countries with an advanced economy, Germany's service sector (i.e., trade, transport, banking, finance, and administration) is a leading employer. This is abundantly clear in urban centres throughout western Germany, with their concentration of retailing, banking, and insurance. The transformation of eastern Germany along these lines is in progress, and the sector's importance has grown considerably there. For example, while the economies of most eastern and western German states were still dominated by manufacturing in the early 1990s, by the end of the decade a majority of states, and the country as a whole, had economies with a higher level of output by private firms providing services (even excepting trade and transport, which are categorized separately). In short, the German economy, for years one of the world's most manufacturing-oriented economies, has become dominated by services. This is particularly well illustrated by Berlin, where manufacturing's importance has declined sharply; indeed, the city has become an increasingly significant centre for both public and private international and national service-sector institutions.

Although foreign tourism to Germany is substantial, receipts from German tourists abroad exceed the receipts from foreign visitors to the country. In comparison with many of its neighbours, Germany does not rely heavily on tourism for income. The Alps and the Rhine and Moselle valleys are leading destinations, though urban areas (e.g., Frankfurt, Munich, and Berlin) also attract many visitors, and local festivals in places such as Bayreuth also entice tourists. Tourism to eastern Germany, particularly to the beaches along the Baltic Sea, has increased significantly since unification.

LABOUR AND TAXATION

Germany's highly urban and industrialized character is reflected in its employment patterns. Services, including trade and finance, account for the largest share of employment. At the turn of the 21st century, about one-fifth of workers were employed in manufacturing, and fewer than 3 percent were employed in agriculture-related indus-

Prior to World War II most German labour unions were organized along partisan lines. After the war, however, trade unions were reconstituted to represent an entire industrial branch rather than simply a single trade or skill, thus avoiding interunion jostling within plants, and an independent German Trade Union Federation (Deutscher Gerwerkschaftsbund; DGB), which represents nearly all the country's unionized industrial employees, was established. The federation is an agglomeration of mostly bluecollar unions (though there are some white-collar unions), the largest of which are the United Service Industries Union (Vereinte Dienstleistungsgewerkschaft), the Metalworkers' Union (IG Metall), the Public Services and Transport Workers' Union (Gewerkschaft Nahrung-Genuss-Gastätten), the Mining, Chemical, and Energy Union (Industriewerkschaft Bergbau, Chemie, Energie). and the Federation of Civil Servants (DBB-Beamtenbund und Tarifunion).

Although Germany's social economy allows collective bargaining, unions are generally viewed as partners rather than opponents of business. The common interests of management and labour are expressed in works councils. Labour also has a right of codetermination (Mithestimmungsrecht) through representation on managerial boards. About one-third of all German workers belong to a trade union. German's average labour costs are among the highest in the world.

Taxes are the major source of revenue for all levels of government. Five types of taxes-value-added, wage, assessed income, energy, and corporate-account for nearly fourfifths of all revenues. The federal government and the states each receive more than two-fifths of the principal taxes, leaving the remainder for local councils. A host of lesser taxes are specific to either the federal level (such as the tax on tobacco and alcohol and customs duties), the states (tax on beer and motor vehicle licenses), or the local authorities (tax on real estate, trade, and public entertainment). The states also benefit from property taxes. Because the taxing potential of the states is unevenly distributed, the economically weaker or smaller states share in the tax revenue of the richer or more populous states through a process of "horizontal financial equalization," which became an especially controversial matter after unification, when the poorer eastern German states became entitled to subsidies from western Germany. The federal corporate tax rate is about 25 percent, and, when local taxes are included, the overall tax burden reaches about 40 percent. Germany imposes a value-added tax of 16 percent to most goods and services. To spur economic growth, the German government reduced personal and business taxes in the late 1990s.

The federal government is obligated to transmit certain revenues to the EU. Germany's disproportionately large payments to the EU have become a significant domestic and EU-wide political issue. As one of the world's richest countries, Germany feels obliged to supplement its regular contributions to the United Nations with complex international aid programs of its own.

TRANSPORTATION AND TELECOMMUNICATIONS

Germany has a dense network of communication facilities. Its geographic location in the heart of Europe also makes Germany responsible for facilitating the transit traffic serving neighbouring countries.

Waterways. The Rhine has the great advantage of having a remarkably even flow, with a spring-summer high water from the Alpine snowmelt supplemented by autumn-winter rains in the Central German Uplands. It is navigable from its mouth to above Basel, Switzerland, with the support in its upper course of the French Grand Canal d'Alsace. Typically, river transport is accomplished by taxes

using push units propelling several barges. Since World War II the Rhine tributaries have been opened up for travel and transport. Navigation on the Moselle has been improved to the Saar region and Lorraine, on the Neckar to Stuttgart, and on the Main to provide a major European link to the Danube. Canals through the Ruhr region allow access to the northern German ports of Emden, Bremen, and Hamburg; waterway connections eastward to Berlin were once inadequate, especially at the crossing of the Elbe, but are being improved.

Seaports. Hamburg, which handles some one-third of the overall tonnage by weight, is Germany's principal port, accommodating the largest share of containers, as well as various ores and a wide range of general cargo. But because the largest tankers can no longer reach the Hamburg refining centre, Wilhelmshaven has become the prime destination for Germany's oil imports, as well as a major port in general. The Weser ports (Bremen and Bremerhaven) also handle a significant amount of total tonnage and containers; Bremen has an important general cargo trade. Although Hamburg, the Weser ports, and Emden are able to transship heavy goods to the interior by waterway, they play a less important role in this area than Rotterdam and other ports located at the mouth of the great Rhine waterway and closer to the Rhine-Ruhr area than the northern German ports are. Because the Elbe River leads to the port of Hamburg in what was West Germany and the Oder River to Szczecin (Stettin) in Poland, East Germany developed a new deep-sea port at Rostock, which was served by motorway and rail but had no waterway link. Some commodities needing fast service continued to arrive at special East German quays at Hamburg. Hamburg has regained much of its former Elbe trade since unification, but Rostock remains busy. Ferries for passengers, road vehicles, or railcars link Germany with Scandinavian destinations

Railways. During the country's partition, the rail system was divided as well. In West Germany the Deutsche Bundesbahn (German Federal Railroad) reconstructed the old system, converting it to electric and diesel traction. The configuration of the country placed the emphasis on northsouth routes. The burdened Rhine valley lines and the difficult routes through Hessen were augmented by a superbly engineered (and extremely expensive) high-speed track that permitted speeds up to 155 miles (250 kilometres) per hour. High-speed passenger rail service now links major German urban centres with one another and with other European destinations. The rail system competes successfully with airlines by offering fast and regular Inter City (IC) and Trans-European Express (TEE) trains.

East Germany retained the old name of Deutsche Reichsbahn ("German Imperial Railroad") for its system. Postwar reconstruction was slow, with efforts centring on rail links with the country's eastern European neighbours and the port of Rostock. The once-important east-west routes across the inner-German boundary were either removed or neglected. The Berlin outer-ring railroad was completed, enabling mainline and local traffic to avoid West Berlin. Unification revealed the dilapidated state of the system. Within Berlin, the trains, buses, and trams of the public transport were totally divided. Yet, when the border reopened, both the S-Bahn (Stadtbahn), an elevated railway system, and the U-Bahn (Untergrundbahn), the subway, were immediately able to resume service from east to west. (Two U-Bahn lines had continued to cross through areas of East Berlin but were not permitted to make stops at intermediate stations.) A lengthy and costly process of fully restoring a unified system, both within Berlin and nationally, began in late 1989 and resulted in significant progress for eastern Germany's railway network.

· Highways. Germany completed the first section of the autobahn, near Berlin, in 1921, and several other countries quickly followed with their own versions of high-speed expressways. In the 1930s Hitler exploited the autobahn for economic, military, and propaganda purposes, but during World War II this German innovation-regarded as a model for modern expressways-was battered. The West German government greatly extended the system from 700 miles (1,125 kilometres) in 1950 to more than 5,000 miles

(8,000 kilometres) by the time of unification. With powerful German automobiles able to cruise at their top speeds without speed limits, the autobahn gained an aura of automobile-centred romanticism throughout the world in the second half of the 20th century. However, road construction has encountered serious opposition from the country's environmentalist movement, and in inhabited areas the roads sometimes have been narrowed rather than widened to reduce traffic speed. Because the growth of the system has been slower than the growth of traffic, congestion is a serious problem, especially on motorways in industrial areas. Attempts to divert shipment of goods to the railways have not prevented a steady rise in the transport of goods by road. Western German motorways have direct transfrontier connections with the similar systems of Denmark. The Netherlands, Belgium, France, and Austria.

With a lower growth rate of motor traffic (and an official policy of giving preference to the railroads), postwar construction of motorways was less advanced in East Germany. There were some improvements in central Germany, and new links to the ports of Rostock and Hamburg were constructed. The Berliner Ring, a circle of expressways around the city, was completed in 1979. With reunification, many transboundary roads were reopened and road surfaces improved. However, the construction of new roads has been hindered by conflicts between those seeking greater accessibility for automobiles and those seeking to protect the landscape and reduce air pollution.

Air transport. Germany's major long-distance airline is Lufthansa, though there also are a number of other carriers that service European and North American destinations. Frankfurt's airport, one of the world's busiest, is the country's largest; airports in Düsseldorf, Munich, and Berlin (Tegel) are also of major importance. During the period of partition, passenger traffic from West Germany to West Berlin was restricted to the airlines of France, the United Kingdom, and the United States. After unification Berlin was opened to German carriers (and indeed to carriers of other countries). East Germany discouraged internal air traffic and the growth of regional airports, using the rail and Berlin subway systems to serve its major international airport, Berlin-Schönefeld, south of the city. During the late 1990s, expansion of Schönefeld began, and it was expected to become united Berlin's only commercial airport by about 2010, after major expansion projects.

Telecommunications. After World War II West Germany developed an advanced telecommunications system. By contrast, the East German telephone system was completely insufficient; people requesting a telephone often were faced with a wait of up to 12 years. The deficiencies of the telecommunications system were a major impediment to the restructuring of the administration and the economy following unification, but by the late 1990s rapid reconstruction of the system using current technology made eastern Germany a world leader in advanced telecommunications infrastructure.

The leading German telecommunications company is Deutsche Telekom AG. During the late 1990s the entire sector was liberalized, increasing the number of telecommunications firms and competition for Deutsche Telekom from companies such as Vodafone and VIAG Interkom. The adoption of telecommunications services by German consumers has been widespread, particularly for cellular services. By the early 21st century more than one-third of the population used the Internet regularly.

1150 (T.H.El./G.H.K./W.H.Be.)

Administration and social conditions

The structure and authority of Germany's government is derived from the Grundgesetz, or Basic Law, which went into force on May 23, 1949, after formal consent to the establishment of the Federal Republic (known as West Germany) had been given by the military governments of the Western occupying powers and upon the assent of the parliaments of the Länder (states) to form the Bund (federation). West Germany then comprised 11 states and West Berlin, which was given the special status of a state without voting rights. The capital was located

The autobahn Internet

The new

Länder

in the small university town of Bonn, as an obviously provisional solution. Virtually simultaneously, on Oct. 7, 1949, the Soviet Zone of Occupation was transformed into a separate, nominally sovereign nation (if under Soviet hegemony), known formally as the German Democratic Republic (and popularly as East Germany). The five federal states (Länder) within the Soviet zone were abolished and reorganized into 15 administrative districts (Bezirke), of which the Soviet Sector of Berlin was the capital.

In the case of West Germany, full sovereignty was achieved only gradually: many powers and prerogatives, including those of direct intervention, were retained by the Western powers and devolved to the Federal Republic only as it was able to grow in economic and political stability and to be integrated into the Western community of nations. The tripartite offices of military governor were replaced upon the creation of the Federal Republic by those of high commissioners, and upon its achievement of full sovereignty on May 5, 1955, the high commissioners became ambassadors accredited to the president of the republic.

The Democratic Republic regarded its separation from the rest of Germany as complete, but the Federal Republic regarded East Germany as an illegally constituted state. until the doctrine of "two German states in one German nation" was developed in the 1970s. A sequence of gradual rapprochements between the two governments helped regularize the anomalous situation, especially concerning travel, transportation, and the status of West Berlin as an exclave of the Federal Republic.

During the process of unification, East Germany, as a condition for integration into the Federal Republic, reconstituted the five former historic states of Brandenburg. Mecklenburg-West Pomerania, Saxony, Saxony-Anhalt, and Thuringia. As states of the united Germany, they have adopted administrative, judicial, educational, and social structures parallel and analogous to those in the states of former West Germany. East and West Berlin were reunited, forming a state by itself.

Because the former East Germany de jure had petitioned to be integrated into the existing Federal Republic and de facto was thoroughly bankrupt and prostrate politically and economically, it entered the German Federal Republic without any bargaining power whatsoever. All changes and adaptations were thus completely on the terms set by Bonn, with few legal concessions allowed for the transitional period.

With the achievement of unification on Oct. 3, 1990, all remaining vestiges of the Federal Republic's qualified status as a sovereign nation were voided. No longer, for example, was Berlin still technically occupied territory, with the ultimate authority vested in the military governors. The very choice of the term Grundgesetz, or Basic Law, had purposely been chosen in 1949 to stop short of implying a permanent constitution (Verfassung), the promulgation and signing of which remains a final formal step in Germany's long progression to complete and unrestricted sovereignty.

In the days of the empire, German society was among the most intricately hierarchical in all Europe. The social upheaval of two major wars and economic change, though loosening this rigidity, left the basic class structure-with certain notable exceptions-essentially intact. Present-day German society is no longer plagued by class consciousness, but a sense of one's station in life is implicitly understood. Education still commands a greater awe in Germany than in many countries; the professor is held in an esteem incomprehensible to foreigners, and the title "doctor" is an all-but-essential credential for advancement not only in the upper echelons of the professions and the civil service, where a certain erudition is not inappropriate, but also-even more baffling to outsiders-in the ranks of business. The older authoritarianism, however, especially after the social upheaval of the 1960s and '70s, was greatly tempered by a healthy skepticism toward those who formerly simply by virtue of their title and position could command respect and obedience. As in other advanced nations, the basis of power has passed to the technical and managerial meritocracy

By the time of unification in 1990, society and social conditions in western Germany had come in close harmony with those of its western European neighbours, while the inhabitants of former East Germany, after 40 vears of one of the most rigid of Marxist-Leninist regimes, had grown radically apart from their kinsmen in the West Collectivism and suppression of individual initiative in return for assured employment and provision of the basic requirements of life free or at low cost had produced a society antithetical to that in the West.

The Basic Law has many affinities with the constitutions in the Anglo-American democracies and its predecessor, the Weimar Constitution (upon which it drew heavily). The parliamentary form of government incorporated many features of the British system, but, since West Germany, unlike Great Britain, was to be a federation, many political structures were drawn from the models of the United States and other federative governments. In reaction to the unitary state of the Nazi era, the Basic Law gave the states considerable autonomy, much of which has been eroded by constitutional amendments, fiscal developments, and a political insistence on uniform living conditions throughout the Federal Republic. In addition to federalism, the Basic Law has two other features similar to the Constitution of the United States: (1) its formal declaration of the principles of human rights and of bases for the government of the people and (2) the strongly independent position of the courts, especially in the right of the Federal Constitutional Court to declare a law unconstitutional and void.

Executive and legislative power. The formal chief of state is the president. Intended to be an elder statesman of stature, he is chosen for a term of five years by an assembly specially convened. His functions are far from being merely honorific. Apart from representing the Federal Republic among other nations and signing all federal legislation and treaties, he nominates the federal chancellor and the chancellor's Cabinet appointments, whom he may dismiss upon the chancellor's recommendation. He cannot, however, dismiss the federal chancellor or the Bundestag, the federal parliament. Among his other important functions are those of appointing federal judges and certain other officials and the right of pardon and reprieve.

The government in power is headed by the chancellor, who is elected by a majority vote of the Bundestag upon nomination by the president; in practice, the chancellor is always the chairman of his party. He is vested with considerable independent powers and initiates government policy. His Cabinet and its ministries also enjoy extensive autonomy and powers of initiative. The chancellor can be deposed only by an absolute majority of the Bundestag and only after a majority has been assured for the election of his successor. This "constructive vote of no confidence," as it is called, makes it unlikely for a chancellor or his government to be unseated, however much his working majority may have dwindled. Only twice has an attempt been made to unseat a chancellor, and only once with success (in 1982 when Helmut Schmidt was replaced by Helmut Kohl). The Cabinet may not be dismissed by a vote of no confidence by the Bundestag. The president may not dismiss a government or, in a crisis, call upon a political leader at his discretion to form a new government, the latter constitutional provision being based on the experience of the sequence of events whereby Adolf Hitler-against the better judgment of the Reich president

The number of Cabinet ministers may vary. Most Cabinet members are delegates to the Bundestag and are drawn from the majority party or proportionally from the parties forming a coalition, but the chancellor may appoint persons without party affiliation from a certain area of technical competence. These nondelegate members speak or answer questions during parliamentary debates.

The chancellor is immediately assisted by his secretaries of state, who administer various aspects of foreign and internal affairs or the conduct of press and information services; they may exercise wide powers of discretion in carrying out the instructions of the chancellor. The The constitutional frame-

of the Weimar Republic-became chancellor in 1933.

Ministries of the Cabinet

Cabinet ministries-apart from the major areas of foreign policy, finance, defense, internal affairs, justice, and economy-are responsible for such technical and social functions as post and telecommunications (including the post office, the telephone system, and certain aspects of broadcasting); youth, family, and health; economic cooperation; education; nutrition; labour; and housing and urban development and regional planning.

Certain individual organs of government administer such areas as internal security, intelligence, press and public information, and statistics; they operate under the direct authority of the chancellor. The Federal Audit Office, independent of both chancellor and Bundestag, is charged with the accounting and budgetary control of all govern-

mental functions.

Methods

of consti-

tuting the

chambers

tarv

parliamen-

The Bundestag is the cornerstone of the German system of government; as of the general election of Dec. 2, 1990 it consisted of 662 members (subject to slight variation). Its delegates are chosen either in general elections held every four years or in special by-elections. In addition to the members elected by each district, a set of state delegates at large is elected simultaneously, both as a means of ensuring stability and continuity of representation by the major parties in the lower chamber and as a corollary to look to the interests of nation, state, party, or bloc of voters at large. In this latter function the delegates at large serve as a counterbalance to the parochial tendencies inherent in strict representation by district constituency mandate.

The Bundestag exercises much wider powers than does the upper chamber, known as the Bundesrat, or Federal Council. In the Bundesrat the states themselves exercise authority to protect their rights and prerogatives. Its members are appointed by the governments of the states, each state sending from three to five members, depending on size and population; the new state of Berlin, for example, sends four members. The delegations are bound by the instructions of their provincial governments. All legislation originates in the Bundestag, and the consent of the Bundesrat is necessary only on certain matters directly affecting the interests of the states, especially in the area of finance and administration and for legislation in which questions of the Basic Law are involved. It may exercise a restraint on the Bundestag by rejecting certain routine legislation passed by the lower chamber, but, unless the bills fall within certain categories, its vote may be overridden by a simple majority in the Bundestag. Should the president be absent abroad for extended periods or withdraw from office, the speaker of the Bundesrat may deputize for him.

The powers of the Bundestag are kept in careful balance with those of the Landtage, the state parliaments. Certain powers are specifically reserved to the republicforeign affairs, defense, currency and minting, post and telecommunications, customs and problems of international trade, and matters affecting citizenship. The Bundestag and the states may pass concurrent legislation in such matters when it is necessary and desirable, or the Bundestag may set out certain guidelines for legislation; drawing from these, each individual Landtag passes appropriate legislation in keeping with the particular needs and circumstances of its own state. In principle, the Bundestag initiates or approves legislation in matters in which uniformity is essential, but the Landtage otherwise are free to act in areas in which they are not expressly restrained by the Basic Law.

Provincial and municipal government. Certain functions are expressly the province of the states, notably education and law enforcement; yet even here an attempt is made to maintain a degree of uniformity among the 16 states through joint consultative bodies. The governments of the states are generally parallel in structure to that of the Bund but need not be. In 13 of the states the head of government has his own Cabinet and ministers; each has its own parliamentary body, but in the city-states of Hamburg, Bremen, and Berlin the mayor is simultaneously the head of government of the state. The municipal senates serve also as provincial parliaments, and the municipal offices assume the nature of provincial ministries.

The administrative subdivisions of the states (exclusive

of the city-states and the Saarland) are the Regierungsbezirke (administrative districts). Below these are the divisions known as Kreise (counties) or, in parts of northern Germany, as Grafschaften, roughly equivalent to counties. Larger communities enjoy the status of what in Great Britain was formerly the county borough. The counties themselves are further subdivided into the Gemeinden. roughly "communities" or "parishes," which through long German tradition have considerable autonomy and responsibility in the administration of schools, hospitals, housing and construction, social welfare, public services and utilities, and cultural amenities.

State and federal courts. The German court system differs from that of some other federations, such as the United States, in that all the trial and appellate courts are state courts, while the courts of last resort are federal. All courts may hear cases based on law enacted on the federal level, though there are some areas of law over which the states have exclusive control. The federal courts assure the uniform application of national law by the state courts. In addition to the courts of general jurisdiction for civil and criminal cases, the highest of which is the Federal Court of Justice, there are four court systems with specialized jurisdiction in administrative, labour, social security, and tax matters. The jurisdiction of the three-level system of administrative courts extends, for example, to all civil law litigation of a nonconstitutional nature unless other specialized courts have jurisdiction.

Structure of the system

While all courts have the power and the obligation to review the constitutionality of government action and legislation within their jurisdiction, only the Federal Constitutional Court in Karlsruhe may declare legislation unconstitutional. Other courts must suspend proceedings if they find a statute unconstitutional and must submit the question of constitutionality to the Federal Constitutional Court for its determination. In serious criminal cases the trial courts sit with lay judges, similar to jurors, who are chosen by lot from a predetermined list. The lay judges decide all questions of guilt and punishment jointly with the professional judges. Lay judges participate also in some noncriminal matters.

Judges play a more prominent and active role in all stages of legal proceedings than do their common-law counterparts, and proceedings in German courts tend to be less controlled by prosecutors and defense attorneys. There is less emphasis on formal rules of evidence, which in the common-law countries is largely a by-product of the jury system, and more stress on letting the facts speak for what they may be worth in the individual case. Observers from common-law countries might find the lack of certain elements of the adversarial process, particularly in criminal trials, difficult to reconcile with their notion of fairness, but Germans are not necessarily persuaded that such a process leads to greater justice. There is no plea bargaining in criminal cases. In Germany, as in most European countries, litigation costs are relatively low as compared with the United States, but the losing party in any case usually must pay the court costs and attorney fees of both parties.

While codes and statutes are viewed as the primary source of law in Germany, the role of precedent is of great importance in the interpretation of legal rules. German administrative law, for example, is case law in the same sense that there exists no codification of the principles relied upon in the process of reviewing administrative action. These principles are mostly judgemade law. Germans see their system of judicial review of administrative actions as implementation of the rule of law. In this context, the emphasis is on the availability of judicial remedies. While in the United States there is a tendency to consider procedural safeguards, such as a requirement for a hearing before an administrative decision is made, to be a major requirement of the rule of law, a citizen's rights in this formative stage have been of lesser concern in Germany.

Integration of former East Germany. The integration and adaptation of the administration of justice of the new

Administrative

Voting

age

Party

states into the system operative in the Federal Republic was greatly complicated by an unavoidable incapacitation of a large number of judges. They had to be dismissed either because they owed their appointment as judges mainly to their loyalty to the old SED or because of their records. To fill the many vacancies created in the courts of the new Länder, judges and judicial administrators had to be recruited from former West Germany. A large number were "put on loan" from the western Länder and many others urged out of retirement to help during the transition.

POLITICAL INSTITUTIONS

The electorate. Both the quadrennial general and provincial elections as well as local elections are attended with the greatest interest and involvement on the part of the electorate. The public is kept informed on political issues through intense coverage in the press, television, and radio, and political affairs frequently provide a topic for debate among German citizens. In 1970 the voting age was reduced from 21 to 18. Although voting is not compulsory, an extremely high percentage of citizens participate. Since elections in the states are staggered throughout the life of each Bundestag, they act as weather vanes of public opinion for the incumbent federal government.

Political parties. Germany's political parties, the sheer proliferation of which contributed to the downfall of the Weimar Republic in 1933, tended to consolidate during the early days of the Federal Republic. Smaller parties either allied themselves to the larger ones, shrank into insignificance, or simply vanished. Reunified Germany has, in effect, only two numerically major parties, the Christian Democratic Union (CDU) and the Social Democratic Party of Germany (SPD), neither of which can easily attain a parliamentary majority. In addition, there are three numerically small but powerful parties, the Christian Social Union (CSU, the Bavarian sister party of the CDU), Alliance 90/the Greens (the Greens), and the Free Democratic Party (FDP). Two minor parties, the Party of Democratic Socialism (PDS) and the German People's Union (DVU), hover above or below the threshold of representation in the Bundestag or the state diets set by the "5 percent rule," whereby a party may send delegates only if it wins at least 5 percent of the vote in a given election. This rule has proved a highly effective instrument in excluding radical parties of whatever stripe and in preventing the formation of splinter parties. Since 1961 the major parties have had to hold their power through coalitions with an additional party. Dissent within the major parties is contained in the wings and factions of each respective party.

The Christian Democratic Union (Christlich-Demokratische Union) is the party of the centre-right-the "bourgeois" party in older European terms. It headed Bonn governments from 1949 to 1966 and governed from 1982 to 1998 in alliance with the FDP and CSU. It is established in all states except Bavaria, where the more conservative CSU (Christlich-Soziale Union) functions as its counter-

part in effectively a permanent coalition.

In its origins, the Christian Democratic Union represents a merger of the old Catholic Centre Party with kindred constituenbourgeois parties, either Protestant or nonsectarian. In a nation in which one's religion had also often been one's politics, the party's strongest constituencies are still in the Roman Catholic districts, although the sectarian Christian aspect is of only incidental emphasis, chiefly among older voters. The party's policies emphasize a free-market economy, national unity, and Germany's place in the Western community, the European Union (EU), and the North Atlantic Treaty Organization (NATO).

Throughout the existence of the Democratic Republic, an eastern branch of the CDU (known as CDU-Ost) had been tolerated to preserve the facade of a multiparty system. With the overthrow of the ruling SED in East Germany's first free elections on March 18, 1990, it was this rump party that took power by a large mandate, with Lothar de Mazière as minister president presiding over the six-month transitional period to unification.

The Social Democratic Party of Germany (Sozialdemokratische Partei Deutschlands), which governed Ger-

many in coalition with the FDP from 1969 to 1982 and regained power in coalition with the Greens in 1998, is the heir to the Marxist parties dating from the 19th century. In East Germany, which historically had been a stronghold of the socialist movement in Germany, the SPD had been subsumed by the Socialist Unity Party (Sozialistische Einheitspartei Deutschlands, or SED), in 1946. Ostensibly a combination of the old Communist Party of Germany (Kommunistische Partei Deutschlands) and the Socialist Party, the SED was in fact simply the ruling communist party. In West Germany the SPD's early postwar leadership, drawing strength from its record of opposition to Nazism, maintained a rigorous policy of adherence to classic Marxist doctrine, vehement opposition to the communist movement from which it had split in the early 20th century, and rejection of rearmament for West Germany and its integration into the Western military defense system. In 1959, however, the SPD, in the Bad Godesberg Resolution, changed its approach; the call for nationalizing large industries was forsaken in favour of gradualist reform, and appeals to class warfare were abandoned. The party was able, thereby, to attract greater middle-class support, whether for reasons of ideology or as an alternative to continued CDU leadership.

In its approach to unification, the SPD called for caution and has profited from a backlash against the high financial and emotional costs of the rush to unification spearheaded by the CDU-CSU. While the SPD suffered electoral losses immediately after reunification, it replaced the CDU-CSU as the leading party in the 1998 federal elections.

Because neither the CDU-CSU nor the SPD could generally elect enough delegates to form a viable majority in the Bundestag, the balance of power, with short exceptions, was in the hands of the Free Democratic Party (Freie Demokratische Partei) through coalitions with either of the larger parties. The FDP is the successor of older German liberal parties with a free-trade, pro-business, and anticlerical cast. Today it serves as a liberal, bourgeois alternative to the CDU and SPD and sometimes exercises a power beyond the 5 to 10 percent it commands from the electorate. A small counterpart party that existed in the East, the Liberal Democratic Party (Liberal-Demokratische Partei) lent surprising strength to the FDP in the 1990

Alliance 90/the Greens (Bündnis 90/die Grünen), an environmentalist party formed in 1993 through a merger of the East German Alliance 90 (founded 1991) and the West German party the Greens (founded 1979), is the only successful completely new party of the postwar era. Formed by mainly younger groups of environmentalists, opponents of nuclear power, feminists, and pacifists, the Greens successfully broke the 5 percent barrier in 1983 by winning in by-elections. The Greens advocate expanded rights for minorities as well as environmentally conscious policies, and they tend to appeal to young, educated voters. After losing support in 1990, the Greens benefited from growing disillusionment with the CDU-CSU government during the mid-1990s. In 1994 the Greens replaced the FDP as the third most popular party, and in 1998 they displaced the FDP from its traditional political role by forming a governing coalition with the SPD.

The Party of Democratic Socialism (Partei des Demokratischen Sozialismus, or PDS) is the successor party to the former Socialist Unity Party of Germany. It advocates state intervention in the economy on behalf of the disadvantaged and expresses the grievances of easterners who have not benefited from unification. It exceeded the 5 percent barrier in the 1998 federal elections and commands about 20 percent of the vote in eastern Germany.

Of the small and fringe parties, only the rightist-nationalist groups the Republican Party (Republikaner) and the German People's Union (Deutsche Volksunion), together with a handful of special-interest bodies, are visible in national or regional elections, but they have been unable to surmount the 5 percent barrier in most states or in the Bundestag. In an exception to the ban, a small party of the Danish minority, the Southern Schleswig Voters Association, sends one delegate to the Schleswig-Holstein state

Greens

ARMED FORCES

The

Federal

Armed

Forces

The Federal Republic has been a member of the North Atlantic Treaty Organization (NATO) since the implementation of the Paris Treaties in May 1955. Until unification West Germany was the only NATO country of western Europe with territory bordering two member nations of the Warsaw Pact, and planning from the early days of the Western defense system was posited on West Germany's vulnerability to an armed invasion and to becoming the possible site of a land war.

The German contribution to the Western defense system, apart from playing host and contributing to the continued presence of Allied troops on its soil, takes the form of its combined arm of defense known as the Federal Armed Forces (Bundeswehr). Constituting the largest contingent of NATO troops in Europe, the armed forces are divided into an army, navy, and air force. From its inception it was envisioned as a "citizens' " defense force, decisively under civilian control through the Bundestag, and its officers and soldiers trained to be mindful of the role of the military in a democracy. Conscription for males is universal, the military liability beginning at 18 and ending at 45 years of age. The period of compulsory active service is 18 months. The right to refuse to enter military service on grounds of conscience is guaranteed under Article 4 of the Basic Law; instead, a recognized conscientious objector must perform 20 months of socially useful service. After unification the exercise of this right increased nearly twofold.

The Federal Republic maintains a separate Coast Guard and Border Patrol. As a concession to Bavaria's oncespecial position within the old German Empire, this force. although maintained by the federal government, is still

known there as the Bavarian Border Patrol.

Upon unification the former People's Army (Volksarmee) of the Democratic Republic was integrated into the Federal Armed Forces, with officers from the west assuming top command and overseeing the assimilation into a NATO force of what had been implacable enemies. The special Border Troops set up to guard the Berlin Wall and boundary with former West Germany, together with the factory militia, were disarmed and dissolved.

LAW ENFORCEMENT

There is no nationwide German police force, and law enforcement remains a province reserved to the states. Each state maintains its own force, which is charged with all phases of enforcement, except where its function is assumed by a municipal police force. In a state of national emergency the federal government may commandeer the services of various state police units, together with the standby police reserve that is trained and equipped by each state for action during civil emergencies. Federal officers investigate certain actions, however, notably those inimical to the security of the state or criminal actions that transcend the confines of any given state. The Federal Crime Agency (Bundeskriminalamt) assists the federal and state units as a clearing agency regarding criminals and criminal actions.

The former People's Police of the Democratic Republic was dissolved upon unification, and its members integrated into the police force of the new states. The loathed Ministry for State Security (Ministerium für Staatssicherheit, popularly known as Stasi), the offices of which had been stormed in popular uprisings and whose files had been removed into Western custody, was dissolved.

EDUCATION

Preschool, elementary, and secondary. Schooling is free and compulsory for children 6 to 18 years of age. While control of education is the sovereign prerogative of the states, a permanent commission strives for a certain uniformity in curriculum, requirements, and standards, the implementation of which may vary, depending on the priorities of the individual state. Some of the books and study materials are free, and financial assistance and other forms of support are available in cases of hardship.

Preschooling, to which the notably German contribution in modern times is enshrined in the universal word kindergarten, can begin at 3 years of age. All children attend the

Grundschule ("basic school") from age 6 until about age 10. Somewhat less than half continue elementary schooling in a junior secondary school called the Hauntschule ("main school") until about age 15 or 16, at which time they are assigned to a Berufsschule ("vocational school"). attended part-time in conjunction with an apprenticeship or other on-the-job training. This program makes it possible for virtually every young person in the vocational stream to learn a useful skill or trade, constantly adapted to the actual demands of the employment market

Children who receive a commercial or clerical education. somewhat less than one-third of the school-age population, attend an intermediate school called the Realschule (roughly meaning practical school) and earn an intermediate-level certificate that entitles them to enter a Fachschule ("technical" or "special-training school"), completion of which is a prerequisite for careers in the middle levels of business, administration, and the civil service.

Approximately one-fourth of all children are chosen for study at the Gymnasium (senior secondary school, equiv- Gymnaalent to a grammar school in Great Britain), in which a rigorous program lasting for nine years (levels 5 to 13) prepares them-with emphasis variously on the classics. modern languages, mathematics, and natural sciencefor the Abitur or Reifezeugnis ("certificate of maturity"). the prerequisite for matriculation at a German university. The traditional structure of the German Gymnasium has mainly shifted from being built around a single branch of studies to offering a "reformed upper phase" with a

choice of courses. A small number of so-called Gesamtschulen (equivalent to British comprehensive schools) are now operated in each state. These are intended as an alternative to the previously rigid division into three levels, often criticized for forcing the choice of a child's future at too early an age. a choice that, once entered upon, was almost impossible to change. These schools offer a large range of choices and permit pupils more freedom in seeking the level best suited for them

Higher education. The German universities, famed in history and noted for their enormous contributions to learning, especially in the 19th and early 20th centuries, have been put under severe strain by the swelling numbers of students and changing social conditions that have taxed the traditional structures of the universities beyond their capacities or accustomed functions. Today it has become all but impossible for students to take as long as they wish to complete their studies or to move from university to university as they please. Lecture rooms, seminars, and libraries are disastrously overburdened, and the explosion of knowledge and of higher education has undermined the usefulness of original research.

To meet the rapidly rising demand for higher education, the Federal Republic has steadily added to the number of existing universities. It has created entirely new academic universities to add to the ranks of the ancient universities, and it has upgraded the status of institutes and colleges of technology, education, and art to university rank, while creating new specialized or technical institutions such as the Fachhochschule, a higher technical college specializing in a single discipline, such as engineering, architecture, design, art, agriculture, or business administration. Little or no difference in prestige is attached to whether a student has studied at Heidelberg, founded in 1386, or at the new multimedia university at Hagen, Westphalia, established in 1976, where the teaching is accomplished largely by correspondence through regional study centres. In 1991 Germany had 97 universities and 200 institutions of equivalent rank. The doctorate is the only degree offered as such (although the Magister, or Master of Arts, abandoned in the 17th century, has been partially revived). The rough equivalent of a bachelor's degree is a Diplom or completion of a Staatsexamen (state examination).

There is an extensive range of possibilities for extended education or extramural studies. About 860 Volkshochschulen (adult education centres) enroll some 5.2 million adults for complete courses or individual subjects, whether in preparation for, or furtherance of, a career or out of personal interest. The government has also pro-

Volkshochschulen moted the retraining and further vocational education of workers

Problems of transition. Integration of the educational system of the former Democratic Republic brought a host of problems. Since the focus of education was to inculcate the values of the communist state, even the textbooks and some of the school materials were unsuitable for the educational aims of the Federal Republic. English replaced Russian as the first foreign language, rendering untold numbers of Russian teachers useless and creating a shortage of qualified English teachers. The reorientation of primary and secondary school teachers to the standards and aims of the republic became an important concern.

At the university level the issue of competence became acute. Since many of the faculty of East Germany's universities had been appointed for their soundness in Marxism-Leninism or loyalty to the SED, their qualifications became obsolete upon unification. The federal authority for qualifying universities to confer degrees and diplomas was hard put to give recognition to some institutions of university rank, while the ministers of education of the new states were subjected to great pressures to reconfirm existing appointments. Whereas in former East Germany research institutions had generally been separate from universities, the Western system combining research and teaching was implemented nationally following unification.

HEALTH AND WELFARE

Germany's system of social benefits is one of the most elaborate and all-embracing in the world. The country's pioneer work in social legislation was initiated in the 1880s to cover health and accident insurance, workers' and employee's benefits and pensions, miners' insurance, and the like. It has served as a model for similar programs in other countries

Insurance and services. Health and retirement insurance are compulsory for all workers and employees earning below a certain level of income geared to the cost of living. Under German labour law, a categorical distinction is made between hourly wage earners and salaried employees. and differing rules and rates apply to each group. Employees above a certain salary level or self-employed persons are generally exempt from most obligatory payment systems; however, although the former usually participate in a firm's retirement plan, almost all persons in the upper salary brackets or the self-employed are covered by private insurance as comprehensive as the government-sponsored plans. With increasing prosperity, an increasing percentage of the population is subscribing to these somewhat more expensive but also more generous private plans. Nearly 90 percent of the population is covered by compulsory health insurance, and the Federal Republic ranks highest among comparable nations of continental western Europe in the proportion of money allowed toward health costs-about 90 percent of all medical costs incurred. Contributions range from about 8 to 12.5 percent of wages or salaries.

Medical care is of a high standard, and rural areas are well served. Hospitals are usually operated by municipalities or religious bodies or as proprietary institutions owned by one or more physicians. Public health standards are high. A triumph of the public health system has been the conquering of tuberculosis, a disease formerly endemic to Germany but now rarely encountered. The extensive health-care system operative in the former Democratic Republic, in which universal free health care, medication, child care, nursing care, and pensions were funded by an obligatory state insurance system, underwent a reorganization from the exclusive management of the system by the trade unions to an alignment with the various employment, health, and retirement insurance systems of the Federal Republic.

Accident and retirement insurance are tied to healthand medical-care plans. The rate of compulsory accident insurance rises with the risks involved in one's job. The three major pension plans cover miners (the oldest, dating from Bismarck's introductory social legislation), workers, and employees. In general, men are eligible for retirement at 65 and women at 60, but both sexes may retire earlier or later under special circumstances. Additional benefits. The Federal Republic provides several special systems of coverage for such special groups as war widows, orphans, and farmers. Unemployment insurance is funded through deductions from wages and salaries. Allowances are made for families with one or more children. Additional public allowances are granted to persons suffering disabilities from wartime injury, whether as military personnel or as civilians. Some small indemnification has been made to property owners whose holdings lay in former German territories now outside the Federal Republic. (For a discussion of property rights with regard to German reunification, see above The economy: Problems of economic unification.

War reparations. Under agreements concluded with 12 European nations, the Federal Republic has paid compensation to the nationals of those countries who were victims of Nazi oppression or to their families and successors. The Federal Republic from the time of its foundation assumed the immense financial responsibility of making restitution to the Jewish victims of National Socialism. Claims for property confiscated during the Third Reich have been honoured, and Jewish refugees and expellees from that era, the vast majority of whom reside abroad, have been paid indemnifications and pensions. Massive reparations have been paid to Israel in the name of the Jewish people at large. The former Democratic Republic, on the other hand, ignored all such claims until 1990, when the transition government of Lothar de Mazière undertook similar restitution.

HOUSING

Private and government roles. Most of the capital for new housing is met by the private sector. Assistance is provided by the federal government to all citizens wishing to avail themselves of a building savings policy. After a certain minimum contribution by the policyholder has been deposited over a set period of years, the government provides a housing loan on generous terms for those wishing to build their own house or buy an apartment.

Ing to outlet their own nouse or buy an apartment. Much of the housing built with government subsidies is devoted to "social housing," dwellings provided at "cost rent" far below the market rental value for families with many children, the disabled, the elderly, and persons with low incomes. More stringent definitions of tenants' rights, including injunctions against arbitrary or unfair evictions and protection against precipitous rent increases, seek to balance the city of the energy of the contractions.

"Social

housing"

balance the rights of tenants with those of landlords, on The rebuilding of the cities in the 1950s and '60s, coupled with increased automobile ownership, invariably led to an initial emptying of the older city centres. Moves to counter the trend away from the inner city have been made, however, in the form of easier access and parking near the town centres, as well as improved public transport, large-scale refurbishing of ancient buildings, and the creation of pedestrian zones, with special entertainments, festivals, and attractions to lure the public back to town in the evenine.

The physical appearance of villages and towns throughout West Germany was improved on a grand scale during the 1970s and 80s through extensive renovation programs undertaken by the states; grants, subsidies, and matching funds were made available to restore the exteriors of historic monuments and older buildings to their pristine condition.

The former eastern territories. In principle, under the communist government of the Democratic Republic each citizen and his or her family had the right to adequate accommodations. Rents everywhere, together with charges for heating and electricity, were held at extremely low, ever held at extremely low, every the construction of the control of the

Upon unification, the decrepitude of most older buildings in the east came as a shock to visitors from the west. With the exception of a few showpieces, the great majority of urban housing constructed between 1871 and 1914 (see above) seemed to have gone unpainted or unrefurbished since before World War II. The contrast of the gray, cheerless, and shabby cities, towns, and villages of the former Democratic Republic with the picture-postcard

Compulsory national and private insurance plans

Medical

lustre of the western sector was an eloquent testimony to the divergences that had to be overcome.

STANDARDS OF LIVING

Savings

incentives

Effects of

on the standard of

living

unification

The standard of living in the old states of the Federal Republic ranks as one of the highest in the world. The distribution of wealth compares favourably with that of other advanced nations. Powerful incentives to save are offered by the state not only in the form of housing subsidies and tax concessions but also through bonus saving schemes. Thus, for persons whose income does not exceed a certain level, savings of up to a fixed amount kept in a bank or savings institution for six or seven years will be granted a bonus of 14 percent of the principal by the government. Under the "DM 624 Law" the accumulation of capital assets is encouraged under a plan whereby workers below a certain earning level who agree to pay 52 deutsche marks per month (or 624 deutsche marks per annum) into a longer-term savings agreement, such as a home-savings contract, are given a "worker savings grant" by the state. Altogether 20 million workers participate in the federal asset-building program and a further 12 million in the state savings grant. The government has contributed some 140 billion deutsche marks to the asset-building scheme, through which savings of 600 billion deutsche marks have been accumulated by participants.

Earning power for both workers and employees assures an adequate income to meet the cost of living. There is no exaggerated difference between the earning power of bluecollar workers and white-collar employees, salaries tending to be only moderately higher than wages. While above a certain level of management incomes and benefits rise precipitously, chief executive officers in Germany earn only 6 to 7 times the average worker's pay (as opposed to the vastly higher ratio in the United States). Since, as in all the EC countries, a major portion of tax revenue derives from excise levies and the value-added tax, low- and mediumincome workers collectively bear the greater tax burden.

The absorption of the East German population and economy into that of the Federal Republic had no more than a marginal effect on living standards in the regions of the western sector despite a rise in unemployment and a housing shortage. Even the exorbitant cost of unification that became apparent only after the borders disappeared (and brought about a much-resented tax increase) seemed to cause few changes in western Germany. The deutsche mark held its strength and grew even stronger. By contrast, the introduction of the West German currency in East Germany in July 1990, far from being the "magic bullet" hoped for, tended to have a depressing effect at the microeconomic level. The eastern population with its much lower earning power suddenly had to pay Western prices for food and other commodities. The wholesale shutdown of former state factories and enterprises caused vast unemployment in especially the industrial cities of Thuringia, Saxony-Anhalt, and Saxony and resulted in much hardship and discontent.

The 40 years of the Democratic Republic had produced a society in which employment was guaranteed and in which most of the requirements of life were provided free or at low cost. The demands of work were slight; competitiveness, initiative, and individuality were not qualities highly prized in a Marxist-Leninist society. The working population was thus ill-suited-even more than, say, the people of Poland, Czechoslovakia, or Hungary-for a blind, cold plunge into a free-market economy. But, unlike those in the latter countries, the East Germans had a rich and strong next-door relation that was sure to bail them out.

Cultural life

THE CULTURAL MILIEU

During the partition, the Federal Republic, as heir to Germany's older regions, was custodian to the greater portion of the country's rich cultural legacy. The major wealth of Germany's architectural monuments-of Roman Germany, of medieval Romanesque, of south German Baroque-fell within the borders of West Germany after World War II, as did many of the great libraries,

archives, and facilities for the performing arts. Yet some of the greatest monuments of Germany's cultural and historical achievement were located in the German Democratic Republic, including the Wartburg of Luther near Eisenach, the Weimar of Goethe, the Leipzig of Bach; a large share of prewar Germany's art treasures rested in East Germany. especially in East Berlin and Dresden. After the division of Germany, many of the cultural assets originally from the eastern sector were removed to the west. Many of East Germany's artists, writers, and institutions, including entire publishing houses, transplanted themselves to West Germany or set up successor organizations there.

Yet, despite the political division, the German cultural and artistic tradition remained identifiably the same. In the German-speaking world a writer or painter or composer or playwright or sculptor was still German, whether holding a passport from the Federal Republic or from the Democratic Republic, Moreover, in the matter of art and literature, the adjective deutsch ("German") still knows no strict political boundaries. The Austrian Gustav Mahler, for example, is called a "German" composer and the Swiss Friedrich Dürrenmatt is a "German" playwright because they are in the German cultural tradition.

During the 40 years of separation it was inevitable that Continuity some divergence would occur in the cultural life of the two parts of the severed nation. Both West Germany and East Germany followed along traditional paths of the common German culture, but West Germany, being obviously more susceptible to influences from western Europe and North America, became more cosmopolitan. Conversely, East Germany, while remaining surprisingly conservative in its adherence to some aspects of the received tradition, was powerfully molded by the dictates of a socialist ideology of predominantly Soviet inspiration. Guidance in the required direction was provided by exhortation through a range of associations and by some degree of censorship; the state, as virtually the sole market for artistic products, inevitably had the last word.

Admirably enough, the cultural commissars of the Democratic Republic steadfastly upheld certain cultural monuments that fell within East German borders-even though their provenance was regal, aristocratic, liberal, bourgeois, or religious and the content hardly reconcilable with the aspirations of the "State of Workers and Peasants": the Goethe House and Goethe National Museum on the Frauenplanstrasse in Weimar were carefully restored after the war and meticulously maintained; the Thomanerchor at the St. Thomas Church in Leipzig, the boys' choir made famous by Johann Sebastian Bach, continued to perform the cantatas and motets of the master in exactly the style of two and a half centuries previously; Dresden, although devastated by wartime bombing, made it an early priority to restore its opera house; and the music ensembles of the Democratic Republic, especially the Dresden Philharmonic and the Dresdner Staatskapelle, together with the Gewandhaus and Rundfunk orchestras of Leipzig, actually remained part of the mainstream of European music, going on tour in the West and freely exchanging performers, conductors, and producers.

It has been remarked that, during their separation, the two Germanys diverged not at all in music and only slightly in literature and the theatre but sharply in architecture and the plastic arts.

STATE OF THE ARTS

Government and audience support. For four centuries Germany has enjoyed a tradition of governmental support of the arts. Before the founding of the German Empire in 1871, the many small kingdoms, principalities, duchies, bishoprics, and free cities that preceded it-as well as Austria and German-speaking Switzerland-supported the arts; they established theatres, museums, and libraries, and their leaders acted as patrons to poets, writers, painters, and performers. The institutions thus founded and the convention of generous public support have continued uninterrupted to the present.

The quantitative dimensions of Germany's cultural life astound foreigners. In the Federal Republic a few hundred theatres are subsidized by the federal government, the

and divergence in East and

West

states, and the cities, in addition to the many privately financed theatres. Unlike the United States, Britain, and France in which theatre is more often than not centred in one city, no one city in Germany dominates over the others. Also, productions in Vienna and in Zürich, Switz... are significant to the artistic life of the Federal Republic, and artists and resources move easily and freely among the theatrical and operatic companies within the Germanspeaking regions. Only in Vienna, the capital in which the arts arouse far more intense passions than do politics, does theatre have a broader audience base than in Germany. Audiences in Germany are not limited to a small intellectual or social elite but are drawn from all ranks of society. Season tickets, group arrangements, bloc tickets bought by business firms, and theatre clubs constitute the major patronage of such production companies as the People's Independent Theatre (Theater der Freien Volksbühne), dating from 1890 in Berlin. Going to the theatre or opera in Germany is about as affordable and as unremarkable as attending the cinema is elsewhere.

The same is true of concert music. Every major city has one or more symphony orchestras offering many concerts and recitals each week; in the smaller cities and towns the music and concert fare is less well provided for only in terms of quantity and, perhaps, professional quality.

In rew countries of the world are the arts so lavishly cultivated as in the Federal Republic in terms of ith proliferation of cultural amenties, the funds allotted to them, and the attendance upon them. While this abundance and generous support has not called forth a new era of brilliance able to rival that of the Weimar Republic—when Germany (especially Berlin) experienced a resurgence in the arts and a proliferation of creative talents unparalleled since German Classicism and Romanticism—there are a number of noteworthy individual talents and movements dotting the contemporary landscape.

Traditional arts and crafts. The incursions of modern patterns of life have done much to weaken the traditional arts, entertainments, and customs of regional and rural Germany, although less so in southern Germany, where the older arts and usages have persisted concurrently with a gradual adaptation to a modern, urban pattern of life; the old and the new coexist in an incongruous compatibility. The young still dance around the village maypole, but they also dance to the disco beat. The woodcarvers, violin makers, and gunsmiths of Upper Bavaria continue, under great economic pressure, to follow their trades, not because it is quaint but because they still believe in the work itself; peasant women in the Black Forest still wear elaborate costumes known as Tracht on festival days, not to amaze tourists but because they have always done soyet these are the areas in which the tourist industry is most highly developed. Some usages have all but disappeared in

Otto Stador - O Severala

Costumes with wooden masks worn during the pre-Lenten celebrations in Rottweil, Baden-Württemberg.

the villages: older women now seldom wear black dresses and scarves, and the village men no longer appear in top hat and cutaway for a funeral procession.

Popular festivals still abound in the west, southwest, and south, the regions that have clung most to the practices of a traditional, preindustrial age. Near-heathen usages such as the donning of elaborate wooden masks during the pre-Lenten celebrations in the southwest remain unaffected in spite of being televised; hundreds of smaller towns and larger villages in the south still commemorate an anniversary from the Thirty Years' War by a parade in 17th-century costume or, in Roman Catholic areas, march in full procession on Corpus Christi Day, What is remarkable in not merely that these traditions survive but also that the homelier and less celebrated of them remain truly genuine and naive in the observance.

Literature and theatre. German literature holds less than its deserved status in world literature in part because the lyrical qualities of its poetry and the nuances of its prose defy the most inspired translation. Even the most sublime of figures in German literary history, such as Goethe and Schiller, are doomed to remain known to the world outside the German regions largely by reputation. In the 20th century perhaps four German poets and writers have won a permanent niche in world literature-Franz Kafka, Thomas Mann, Rainer Maria Rilke, and Bertolt Brecht, all of whose works date from the early decades. Two German novelists have won a popular following abroad in translation-Heinrich Böll (a Nobel laureate) and Günter Grass; some others gaining widespread recognition more recently are Siegfried Lenz, Peter Weiss. Uwe Johnson, Hans Magnus Enzensberger, Walter Kempowski, Peter Handke, and Gabriele Wohmann, During the partition, many East German writers departed to the West, some after a term of imprisonment. Among those of international significance who remained in East Germany were Stefan Heym, Anna Seghers, and Christa Wolf.

The German theatre has long been faced with the dilemma of either relying on the rich repertoire of German classics from the 18th and 19th centuries, along with a restricted number of established 20th-century dramas. as, say, those of Brecht or Carl Zuckmayer, together with contemporary plays in translation from Britain, France. and the United States, or of being bold and innovative. On the one hand, the system of public subsidies and ticket subscriptions favours a steady diet of Goethe, Schiller, Gotthold Ephraim Lessing, Shakespeare, Shaw, Jean Anouilh, Chekhov, and Brecht; but, on the other hand, it also allows for risks to be taken and for the plays of newer dramatists such as Martin Walser and Patrick Süskind to be performed. Small experimental theatres enjoy a lively, if hazardous, existence in the major cities and often closely resemble Germany's long-lived and still lively convention of political cabaret.

In the Democratic Republic, all theatres were owned by the state. The German Theatre (Deutsches Theater) in Berlin reopened in September 1945 and was the first German theatre to perform following the Nazi collapse. The old German National Theatre (Deutsches Nationaltheater) in Weimar was the first to be rebuilt after 1945. Understandably, Berlin dominated theatrical developments, especially because of the work of Brecht at the Theater am Schiffbauerdamm. Given a haven in East Germany-a theatre and a company, along with the political and artistic latitude he required-Brecht was able to produce and perform his own works exclusively. The Berliner Ensemble, as his group was named, possibly commanded more critical and popular attention in the West than on its home ground; his plays are still widely performed in the West, and his dramatic theory, notably the "alienation effect" (Verfremdungseffekt), has become a rubric in the canon of the performing arts. After his death in 1956, the theatre continued intact under the direction of, first, his widow, the actress Helene Weigel, and then various successors.

Music and dance. Germany's concert halls are faced with the same dilemma as its theatres, of whether to defer to the public's preference for 18th, 19th, and early 20th-century composers or to give contemporary works a better hearing. The works of Hans Werner Henze, whose opera

Bertolt Brecht in Berlin

Popular

The Young Lord won international acclaim, joined Bernd Alois Zimmerman and especially Karlheinz Stockhausen as the most significant German composers in the last half of the 20th century. The rich legacy of German music (which until the 20th century is understood to encompass the contributions of Austrian composers) includes the work of German-born English composer George Frideric Handel, Georg Philipp Telemann, and Johann Sebastian Bach, the last of whom dominated the late Baroque period, along with that of Austrians Franz Josef Haydn and Wolfgang Amadeus Mozart from the Classical period and Ludwig van Beethoven and Franz Schubert, who bridged the 18th and 19th centuries and the Classical and Romantic periods, and German romantic composer Felix Mendelssohn. Other significant contributors to the history of German music are Robert and Clara Schumann, Carl Maria von Weber, Johannes Brahms, and Richard Wagner (19th century), Richard Strauss and Austrian Gustav Mahler (late 19th and early 20th century), and Kurt Weill, Paul Hindemith, and Austrian Arnold Schoenberg (20th

The Berlin Philharmonic is among the world's leading orchestras, as are the Gewandhaus Orchestra of Leipzig: the Bamberg Symphonic Orchestra; the Bavarian Radio Symphony Orchestra; and the Stuttgart Chamber Orchestra. Moreover, the opera houses of Hamburg (the oldest), Berlin, Cologne, Frankfurt, and Munich are world famous. Among the Germans who left their mark on rock music are the groups Can, Faust, and Tangerine Dream, whose music was dubbed "Krautrock" by Anglo-American critics, and Kraftwerk, who helped lay the foundation for modern techno music.

Dance has also been important in Germany. In the 18th century the waltz developed from regional social dances of southern Germany and Austria and gained popularity throughout Europe. Modern dance was embraced as Ausdruckstanz ("expressionistic dance"). One of its bestknown proponents was Kurt Jooss. Dancer Mary Wigman and her student Hanva Holm had a significant impact on modern dance, particularly in the United States. The Stuttgart Ballet rose to world prominence in the 1960s under its South African-born director John Cranko, and in the 1970s in Wuppertal choreographer Pina Bausch pioneered the influential Tanztheater ("dance theatre").

The visual arts. Germany's tradition in the visual arts dates from the reign of Charlemagne. In the 15th and 16th centuries the painters Albrecht Dürer, Lucas Cranach the Elder, Matthias Grünewald, and Hans Holbein the Younger ushered in a golden age of German art, which nevertheless did not develop a definite national character until the mid-18th century. At the turn of the 19th century. Romanticism blossomed, perhaps best exemplified in the work of Caspar David Friedrich. German painters of the 20th century, especially those in groups such as Die Brücke ("The Bridge") and Der Blaue Reiter ("The Blue Rider"), developed a new Expressionist current in European art. Beginning in 1916, Kurt Schwitters, George Grosz, Hannah Höch, and others explored the more theoretical concerns of Dada, while in the 1920s artists such as Otto Dix and photographer August Sander worked in the realistic, socially critical style known as Neue Sachlichkeit ("New Objectivity").

These and other developments came to a halt in 1933 with the rise of the National Socialists, who considered such art "degenerate." After World War II, German art struggled to regain a sense of direction, challenged by the emigration of many important German artists. In East Germany a form of Socialist Realism dominated; in West Germany artists experimented with avant-garde movements such as Abstract Expressionism, Pop art, minimalsism, and Op art. Beginning in the 1960s, Joseph Beuys created sculpture, performance art, and installation art that challenged the very definition of "high art," while Gerhard Richter gained fame in the 1970s for his paintings based on photographs. German painters such as Georg Baselitz, Anselm Kiefer, and Sigmar Polke were at the centre of the art world when Neo-Expressionism became dominant internationally in the 1980s. At the turn of the 21st century, German photographers Wolfgang Tillmans, Bernd and Hilla Becher, Thomas Struth, and Andreas Gursky won international art prizes and prominence.

Contemporary German architecture-indeed world architecture-is very much the creature of the Bauhaus school, founded in Weimar in the 1920s by Walter Gropius and directed for a time by Ludwig Mies van der Rohe. After World War II the dogmas of the Bauhaus schoolthe insistence on strict harmony of style with function, and on the intrinsic beauty of materials, as well as a puritan disdain of decorativeness-were widely applied. Yet in the 1960s and '70s, the stark Bauhaus style began to yield to the more free-ranging postmodernism, which took as its precept "not just function but fiction as well."

Reflecting the Soviet influence, buildings in eastern Germany differ from those in western Germany in the immensity of their proportions. The major showpieces in eastern Berlin-the government buildings, apartment blocks, hotels, and public spaces along Unter den Linden. Marx-Engels-Platz, Alexanderplatz, Karl-Marx-Allee, and Leipziger-Strasse-and their exaggerated decorations testify to a propensity for sheer vastness. After unification the long-deserted Potsdamer Platz in Berlin came alive with the construction of an array of public and private buildings

by internationally renowned architects.

Film. Before World War II Germany helped set the pace in motion pictures. Directors such as Fritz Lang, Ernst Lubitsch, F.W. Murnau, and G.W. Pabst had virtually defined cinematic art in the 1920s and early '30s. In the Nazi period, however, most noteworthy German filmmakers, including Lang, Lubitsch, Murnau, and Billy Wilder, relocated to Hollywood, as did actors such as Marlene Dietrich and Conrad Veidt, Documentarian Leni Riefenstahl (Triumph of the Will, 1935), however, remained in Germany.

After World War II the studios of the giant UFA (Universum-Film-Aktiengesellschaft), which were in East German hands, continued as a government-owned enterprise known as DEFA (Deutsche Film-Akademie), noted for animation, documentaries, and feature films. Germany's reunification in 1990, however, cut short attempts to forge a national cinematic identity in eastern Germany. In West Germany a group of young filmmakers, first organized at the Oberhausen Film Festival in 1962, established das neue Kino, or the New German Cinema; though they had little commercial success outside of Germany, the films of directors such as Rainer Werner Fassbinder, Volcker Schlondorff, Margarethe von Trotta, Werner Herzog, and Wim Wenders won international critical acclaim, as did the work of actors such as Klaus Kinski, Bruno Ganz, and Hanna Schygulla. Some German filmmakers also found success in the United States, including Roland Emerich, who established himself in the action-adventure genre, and Wolfgang Petersen (Das Boot, 1982), who became one of Hollywood's more noted practitioners of the thriller. Though at the beginning of the 21st century there was no shortage of German filmmaking talent, few German directors were producing German films.

Arts festivals. Most major cities and scores of small towns sponsor festivals. Among the best known is the Bayreuth Festival celebrating the works of Richard Wagner (who founded the festival himself in 1876). The oldest German festival is the Passion play, first held in 1634 and now held every 10 years in Oberammergau (Bavaria).

Berlin has five major festivals: the Berliner Festwochen (Berlin Festival Weeks) in September and October, with five weeks of musical events; the Berliner Jazzfest in November; the Berlin International Film Festival in February; the Theatertreffen Berlin ("Berlin Theatre Meeting"), featuring productions from throughout the German-speaking world; and the Karneval der Kulturen ("Carnival of Cultures"), a festival of world cultures. Munich has an opera festival in July and August, with emphasis on Richard Strauss. Festivals in Würzburg and Augsburg celebrate Mozart. Ansbach has a Bach festival, and Bonn has one honouring Beethoven. Other noteworthy events include Documenta, an arts festival held every five years in Kassel, the International May Festival in Wiesbaden, and the Festival of Contemporary Music in Donaueschingen. Expo 2000, Germany's first world's fair, was held in Hanover.

Bauhaus

style

Dance

Bayreuth Festival

Publishing. Germany has some 2,000 publishing houses, and more than 50,000 titles reach the public each year, a production surpassed only by the United States. Germany traditionally was home to small and medium-size publishing houses. However, the Gütersloh-based Bertelsmann group, a multinational conglomerate, is one of the world's largest publishers. Book publishing is not centred in a single city but is concentrated fairly evenly in Berlin, Hamburg, and the regional metropolises of Cologne, Frankfurt, Stuttgart, and Munich. Leipzig, prewar Germany's major publishing city, shared with East Berlin the major publishing houses of East Germany. Gotha in Thuringia is renowned for the production of maps and atlases

The press. Germans are voracious readers of newspapers and periodicals. Freedom of the press is guaranteed under the Basic Law, and the economic state of Germany's several hundred newspapers and thousands of periodicals is enviably healthy. Most major cities support two or more daily newspapers, and few towns of any size are without their own daily newspaper. During the 1990s most German newspapers and periodicals published daily or weekly editions on the Internet, enabling access far beyond their traditional print circulation.

The press is free of government control, no newspaper is owned by a political party, and only about 10 percent of newspapers overtly support a political party, though most offer a distinctly political point of view, Laws restrict the total circulation of newspapers or magazines that can be controlled by one publisher or group. The Bundeskartellamt (Federal Cartel Office) oversees German industry (including the media) to ensure against a company abusing its dominant position within a particular industry. Although newspaper and periodical ownership cannot be the monopoly of any one ownership, Axel Springer Verlag AG controls a significant share of the market. The German Press Council, established in 1956, sets out guidelines and investigates complaints against the press.

A national press exists on one level in the form of Süddeutsche Zeitung (Munich), Die Welt (Berlin), and the Frankfurter Allgemeine Zeitung, together with regional newspapers (e.g., the Stuttgarter Zeitung and the Frankfurter Rundschau), which also command international circulation and respect. The nationally circulated tabloid Bild (Hamburg), which has the largest readership of any paper,

publishes several regional editions.

Berlin has many daily newspapers, including the liberal Der Tagesspiegel and the conservative Berliner Morgenpost. Originally published in East Germany but acquired by western press interests after unification, the Berliner Zeitung has become the city's preeminent newspaper. Other leading newspapers of the former East Germany were also bought by western publishers.

The major editions of German newspapers are published on Saturdays. A lively Sunday press complements the daily newspapers, providing an overview, perspective, and interpretation of major news developments as well as political comment and artistic criticism; the most prestigious and influential of these is Die Zeit (Hamburg). Others include the venerable Rheinischer Merkur (Bonn), the Bayernkurier (Munich), and the Deutsches Allgemeines Sonntagsblatt (Hamburg). Sunday counterparts of the major dailies, Welt am Sonntag and Bild am Sonntag, are run virtually as sep-

arate newspapers.

The genre of the Illustrierte (pictorial) dominates the German magazine market. Some of these popular weekly glossies, such as Stern and Bunte, carry features, including investigative reporting, of a high calibre; others cater to the public thirst for the escapades of celebrities, bizarre crime, tales of gracious living, and sundry escapist topics. There is also a wealth of specialized journals and quality businessoriented magazines. A special niche is occupied by the weekly newsmagazine Der Spiegel, a journalistic power in its own right. Founded in the aftermath of World War II, it has shaped public opinion in Germany through its editorial posture as the skeptical, nonaligned observer and guardian of the public conscience.

Broadcasting. Although German radio and television are not state-controlled, only public corporations were permitted to broadcast until the mid-1980s, when a dual sys-

tem was established. Still, in 1986 the Federal Constitutional Court held that the public corporations comprised the "basic supply" of news and entertainment, and commercial outlets were only a "supplementary supply." The Federal Ministry of Post and Telecommunications oversees public broadcasting, though the public corporations have great freedom in establishing their own broadcasting policies, and German television (more than radio) enjoys remarkable latitude and independence. Support is provided by fees paid by the owners of radios and television sets.

Public radio and television are arranged along national and regional lines, with a number of regional corporations that offered two to four radio programming schedules combining to form one evening television offering, ARD (Arbeitsgemeinschaft der Öffentlich-Rechtlichen Rundfunkanstalten Deutschlands). This is complemented by a second television network, ZDF (Zweites Deutsches Fernsehen), which is based in Mainz. A third channel is operated by ARD but is organized and broadcast regionally, with special emphasis placed on local and regional events, along with educational, informational, and fine arts programs. The uneven quality of entertainment in both radio and television is offset by the high-quality news coverage and political and social reporting that makes the German public one of the best-informed of any country.

Two radio stations-Deutschland Radio and Deutsche Welle-are publicly operated to provide a comprehensive German perspective of events: Deutsche Welle is beamed to Europe and overseas. There are also several regional public radio stations and some 200 private radio stations

that are regionally and locally focused.

Cable television has been greatly expanded. Supplied by satellite transmissions, the cable networks offer extensive programming from public and commercial television in Germany and from abroad.

During the years of partition, viewers in East Germany could freely receive radio and television broadcasts from West Germany and from West Berlin, with the result that the public in East Germany kept current on news from the West. The broadcasting facilities in the former East Germany were reorganized along lines of the western statesi.e., each of the new states has its own regional stations.

Sports and recreation. In the early 19th century, coincident with the rise of nationalism, Friedrich Ludwig Jahn founded the turnverein, a gymnastics club, and invented several of the disciplines that are now part of the Olympic gymnastics program. At the same time, Johann Christoph Friedrich GutsMuths helped bring physical education to the forefront of German education. Ideals of health-Gesund-and athletic prowess became important components of the German conception of self and were later critical to the Nazi conception of the ideal German.

In 1936 Berlin hosted the Summer Olympics, which Adolf Hitler transformed into a stage to promote Nazi ideals, though this effort was thwarted somewhat by key victories by African American sprinter and long jumper Jesse Owens and other "non-Aryan" athletes. The 1972 Olympics, held in Munich, were also marred when Palestinian terrorists took hostage and killed 11 members of the Israeli team. Following partition, East and West German athletes competed on the same national team from 1956 to 1964 but split their teams for the next six Olympiads, joining the front lines of Cold War athletic competition. Germany's Olympic teams-East, West, and unified-have dominated many events, especially swimming, in which East German Kornelia Ender won 26 gold medals.

Football (soccer) is a passion for many Germans, and the national Bundesliga is among the world's most respected professional football leagues. Moreover, West Germany won the World Cup in 1974 and 1990. Germans have also excelled in professional tennis, golf, and basketball.

Leisure is a major pursuit in German life. As did workers in most Western industrial countries, Germans once toiled under an unrestricted six-day workweek, often 10 hours a day with breaks only on Sundays and for major feasts and festivals. The German workweek is now 40 hours or less and German workers receive three to six weeks or more of paid vacation time. As a result, Germans have more leisure time than workers of most Western countries. This

Museum

abundance of leisure has become a national preoccupation. To a surprising extent in a country so highly industrialized, ancient feasts and practices are still widely observed in both Roman Catholic and Protestant areas, especially pre-Lenten celebrations known as Fasching in the southern regions or Karneval (carnival) in the Rhineland. In addition to the major religious festivals-Easter, Christmas, Whitsun (which are also national holidays), and, in Roman Catholic districts, Corpus Christi Day and Assumptionthere are many local celebrations-wine, beer, harvest, hunting, and historical festivals-the so-called Volksfeste that are deeply rooted in German custom, the most no-

Oktoberfest table being Munich's Oktoberfest, held each September. Although the traditional observances continue unabated, Germans have adopted many more modern forms of recreation, amusement, and relaxation. Travel has become the favoured pastime of a majority of Germans. More than half of all adults take at least one annual trip for pleasure, and a great number take more than one. Many take both a winter and summer vacation. Older persons often take a paid Kur at a spa to rest and recuperate, in addition to a holiday trip for pleasure. More Germans take leisure trips abroad than the citizens of any other country.

The weekend, a latecomer in Germany, has become firmly established. Private recreation typically includes spectator amusements and sports-especially football, active sports and physical exercise, automobile excursions, the pursuit of hobbies, visits with friends and family, and the long-favoured German pastime of walking or hiking.

It is estimated that about one-fifth of a household's income in Germany's western regions is spent on leisure expenses. Many institutions, including the government, local communities, schools, churches, and companies, encourage citizens to channel their free time into useful, rewarding, and healthful pursuits by providing physical facilities. impetus, and other prerequisites for public recreation. Leisure in Germany is now regarded-much like education and vocational training, housing, a job, good public transportation, health and disability insurance, and pensionsas an entitlement and a valuable adjunct of social policy.

In East Germany, leisure activity was arranged very differently. The state ideal was group leisure, holidays, and travel, often organized by the workplace or a youth organization. Cheap holiday facilities were available, especially along the resorts of the Baltic coast. Residents of East Germany were free to travel privately to any of the Warsaw Pact countries and sometimes to Yugoslavia. It is worth noting that the fall of the communist bloc was precipitated in part by the large number of East Germans who, while visiting Hungary, crossed unimpeded into Austria when the Hungarian government opened its borders.

CULTURAL INSTITUTIONS

Many organizations, maintained entirely or in part by public funds, are devoted to acquainting the world with the culture, life, and language of the German peoples and familiarizing Germans with foreign cultures. Cultural representation abroad is abundantly maintained in the advanced industrial countries of the West and in eastern Europe, but special emphasis is placed on fostering educational and cultural ties with less-developed countries. For them Germany is not only a major lender of technological skill and capital for developing resources but also an important centre for the education of students from these

The Goethe-Institut Inter Nationes (formerly the Goethe-Institut of Munich), founded in 1951 has some 140 branches in over 70 countries. It operates schools in Germany and abroad that offer instruction in the German language. It also maintains lending libraries and audiovisual centres and sponsors exhibits, film programs, musical and theatrical events, and lectures by prominent personalities.

Museums and galleries. Germany has some 2,000 museums of all descriptions, housing some of the world's great collections of painting and sculpture as well as of archaeological and scientific displays. Notable museums and galleries include the museums of the Prussian Cultural Property Foundation in Berlin-i.e., the Pergamon Museum with its vast collection of Classical and Middle Eastern antiquities, located on the "Museum Island" in the River Spree, together with the Old (Altes) Museum, the New (Neues) Museum, the National Gallery (National-galerie), and the Bode Museum-the Zwinger Museum and Picture Gallery in Dresden, the Bavarian State Picture Galleries and the Deutsches Museum in Munich, the Germanic National Museum in Nürnberg, the Roman-Germanic Central Museum in Mainz, the Senckenberg Museum of natural science in Frankfurt am Main, and the State Gallery in Stuttgart. Some museums are highly specialized. devoted to a single artist, school, or genre, but many combine natural science and fine arts. Among the many ethnological museums are the Linden Museum in Stuttgart, the East German Gallery Museum in Regensburg, and the Ethnological Museum in Berlin-Dahlem, Important art treasures are scattered in the scores of smaller museums, libraries and archives, castles, cathedrals, churches, and monasteries throughout the country. The Berlin-Dahlem Botanical Garden and Botanical Museum, founded in the 17th century, is German's oldest botanical garden. Specialized exhibits, from the 500th anniversary celebration of Albrecht Dürer in Nürnberg (1971) to the Cézanne (1993) and Renoir (1996) exhibitions at Tübingen Kunsthalle. have attracted visitors from throughout the world.

Libraries. Among Germany's great libraries are the Bayarian State Library in Munich (the largest) and the library of the Prussian Cultural Property Foundation (formerly the Prussian State Library) and National Library in Berlin. The German Library at Frankfurt am Main is the country's library of deposit and bibliographic centre. The Technical Library at Hannover is Germany's most important library for science and technology and for translated works in the fields of science and engineering. The great university libraries at Heidelberg, Cologne, Göttingen, Leipzig, Tübingen, and Munich are complemented by scores of other good university libraries. A wealth of manuscripts, early printed works, and documents from the Middle Ages to the present are dispersed in smaller collections. There is also an extensive system of lending libraries operated by the states, the municipalities, the library associations of the Roman Catholic and Evangelical churches, and other public associations and institutes. (G.H.K./W.H.Be.) For statistical data on the land and people of Germany, see the Britannica World Data section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Ancient history

Germanic consonant shift

The German peoples are defined by the common language group to which they belong. German history thus originates with the so-called first sound shift (or Grimm's law), which turned a Proto-Indo-European dialect into a new Germanic language group. The Proto-Indo-European consonants p, t, and k became the Proto-Germanic f, b (th), and x (h), and the Proto-Indo-European b, d, and g became Proto-Germanic p, t, and k. The historical context of the shift is difficult to identify because it is impossible to date it conclusively. Clearly the people who came to speak Germanic must have been isolated from other Indo-Europeans for some time, but it is not obvious which archaeological culture might represent the period of the shift. One possibility is the so-called Northern Bronze Age, centred in northern Germany and Scandinavia, that flourished between about 1700 and 450 BC. Alternatives would be one of the early Iron Age cultures of the same region (e.g., Wessenstadt [800-600 BC], or Jastorf [600-300 BC]). Solid historical information begins in about 50 BC when Julius Caesar's Gallic Wars brought him into contact with Germans as well as Celts. He did cross the Rhine in 55 and 53 BC, but the province of Gaul he created used Social

structure

the river as a boundary and most Germans lived beyond it Direct Roman attacks on German tribes began again under Nero Claudius Drusus Germanicus, who pushed across the Rhine in 12-9 BC, while other Roman forces assaulted Germanic tribes through the middle Danube (in modern Austria and Hungary). Fierce fighting in both areas, and the famous victory of the German Arminius in the Teutoburger Forest in AD 9 (when three Roman legions were massacred), showed that conquering these tribes would require too much effort. The Roman frontier thus stabilized on the Rhine and Danube rivers, although sporadic campaigns (notably under Domitian in AD 83 and 88) extended control over Frisia in the north and some

lands east of the confluence of the Rhine and the Danube. Both archaeology and Caesar's own account of his wars show that German tribes then lived on both sides of the Rhine. The Romans also met Germans on the middle Danube. In fact, broadly similar archaeological cultures from this period stretch across central Europe from the Rhine to the Vistula River (in modern Poland), so that Germanic peoples probably dominated all of these areas. Germanic cultures extended from Scandinavia as far south as the Carpathians. These Germans led a largely settled agricultural existence. They practiced mixed farming, lived in wooden houses (working mainly in wood), did not have the potter's wheel, were nonliterate, and did not use money. The marshy lowlands of northern Europe preserve otherwise perishable wooden objects, leather goods, and clothing and shed much light on the Germanic way of life. These bogs were also used for ritual sacrifice and execution, and some 700 "bog people" have been recovered. Their remains are so well preserved that even dietary patterns can be established; the staple was a gruel made of many kinds of seeds and weeds.

Clear evidence of social differentiation appears in these cultures. Richly furnished burials (containing rich jewelry and sometimes weapons) have been uncovered in many areas, showing that a wealthy warrior-prince class was developing. These chiefs became a standard feature of Germanic society, and archaeologists have uncovered the halls where they feasted their retainers, an activity described in the Anglo-Saxon poem Beowulf. This warrior elite followed the cult of a war god (Tiu or Wodan). Tacitus describes in the Germania how in AD 59 the Hermunduri, in fulfillment of their vows, sacrificed defeated Chatti to this god. This elite was also the basis of political organization. The Germans were divided into numerous tribes, which were also united in leagues centred on the worship of particular cults. These cults were probably created by one locally dominant tribe and changed over time. Tribes belonging to such leagues came together for an annual festival, when weapons were laid aside. Apart from worship, these were also times for economic activity, social interaction, and settling disputes.

COEXISTENCE WITH ROME TO AD 350

After Rome had established its frontiers, commercial and cultural contacts were as important as direct conflict. Although it was heavily fortified, the frontier was never a barrier to trade or people. In about AD 50, tribes beside the Rhine learned to use Roman money. Germanic gravesat least the richer ones-began to include Roman luxury imports such as fine pottery, glass, and metalwork. In return, raw materials such as amber and leather, and many slaves, went back across the frontier. Germans also served in Roman armies.

Border raiding was endemic, and periodically there were much larger disturbances. In about AD 150 the Marcomanni, a Germanic tribe, moved south into the middle Danube region, and they even invaded Italy in 167. The emperor Marcus Aurelius and his son spent the next 20 years curbing their inroads, and archaeology shows that the wars were highly destructive. This migration was one manifestation of a broader problem, for between about 150 and 200 a whole series of Germanic groups moved south along the river valleys of central and eastern Europe. These migrations resulted in great violence along the entire frontier during the 3rd century. Parts of Gaul suffered greatly, and Goths ravaged the Danube region,

even killing the emperor Decius in 251. Yet intensive campaigns brought the Germanic tribes back under control, so that by about 280 stability had returned to the Rhine and Danube. The Roman army and an alliance system involving, among others, Franks, Alemanni, and Goths maintained the frontier until about 370.

In the meantime the Germanic world was being transformed. For the balance of power in Europe, most important was the rise of larger and more cohesive Germanic political units, at least among the Germans living on the borders of the empire. This was largely a response to the military threat from Rome. Despite their occasional successes, more Germans than Romans had been killed in 3rd-century conflicts, and the Germans had learned that larger groups were more likely to survive. In the 4th century there were two powerful Germanic confederations: the Alemanni on the Rhine and the Goths on the Danube. These were sustained by the military elite whose control over their fellow tribesmen continued to increase. Other contacts with the empire had fewer political effects. In the 3rd century Germanic cultures began to master the potter's wheel, and there is evidence of improved farming techniques; both were adopted from Rome. The empire was also partly responsible for the Germans' first steps toward literary culture. Gothic, the oldest literary Germanic language, was created in about AD 350 by Ulfilas, a Romansponsored missionary, in order to translate the Bible.

THE MIGRATION PERIOD

The situation was revolutionized by nomadic (non-German) Hunnic horsemen from the east who pushed Germanic peoples into the Roman Empire in several waves. In 376, first of all, Visigoths were admitted by the emperor Valens, but only unwillingly, and confrontation followed. Two years later they killed Valens, winning a famous victory at Hadrianople, though by 382 they had been subdued. Yet, as the Huns moved west, Rome's frontiers came under increasing pressure, and further large incursions (Germanic and others) occurred in 386, 395. 405, and 406. Some of the invaders were defeated, but Germanic Vandals and Suebi established themselves in North Africa and Spain, and the Visigoths exploited the disorders to rebel. Marching to Italy, they demanded better terms, and, when these were not forthcoming, they sacked Rome on Aug. 24, 410.

The Roman Empire nevertheless remained an important power in Europe, having both troops and funds. Hence Germans on the run from the Huns were anxious to make peace; even the Visigoths accepted a settlement in Gaul in 418. Since Germanic groups had no sense of Germanic nationalism, they could be played off against one another; thus Vandals were savaged by the Visigoths between 416 and 418. Until about 450 fear of the Huns meant that the empire could, in moments of crisis, mobilize at least Visigoths, Burgundians (received into Gaul after being defeated by the Huns in 439), and Franks for its defense. Soon after Attila's death in 453, however, the Hun empire collapsed, and Rome lost this diplomatic weapon. It also suffered a progressive loss of revenue as territories were either occupied, or-like Britain-declared themselves independent. The balance thus swung further in the Germans' favour, and they eventually declared themselves independent. In the 470s a Visigothic kingdom emerged in southwestern Gaul and a Burgundian kingdom in southeastern Gaul, and Clovis created a Frankish kingdom in the north. The Vandals already controlled North Africa and the Suebi part of Spain. Ostrogoths freed by the collapse of the Hun empire conquered Italy between 489 and 493, and Gepidae and Lombard kingdoms dominated the Danube.

These Germanic successor states brought the Roman Empire in western Europe to an end. The empire could have resisted any of them singly, but the Hun invasions had pushed too many Germans across the frontier too quickly. Battles, however, were the exception. More often the empire unwillingly, but peacefully, granted areas for settlement, and as Rome became increasingly less powerful, the local Roman provincial population looked to the newly settled Germans for protection. This period thus continued the transformation of the Germanic world. Be-

Transformation Germanic world

The rise of independent kingdoms cause of the danger from Rome and the Huns, Germanic political units again increased in size. The new Germanic groups also fell under the influence of the Roman populations they came to rule. Literate, educated Romans enabled German kings systematically to raise taxation and expand their legal powers. The successor states to the Roman Empire were thus a fusion of Germanic military power and the administrative know-how of Roman provincial aristocrats. Transformation was complete when Germanic warrior and Roman provincial elites quickly intermarried, bringing into being a new aristocracy that was to shape medieval Europe. (PIHe)

Merovingians and Carolingians

When the western Roman Empire ended in 476, the Germanic tribes west of the Rhine were not politically united The west Germanic tribes, however, spoke dialects of a common language and shared social and political traditions. The traditions of these tribes had been influenced by centuries of contact with the Roman world, both as federated troops within the empire and as participants in the broader political and economic network that extended beyond the Roman frontier. In particular a strongly military structure of social organization, under the direction of commanders termed kings or dukes, had developed among the federated tribes within the empire and spread to tribes living outside the empire proper. Likewise, the Ostrogothic kings in Italy extended their influence over much of the Germanic world north of the Alps.

MEROVINGIAN GERMANY

beginnings

domina.

tion

The Franks, settled in Romanized Gaul and western Germany, rejected Ostrogothic leadership and began to expand of Frankish their kingdom eastward. Clovis' conversion to orthodox Christianity was an overt challenge to Ostrogothic hegemony to the east and to Visigothic control to the south. He and his successors, particularly Theodebert I (reigned 534-548), brought much of what would later constitute Germany under Frankish control, including the Thuringians of central Germany and the Alemanni and Bavarians of the south. Generally these heterogenous groups were given a law code including Frankish and local traditions and were governed by a duke of mixed Frankish and indigenous background who represented the Frankish king. In times of strong central leadership, as under Dagobert I (629-639), this leadership could have real effect. At other times, when the Frankish realm was badly divided or embroiled in civil wars, local dukes enjoyed great autonomy, This was particularly true of the Bavarian Agilolfings, who were closely related to the Lombard royal family of Italy and who by the 8th century enjoyed virtual royal status. In the north the Frisians and Saxons remained independent of Frankish control into the 8th century, preserving their own political and social structures and remaining for the most part pagan. In areas under Frankish lordship, Christianity made considerable progress through the efforts of native Raetians in the Alpine regions, of wandering Irish missionaries, and of transplanted Frankish aristocrats who supported monastic foundations.

THE RISE OF THE CAROLINGIANS AND BONIFACE

By the end of the 7th century, Merovingian rule throughout the Frankish world had been destroyed by powerful, competing aristocratic clans, each claiming autonomy and hoping to establish hegemony over the Frankish realm. The clan that finally succeeded was the Carolingian, which drew its strength from extensive estates and loyal aristocratic supporters in the lands between the Meuse and the Rhine. The Carolingians ruled the kingdom from the *730s, although they did not acquire the royal title until 751. They consolidated effective control over the Frankish heartland and the duchies east of the Rhine. Consolidating control over these duchies was facilitated by supporting the missionary activities of churchmen closely allied with Roman hierarchical forms of ecclesiastical organization that favoured political centralization, at the expense of indigenous and Irish ecclesiastical structures. The pattern of Frankish penetration was always the same. Small commu-

nities or churches were settled on land newly won from forest or marsh, granted them by their Carolingian protectors. Thus, from Frisia in the north to Bavaria in the south. religious, economic, and political penetration went hand in hand. A distinguished part was played by Anglo-Saxon missionaries, who linked the Frankish world not only with the high culture of the churches (notably York) from which they set out but also with Rome, the ultimate source of their inspiration. Chief among them were St. Willibrord (c. 658-739), who worked as a missionary and Frankish agent among the Frisians and later the Thuringians, and St. Boniface (c. 675-754), who created a German church structure. Supported by Charles Martel against both the aristocratic Frankish clergy and the preexisting clergy of the Germanic regions, many of whom feared growing Carolingian and Roman control, Boniface led missions into Franconia, Thuringia, and Bavaria, where he founded or reorganized diocesan organization on a Roman model. In 742 he played a large part in the first council of the new German church. By the time of his death at the hands of northern Frisians, all of the continental Germanic peoples except the Saxons were well on the way toward integration into a Roman-Frankish ecclesiastical structure.

Creation of the German church

CHARLEMAGNE

Charlemagne built on the foundations laid by Charles Martel and Boniface. Contemporary writers were vastly impressed by Charlemagne's political campaigns to destroy the autonomy of Bavaria and his equally determined Saxon military campaigns. Under their Agilolfing dukes, who had at times led the opposition to the rising Carolingians, the Bavarians had developed an independent, southward-looking state that had close contacts with Lombard Italy and peaceful relations with the Avar kingdom to the east. Charlemagne's conquest of the Lombards in 774 left Bavaria isolated, and in 788 Charlemagne succeeded in deposing the last Agilolfing duke, Tassilo III, and replacing him with a trusted agent. Thereafter, Charlemagne used Bavaria as the staging ground for a series of successful wars that ultimately destroyed the Avar kingdom.

The subjugation of the north proved much more difficult than that of the south. In the wake of the missionaries. Frankish counts and other officials moved into northeastern Frisia, raising contingents for the royal host and doing the other business of secular government. As for the Rhineland, the richer it grew the more necessary it became to protect its hinterland, Franconia (Hesse) and Thuringia, from Saxon raids. Because there was no natural barrier

behind which to hold the Saxons, this was a difficult task. Unlike the Bavarians, the Saxons were not politically united. Their independent edhelingi (nobles) lived on estates among forest clearings, dominating the frilingi (freemen), lazzi (half-free), and unfree members of Saxon society and leading raids into the rich Frankish world. Thus each of Charlemagne's punitive expeditions bit deeper into the heart of Saxony, leaving behind bitter subjugation memories of forced conversions, deportations, and massacres. These raids were inspired by religious as well as political zeal: Charlemagne tried to break Saxon resistance both to Christianity and to Frankish dominance with fire and sword. Still, the decentralized nature of Saxon society made ultimate conquest extremely difficult. Whenever the Frankish army was occupied elsewhere, the Saxons could be counted on to revolt, to slaughter Frankish officials and priests, and to raid as far westward as they could. Charlemagne in turn would punish the offending tribes and garrison the defense points abandoned by the Saxons. In time resistance to the Franks gave the Saxons a kind of unity under the leadership of Widukind, who succeeded longer than any other leader in holding together a majority of chieftains in armed resistance to the Franks. Ultimately internal feuding led to the capitulation even of Widukind. He surrendered, was baptized, and, like Tassilo, was imprisoned in a monastery for the remainder of his life. Saxony had been savagely repressed, as is reflected in the Capitulatio de partibus Saxoniae (c. 785; "Capitulary for the Saxon Regions") and the Capitulare Saxonicum (797; "Capitulary of the Saxons"), both measures intended to force the submission of the Saxons to the Franks and

of Saxony

THE EMERGENCE OF GERMANY

The kingdom of Louis the German. Charlemagne made no attempt to rule his vast empire in a unified manner and was content to leave each Germanic region largely in the hands of his counts and bishops. His son Louis I (Louis the Pious) was not unpopular with his Germanic subjects; on two occasions he owed his restoration to power largely to their support, but his primary focus was on the Romance-speaking regions of the empire. In 825 he entrusted his son Louis the German (804-876) with the government of Bavaria, whence he was gradually to extend his power over all of Carolingian Germany. This was the first time that the German peoples had had a ruler whose authority was confined to their own lands. Although his ambitions extended throughout the whole Carolingian world, Louis cultivated German language and literature for the first time as a self-conscious cultural and political identity. Under his patronage the Gospels were translated into Germanic dialects and the first attempts at writing Germanic poetry with Christian and traditional themes were undertaken. Louis himself was described as the Frankish king of the eastern kingdom. Much of Louis' reign was taken up with campaigns against neighbouring Slavs, and this external focus maintained stability and royal authority over the aristocracy. By 870 Louis' dominions reached almost the boundaries of medieval Germany. On the east they were bordered by the Elbe and the Bohemian mountains; on the west, beyond the Rhine, they included the districts afterward known as Alsace and Lorraine, Ecclesiastically, they included the provinces of Mainz, Trier, Cologne, Salzburg, and Bremen. Although the close kinship and rivalries of the descendants of Charlemagne still united east and west Francia, the eastern region was taking on the identity of Germany and the west was emerging as France.

Louis' long reign had accustomed the Germanic peoples of his kingdom to a certain unity. After his death the kingdom was divided among his three sons in keeping with Carolingian tradition, but the deaths of two of them, in 880 and 882, restored its unity under Charles the Fat. The ceaseless external blows from Danes, Saracens, and Magyars that fell upon the Carolingian world in the later 9th and 10th centuries weakened the kingdom's cohesion, however. Not only the Carolingians themselves but also their followers were prepared to take advantage of one another, to compromise with the enemy, and to carve out even more dominions from one another's lands. Incompetence in mounting effective resistance to invaders led to revolts and civil wars, as for instance in 887 when Arnulf, an illegitimate son of Louis the German's son Carloman, led an army of Bavarians in a successful revolt against his uncle, Charles the Fat. Arnulf, however, was not equally successful in defending his eastern possessions. After his death in 899, the German kingdom came under the nominal rule of his young son, Louis the Child, and in the absence of strong military leadership it became the prey of the Magyar horsemen and other invaders from the east.

Rise of the duchies. Because the Carolingians themselves were unable to provide effective defense for the whole kingdom, military command and the political and economic power necessary to support it necessarily devolved on local leaders whose regions were attacked. The inevitable result was the decentralization and decay of royal authority to the profit of the regional dukes. Contrary to popular opinion, these dukes were not appointed by the peoples concerned, nor were they descendants of the tribal chieftains of the postmigration period. The socalled Stammesherzogtümer (stem or tribal duchies) were new political and, ultimately, social units. Their dukes were Carolingian counts, part of the international "imperial aristocracy" of the Carolingians, who took the initiative in organizing defense on a local basis, without thereby seeking to shake men's loyalty to the Carolingians. All the same, their initial success established them

in the hearts of those whom they protected. In Saxony the Liudolfings, descendants of military commanders first established by Louis the German, achieved spectacular successes against the Slavs, Normans, and Magyars. In Franconia the Konradings rose to prominence over this largely Frankish region with the assistance of Arnulf but became largely independent during the minority of his son. Thuringia fell increasingly under the protection and lordship of the Liudolfings. In Swabia (Alemannia) the Hunfridinger and Erchanger clans, originally established by Carolingian kings, disputed control with each other and with regional ecclesiastical lords. Similarly the Luitpoldingers, originally named as Carolingian commanders, became dukes of Bavaria. Throughout the kingdom the only force for preserving unity remained the church, but the threat of external foes led to the secularization of much monastic land with episcopal approval, further strengthening the power of the dukes.

The structural transformation of the "imperial aristocracy" to a local elite was accompanied by an increasingly particularist, dynastically oriented aristocratic society that was bound together through ties of vassalage and exercised personal lordship over the free and half-free populations of the regions. This process did not advance as far in Germany as it did in France. Everywhere German society remained closer to older, regional varieties of social organization as well as to traditions of Carolingian ecclesiastical and comital government. (J.M.W.-H.P.J.G.)

Germany from 911 to 1250

THE 10TH AND 11TH CENTURIES

Conrad I (911-918). When in 911 Louis the Child, last of the East Frankish Carolingians, died without leaving a male heir, it seemed quite possible that his kingdom would break into pieces. In at least three of the four stem lands, Bavaria, Saxony, and Franconia, the ducal families were established in the leadership of their tribes; in Swabia (Alemannia) two houses were still fighting for hegemony. Only the church, fearing for its endowments, had an obvious interest in the future of the monarchy, its ancient protector. Against the growing authority of the dukes and the deep differences in dialect, in customs, and in social structure between the tribes there stood only the Carolingian tradition of kingship; but, with Charles the Simple as holder of the West Frankish kingdom, its future was uncertain and not very hopeful. Only the Lotharingians put their faith in the ancient line and did homage to Charles, its sole reigning representative. The other component parts of the East Frankish kingdom did not follow suit.

One can only guess at the motives of the Saxon and Frankish tribal hosts who on Nov. 10, 911, elected Conrad, duke of the Franks, as their king at Forchheim in Franconia. At the opening of the 10th century the Germanic peoples in the lands east of the Rhine and west of the Elbe, the Saale, and the Bohemian forest-as rudimentary and as thinly spread as their settlements werehad to face even more primitive and pagan races pressing in from farther east, especially the Magyars. The Saxons, headed by their duke Otto of the house of the Liudolfings, were threatened by more enemies on their frontiers than any other tribe; Danes, Slavs, and Magyars simultaneously harassed their homeland. A king who commanded resources farther west, in Franconia, might therefore prove to be of help to Saxony. The Rhenish Franks, on the other hand, did not wish to abdicate from their position as the leading and kingmaking people, which gave them many material advantages.

Conrad of Franconia, elected by Franks and Saxons, was soon recognized also by Arnulf, duke of Bavaria, and by the Swabian clans. In descent, honours, and wealth, however, Corrad was no more than the equal of the dukes who had accepted him as king. To gain a lead over them, to found a new royal house, and to acquire those wonderworking attributes that the Germans venerated in their rulers long after they had been converted to Christianity, he had yet to prove himself able, lucky, and successful. In this period, political affairs became the monopoly of the German kings and a few soore families of great magnates.

Changes in social organization

Germany and France

Germany in the 10th and 11th centuries

The reason for this concentration of power was that, at the very foundation of the German kingdom, circumstances had long favoured those men whom birth, wealth, and military success had raised well above the ranks of the ordinary free members of their tribe. Their estates were cultivated in the main by half-free peasants-slaves who had risen or freemen who had sunk. The holdings of these dependents fell under the power of the lord to whom they owed service and obedience. Already they were tied to the lands on which they laboured and were dependent on their protectors for justice. For many reasons ordinary freemen tended generally to lose their independence and had to seek aid from their more fortunate and powerful neighbours; thus, they lost their standing in the assemblies of their tribe. Everywhere, except in Friesland and parts of Saxony, the nobles wedged themselves between king or duke and the rank and file. They alone could become prelates of the church, and they alone could compete for the possession and enjoyment of governmental rights. At the level below the dukes, the bulk of administrative authority, jurisdiction, and command in war lay with the margraves and counts, whose hold on their charges developed gradually into hereditary right. The commended men and the half free disappeared from the important functions of public life. In the local assemblies they came only to pay dues and to receive orders, justice, and penalties. Their political role was passive. Those lords whose protection was most worth having also had the largest throng of dependents and thus became more formidable to their enemies and to the remaining freemen. Lordship and submission to it were hereditary, and thus the horizon of the dependent classes narrowed until eventually the lord and his officials filled the place of all secular authority and power in their lives. Military strength, the possession of arms and horses, and tactical training in their use were decisive. Most dependent men were disarmed; that became part of their degradation.

The accession of the Saxons. Conrad I was quite unequal to the situation in Germany. According to the beliefs of contemporaries, his failure meant that his house was luckless and lacked the prosperity-bringing virtues that belonged to true kingship. On his deathbed in 918, he therefore proposed that the crown, which in 911 had remained with the Franks, should now pass to the leading man in Saxony, the Liudolfing Henry (later called the Fowler). Henry I was elected by the Saxons and Franks at Fritzlar, their ancient meeting place, in 919. With a mourant of their own race, the Saxons now took over the burden and the rewards of being the kingmaking people. The centre of gravity shifted to eastern Saxony, where the Liudolfing lands lay.

The transition of the crown from the Franks to the Saxons for a time enhanced the self-sufficiency of the south German tribes. The Swabians had kept away from the Fritzlar election. The Bavarians believed that they had a better right to the Carolingian inheritance than the Saxons (who had been remote outsiders in the 9th century) and in 919 elected their own duke Arnulf as king. They, too, wanted to be the royal and kingmaking people. Henry I's regime rested in the main on his own position and family demesne in Saxony and on certain ancient royal seats in Franconia. His kingship was purely military. He hoped to gather authority by waging successful frontier wars and to gain recognition in the first place by concessions rather than to insist on the sacred and priestlike status of the royal office that the church had built up in the 9th century. At his election he refused to be anointed and consecrated by the archbishop of Mainz. In settling with

Development of serfdom

> The election of Henry I the Fowler

Reliance on the

clergy

the Bavarians, he abandoned the policy of supporting the internal opposition that the clergy offered to Duke Arnulf, a plank to which Conrad had clung. To end Arnulf's rival kingship. Henry formally surrendered to him the most characteristic privilege and honour of the crown: the right to dispose of the region's bishoprics and abbeys. Arnulf's homage and friendship entailed no positive obligations toward Henry, and the Bavarian duke pursued his own tribal interests-peace with the Hungarians and expansion across the Alps-as long as he lived.

From these unpromising beginnings the Saxon dynasty not only found its way back to Carolingian traditions of government but soon got far better terms in its relations with the autonomous powers of the duchies, which had gained such a start on it. Nonetheless, the constitution that it bequeathed to its Salian successors was self-contradictory; while seeking to overcome the princely aristocracies of the stem lands by leaving them to themselves, the Saxon kings came to rely more and more, both for the inspiration and for the practice of government, on the prelates of the church, who were themselves recruited from the ranks of the same great families. They loaded bishoprics and abbeys with endowments and privileges and thus gradually turned the bishops and abbots into princes with interests not unlike those of their lay kinsmen. These weaknesses, however, lay concealed behind the personal ascendancy of an exceptionally tough and commanding set of rulers up to the middle of the 11th century. Thereafter, the ambiguous system could not take the strain of the changes fermenting within German society and even less the attack on its values that came from withoutfrom the reformed papacy.

The Liudolfing kings won military success, and with it they gained that respect for their personal authority that counted for so much at a time when the great followed only those whose star they trusted and who could reward services with the spoils of victory. In 925 Henry I brought Lotharingia back to the East Frankish connection. Whoever had authority in that half-French-speaking. half-German-speaking region could treat the neighbouring kingdom of the West Franks as a dependent. The young Saxon dynasty thus won for itself and its successors a hegemony over the west and the southwest that lasted at least until the mid-11th century. The Carolingian kings of France, as well as the great feudatories who sought to dominate if not to ruin them, became, in turn, petitioners of the German court during the reign of the Ottos. The kings of Burgundy-whose suzerainty lay over the valleys of the Saône and the Rhône, the western Alps, and Provence-fell under the virtual tutelage of the masters of Lotharingia. Rich in ancient towns, this region, once the homeland of the Carolingians, was more thickly populated and wealthier than the lands east of the Rhine. Lotharingian merchants controlled the slave trade from the Saxon marches to Córdoba.

The eastern policy of the Saxons. Greater prestige still and a claim to imperial hegemony fell to the Saxon rulers when they broke the impetus of the Hungarian invasions, against which the military resources and methods of western European society had almost wholly failed for several decades. In 933, after long preparations, Henry routed a Hungarian attack on Saxony and Thuringia. In 955 Otto I (reigned 936-973), at the head of a force to which nearly Hungarians all the tribes had sent mounted contingents, annihilated a at the Lech great Hungarian army on the Lech River near Augsburg. The battle again vindicated the efficiency of the heavily armed man skilled in fighting on horseback.

With a Saxon dynasty on the throne, Saxon nobles gained office and power, with opportunities for conquest along the eastern river frontiers and marches of their homeland. Otto I indeed had an eastern policy that aimed at getting more than slaves, loot, and tribute. Between 955 and 972 he founded and richly endowed an archbishopric at Magdeburg, which he intended to be the metropolis of a large missionary province among the heathen Slavs beyond the Elbe. This would have brought their tribes under German control and exploitation in the long run; but the ruthless methods of the Saxon lay lords clashed with the church's efforts at more peaceful penetration.

In the 10th century there was little or no German agricultural settlement beyond the Elbe. Far too much forest clearing remained to be done in all the regions of western and southern Germany. The Saxon conquests up to the Oder were secured by military strongholds, called burgwards, and were held only as long as their garrisons had the upper hand. Beyond the Slav peoples of Brandenburg and Lusatia, moreover, new Slavic powers rose: the Poles under Mieszko I and, to the south, the Czechs under the Přemyslids received missionaries from Passau and Magdeburg without falling permanently under the political and ecclesiastical domination of Bavarians and Saxons. The heathen Elbe Slavs, subjugated by the Saxon margraves, rose in 983 when the military occupation collapsed along with the missionary bishoprics that had been founded at Oldenburg, Brandenburg, and Havelberg, Farther south the defenses of the Thuringian marches between the Saale and the middle Elbe remained in German hands, but only after a long and fierce struggle against Polish invaders early in the 11th century. The northern part of the frontier reverted to what it had been before Otto's trustees. Hermann Billung and Gero, opened their wars. Missionary enterprises directed from Bremen and Magdeburg achieved little before the 12th century. The Saxon ruling class, bishops, and margraves must bear the responsibility for the fiasco of eastward expansion in the 10th century. The prelates, too, saw their missions as means to found ecclesiastical empires with subject dioceses and tithes on Slav soil. The tribes across the Elbe therefore remained unconverted and implacable foes, a standing menace to the nearby churches. The wars also left a legacy of savagery on both sides so that from about 1140 onward the substitution of German settlers for the native Slavs became the common policy of both the church and the princes.

Dukes, counts, and advocates. Conrad I's and Henry I's kingships rested on the will of the tribes-or rather on that of their leaders and of the higher aristocracy. It was in the first place an arrangement between the Franks and the Saxons that the Bavarian and Swabian dukes recognized at a price by acts of personal homage, but the German kings, of whatever dynasty, had to live under Frankish law. After the death of Conrad I's brother Eberhard in 939, Otto I kept the Franconian dukedom vacant and the Franconian counts henceforth stood under the immediate authority of the crown. In Saxony, too, Otto kept in his hands the dukedom of his ancestors. The march-duchy of the Billungs, a bulwark raised against the Danes and the northern Slav tribes, did not give the Billung family

authority over all the other Saxon princes. In the south the Ottonians sought to turn the dukedoms of the stem lands into royal fiefdoms and to supplant native dynasties by aliens and members of their own clan. When even that policy did not stop rebellions under the banner of tribal self-interest, they began to break up the ancient Bavarian stem land by creating a duchy in Carinthia to cut off the spearhead of Bavarian expansion southward. The first two Salians, Conrad II (reigned 1024-39) and Henry III (reigned alone 1039-56), also bestowed vacant duchies quite freely on their own kin and on men from outside the stem boundaries. They competed against ducal power but could neither abolish nor replace it. In the 11th century as before, the dukes held assemblies of their folk, led the tribal host in war, and enforced peace.

The counts, who were the ordinary officers of justice in serious, criminal cases, obeyed the ducal summons; but, for the most part, they received their "ban," the power to do blood justice, from the king himself. The fiefs and the customary rights attached to their office, and indeed the office itself, not only became hereditary but also came to be treated more and more as a patrimony to which they had an inherent right against all men, king and duke included. Even so, however, a good many lines died out and their counties fell back into the king's hands. From Otto III's reign (983-1002) onward, it became not at all unusual to bestow these counties on bishoprics and certain great abbeys rather than to grant them out again to other lay magnates. The bishops, however, could not perform all the functions of the counts; in particular, their holy orders forbade them to pass judgments of blood. They often

The rise of the advocates subinfeudated their countships, and they needed officials called advocates (Vögte; singular Vogt) to take charge of the higher jurisdiction in the franchises that their churches possessed by royal grant. In the 10th and 11th centuries these advocates had to be recruited from the aristocracy, the very class whose greed for hereditary office was to be checked, because ordinary freemen could not enforce severe sentences or defend the privileges of the church against armed intrusion. Dangerous neighbours of bishoprics and abbeys in any case, the nobles as advocates and protectors of ecclesiastical possessions were anything but reliable servants of their ecclesiastical overlords.

Thus, there arose in nearly all German lands, whether the ducal office survived or not, powerful lines of margraves, counts, and hereditary advocates who enriched themselves at the expense of the church (which meant also the crown) and in competition with one another. From the abler, more fortunate, and long-lived races among these dynasts sprang the territorial princes of the later 12th and 13th centuries, absorbing and finally inheriting most of the

rights of government.

Power of the kings

The king was the personal overlord of all the great. His court was the seat of government, and it went with him on his long journeys. The German kings, even more than other medieval rulers, could only make their authority respected in the far-flung regions of their kingdom by traveling ceaselessly from duchy to duchy, from frontier to frontier. Wherever they stayed, their jurisdiction superseded the standing power of dukes, counts, and advocates, and they could collect the profits of local justice and wield some control over it. As they came into each region, they summoned its leaders to attend their solemn crown wearings, deliberated with them on the affairs of the Reich and the locality, presided over pleas, granted privileges. and made war against peacebreakers at home and on ene-

The promotion of the German church. The royal revenues came from the king's demesne lands and from his share of the tributes that Poles, Czechs, heathen Slavs, and Danes paid whenever he could enforce his claims of overlordship. There were also profits from tolls and mints that had not yet been granted away. The king's demesne was his working capital. He and his household lived on its produce during their wanderings through the Reich, and it also served to provide for his family, to found churches, and to reward faithful services done to him, especially in war. To swell the hosts, vassals had to be enfeoffed, and alienations were inevitable. The Salians, though they inherited the remains of Ottonian wealth as imperial demesne, brought little of their own to make up for its diminution. The last Saxon, Henry II (1002-24), and after him Conrad II. accordingly took to enfeoffing vassals with lands taken from the monasteries. Since the beneficiaries were often already powerful and wealthy men in their own right, no class of freeborn, mounted warriors linked permanently with the crown sprang from the loyalties and rewards of one or two reigns. In any case, the lion's share of grants

The growth of central government

went to the German church. From the Carolingians, the German kings inherited their one and only institution of central government: the royal chapel, with the chancery that does not seem to have been distinct from it. Service there became a recognized avenue of promotion to the episcopate for highborn clerks. In the 11th century, bishops and abbots conducted the affairs of the Reich much more than the lay lords, even in war. They were its habitual diplomats and ambassadors. Unlike Henry I, Otto I and his successors sought to free the prelates from all forms of subjection to the dukes. The king appointed most of them, and to him alone, as to one sent by God, they owed obedience.

* Thus, there arose beside the loose association of stem lands in the German kingdom a more compact and uniform body with a far greater vested interest in the Reich: the German church. By ancient Germanic custom, moreover, the founder of a church did not lose his estate in the endowment that he had made; he remained its proprietor and protecting lord. The bishoprics, it is true, and certain ancient abbeys, such as Sankt Gallen, Reichenau, Fulda, and Hersfeld, did not belong to the king; they were members of the kingdom but under his guardianship. The greater churches therefore had to serve the rulers with mounted men, money, and free quarters. Gifts of royal demesne to found or to enrich bishoprics and convents were not really alienations but pious reinvestments as long as the crown controlled the appointments of bishops and abbots. The church did not merely receive grants of land, often waste, to settle, develop, and make profitable; it was also given, as has been shown, powers of jurisdiction over its dependents. Nor did the kings stint the prelates in other regalian rights, such as mints, markets, and tolls. These grants broke up counties and to some extent even duchies, and that was their purpose: to disrupt the secular

lords' jurisdictions that had escaped royal control. This policy of fastening the church, a universal institution, into the Reich, with its well-defined frontiers, is usually associated with the name of Otto I, but it gathered momentum only in the reigns of his successors. The policy reached a climax under Henry II, the founder of the see of Bamberg in the upper Main valley; nonetheless, Conrad II, though less generous with his grants, and his son Henry III continued it. Bishops and abbests became the competitors of lay princes in the formation of territories, a rivalry that more than any other was the fuel and substance of the ceaseless feuds, the smoldering internal wars in all the regions of Germany for many centuries. The welter and the confused mosaic of the political map of Germany until 1803 is the not-so-remote outcome of these 10th- and 11th-century grants and of the incompat-

ible ambitions that they aroused.

The Ottonian conquest of Italy and the imperial crown, Otto I's marriage with Adelaide (Adelheid), daughter of Rudolph II of Burgundy, and the Italian rivalries between his son Liudolf, duke of Swabia, and Otto's brother Henry I, duke of Bavaria, drew him southward. After 951, expeditions into Italy were a matter for the whole Reich under the leadership of its ruler and no longer just an outlet for the expansion of the south German tribes. For the Saxon military class, too, the south was more tempting than the primeval forests and swamps beyond the Elbe. With superior forces at their back, the German kings gained possession of the Lombard kingdom in Italy. There, too, their overlordship in the 10th and the 11th centuries came to rest on the bishoprics and a handful of great abbeys.

After his victory over the Magyars in 955, Otto I's hegemony in the west was indisputable. By the standards of one chronicler, the Saxon Widukind, he had already become emperor because he had subjected other peoples and enjoyed authority in more than one kingdom. But the right to confer the imperial crown, to raise a king to the higher rank of emperor, had fallen to the papacy, which had crowned Charlemagne and most of his successors. The Carolingian order in the west was still the model and something like a political ideal for all Western ruling families in the 10th century. Otto had measured himself against the political tasks that had faced his East Frankish predecessors and more or less mastered them. To be like Charlemagne, therefore, and to clothe his newly won position in a traditional and time-honoured dignity, he accepted the imperial crown and anointment from Pope John XII in Rome in 962. The substance of his empire was military power and success in war; but Christian and Roman ideas were woven round the Saxon's throne by the writers of his own and the next generation. Although the German kings as emperors did not give the law to the Roman church in matters of doctrine and ritual, they became its political masters for nearly a century. The imperial crown enhanced their standing even among the nobles and knights who followed them to Italy and can hardly have understood or wanted all its outlandish associations. Not only the king but also the German bishops and lay lords thus entered into a permanent connection with an empire won on the way to Rome and bestowed by the papacy.

Otto II (reigned alone 973-983) and above all Otto III (983-1002) were strongly drawn toward their new Mediterranean sphere of action, but Henry II (1002-24) returned to a sober regime centred on Germany and contented himself with three brief Italian expeditions.

The formation of the Holy Roman Empire

Effects

of the

reformed

papacy

The papal reforms and the German church. More than any other feudal society in early medieval Europe, Germany was divided and torn by the revolutionary ideas and measures of the reformed papacy. Beginning with the pontificate of Leo IX (1048-54)-one of Henry III's nominees-the most determined and inspired spokesmen of ecclesiastical reform placed themselves at the service of the Holy See. Only a few years after Henry III's death (1056). they agitated against lay authority in the church, founded on proprietary rights. They regarded the laity as passive partakers of the sacraments and denied the supernatural status of kingship. Priests, including bishops and abbots, who accepted their dignities from lay lords and emperors at a price, according to the reformers, committed a sin; for these earthly powers could not rightly confer churches at all, nor could they own them. They believed, moreover, that thorough reforms could be brought about only by the exaltation of the papacy so that it commanded the obedience of all provincial metropolitans and was out of the emperor's and the local aristocracy's reach.

The endless repetition of the reformers' teachings in brilliant pamphlets and at clerical synods spread agitation in Italy, Burgundy, and Lotharingia-all parts of the empire. Their new program committed the leaders of the movement to a struggle for power because it struck at the very roots of the regime to which the German church had grown accustomed and on which the German kings relied. The vast wealth that Henry IV's predecessors had showered on the bishoprics and abbeys would, if the new teaching prevailed, escape his control and remain at the free disposal of prelates whom he no longer appointed, Under Roman authority the churches were to be freed from most of the burdens of royal protection without losing any of its benefits. The most fiery spirits in Rome did not flinch from the consequences of their convictions. Their leader Hildebrand, later Pope Gregory VII (reigned 1073-85), was ready to risk a collision with the empire.

Henry IV was not yet six years old when his father died in 1056. The full impact of the Gregorian demandscoming shortly after a royal minority, a Saxon rising, and a conspiracy of the south German princes-has often been regarded as the most disastrous moment in Germany's history during the Middle Ages. In fact, the German church proved thoroughly unreliable as an inner bastion of the empire even before Rome struck. Its leaders, Anno and Adalbert, archbishops of Cologne and of Hamburg-Bremen respectively, shamelessly exploited their hold over the young king by hunting for spoils out of the imperial demesne. In 1074 and 1075 Gregory proceeded against simony (the buying and selling of church office) in Germany and humiliated the aristocratic episcopate by summonses to Rome and sentences of suspension. These papal actions demoralized and shook the German hierarchy. The prelates' return to their customary support of the crown was not disinterested, nor wholehearted, nor unanimous.

The discontent of the lay princes. Henry IV's minority also gave elbowroom to the ambitions and hatreds of the lay magnates. The feeble regency of his mother, Agnes of Poitou, faltered before the throng of princes, who respected only authority and forces greater than their own. The ruling influence of the higher clergy at the court of

Henry III and the renewed flow of grants to the church had estranged them from the empire. It is likely also that these eternally belligerent men were lagging behind the prelates in the development of their agrarian resources. The prelates had a vested interest in peace, and under royal protection they improved and enlarged their estates by turning forests into arable land and also by offering better terms to freemen in search of a lord. The bishops' market and toll privileges brought them revenues in money, which many of the lay princes lacked. So far, however, the princes' military power, their chief asset, had remained unchallenged. Now, for the first time, they also had to face rivals within their own sphere of action. Henry III and the young Henry IV began to rely on advisers and fighting men drawn from a lower tier of the social order-the poorer, freeborn nobility of Swabia and, above all, the class of unfree knights, known as ministeriales. These knights had first become important as administrators and soldiers on the estates of the church early in the 11th century. Their status and that of their fiefs was fixed by seignorial ordinances, and they could be relied on and ordered about, unlike the free vassals of bishops and abbots. Beginning with Conrad II, the Salian kings used ministeriales to administer their demesne, as household officers at court and as garrisons for their castles. They formed a small army, which the crown could mobilize without having to appeal to the lay princes, whose ill will and antipathy toward the government of the Reich grew apace with their exclusion from it.

Having come of age, Henry IV used petty south German nobles and his ministeriales to recover some of the crown lands and rights, which the lay princes and certain prelates had acquired during his minority, particularly in Saxony. His recovery operations went further, however, and a great belt of lands from the northern slopes of the Harz Mountains to the Thuringian Forest was secured and fortified under the supervision of his knights to form a royal territory, where the king and his court could reside. The south German magnates were thus kept at a distance when Henry and his advisers struck at such neighbouring

Saxon princes as Otto of Northeim and the Billung family. The storm broke in 1073. A group of Saxon nobles and prelates and the free peasantry of Eastphalia, who had to bear the brunt of statute labour in the building of the royal strongholds, revolted against the regime of Henry's Frankish and Swabian officials. To overcome this startling combination and to save his fortresses, the king needed the military strength of the south German princes Rudolf of Rheinfelden, duke of Swabia; Welf IV, duke (as Welf I) of Bavaria; and Berthold of Zähringen, duke of Carinthia. Suspicious and hostile at heart, they took the field for him only when the Eastphalian peasantry committed outrages that shocked aristocratic caste feeling everywhere. Their forces enabled Henry to defeat the Saxon tribal rebellion at Homburg near Langensalza in June 1075, But, when the life-and-death struggle with Rome opened only half a year later, the south German malcontents deserted Henry and, together with the Saxons and a handful of bishops, entered into an alliance with Gregory VII. Few of them at this time were converted to papal reform doctrines, but Gregory's daring measures against the king gave them a chance to come to terms with one another and to justify a general revolt.

The civil war against Henry IV. On Feb. 22, 1076, the pope absolved all men from their oaths to Henry and solemnly excommunicated him. In October Gregory's legates met the German lords at Tribur (modern Trebur) to decide on the future of the king, whom his last adherents now abandoned. Although Henry was absolved by Gregory at Canossa in January 1077, the princes two months later elected Rudolf of Rheinfelden to rule in his place.

The war that now broke out lasted for almost 20 years. A majority of the bishops, most of Rhenish Franconia (the Salian homeland), and some important Bavarian and Swabian vassals sided with Henry. He thus held a central position, dividing his south German from his Saxon enemies, who could not unite long enough to destroy him. With the death in battle of Rudolf of Rheinfelden (1080) and the demise of another antiking, Hermann of

Formation of a royal territory

Decrees of Gregory VII

> Division of Henry's enemies

Salm (1088), the war in Germany degenerated into a number of local conflicts for the possession of bishoprics and abbeys. It almost died down in 1098, when the south German adherents of the papacy came to terms with Henry for the time being, though without recognizing his antipope Clement III. Throughout these years the crown, the churches, and the lay lords had to enfeoff more and more ministeriales in order to raise mounted warriors for their forces. Though this recruitment and frequent devastations strained the fortunes of many nobles, they knew how to recoup themselves by extorting more fiefs out of neighbouring bishoprics and abbeys. The divided German church thus bore the brunt of the costs of civil war, and it needed peace almost at any price.

Henry V and results of the conflict. The Salian dynasty and the rights for which it fought were saved because Henry IV's son and heir himself seized the leadership of a last rising against his father (1105). This maneuver enabled Henry V (reigned 1106-25) to continue the struggle for the crown's prerogative over the empire's churches against the inexorable demands of the papacy. The conflict now shrank into a legalistic dispute over the right to invest bishops and abbots with their dignities and the secular possessions attached to them. As the struggle continued, the princes became the arbiters and held the balance between their overlord and the pope, In 1122, acting as intermediaries and on behalf of the Reich, they forced the temporary concessions known as the Concordat of Worms out of the Holy See and its German spokesman, Archbishop Adalbert of Mainz, the bitter personal enemy of Henry V and the territorial rival of the Hohenstaufen sons of Henry's sister Agnes. By then, however, the princes had for the most part defeated efforts to restore royal rights in Saxony and to stem the swollen jurisdictions and territorial powers of the aristocracy elsewhere.

When Henry V, the last Salian, died childless in 1125, Germany was no longer the most effective political force in Europe. The brilliant conquest states of the Normans in England and Sicily and the patient, step-by-step labours of the French kings were achieving forms of government and concentrations of military and economic strength that the older and larger empire lacked. The papacy had dimmed the empire's prestige, and Rome became the true home of universalistic causes. When Pope Urban II preached the first crusade in 1095, Henry IV, cut off and surrounded by enemies, was living obscurely in a corner of northern Italy. The Holy See, by its great appeal to the militant lay nobility of western Europe, thus won the initiative over the empire. At this critical moment the Reich also lost control in the Italian bishoprics and towns, just when their population, trade, and industrial production were expanding fast. Germany did not even benefit indirectly from the crusaders' triumphs, although some of their leaders (e.g., Godfrey of Bouillon and Robert II of Flanders) were vassals of the emperor. The civil wars renewed for a time the relative isolation of the central German regions.

German

power after

of Henry V

the death

loss of

Internally, the crown had saved something of the indispensable means of government in the control over the church; but it was a bare minimum, and its future was problematic. The ecclesiastical princes henceforth held only their temporal lands as imperial fiefs, for which they owed personal and material services. As feudatories of the empire, they came to represent the same interests toward it as did the lay princes; at least, their sense of a special obligation tended to weaken. The king's jurisdiction continued to exist alongside and in competition with that of the local powers. The great tribal duchies survived as areas of separate customary law. Each developed differently, and the crown could not impose its rights on all alike or change the existing social order. The most tenacious defenders of this legal autonomy had been the Saxons; but it also prevailed in Swabia, where distinct territorial lordships grew fast.

The Gregorian reform movement therefore aggravated the age-old contradictions in Germany's early medieval constitution, but its monastic culture and its intellectual interests were anything but barren. Both sides fought with new literary weapons to work on public opinion in cathedrals and cloisters and perhaps also in the castles of the lay aristocracy. In their hard-hitting polemical writings they attempted to expound the fundamental theological. historical, and legal truths of their cause. The agitation did something to disturb the cultural self-sufficiency of the German laity. It drove many of the south German nobles to maintain direct connections with the Holy See, and whether they wanted to or not, they had to fall in with the aspirations of the religious leaders. The reform movement of the 11th and 12th centuries, it might almost be said, very nearly completed the conversion of Germany that had begun five centuries before

GERMANY AND THE HOHENSTAUFEN, 1125-1250

Dynastic competition, 1125-52. The nearest kinsmen of Henry V were his Hohenstaufen nephews-Frederick, duke of Swabia (1105-47), and his younger brother Conrad, the sons of Henry's sister Agnes and Frederick, the first Hohenstaufen duke of Swabia. Some form of election had always been necessary to succeed to the crown, but, before the great civil war, nearness to the royal blood had been honoured whenever a dynasty failed in the direct line. By 1125, however, the princes, guided by Archbishop Adalbert of Mainz, no longer respected blood right. Affinity with Henry V was no recommendation to them, and hereditary succession seemed to lower their authority in the government of the Reich, Instead of Frederick they chose the duke of Saxony, Lothair of Supplingenburg (reigned as king 1125-37, reigned as emperor 1133-37). Like the Hohenstaufen, he had risen by a lucky marriage and a successful career of continuous fighting into the first rank of dynasts; but, unlike them, he had served the cause of the Saxon opposition to the Salians.

With the enormous Northeim and Brunonian inheritances behind him, Lothair III (sometimes called Lothair II) could humble the Hohenstaufen brothers (1134) after marrying his only daughter and heiress to a Welf, Henry the Proud. Even without this dazzling alliance, the Welfs, already dukes of Bavaria and possessors of vast demesnes, countships, and ecclesiastical advocacies there, in Saxony, and in Swabia, were somewhat better off than their Hohenstaufen rivals. On the death of Lothair in 1137, however, the fears of the church and a few princes turned against the Welfs. Instead of Henry the Proud, who now held the duchies of Saxony and Bayaria and the Mathildine lands in Italy, they chose Conrad (reigned 1138-52), who had been Lothair's unsuccessful Hohenstaufen opponent.

The battle against the Welfs, which Conrad III put foremost on his political program, was abandoned with his death in 1152, when an election once again decided the succession and the political situation in Germany for the next 30 years. The princes then chose Frederick I Barbarossa (reigned as king 1152-90; as emperor 1155-90), the son of Conrad's elder brother Frederick and the Welf princess Judith. Frederick I agreed to share power in Germany with his Welf cousin Henry the Lion. The price of his election was dualism. In 1156 the duchy of Bayaria, which Conrad had tried to wrest from the Welfs. was restored to Henry the Lion, already undisputed duke of Saxony. The Babenberg margrave of Austria, Henry's rival, had to be compensated with a charter that raised his margravate into a duchy and gave him judicial suzerainty over an even wider area. Taken out of the Lion's duchy, it was to be held as an imperial fief that might descend both to sons and daughters. A perpetual principality, it served as a model for the aspirations of many other lay princes.

Colonization of the east. The history of Germany in the 12th and 13th centuries is one of ceaseless expansion. A conquering and colonizing movement burst across the river frontiers into the swamps and forests from Holstein to Silesia and overwhelmed the Slav tribes between the Elbe and the Oder. Every force in German society took part; the princes, the prelates, new religious orders, knights, townsmen, and peasant settlers. Agrarian conditions in the older lands of Germanic occupation seem to have favoured large-scale emigration. With a rising population, there was much experience in drainage and wood clearing but a diminishing fund of spare land to be attacked in the west. Excessive subdivision of holdings impoverished tenants and did not suit the interests of their lords. Some-

Disregard for blood

conquering colonizing movement of the 12th and 13th centuries

times also, seignorial oppression is said to have driven peasants to desert their masters' estates. They certainly found a better return for their labour in the colonial area: personal freedom, secure and hereditary leasehold tenures at moderate rents, and, in many places, quittance from

services and the jurisdiction of the seignorial advocate. The colonists brought with them a disciplined routine of husbandry, an efficient plow, and orderly methods in siting and laying out their villages. Very soon, even the Slav rulers of Bohemia and Silesia were competing for immigrants. First and foremost, however, the princes of the Saxon and Thuringian marches sought to attract settlers for the lands that they had conquered and the towns that they had founded to open up communications and trade routes. The older regions of the Reich, moreover, had not only peasants but also men of the knightly class to sparesoldiers who needed fiefs and lordships to uphold their rank. Both could be gained beyond the Elbe under the leadership of successful princes. The Germanized east thus became the home of fair-sized principalities in the 13th century, while all along the Rhine River valley the rights of government were tending to be scattered over smaller and less compact territories. The Ascanian dynasty, for instance, which under Albert the Bear began to advance into Brandenburg, by 1250 not only ruled over a broad belt of land up to the Oder River but had already established itself on the eastern banks ready for further advances. Farther south the Wettin margraves of Meissen busied themselves with settlements and town foundations in Lusatia.

For a time Henry the Lion, as duke of Saxony (1142-80). overshadowed all these rising powers, and the Welf profited as much by the ruthless use of his resources against weaker competitors as by his own efforts in Mecklenburg. As his was the only protection worth having in northeastern Germany, the newly established Baltic bishoprics were at his mercy, and he alone could attract the traders of Gotland to frequent the young port town of Lübeck, which he extorted from one of his vassals in 1158.

The Reich, too, possessed demesnes in the east, notably the Egerland, Vogtland, and Pleissnerland in the Thuringian March. The Hohenstaufen kings therefore took some part in opening up these regions. They, too, founded towns and monasteries on their thickly wooded lands and established their ministeriales as burgraves and advocates over them. But in this, as in many other things, they only competed with the princes. They did not and could not control the eastward movement as a whole.

Hohenstaufen policy in Italy. In the other great field of German expansion in the 12th century-Lombardy and central Italy-the emperors and their military following

The Italian policy

Surrender

and exile

of Henry the Lion

alone counted. The rural population of Germany had no direct interest in the wars waged to recover and exploit regalian rights over the growing Lombard city communes. The connection between the German crown, the empire, and dominion over Italy has indeed been regarded as a disaster for Germany, and the ever-increasing concern of the Hohenstaufen dynasty with the south as its most tragic phase. Although Frederick Barbarossa's policy was opportunistic, he had really very little choice. Having bought off the Welfs and reconciled other great families with yet more concessions and lastly endowed his own cousin. Conrad III's son Frederick, with Hohenstaufen demesnes in Swabia, he had to try to mobilize their goodwill for the empire while it lasted. He now aimed to set up a regime of imperial officials and captains who were to exact dues and to control jurisdiction that the communes had usurned from the failing grasp of their bishops. The Germans in Italy did not bring valuable accomplishments to poor and primitive tribesmen, but they attacked economically advanced and better developed communities, to which they had nothing to offer in return for the rights and taxes they demanded. Military power was their chief asset in Lombardy, and they used it ruthlessly

For the Hohenstaufen ministeriales the rule of their masters in northern and central Italy was a career. Because they could be deployed continuously, they became the backbone of the imperial occupation. A handful of minor dynasts also served Barbarossa for many years in the powerful and profitable commands that he established. The German bishops and certain abbots still had to supply men and money, and some of them threw themselves wholeheartedly into the war; for instance, Rainald of Dassel and Philip of Heinsberg, archbishops of Cologne from 1159 to 1167 and from 1167 to 1191 respectively, who, as archchancellors for Italy, had a vested interest in it. The support of the lay princes, conversely, was fitful and sporadic. Even at critical moments they could not be counted on unless they individually agreed to serve or to send their much-needed contingents for a season. The refusal of the greatest of them, Henry the Lion, in 1176 brought about the emperor's defeat at the Battle of Legnano and spoiled many years' efforts in Lombardy.

The fall of Henry the Lion and the estate of princes. Forced to retreat before the papacy and the Lombard League in 1177, Barbarossa cooled toward his Welf cousin, whom he could justly blame for some of his setbacks. Dualism in Germany had outlived its purpose. Hitherto, the enemies of Henry-the princes, bishops, and magnates of Saxony-had been unable to gain a hearing against him at the emperor's court days. By 1178, however, the emperor was ready to help them. Outlawed (1180), beaten in the field and deserted by his vassals. Henry had to surrender and go into exile in 1182. His duchies and fiefs were forfeited to the Reich.

His fall left a throng of middling princes face to face with an emperor whose prestige, despite reverses, stood high and whose resources had greatly increased since he began to reign. The princes were nonetheless the chief and ultimate gainers from the events of 1180. The final judgment by which Henry the Lion lost his honours was not founded on folk law but on feudal custom. The princes who condemned him regarded themselves as the first feudatories of the empire, and they decided on the redistribution of his possessions among themselves. During the 12th century the stem duchies of the Ottonian period finally disintegrated. Within their ancient boundaries not only bishops but also lay lords succeeded in eluding the authority of the dukes. In their large immunities they themselves wielded stem-ducal powers. To enforce the imperial peace laws became both their ambition and their "justification. Everywhere the greater lay dynasties and even some bishops tried to acquire a ducal or an equivalent title that would enable them to consolidate their scattered jurisdictions and, if possible, to force lesser freelords to attend their pleas.

These highest dynasts had interests in common, and they closed their ranks not only against threats from above but also against fellow nobles who had been less successful in amassing wealth, counties, and advocacies and who did not possess the superior jurisdiction of a duke, a margrave, a count palatine, or a landgrave. They and they alone were now called princes of the empire. To lend a certain cohesion to their varied rights, they were willing to surrender their houselands to the Reich and receive them back again as a princely fief. For the emperor it was theoretically an advantage that men so powerful in their own right should owe their chief dignity and most valued privileges to his grant. It opened the possibility of escheats (reversions), for in feudal custom the rules of inheritance were stricter than in folk right. In Germany, however, the political misfortunes of rulers succeeded, by and large, in ensuring that ancient caste feeling and notions of inalienable right conquered the principles of feudal law. By 1216 it was established that the emperor could neither abolish principalities nor create princes at random.

The "heirs" of Henry the Lion had to fight a ceaseless battle to establish and maintain themselves. In Bavaria the Wittelsbachs had received the vacant duchy, but they were not recognized as superiors by the dukes of Styria or by the dukes of Andechs-Meran. In Saxony the archbishop of Cologne was enfeoffed with Henry the Lion's Jucal office and with all his rights in Westphalia, while an Ascanian prince, Bernard of Anhalt, received the eastern half of Henry's duchy. Neither Bernard nor the archbishop, however, could make much out of their dukedoms, except in the regions where they already had lands and local jurisdictions. All over the Reich these and regalian rights, such as mints, fairs, tolls, and the right of granting safeconducts, were the substance of princely power. To possess them as widely as possible became the first goal of the abler bishops and lay lords.

The Hohenstaufen conflict with the papacy, 1159-1215. The attempt to establish a direct imperial regime in Italy antagonized the papacy once again and led to a new struggle with Rome, the ally of the Lombard communes. Political and territorial rather than ecclesiastical interests were at stake; but the popes could only fight as heads of the universal church, defending its liberty against a race of persecutors, and they had to employ their characteristic weapons-excommunication, propaganda, and intrigue. Nonetheless, the German bishops stood by Barbarossa and, for the most part, followed him in maintaining a prolonged schism against Pope Alexander III. Unsuccessful in Lombardy, the centre of Hohenstaufen ambitions after 1177 shifted to Tuscany, Spoleto, and the Romagna. This redoubled the fears and the resentment of the popes, particularly after 1189 when Frederick's son and chosen successor, Henry VI (reigned 1190-97), became the legitimate claimant to the Sicilian kingdom through his wife

Constance, the sole surviving legitimate heiress. With their backs to the wall, the popes had to make what use they could out of any opposition to the Hohenstaufen. Their chance came in 1197 when Henry VI died prematurely, leaving a three-year-old son, Frederick, to succeed him. To escape the chaos of a minority regime, the bulk of the German princes and bishops in 1198 elected the boy's uncle Philip of Swabia; but an opposition faction in the lower Rhenish region, led by the archbishop of Cologne and financed by Richard I of England, raised an antiking in Otto IV, a younger son of Henry the Lion. Pope Innocent III had to enlarge on his rights over imperial coronations and become a partisan in the German electoral feud if he wished to defend his recovered holdings in Italy against Hohenstaufen claims. Territorial interests in the Romagna tempted the papacy to exploit the weaknesses of the empire's constitution, the uncertainties of electoral custom, and the lack of strict legal norms in Germany. During the war for the crown, much hard-won demesne Civil war and useful rights over the church had to be sacrificed by the rivals to bribe their supporters.

Frederick II and the princes. Henry's son Frederick II entered Germany to regain his own against Otto IV in 1212 and secured the crown in 1215. Despite promises to divide his inheritance, he kept the kingdom of Sicily and the empire together, and thus he also became locked in the inevitable life-and-death struggle with the papacy. The Hohenstaufen demesne in Swabia, Franconia, and Alsace and on the middle Rhine was still very considerable, and

Frederick even recovered certain fiefs and advocacies that had been lost during the earlier civil wars. Their administration was improved, and they provided valuable forces for his Italian wars. The great peace legislation of 1235, moreover, showed that the emperor had not become a mere competitor in the race for territorial gain. But, except for brief intervals, the princes and bishops were left free to fight for the future of their lands against one another and against the intractable lesser dynasts who refused to accept their domination. The charters that Frederick had to grant to the ecclesiastical princes (the so-called Confoederatio cum principibus ecclesiasticis, 1220) and later to all territorial lords (Constitutio, or Statutum in favorem principum, 1232) gave them written guarantees against the activities of royal demesne officials and limited the development of imperial towns at the expense of episcopal territories. But the charters were not always observed, and until 1250 the crown remained formidable in southern Germany, despite the antikings Henry Raspe and William of Holland, whom the papacy caused to be elected by the Rhenish archbishops in Germany in 1246 and 1247.

The Reich after the Hohenstaufen catastrophe. Frederick II died in 1250, in the midst of his struggle against Pope Innocent IV. His son Conrad IV left the north in 1251 to fight for his father's Italian possessions. William of Holland, antiking from 1247 to 1256, was thus without a rival in an indifferent Germany that had lost interest in its rulers. The bishops' cities and the towns, many of them founded on royal demesne, could not be absorbed. Their economic power challenged the age-old aristocratic order in German society, and, deprived of royal protection, they banded together to defend their autonomy. Within the nobility each rank tended to acquire some of the personal rights of its betters. The Hohenstaufen breakdown after 1250 left a gap in Swabia that no rising territorial power was able to fill. Countless petty lords and imperial ministeriales of the southwest succeeded in holding their seigniories as immediate vassals of the Reich. Their independent territories often survived for centuries.

The ministeriales elsewhere, too, ceased to be the dependable servants that they once had been. Many free nobles voluntarily joined their ranks, and the knights thus assimilated the rights of the free aristocracy. They became the governing class of the territorial principalities, the standing councillors of their masters, whose household offices and local justice they monopolized and held in fee for many generations. Without the consent of this territorial nobility, the princes could neither tax nor legislate. Even the less important ministeriales, who only administered manors for their lords, entrenched themselves as hereditary bailiffs, who kept surplus produce for themselves and usurped seignorial dues, so that it paid the owners to commute the labour services of their villeins into money rents and to lease out those portions of the demesne that the unfree peasants had cultivated for them. Even then, however, the hereditary officials could not be easily dislodged. Finally, the ambitions of the princes themselves did not aim above the patrimonial policies of the past. They were acquisitive and attempted to build up their territories by usurpation, inheritance, marriage treaties, and escheats. They also tried, where possible, to administer their lands with officials whom they could depose at will. Yet they did so not to found sovereign states but chiefly to provide for their families. Again and again, they divided their dominions among sons, who, in turn, founded cadet lines and set them up on a fraction of the principality.

By 1250 there was thus no really effective central authority left in Germany. The prince-bishoprics had become fiercely contested prizes between neighbouring dynasties, often vassals of the see (i.e., the bishopric). But constant feuds, disorder, and insecurity did not, by any means. frustrate the immense energies of the Germans in the 13th century. Eastward expansion continued under the leadership of the princes and, above all, of the Knights of the Teutonic Order. Their advance into Prussia went hand in hand with the opening up of the Baltic by the merchants of Lübeck. It is possible that three centuries of complete security from foreign invasion made it unnecessary for the German aristocracy to learn the virtues of political selfdiscipline and subordination; but it would be a great mistake to judge Hohenstaufen Germany solely by its failure to achieve political and administrative unity.

Germany from 1250 to 1493

1250 TO 1378

The extinction of the Hohenstaufen dynasty. The death of Frederick II in 1250 and of his son Conrad IV in 1254 heralded the irreversible decline of Hohenstaufen power in Germany and in the conjoint kingdoms of Naples and Sicily. Conrad's infant son Conradin, heir to Naples and Sicily, remained in Germany under the guardianship of his Bayarian mother. His uncle Manfred seized the reins of government in both Italian kingdoms and in 1258 formally supplanted Conradin by engineering his own coronation in Palermo. Manfred's defiance of papal claims to suzerainty over the kingdoms impelled the Frenchborn Pope Urban IV to grant them to Charles of Anjou, brother of Louis IX of France. Papal taxation of the French clergy and loans from Florentine bankers enabled Charles to raise a large mercenary army for an expedition to Italy. Manfred, deserted by his barons, was defeated and slain near Benevento in 1266. Conradin then rallied his German supporters and led them across the Alps, But Conradin's financial resources were inadequate; unpaid troops deserted, and his depleted following was routed by Charles near Tagliacozzo (1268). Conradin was captured as he fled toward Rome, convicted of lese majesty (a form of treason), and beheaded in the public square at Nanles The Great Interregnum. In Germany, the death of Frederick II ushered in the Great Interregnum (1250-73). a period of internal confusion and political disorder. The antikings Henry Raspe (landgrave of Thuringia, 1246-47) and Count William of Holland (ruled 1247-56) were elected by the leading ecclesiastical princes at the behest of the papacy. William's title was recognized initially only in the lower Rhineland, but his marriage to Elizabeth of Brunswick in 1252 ensured his acceptance by the interrelated princely dynasties of north Germany. The death of the Hohenstaufen Conrad IV left William without a rival in Germany. His growing strength and independence enabled him to escape from the tutelage of his ecclesiastical electors and to devote himself to purely dynastic policies. He pursued his feud with Margaret, countess of Flanders, over their conflicting territorial claims in Zeeland at the mouth of the Rhine. He renewed the attempts of his dynasty to obtain complete mastery of the Zuider Zee by thrusting eastward at the expense of Friesland; he died at the hands of the Frisians in 1256.

Pope Alexander IV forbade the election of a Hohenstaufen but interfered no further with the succession. Hence the initiative was taken by a small group of influential German princes, lay and ecclesiastical, acting out of self-interest. None desired the election of a ruler powerful enough to threaten their growing independence as territorial princes; nor did they single out a German candidate. who might prove to be as uncontrollable as William Archbishop Conrad of Cologne approached Richard, Earl of Cornwall, brother of Henry III of England. Richard's gifts and assurances of future favour brought him the votes of the archbishops of Cologne and Mainz, the count palatine of the Rhine, and Otakar II of Bohemia. He was formally elected in 1257 and crowned king at Aachen (Aix-la-Chapelle). Three months after Richard's election. Alfonso X of Castile, who aspired to the empire in order to strengthen his foothold in Italy, was chosen in similar fashion by the archbishop of Trier, the duke of Saxony,

the margrave of Brandenburg, and the devious Otakar. The candidates were distracted by the turbulence of the aristocracy in their countries-Richard paid four fleeting visits to Germany; Alfonso failed to appear at all. Both appealed to the papacy for confirmation of their election. Their claims were summarized in Urban IV's bull Qui Coelum (1263), which assumed that the exclusive right of election lay with the seven leading princes involved in the double election of 1257.

The rise of the Habsburgs and Luxembourgs. Rudolf of Habsburg. When Richard died in 1272 the electoral

ales

princes were spurred into action by Pope Gregory X, who desired the election of a German monarch sympathetic toward a crusade for the recovery of the Holy Land. The princes, dreading an overly powerful king, rejected the advances of Philip III of France and Otakar, They chose instead Rudolf of Habsburg (1273), a minor count of Swabia who lacked the strength to regain the crown domains the electors had usurped during the Interregnum. Papal diplomacy persuaded Alfonso X to abandon his pretensions to the throne; but Otakar denounced the election on the ground that the duke of Bavaria had voted as lay elector in his stead. Rudolf allied himself with the Wittelsbach family of Bavaria and with other envious neighbours of Otakar, who was defeated and slain (1278). The duchies of Austria and Styria, overrun by Otakar during the Interregnum, were declared vacant and conferred jointly on Rudolf's sons Albert and Rudolf (1282). These acquisitions placed the Habsburgs in the first rank of the German territorial princes and lent impetus to a gradual shift in the political centre of gravity from the Rhineland to east Germany. The growing Habsburg power, however, disquieted the electoral princes, who frustrated the king's attempts to secure the election of his elder son Albert in 1287 and of his younger son Rudolf in 1290.

Adolf of Nassau. On the death of Rudolf in 1291, the electors averted the danger of a hereditary Habsburg monarchy by choosing Count Adolf of Nassau as his successor. Adolf, possessing only a small patrimony to the south of the river Lahn, strengthened himself financially by promising military aid to and receiving subsidies from both sides in the current Anglo-French war. He took possession of Meissen when the cadet branch of the Wettin dynasty died out, and he used his foreign subsidies to purchase Thuringia in 1295. He was thus able to adopt a more independent attitude toward his electors. On June 23, 1298, five of the electors pronounced Adolf unfit to rule and deposed him; on the following day they elected Albert of Austria in his stead. Albert marched westward from Austria at the head of a large army, and in a battle at Göllheim, Adolf was slain and his supporters fled.

Albert I of Habsburg. By restoring the Habsburg Albert I (ruled 1298-1308) to the kingship, the electors placed themselves in jeopardy. The new ruler, backed by the ample resources of his Austrian dominions, was more powerful and unscrupulous than his predecessor. The electors regarded his treaty of friendship with Philip IV of France (1299) as a move to enlist French support for the election of his son Rudolf as his successor in Germany. His attempt to seize Holland and Zeeland as a vacant fief of the empire was rightly interpreted by the electors as an effort to establish Habsburg influence on the lower Rhine (1300). The four prince-electors of the Rhineland (the archbishops of Mainz, Trier, and Cologne and the count palatine) conspired to depose Albert. But Albert wrecked the design by decisive military action (1301-02), and he sealed his victory over the electors by obtaining confirmation in 1303 of his election from Pope Boniface VIII in return for an unprecedented oath of fealty and obedience to the papacy. Albert subsequently renewed Adolf's claims to Meissen and Thuringia, but his authority there was still disputed when he died by assassination in 1308. Albert temporarily tamed the electoral princes, placated the papacy, and renounced intervention in Italy; but this policy foundered at his death, and the electors were given a fresh opportunity to reassert their influence over the German monarchy.

Henry VII of Luxembourg. The princes, released from Albert's heavy hand, sought a servant, not a master. Archishop Baldwin of Ther sponsored the candidature of his brother, Count Henry of Luxembourg, who was elected at Frankfurt (modern Frankfurt am Main) in 1308 as Henry VII. The house of Luxembourg (Luxemburg) was not a major territorial power, and Henry lost no time in exploiting his new status to extend its possessions. Under his direction the Diet of Frankfurt (1310) closed the long-disputed question of the Bohemian succession by awarding he kingdom, with the consent of the Bohemian estates, to Henry's son John. Thus, in common with the Habsburgs, the main weight of Luxembourg interests gravitated

eastward. But Henry, unlike his Habsburg predecessors, dreamed of a restoration of the ancient authority of the empire in Italy, His Italian expedition (1310–13) opened brilliantly, and in 1312 he was crowned Holy Roman emperor at Rome. The old fear of German domination, however, stiffened the resistance of the Italian states. Pope Clement V was alarmed by Henry's preparations to invade the kingdom of Naples, a papal fief, and threatened excommunication. A renewed collision of empire and papacy seemed imminent when Henry died in 1313.

The growth of territorialism under the princes. The decine of Hohenstaufen influence in Germany, the Interregnum, and the rapid alternation of dynasties on the German throne created favourable conditions for the territorial princes, lay and spiritual, to gain power. Frederick II had purchased the support of the princes by laving grants of crown lands, chiefly in the Rhineland had Thuringia; in 1220 he procured the cooperation of the ecclesiastical princes in the election of his son Henry as king and eventual heir to the empire by renouncing his regalian rights of building castles, issuing coingae, and imposing tolls on merchandise in their territories. Henry himself had extended similar concessions to the lay princes in 1231.

Thenceforth the direct action of royal authority was virtually precluded in the princely domains. The princes were at liberty to multiply castles and toll stations, establish mints, exploit mineral deposits, and settle all judicial cases except those transferred on appeal to the court of the emperor. The machinery of administration under the prince and his council (Hofrat) was, nevertheless, still rudimentary. Public taxation was intermittent and restricted to emergency occasions, and it was subject to the consent of the three estates of the principality (clergy, nobles, townspeople), which were consulted separately by the prince. The estates grasped the opportunity to ventilate their grievances and to press their advice upon the prince. The emerging territorial state was thus under the dual government of the prince and the estates, and its development was to be heavily influenced by a shifting balance of power between them.

Constitutional conflicts in the 14th century. The death of Henry VII led to a disputed election and a civil war in Germany. The electors' impulse to choose another lesser count as king was checked by the houses of Habsburg and Luxembourg, which pressured the prince-electors to choose between their candidates. The pro-Habsburg majority elected Frederick the Handsome, duke of Austria. The minority withdrew their support from Henry VII's son John and transferred it to a more formidable candidate, the Bavarian duke Louis of Wittelsbach, who had recently broken an Austrian invasion of his duchy.

Electoral custom did not yet acknowledge the majority principle. The papacy, which had claimed the right to adjudicate disputed elections since 1201, was vacant. Hence the two claimants settled their differences by the sword. In 1322 Louis defeated and captured his rival at Midhlorf, but his triumph in Germany merely raised the curtain on a long and bitter dispute with the papacy.

Pope John XXII, guided by canon law and precedent, affirmed that Louis might not legally rule until confirmed by the papacy; thus the disputed election of 1314 and the absence of papal approbation invalidated Louis' royal title and his right to govern. Louis contended, however, that election by a majority conferred a legitimate title and administrative power and did not require papal confirmation. His defiance of the pope exposed him to excommunication (1324) and to the procedures of canon law, whereby he was required to submit entirely to the papal terms before absolution could be granted. Louis warned the electors that their rights were endangered by the subjection of the elections to papal confirmation. Six electors responded in the Declaration of Rhens (1338), proclaiming as an ancient custom of the empire that election by a majority was valid and that the king-elect assumed his administrative power immediately, without the intervention of papal approbation. Under Louis' direction the declaration was repeated at the subsequent Diet of Frankfurt as an imperial law, and offenders against it were declared guilty of lese majesty.

John XXII and his successors were unyielding. In 1343 Pope Clement VI made diplomatic overtures to Charles of Luxembourg, heir to the Bohemian throne, with the object of procuring his election to the German kingship in Louis' stead. The electors, led by Baldwin of Luxembourg, archbishop of Trier, began to desert Louis one by one. The pope thereupon urged a new election. Charles assured the pope secretly that he would await papal confirmation of his forthcoming election before exercising governmental power in the Italian possessions of the empire, but, despite intense pressure by Clement, he would accept no such restriction with regard to Germany. In 1346 only two electors remained faithful to Louis: his son Louis of Brandenburg and his kinsman Rudolf, count palatine of the Rhine. The other five assembled at Rhens on July 11 and elected Charles under the title of Charles IV. The new king was spared a lengthy conflict with his rival, who died

Charles IV and the Golden Bull. Charles IV (ruled 1346-78) readily perceived that disputed elections exploding into civil war had been a standing malady of the German body politic since 1198 and that the stability of the German monarchy depended largely upon the degree of cooperation achieved with the territorial princes, more especially with the prince-electors. On his return from his imperial coronation as Holy Roman emperor (1355) he promulgated, with the consent of the German assembly of estates or diet (1356), a basic constitutional document, known as the Golden Bull from its pendant gold seal (bulla). Charles's double objective was to minimize areas of dispute in future elections and to strengthen his ties with the electors. Unanimity among the electoral princes had always been difficult to attain; hence the validity of election by majority vote, a principle already set forth in the Declaration of Rhens, was reaffirmed. The territories of the lay electors were declared indivisible and heritable only by the eldest son. Thus, partitions of land by family agreement and consequent uncertainty concerning the holder of the electoral vote were eliminated. In conformity with ancient custom the archbishop of Mainz was to convene the electors and to request them to name their favoured candidate. He was to announce his own choice after the other electors had given their vote verbally, and so he could cast the deciding vote in the event of a tie. The election was to be held in Frankfurt, the royal coronation in Aachen

The membership of the electoral body was fixed at the traditional number of seven: the archbishops of Mainz, Cologne, and Trier, the count palatine of the Rhine, the king of Bohemia, the margrave of Brandenburg, and the duke of Saxony. When the throne was vacant the count palatine would be regent in south Germany and the duke of Saxony in the north; thus the long-standing papal claim to govern the empire during a vacancy was tacitly rejected. The question of papal confirmation of elections was ignored; neither Charles nor his electors were prepared to yield, but an open affirmation of their position would have been ill-received by the papacy, which had played a leading role in Charles's election.

The Golden Bull consolidated and extended the territorial power of the electors. Their right to construct castles, issue coinage, and impose tolls was confirmed. They could judge without appeal. Conspiracy or rebellion against them was deemed high treason. They were to meet the ruler once yearly as supreme advisory council on affairs of state. The formation of city leagues against them was specifically prohibited. On the basis of these enactments the Golden Bull has been called the Magna Carta of German particularism. The electors in their capacity of territorial lords were its chief beneficiaries; the rest of the princes were envious and strove thenceforth to acquire an equally large measure of territorial sovereignty,

Rudolf IV of Austria ordered his chancery to fabricate a series of imperial charters, including two from Julius Caesar and Nero, as evidence of his virtual independence of the empire. Charles IV submitted them for examination to the Italian humanist Petrarch, who declared the charters to be spurious. Rudolf took up arms and was bought off by the recognition of his claim to Tirol (1364).

The election of Charles's son Wenceslas (Wenzel) as king in 1376 (two years before Charles's death) was a striking example of the emperor's skill in securing the cooperation of the electors for his dynastic purposes. The election of an emperor's son as king of the Romans during the father's lifetime had not occurred since 1237; the princeelectors, in their anxiety to prevent any single dynasty from strengthening its grip on the succession, had checked all subsequent attempts. But unprecedented gifts, concessions, and a renewed prohibition of city leagues by Charles overcame the opposition of the electors. Pope Gregory XI had previously announced that the election would be invalid without papal confirmation. Charles, in concert with the electors, speeded the election and subsequent coronation of his son and then submitted an antedated request for confirmation to the pope, who countered these devious tactics by delaying confirmation; it was still under consideration at Gregory's death in 1378. The decline of the papacy during the Great Schism (1378-1417) precluded the vigorous assertion of its right of confirmation, which became a mere formality and was subsequently tacitly abandoned.

Decline of the German monarchy. Charles IV's power was based primarily upon the territorial possessions of the house of Luxembourg, which he greatly extended by the purchase of the electorate of Brandenburg (1373). The German monarchy was a source of dignity and influence. but in terms of land and revenue it was outranked by Charles's hereditary domains in the east and northeast. The Golden Bull, replete with privileges to the electors. attacked none of the fundamental problems of the monarchy; dwindling crown lands, slender revenues, lack of an army and of an expert bureaucracy.

The financial problem was acute and of long standing. The succession of disputed elections between 1198 and 1257 had compelled the various claimants to purchase support by grants of royal land and revenues; the attempt by Rudolf of Habsburg to recover possession of crown lands alienated since 1245 had been opposed by his electors, who were unwilling to set an example by surrendering their own considerable acquisitions. At every election the votes of the princes had been secured by the grant or pledge of royal rights and property; thus, every king began his reign with a financial millstone round his neck and could attain freedom of action only by the possession or acquisition of extensive dynastic territories. The system of pledging crown lands involved the transference of the land and its revenues to the creditor. These revenues did not reduce the original debt, and the alienation tended to become permanent. The imperial cities (Reichsstädte) had been heavily taxed by Rudolf, and before his acquisition of Austria they had furnished the bulk of his revenue. His less provident successors had pledged them in a few cases to the local territorial princes and had thus lost the right of taxation. Charles IV carefully cultivated his dynastic revenues from Bohemia, but he lavishly expended crown assets in Germany to expand his family possessions. His financial exploitation of the cities for purely dynastic purposes naturally stiffened their resistance to taxation. By 1400 the annual revenues from all the German crown possessions averaged only 30,000 florins.

The enforcement of the public peace, a taproot of royal power in other countries, had long since slipped from the hands of the German monarchs. The German monarchy possessed no executive officials comparable with the English sheriff or justice of the peace, and it was diverted from its guardianship of law and order by recurrent conflicts with the papacy and by its absorption in purely dynastic matters. Consequently, the proclamation and enforcement of the peace fell into the hands of regional associations of cities and of the individual territorial princes. Thus the monarchy was prevented from using its function as defender of the public peace as an entering wedge to invade the jurisdiction of the municipalities and the territorial lords.

In sum, the German rulers were being gradually deprived of their triple role of feudal suzerains, defenders of the church, and keepers of the peace. The sweeping privileges granted to the princes in 1220 and 1231 had undermined

Financial problems

Flection

Wenceslas

to princely

nower

their position as feudal suzerain. Their bitter struggles with the papacy cast doubt on their credibility as protectors of the church. They allowed their powers as guardians of the public peace to slip into the hands of others.

The continued ascendancy of the princes. By Charles IV's death in 1378, the division of Germany into loosely defined territorial principalities had reached an advanced

Division

territorial

princi-

palities

into

Southern Germany. In south Germany the dissolution of the Hohenstaufen duchy of Swabia gave territorial predominance to the Habsburgs, whose original possessions lay in Alsace, Breisgau, the Vorarlberg, and Tirol. Rudolf's acquisition of Austria and Styria (1282) had more than doubled the Habsburg patrimony and established its centre of gravity in eastern Germany. The Habsburg's rivals and neighbours to the north, the counts of Württemberg had combined with the Swabian nobles to foil the attempt of Rudolf to revive the defunct duchy of Swabia for one of his sons (the counts, insatiably acquisitive and the inveterate enemies of the cities of the region, were finally raised to ducal status in 1495). The margraves of Baden were chiefly preoccupied with the southward expansion of their territory on the upper Rhine at the expense of the independent small nobles and cities of Swabia.

These three large entities contained lesser lordships, which were in constant danger of absorption by marriage, purchase, or feud. Bavaria, granted to the house of Wittelsbach as a duchy in 1180, was strengthened by the acquisition of the Palatinate in 1214; but subsequent testamentary partition restricted this important gain to the

Upper Palatinate.

Central Germany. In central Germany the margraves of Meissen of the Wettin dynasty thrust steadily eastward and received the electorate of Saxony in 1423, when the Ascanian line of electors died out; in the west they obtained Thuringia (1263) and clung to it tenaciously despite repeated royal attempts to oust them by claiming it as a vacant fief. The landgraves of Hesse, though surrounded by powerful neighbours, contrived to make modest territorial gains at the expense of the Wettin dynasty and the archbishops of Mainz. East and south of Hesse, the Rhine-Main region was a land of great ecclesiastical princes: the archbishops of Mainz, Trier, and Cologne; the bishops of Spever, Worms, Würzburg, and Bamberg; and the wealthy abbots of Fulda and Lorsch. It abounded in counts of the second rank, dominated by a great secular prince, the count palatine of the Rhine. The area contained four electorates and was therefore of crucial political importance. Northern Germany. In north Germany the dukes of Brunswick dissipated their strength by frequent divisions of their territory among heirs. Farther east the powerful duchy of Saxony was also split by partition between the Wittenberg and Lauenburg branches; the Wittenberg line was formally granted an electoral vote by the Golden Bull of 1356. The strength of the duchy lay in the military and commercial qualities of its predominantly free population. But the vigour of its eastward expansion into the Slav lands beyond the Elbe tended to diminish its involvement in the internal politics of the Reich.

Eastern Germany. In eastern Germany the duchy of Mecklenburg, Germanized by a steady stream of immigrants, was drawn deeply into Scandinavian affairs and in 1363 provided Sweden with a new royal dynasty in the person of Albert of Mecklenburg. The electorate of Brandenburg, purchased by Charles IV and bequeathed to his second son, Sigismund, was dominated by a disorderly and rapacious nobility. Sigismund granted this dubious asset in 1415 to his faithful ally Frederick, burgrave of Nürnberg. The kingdom of Bohemia remained the durable territorial core of the Luxembourg dominions, and its silver mines at Kuttenberg, under German supervision, vastly increased crown revenues. The Slav population resented increasingly the economic and cultural influence of the German minority, and this created antagonisms profoundly disturbing to the monarchy.

Inside the various

territories the consolidation of the princely authority was far from complete. The principalities were often ragged in outline and territorially dispersed because of the accidents of inheritance, grant, partition, and conquest. Everywhere lesser nobles disputed the power of the prince and formed associations in defense of their rights and fiefs. In the ecclesiastical princedoms the ascendancy of an archbishop or a bishop was contested by the cathedral chapter, which had become a preserve of the nobility. The self-governing cities fought to protect their chartered liberties and drew together in formidable leagues to resist princely encroachment. Thus the princes, trying to enforce their authority. tended to consolidate the opposition and to excite potential or open hostility.

In this crucial struggle the great secular potentates impaired their own strength by persisting in the Germanic custom of dividing their territory among their sons instead of transmitting it intact to the eldest. By 1378 the Bayarian lands of the house of Wittelsbach were shared between three grandsons of Louis IV. In 1379 the wide possessions of the Habsburgs were partitioned by family agreement between Albert III and his younger brother Leopold

The ecclesiastical princes, vowed to celibacy and elected by their cathedral chapters, could not hand on their lands to their descendants. Still, their policies and aspirations were not much different from those of the secular princes. and most of them managed to install their relatives in rich canonries and prebends.

1378 TO 1493

Internal strife among cities and princes. The electors had voted for Wenceslas reluctantly during Charles IV's reign, fearful that the monarchy might become a perquisite of the house of Luxembourg. Most of the other princes shared their concern over the continued ascendancy of the dynasty.

Wenceslas. Wenceslas (ruled 1378-1400) inherited a variety of problems, which grew after his father's statesmanlike hand had been removed. Wenceslas' habitual indolence and drunkenness, vices that increased as he grew older, excited the indignation of his critics. His prolonged periods of residence in Bohemia betrayed his lack of interest in German affairs and allowed the continuous friction between princes, cities, and nobility to develop into open warfare.

The collision of princes and cities was prompted by vital issues of long standing. The flight of the rural population from servile tenures on the land to the free air of the cities reduced the labour force and impaired the revenues of territorial lords. Others who stayed on the land accepted the protection and jurisdiction of the neighbouring city as "external" citizens (Ausbürger, Pfahlbürger) and thus withdrew themselves and their land from seignorial control. Only the most powerful cities (e.g., Nürnberg, Rothenburg) were able to extend their extramural territory to a substantial degree by force, but all strove to expand the area of their jurisdiction at the expense of local lords, partly to prevent village industries from competing with the city guilds.

A second major issue was the insistence of territorial lords on imposing tolls on city merchandise in transit through their possessions. In theory, tolls on road and river traffic were exacted in return for the protection of merchants and their goods, but the multiplication of toll stations hampered trade and provoked innumerable disputes, which often culminated in the seizure of merchants and merchandise by exigent lords.

The third and immediate cause of the crisis lay in the financial policy of Wenceslas himself. His Bohemian revenues, though large, were strained by the great sums payable to the electors in return for his elevation to the kingship. Hence he attempted to tap the resources of the imperial cities by demanding heavy taxes, and he threatened to mortgage recalcitrant cities to the neighbouring princes, their capital enemies.

On July 4, 1376, an alliance of 14 imperial cities of Swabia was formed under the leadership of Ulm and Constance for mutual protection against unjust taxes and alienation from the empire. The Swabian League counted 40 members by 1385 and was linked with similar coalitions in Alsace, the Rhineland, and Saxony. Wenceslas' initial hostility to the league faded as its membership in-

Conflict hetween princes and creased, and in 1387 he gave it his verbal and unofficial recognition. He feared to offend the territorial princes by extending full recognition; further, a clause of the Golden Bull had declared all city leagues to be illegal. Thus he temporized and awaited the outcome of the approaching trial of strength between cities and princes. On Aug. 28, 1388, the princes of Swabia and Franconia routed the largely mercenary forces of the Swabian League at Döffingen, near Stuttgart. The stipendiaries of the Rhenish League were put to flight by the count palatine Rupert II near Worms on November 6.

The cities triumphantly withstood the ensuing siege operations, but their economy was injured by the forays, ambuscades, and blockades instituted by the princes. The protracted campaigns also exhausted the financial resources of the princes. When Wenceslas intervened in 1389, both parties were ready for peace. At the Diet of Eger (May 2) he ordered them to desist and declared the city leagues to be dissolved. The contestants complied. The princes were satisfied with the prospective disbandment of the cities, and the cities feared the consequences of further resistance, but Wenceslas' opportunism was relished by neither side. The princes disliked his political flirtation with the cities, and the cities resented his final championship of the cause of the princes.

alienation

Wenceslas'

cities and princes

Wenceslas' early gestures of support for the cities rankled with the electors, who in 1384 and 1387 discussed the advisability of replacing him by an imperial vicar or regent. Wenceslas, however, learned of the plan and conveyed his opposition; nor could the electors unite on their choice of a regent. Some electors turned to a more drastic solutionhis deposition. In 1394 Rupert II and the archbishop Frederick of Cologne considered the election of Richard II of England but failed to win the support of their electoral colleagues. In the following year, however, Wenceslas' elevation of Gian Galeazzo Visconti, imperial vicar of Milan, to the status of duke was assailed as a dismemberment of the empire and enabled the electors to act as the indignant defenders of the integrity of the Reich against a wasteful and profligate king. Wenceslas attempted to conciliate the princes by appointing his younger brother Sigismund as German regent (1396). But the Milanese issue enabled Rupert and Frederick to enlist the support of the archbishops of Mainz and Trier for their proposed deposition of Wenceslas. The death of Rupert in 1398 occasioned some delay. But at length the electors compiled a lengthy series of charges against the king, and in September 1399 they openly proclaimed their intention of deposing him.

At this critical stage further proceedings were temporarily checked by serious differences concerning the choice of Wenceslas' successor. The favoured candidate of the Rhenish electors was the count palatine Rupert III, himself an elector. But another elector, Duke Rudolf of Saxony, and a powerful group of north German princes contended that the electors could not raise one of their own members to the kingship. The Golden Bull had declared otherwise, but Rudolf held his ground and declined to participate in the subsequent proceedings. On June 4, 1400, the four Rhenish electors invited Wenceslas to Oberlahnstein to consider measures for the reform of the empire and threatened to release themselves from their oath of allegiance if he failed to appear. The king's efforts to rally support for his cause were utterly fruitless, and he decided to stay in Bohemia. On August 20 Archbishop John of Mainz, on behalf of the four electors, publicly proclaimed the deposition of Wenceslas as an unfit and useless king and freed his German subjects from their allegiance to him. On the following day the three archbishops elected Rupert in Wenceslas' stead. Rupert's consent to his election was presumed to furnish the necessary majority required by the Golden Bull.

Rupert. Rupert (ruled 1400-10) lacked the skill and resources necessary to revive the drooping power of the German monarchy. His title was not beyond dispute while Wenceslas lived, and the territorial princes and cities were therefore slow to acknowledge him. Pope Boniface IX, maintaining that only a pope might legally depose a German monarch, withheld his approbation of Rupert. An expedition against Wenceslas (1401) failed before the walls of Prague. Rupert then embarked upon an Italian expedition (1401-02), hoping to obtain the imperial crown from the pope and thus dispel the cloud of uncertainty that hung over his title. The enterprise was crippled by lack of financial means, Boniface's conditions were exorbitant, and Rupert returned to Germany without the coveted imperial coronation. Fortunately, he had little to fear from Wenceslas, who was fully occupied in protecting his Bohemian throne from the machinations of his ambitious younger brother Sigismund. Far more dangerous was the degeneration of Rupert's relations with the Rhenish electors. In 1405 he offended Archbishop John of Mainz by refusing him military aid in his war against Hesse and Brunswick, Consequently the archbishop united all the enemies of Hesse and Brunswick in the League of Marbach. which included 18 imperial cities. Rupert contended that coalitions of cities were prohibited by the Golden Bull. and he denounced the league as illegal. The dispute was arrested by the mediation of the archbishop of Cologne. but the memory rankled. Rupert's prospects darkened still further in 1408, when he lent his support to Pope Gregory XII against the cardinals who wished to summon a general council to end the Great Schism in the church. The archbishops of Mainz and Cologne and the vast majority of the German prelates favoured the conciliar solution and strongly approved the policy of the cardinals. Wenceslas shrewdly followed suit and in return received assurances from the cardinals that the future general council would recognize him as German king. The powerful proconciliar party in the German church proceeded to agitate openly for the restoration of Wenceslas to the throne. The threat of civil war, however, was averted by Rupert's death on May 18, 1410.

Sigismund. On the death of Rupert the movement for the reinstatement of Wenceslas immediately lost headway. The Rhenish electors, having deposed Wenceslas 10 years previously on ground of his unfitness, could not reelect him without admitting their inconsistency. Nonetheless, the House of Luxembourg was powerful and would assuredly throw its full weight against any non-Luxembourg candidate to the German throne. The four electors agreed on the expediency of selecting Rupert's successor from the Luxembourg dynasty but disagreed on the choice of candidate. Rupert's successor, the count palatine, and the archbishop of Trier elected Wenceslas' brilliant but unreliable brother, Sigismund, at Frankfurt on Sept. 20, 1410. Eleven days later, the archbishops of Cologne and Mainz elected Wenceslas' turbulent and treacherous cousin, Jost of Moravia. Jost died the next year, and Wenceslas agreed to accept Sigismund on condition that he himself retained the title of German king. But Sigismund ignored the reservation and assumed the disputed title. Wenceslas' protests were greeted with indifference in Germany and quickly died away. A second election of Sigismund at Frankfurt (July 21, 1411) gave him an ample majority and removed all doubt concerning the validity of the previous election.

Sigismund was energetic, versatile, and intelligent; but long experience never blunted his rashness in rushing into new projects, and his financial incapacity never ceased to astonish his contemporaries. His pursuit of personal power and dynastic possessions was unceasing and was conducted with complete unscrupulousness. His kingdom of Hungary and his later acquisition, Bohemia, were his primary concerns, and the interests of Germany were constantly set aside in their favour. The disastrous reigns of his predecessors, Wenceslas and Rupert, had emphasized Germany's basic problems: the weakness of the monarchy, the friction between princes and cities, and the unchecked growth of lawlessness and disorder. During his long reign (1410-37) Sigismund appeared less and less frequently in Germany and did little to correct these evils.

The Hussite controversy. Sigismund's prolonged absences were caused in great part by the explosive Hussite controversy in Bohemia. The Czech church in Bohemia had long retained a marked individuality and much autonomy in its liturgy. This independent temper in ecclesiastical affairs was being slowly fused in the late 14th century with a rising sentiment of nationality among the Czechs. The upsurge of feeling took the negative form of a growSigischaracter

Deposition Wenceslas

ing hatred of the German minority, which dominated the towns by virtue of its economic power and cultural influence. The luxury and immorality of the Bohemian clergy were castigated by a series of religious reformers such as Conrad of Waldhauser, Thomas of Štítný, John Milíč of Kroměříž (Kremsier), and Matthew of Janov. The teachings of Conrad and Milič assumed a strongly puritanical tinge; in opposition to the wealthy sacramental church with its external means of grace they held up the ideal of the primitive church in a condition of apostolic poverty and the exclusive authority of the Bible as the foundation stone of faith and belief. These three movements met and intermingled in the person of Jan Hus.

Jan Hus. A graduate in divinity of Charles IV's foundation, the University of Prague, Hus was appointed incumbent of the Bethlehem Chapel in Prague (1402) and immediately attracted wide attention by his sermons. which were delivered in Czech in accordance with the foundation charter of the chapel. In 1403 he strongly defended a number of extracts drawn from the religious writings of the Englishman John Wycliffe. Czech opinion in the university solidly supported Hus, but the more numerous German masters carried the day, and the teaching of the controversial extracts was forbidden. Similarly, when Pope Gregory XII's cardinals rebelled against the pope and demanded a general council to terminate the schism in the papacy (1408), the Czech members of the university aligned themselves with the cardinals, while the Germans stood with the pope. On matters of general policy the masters of the university voted by "nations," of which there were four: Bohemian, Bavarian, Saxon, and Polish, the last consisting in fact largely of Germans. Thus the Germans controlled three votes, the Czechs only one. When King Wenceslas reversed the proportion by decree, the German masters and students seceded to found their own university at Leipzig, and the mutual enmity deepened.

In 1410 Hus was excommunicated by Archbishop Zbyněk of Prague but refused to appear at the papal court for judgment and continued to preach. Two years later he protested against the sale of indulgences and was placed under papal sentence of excommunication. The city of Prague was subjected to a papal interdict. Hus left the capital at Wenceslas' request but preached throughout the land and vastly enlarged his following. From the lower Czech clergy who popularized Hus's doctrines, the masses learned that the German minority were intruders, foes of Bohemia and of the true religion. Lesser nobles who had lost their lands by mortgage or purchase to the prosperous German burghers of the cities were readily converted. The more self-interested members of the upper nobility were attracted by Hus's proposed reduction of the Czech church to apostolic poverty, which would bring the rich territorial possessions of the higher clergy within their grasp

The rising ferment in Bohemia disquieted the heir apparent, Sigismund, and he intervened with the suggestion that Hus should expound and justify his opinions to the Council of Constance (1414-18), recently convened to heal the schism in the papacy. Hus accepted, and Sigismund furnished him with a comprehensive safe conduct. The conciliar commission that examined Hus focused the debate on two issues: the unauthorized Bohemian practice of extending communion in both kinds (bread and wine) to the laity, and the points of agreement between Wycliffe and Hus. Hus declined to retract his Wycliffite opinions until they were refuted by Holy Writ, and thus he defied the authority of the council in matters of doctrine. He was arrested on Nov. 28, 1414, and died at the stake on July 6, 1415. Sigismund's protests against the breach of his safe conduct were silenced by the argument that excommunicates automatically lost imperial protection.

The Hussite wars. The death of Hus enshrined him at once as a martyr and a national hero in the memory of his followers among the Czechs. They raised a storm of denunciation against Sigismund and expressed their resentment by widespread attacks on orthodox priests and churches. The Catholics retaliated in kind, and Bohemia was in a state of civil war when the death of Wenceslas (Aug. 16, 1419) brought Sigismund to the tottering throne. The new king's talent for conciliation and compromise was useless in the heated religious atmosphere. Pope Martin V urged him on against the Hussites and promised him imperial coronation as his reward. Under his prompting, Sigismund raised a motley host in Germany and launched it into Bohemia under the banner of a papal crusade (March 1, 1420). But the invaders were thrown back from the walls of Prague, and on July 7, 1421, Sigismund was declared deposed by the Bohemian assembly of estates. The shock of defeat forced Sigismund to attempt a fuller mobilization of German resources. Under the traditional system, princes and cities had been allowed to fix at their own discretion the quota of men provided by each when a royal campaign was in prospect. Naturally, both estates used their discretionary power to reduce contributions to a minimum. In 1422, however, Sigismund himself fixed the strength of the contingents demanded from the individual princes and cities throughout Germany. The response was disappointing. In 1426 the king raised his requirements, but to no effect. Hence the yearly campaigns against the Hussites were waged largely by mercenary armies. To meet the rising costs, the Diet of Frankfurt was persuaded in 1427 to vote a general tax, the so-called Common Penny. But there was little enthusiasm. in Germany for the crusade; massive evasions of payment occurred, and the strength of local feeling hampered the coercion of defaulters.

In 1429-30 the irrepressible Hussites swept through Sax- Hussite ony, Thuringia, and Franconia in a destructive foray. Sigismund, exploiting the general alarm, reverted to the older system and demanded contingents from each prince and city. The response improved, and a large army invaded Bohemia, only to meet complete disaster at Taus (Domažlice in modern Czechoslovakia) in 1431. It was evident that the veteran Hussites could not be crushed by force. Sigismund therefore welcomed the opportunity to transfer the problem of reconciling the Hussites with the church to the Council of Basel (1431-49). The Hussite extremists, the Taborites, were inflexible. They condemned the hierarchical system of church government and affirmed the priesthood of all true believers. Hence the council conducted its long and arduous negotiations with the majority party among the Hussites, the Calixtines or Utraquists, who were prepared to accept the grant of communion in both kinds as a basis of settlement. The Utraquist nobles annihilated the protesting Taborites at the Battle of Lipany (May 30, 1434), made peace with the council by the Compact of Iglau (July 5, 1436), which conceded them communion in both kinds, and reunited with the Roman Catholic church. The Utraquist nobles extracted far better terms from Sigismund as the price of their recognition. He agreed to accept the guidance of Czech councillors in governmental affairs, to admit only Czechs to public office, to grant an amnesty for all offenses committed since the death of Wenceslas, and to allow the Czechs a large measure of autonomy in their civil and religious life. It is unlikely that the slippery Sigismund intended to honour these pledges, but they cleared the way for his triumphant return to Prague in August 1436.

In Germany, the Hussite threat had clearly revealed the Effects inadequacies of the existing financial and military systems, but the incentive to press Sigismund's reforms to a successful conclusion faded when the Hussite peril was scotched by negotiation. The general apathy was demonstrated in 1434, when Sigismund proposed to the princes a land peace embracing the whole of Germany. The abolition of private wars and feuds by such a peace was undeniably a paramount necessity. The princes themselves, however, were among the chief offenders against law and order, and their nominal approval of the plan deceived no one. Sigismund himself, increasingly absorbed in crucial negotiations with the Hussites, did not persevere, and the project gathered dust in the imperial archives. The impulse he gave to the cause of reform did not, however, fade entirely, though Sigismund did not live to see the sequel. His death on Dec. 9, 1437, terminated the tenure of the German throne by the House of Luxembourg and opened the door of opportunity to the Habsburg dynasty.

The Habsburgs and the imperial office. Albert II. In the

raids into Germany

wars on Germany

Council of Constance

absence of a male heir. Sigismund had named his son-inlaw Albert of Habsburg, duke of Austria, as his successor, Albert was able and vigorous, and the union of the territories of the two dynasties enabled him to exert considerable leverage in German politics. Albert declared his neutrality in the current dispute between Pope Eugenius IV and the Council of Basel on the subject of conciliar sovereignty and thereby evaded an issue on which the electors were strongly divided; thus, on March 18, 1438, he was unanimously elected at Frankfurt. The electors attempted to elicit from the new king an understanding that he would grant privileges to his subjects only with their advice and consent. They also submitted a project for the division of Germany into four new administrative units (Kreise) in which the enforcement of the land peace would be entrusted to captains of princely rank. Albert judged that the princes were seeking to enlarge their power and influence under the guise of introducing reforms for the common good. The German cities also doubted the impartiality of the princes as custodians of law and order. Both proposals were therefore stillborn. The king hastened from Frankfurt to defend his kingdom of Hungary, endangered by Turkish raids on Siebenbürgen (Transvlvania in modern Romania). The campaign was brought to a premature close by the death of the king on Oct. 27, 1439.

Frederick III. Albert II had left only an infant son, and the leadership of the House of Habsburg passed to his cousin Frederick, duke of Styria. Inside the electoral college the duke was vigorously supported by his brother-inlaw Frederick of Saxony and was elected unanimously on Feb. 2, 1440. The choice of Frederick tightened the hold of the Habsburgs on the German kingship. It also brought to the throne a ruler who, absorbed in dynastic concerns and in astrology, had no more than a passing interest in Germany. Under the absentee government of Frederick III, the feuds among the princes and the collisions between the princes and the cities developed into savage wars accompanied by widespread ravaging and pillage. All paid lip service to the need for peace; but who was to enforce it? Was it to be enforced by the monarchy, which lacked power and executive machinery? Was it to be enforced in the courts of the princes, whose judicial impartiality was suspect? Were complaints against the princes to be heard and decided in the king's court (Hofgericht)? Or must they be adjudicated by the council (Hofrat) of the prince concerned? The right to enforce peace effectively was a major source of power to the holder; hence the struggle between Frederick and the princes was long, bitter, and inconclusive.

These issues were brought to a head by the rapid westward progress of the Ottoman Turks after their victories at Varna on the Black Sea (1444) and at Kossovo in Serbia (1448). The Habsburg kingdom of Hungary and Frederick III's own duchy of Styria lay full in the path of the invaders. In 1453 the fall of Constantinople extinguished the Eastern Empire and aroused fears in Germany that the Western Empire would meet the same fate. The king used the opportunity to demand financial aid against the Turks from the diet, the German assembly of estates. Under the leadership of the princes, the diet reminded him that Germany's capacity for defense was weakened by the current internal anarchy. In 1455 six electors proposed to the king the establishment of an imperial court of justice in which all three estates (electors, princes, and cities) should be represented. Frederick dismissed the scheme as an attempted invasion of his authority and stubbornly maintained his disapproval in a series of stormy interviews.

In time an increasing number of princes became convinced that reform would make no significant progress until Frederick was removed. As early as 1460 the Wittelsbach princes urged his deposition in favour of George of Poděbrady, the able and resourceful king of Bohemia. To check the danger, Frederick began to dole out reforms with a sparing hand. In 1464 he consented to make the court of the treasury (Kammergericht) independent of his person, to staff it with representatives of the three estates, and to extend its jurisdiction into fields other than financial. It was the acquisition of Austria in 1463 on the death of his brother Albert that finally proved his undoing. The unruly

Austrian nobility early took the measure of Frederick and thereafter disregarded his authority. On the east and south the duchy was imminently threatened by the expanding kingdom of Hungary under its land-hungry ruler Matthias Corvinus. The southern borders of the Habsburg lands were also ravaged by the Turks. Frederick's continuing irresolution and passivity encouraged Matthias Corvinus. who had already seized a portion of Bohemia, to launch a campaign against Austria. The Austrian nobility made no move against him, and Vienna fell to him in 1485. Frederick fled to Germany and made pitiful appeals for help to the princes. His misfortune provided the party of reform with a long-awaited opportunity. Led by Berthold of Henneberg, the able and resolute archbishop of Mainz, they pressed the aging and afflicted Frederick to relinquish the kingship in favour of his son Maximilian, Solaced somewhat by the assurance of a Habsburg succession, he gave a reluctant acquiescence, and Maximilian was elected on Feb. 16, 1486. Frederick retained the title of emperor. held since his imperial coronation at Rome in 1452. But he played no part in the government of Germany, and his death on Aug. 19, 1493, passed almost unnoticed.

Developments in the individual states to about 1500. princes and the Landstände. In the various principalities the outcome of the struggle between the territorial princes and the assembly of estates (Landstände) was not fully decided by 1500. The vigour of the conflict arose partly out of the contrasting conceptions of government held by the protagonists. The secular princes looked upon their lands as private possessions that could be divided by agreement among their sons and drew little distinction between their private and their public revenues. The three estates regarded themselves as the corporate representatives of the whole territorial community and maintained that actions by a prince affecting their interests and privileges should be subject to their consent. They therefore opposed the partition of the territory by family pact among the princes' sons. The inadvisability of breaking up the principalities into petty territorial lordships was at length conceded by the more prudent princes. By 1500 the rulers of Bavaria. Brandenburg, Saxony, and Württemberg had accepted the principles of territorial indivisibility and primogeniture.

In financial matters the imposition of extraordinary taxes (Notbeden) remained the crucial issue between the princes and the estates. The mounting cost of war and administration outstripped the ordinary revenues of the ruler, plunged him deeply into debt, and compelled him to seek financial aid from the estates with increasing frequency. In the absence of a clear distinction between public and private revenue, the estates often contended that the deficit was a private debt of the prince and disclaimed responsibility. Needy princes were thus forced to buy temporary solvency by concessions that later shackled them in their dealings with the estates. The estates regarded the Notbede strictly as an occasional emergency tax and insisted that it should be reasonable in amount. Indeed, the estates of Bavaria and Brunswick extracted from their respective princes in the course of the 14th century a formal recognition of their right of armed resistance to extortionate taxation. Similarly, any prince who broke his agreements with the estates was subject to the right of resistance. Thus the aims of these territorial assemblies were mixed. They sought to preserve the privileges of the three orders, to restrain the power of the prince, and to limit taxation. They were, however, also actively interested in good government, and the more enlightened rulers usually issued their ordinances only after consultation with the estates.

The princes proceeded against these powerful and often turbulent bodies with great caution. They persistently demanded that territorial assemblies convene only at the summons of the prince. They discountenanced the widespread conviction that absentees from the assembly were not bound to pay the taxes that it voted. In consequence, the peasants, who were not represented except in the Swiss cantons, Baden, Friesland, and Tirol, remained in the grasp of the princes' tax collectors. In these directions the princes had generally made notable advances by 1500, but in the vital matter of the Notbede they were still obliged to bargain with the estates as equals. They had

Dispute taxation

nowhere attained their ultimate objective: to transform the tax into a regular imposition voted automatically by the estates on demand.

Beyond the confines of the assembly of estates the attempts of the princes to curb their overmighty subjects aroused vigorous resistance. The noble vassals, proud and unruly, readily combined against any prince who sought to tamper with their liberties. Wise rulers deflected the nobles' energies into useful channels by employing them as stipendiaries. Hence even the most powerful princesthe Habsburgs in Austria and the Hohenzollerns in Brandenburg-proceeded circumspectly, and the difficult task of bringing the nobility to heel was far from completed in 1500. The cities of the princely territories defended their independence no less stubbornly. The princes revoked their charters, influenced municipal elections, and forbade the cities to associate in self-defense. The struggle was most intense in the north and east, where the Hohenzollern dynasty of Brandenburg emerged as the chief foe of municipal freedom. In 1442 the elector Frederick II ("Iron Tooth") crushed a federation of Brandenburg cities and deprived its leader, Berlin, of its most valued privileges. In the Franconian possessions of the dynasty, Albert Achilles of Hohenzollern waged a destructive war (1449-50) against a city league headed by Nürnberg. He suffered a resounding defeat in a pitched battle near Pillenreuth (1450). The elector John Cicero took up the battle 38 years later, when the cities of the Altmark in west Brandenburg refused to pay an excise tax on beer voted by the assembly of estates. He discomfited the cities in the ensuing "Beer War" and radically revised their constitutions to his own advantage. On the other hand, the great cities of south Germany, enriched by the Italian trade, were more than a match for the local princes: the Wittelsbach dukes of Bavaria were decisively worsted by Regensburg in 1488.

The growth of central governments. Between 1300 and 1500 the organs of central government in the territorial states became more specialized and diversified. The parent body was the advisory council (Hofrat) of high nobles and ecclesiastics, whom the prince consulted at his discretion. Its business was not differentiated, and there was no division of labour among the councillors. It met at the summons of the prince and did not convene at regular intervals. Its membership was not fixed, and some advisers did not attend except at special invitation. Others were regional councillors who attended the prince only when he appeared in their locality. A body so unspecialized and fluctuating was ill-adapted to cope with the increasingly complex problems of central government. Hence in the 14th and 15th centuries a professional element of "daily" or permanent councillors was introduced. They were usually legists, trained in Italy or in the newly founded universities of Prague (1364), Vienna (1365), Heidelberg (1386), Rostock (1419), and Tübingen (1477). They were well versed in Roman law, which, with its centralizing and authoritative precepts, provided a congenial climate for the growth of the powers of the territorial princes everywhere save in Saxony and Schleswig-Holstein, where the ancient customary codes were deeply rooted. Financial administration, which required specialized skills, was placed under the direction of a separate department of government, the chamber (Hofkammer). An inner ring of favoured advisers, the privy council (Geheimrat), was also instituted to counsel the prince on affairs of state. The besetting weakness of the new administrative structure was financial. Few princes followed the example of the Hohenzollern dynasty in drawing up an annual budget and requiring financial officials to submit regular accounts to the government. On the positive side, chanceries gradually created a common German language, which Luther later used to spread his message.

German society, economy, and culture in the 14th and 15th centuries. Transformation of rural life. Despite the impressive advance of trade and industry in the later Middle Ages, German society was still sustained chiefly by agriculture. Of an estimated population of 12 million in 1500, only 1.5 million resided in cities and towns. Agriculture exhibited strong regional differences in organization. The more recently settled areas of the north and northeast were characterized by great farms and extensive estates that produced a surplus of grain for export through the Baltic ports. The south and southwest was a region of denser population, thickly sown with small villages and the "dwarf" estates of the lesser nobility. In the northeast the great landlords, headed by the Knights of the Teutonic Order, tightened their control of the originally free tenants, denied them freedom of movement, and ultimately bound them to the soil as serfs. In the south the heavy urban demand for grain chiefly benefited the larger peasant proprietors, who sold their surplus production in the nearest town and used their gains to acquire more land. The lesser peasantry, with their smaller holdings, practiced chiefly subsistence farming, produced no surplus and therefore failed to benefit from the buoyant urban demand. The frequent division of the patrimony among heirs often reduced it to uneconomically small fragments and encouraged an exodus to the cities. On the other hand. landless day labourers who survived the Black Death in the mid-14th century were able to command higher wages for their services

In south Germany the strain of transition in rural society was heightened by the policies of the landloids, lay and ecclesiastical. Confronted by labour shortages and rising costs, many landlords attempted to recoup themselves at the expense of their tenants. By means of ordinances passed in the manorial courts they denied to the peasantry their traditional right of access to commons, woods, and streams. Further, they revived their demands for the performance of obsolete labour services and enforced the collection of the extraordinary taxes on behalf of the prince. The peasants protested and appealed to custom, but their sole legal recourse was to the manorial court, where their objections were silenced or ignored. Ecclesiastical landlords were especially efficient, and peasant discontent assumed a strong anticlerical tinge and gave rise to the localized disturbances in Gotha (1391), Bregenz (1407), Rottweil (1420), and Worms (1421). Disturbances recurred with increasing frequency in the course of the 15th century on the upper Rhine, in Alsace, and in the Black Forest. In 1458 a cattle tax imposed by the archbishop of Salzburg kindled a peasant insurrection, which spread to Styria, Carinthia, and Carniola. In Alsace the malcontents adopted as the symbol of revolt the Bundschuh, the wooden shoe usually worn by the peasants. They also formulated a series of specific demands, which included the abolition of the hated manorial courts and the reduction of feudal dues and public taxes to a trifling annual amount. On these fundamental points there was little room for compromise, and the outbreaks were stifled by the heavy hand of established authority. But the rigours of repression added fuel to peasant discontent, which finally burst forth in the great uprising of 1524-25 (see below).

The nobility. The lesser nobility included two distinct elements. The imperial knights (Reichsritter) held their estates as tenants in chief of the crown. The provincial nobility (Landesadel) had lost direct contact with the crown and were being compelled by degrees to acknowledge the suzerainty of the local prince. The imperial knights had been extensively employed by the Hohenstaufen emperors in military and administrative capacities and were chiefly concentrated in the Hohenstaufen possessions in Swabia, Franconia, Alsace, and the Rhineland. With the extinction of the Hohenstaufen dynasty they lost their function and rewards as a nobility of service. The revenues from their small estates sank in purchasing power as prices rose. Caste prejudice prevented them from seeking an alternative role in trade or industry. Resentful of the decline in their fortunes and fiercely independent, they clung grimly to their remaining privileges: exemption from imperial taxes and the right to indulge in private war. They stubbornly resisted the persistent attempts of the princes to reduce them to subject status, and in Trier and Württemberg especially they were given valuable aid by the provincial nobles. For purposes of defense or aggression the imperial and provincial knights combined freely in powerful regional leagues, usually directed against the local princes or cities. In the course of their chronic feuds with the cities, many knights

The "Beer

Warn

The guild

system

became mere highwaymen. Many others, who had been forced to sell their estates or who were encumbered with debts, took service in Germany or Italy as mercenaries (Soldritter). In east Germany the knights, though equally unruly, were far more affluent. The knightly estate (Rittergut) was larger and produced a profitable surplus for export. The knights sat in the assembly of estates, and taxation by the prince required their consent. They were therefore well entrenched against the encroachments of princely power.

Urban life. Urban society in 15th-century Germany was concentrated in some 3,000 cities and towns. About 2.800 of the total were extremely small, with populations varying from 100 to 1,000. Of the remainder, no more than 15 cities contained more than 10,000 inhabitants. In this restricted group three were preeminent. Cologne reached its peak in the 13th century with a population of 60,000, but sank to 40,000 by 1500 following internal disputes, expulsions, and steady emigration. In 1500 Augsburg was the most populous German city, with a resident population of 50,000. Third place was held by fast-growing Nürnberg, which counted 30,000 souls. The social unity of the citizen body had been most marked in the 13th century, when the guilds joined the dominant patrician families (Geschlechter) in wresting the right to form an independent city council (Stadtrat) from the lord of the city. In the 14th century the guild masters, methodically excluded from the council by the patrician oligarchy, broke into open revolt in Speyer (1327), Strassburg (1332), Nürnberg (1348), and elsewhere. In its economic aspect the ensuing conflict embodied an attempt by the guildsmen as industrial producers to free urban industry from the tight control exercised by the merchant patriciate. By 1500 the guilds almost everywhere had gained varying degrees of representation in the city council.

In the meantime the guilds themselves had become increasingly oligarchical and exclusive as the established masters restricted the entry of new members in order to reduce competition. The ascent of journeymen and apprentices to the rank of master was obstructed by the imposition of excessive fees, and in many guilds membership became virtually hereditary. In consequence, the journeymen began to associate in fraternities of their own to press their demands for higher wages and a shorter working day. The masters denounced the fraternities as illegal, compiled blacklists of leading agitators, and formed intercity associations to enforce low wage rates. The day labourers and casual workers outside the guild structure had no protective organization and suffered heavily in periods of economic depression. The surviving tax records of the German cities, though not wholly reliable guides, nevertheless suggest wide extremes of wealth and poverty. In late 15th-century Augsburg, 2,985 of a total of 4,485 households (66 percent) were recorded on the tax rolls as exempt from taxation on the ground of insufficient means. At the other extreme stood the enterprising and prosperous business dynasties of the Fugger and the Welser. Not all wealthy citizens lacked public spirit, however, and hospitals, almshouses, and charitable foundations multiplied within the city walls. The spreading problem of mendicancy was combated by stringent legislation against ablebodied beggars in Esslingen (1384), Brunswick (1400), Vienna (1442), Cologne (1446), and Nürnberg (1447).

The decline of the church. The vigour and assertiveness of secular society in Germany was exercised increasingly at the expense of the clergy and the church. Among the upper clergy more than 100 archbishops, bishops, and abbots were temporal rulers. The prelates were usually sons of the nobility and did not allow election to church office to interfere with their aristocratic ardour for war and territorial acquisition. They were expert in the accumulation of benefices and were notoriously lax in the performance of their spiritual duties. Their influence was freely used to advance their kinsmen and partisans among the greater and lesser nobles, who dominated the cathedral chapters and ruled the abbeys. The monasteries were filled with monks and nuns who were distinguishable from the lay aristocracy only by a nominal celibacy. Among the secular princes, the rulers of Austria, Brandenburg, and

Saxony wrested a right of appointment to a fixed number of bishoprics and lesser church offices from the papacy, which had been gravely weakened by the schism and the conciliar movement of the 15th century. All lay and ecclesiastical princes imposed heavy extraordinary taxes on the clergy. The steady invasion of the church by secular interests was also exemplified by the moral and material condition of the lower clergy. The Black Death of 1348-49 had decimated the ranks of the more dedicated priests who ministered to their plague-stricken flocks instead of seeking safety by flight. The new recruits who rushed into holy orders were often self-seeking and spiritually unqualified. As the inflow continued, the problem of clerical unemployment and inadequate stipends attained greater proportions. Many were compelled by need to accept illpaid livings. Others obtained no benefice at all and lived precariously as chantry priests or as itinerant chaplains. Their moral and intellectual defects were bitterly assailed by church reformers and by an increasingly well-informed laity. Many pious Christians, especially in the cities, began to turn away from the priesthood in their search for spiritual comfort and to seek relief in mysticism or in lay associations practicing a simple, undogmatic form of Christianity.

Trade and industry. The most impressive achievements of the German economy between 1200 and 1500 lay in trade and industry. German trade benefited from the Hundred Years' War between France and England, which diverted northbound Mediterranean merchandise from the customary Rhône valley route to the eastern Alpine passes; from the fierce internal warfare between the Italian city-states, which weakened their supremacy in longdistance trade; and from the rapid economic development of "colonial" eastern Europe between the Baltic and the Danube. The north German trade was chiefly based on staple commodities such as grain, fish, salt, and metals; but the south German merchants, in their capacity as middlemen between Italy and the rest of Europe, had taken the lead by 1500. They combined trade and industry in the great Ravensburg Trading Company (1380-1530). which produced and exported Swabian linen and laid the foundation of the fortunes of the Höchstetter, Herwart, Adler, Tucher, and Imhof families. The most important independent concern was that of the Fugger, whose founder, Hans Fugger, began his career as a linen weaver in Augsburg. The Fuggers' accumulated profits provided capital for moneylending and banking, which they conducted with the aid of business techniques borrowed from the more advanced Italians. The wealth and prosperity of Germany, which Machiavelli remarked on in 1512, stood in sharp contrast to its political and military weakness, a disparity that contributed significantly to a profound sense of malaise and discontent on the eve of the Reformation. Cultural life. In the absence of a strong centralized monarchy to act as a focus, German culture continued to be regional in character and widely diffused. The mysticism of Meister Eckhart, Johann Tauler, and Heinrich Suso, which commanded all men to look for the kingdom of God within themselves, flourished chiefly in the cities of the Rhineland, where lack of diligent pastoral care forced Christians to call upon their own inner resources. In the same region social and moral satire attained an urgent and vivid realism. Sebastian Brant (1458-1521), born at Strassburg, spared no class in his epic on human stupidity, the Narrenschiff, or Ship of Fools. But it was in the thriving cities of south Germany, as yet little affected by Italian humanism, that late Gothic culture reached magnificent heights in art, architecture, and sculpture. Albrecht Dürer, born in Nürnberg in 1471, challenged his generation with his evocative engraving of "Melancolia I" in which a brooding figure with closed wings sits idly amid a chaos of scientific instruments and meditates on the futility of human endeavour. In architecture the hierarchical elaboration of the late Gothic style maintained its ascendancy and even made a notable conquest in Italy with the construction of the great cathedral of Milan, begun in 1387. The sculptured carvings of Tilman Riemenschneider (c. 1460-1531) in the castle of Würzburg revealed the anxiety, the deep piety, and the religious sensibility of

The Ravens. burg Trading Company Christian men engaged upon a spiritual pilgrimage that was to continue to the Reformation and beyond. His work was the pinnacle of a great flowering of sculpture, one of the greatest in German history (C.C.B./L.G.D.)

Germany from 1493 to c. 1760

REFORM AND REFORMATION: 1493-1555

The empire in 1493. The reign of Maximilian I (1493-1519) was dominated by the interplay of three issues of decisive importance to the future of the Holy Roman Empire: the rise of the Austrian House of Habsburg to international prominence, the urgent need to reform the empire's governing institutions, and the beginnings of the religious and social movement known as the Reformation. The accession of the dynamic and imaginative Maximilian to the German throne aroused in many Germans, and in particular among humanists, expectations of a time when the old imperial idea-the vision of the empire as the political expression of a united Christendom in which the emperor, as God's deputy, rules over a universal realm of peace and order-might become a reality. Since the extinction of the Hohenstaufen dynasty in 1254, imperial authority had been in disarray; as weak emperors had become absorbed in struggles against foreign and domestic, secular and ecclesiastical rivals, real power in the empire had moved toward the governments of territorial states and independent cities. From their first appearance on the historical scene (briefly from 1273 to 1308, then from 1438 in a nearly unbroken line until the dissolution of the empire in 1806), Habsburg rulers had fostered imperial unity. But they had been notably unsuccessful in creating agencies for its attainment, partly because they were assiduously working to build up a power base for their own house. This, in turn, brought them into conflict with European antagonists, chiefly France. The long reign of Maximilian's father, Frederick III (1440-93), was regarded by nationalists as lamentable in its inattention to the problems pressing on the empire. The solutions proposed for them were subsumed under the name of "reform," a highly charged word that acquired enormous additional force in the 15th century when the conciliar movement and its lay and clerical proponents exerted pressure for religious renewal. Maximilian's arrival on the throne thus generated a surge of anticipation, expressed in an outpouring of agendas for restructuring what was then coming to be called the "Holy Roman Empire of the German Nation.'

Imperial reform. Inevitably, perhaps, Maximilian's performance with regard to the empire disappointed. But he was successful in significantly extending the dynastic might of his family. He took over the duchy of Tirol with its vast mining resources. Ambitious marriage alliances spread Habsburg entitlements west and east: in 1496 Maximilian's son Philip wed Joan, the daughter of the king and queen of Spain, thus linking Habsburg Austria to Spain and the Netherlands (the future Charles V was born of this union in 1500); and in 1516 Maximilian's grandson Ferdinand was betrothed to the heiress of Hungary and Bohemia. But these connections only escalated Maximilian's internal and external problems. In foreign politics his ventures ended, for the most part, in calamities for the empire. Switzerland was lost (1499), several Italian campaigns were repulsed, and an attempt against the duchy of Burgundy brought the hostility of France and led to the fall of Milan. Even the imperial crown eluded Maximilian: his advance on Rome for this purpose was halted, and he had to be content with the self-bestowed title of "Roman Emperor Elect.'

These reverses strengthened a reform party among leading members of the empire's estates (Stände), especially their spokesman, the archbishop-elector of Mainz, Berthold von Henneberg. Given the long rivalry between emperor and estates, it goes without saying that their respective plans for reforming the empire diverged on crucial points of direction and control. The estates, acting from their-to them entirely legitimate-sense of the prerogatives of particularism, favoured a central administration responsive to them; the emperor, to the contrary, insisted on organs subservient to him, modeled on bureaucratic agencies recently established in Burgundy and Austria and shored up by the authority-enhancing principles of Roman law

At the Imperial Diet held in the city of Worms in 1495 the estates, whose members had begun to see themselves as the authentic representatives of the whole country prevailed. The four reform measures adopted on this occasion were in large part intended to limit the emperor's powers. An "Eternal Peace" outlawed private feuds, and steps were taken, agreed to by the emperor, to implement this pacification. An Imperial Chamber Court functioned as supreme tribunal for the empire, most of its judges being named by the estates. An empirewide tax, the "Common Penny," was imposed, the collection of which fell to the estates. To these measures was added, in 1500, an Imperial Governing Council to monitor, under the domination of the electors, the empire's foreign policy. Maximilian was able to impede the operation of this body (it was reestablished in 1521), but overall the emperor's reform objectives had come to nothing.

The historical judgment on this failure has swung between scorn for Maximilian's imperial "fantasies"-for whose realization a reorganized Germany was to furnish the means-and respect for his grasp of the country's perilous geopolitical situation, and between sympathy for the estates' single-minded pursuit of the imperatives of regional state building and disdain for the parochialism of their political vision. Most historians have found Maximilian's actions distorted by a species of romantic idealism (he in all seriousness proposed to Bayzid II that Turks and Christians should settle their differences by the rules of the tournament; he also cherished for a time the hope of becoming pope as well as emperor). What is clear is that the reform effort so briskly launched at the beginning of his reign resulted in permanent confrontation between sovereign and estates, a posture in which neither party could outmaneuver the other and every matter of policy required tenacious negotiation. In light of this permanent tug of war, the notion of a universal realm ruled by a "German" emperor does seem fantastic, though it never lost its ideological force. No one in the empire possessed plenary authority, but real power was shifting to territorial rulers and their bureaucratic agents and to the magistrates of larger cities. This shift was to be of the greatest importance in determining the direction in which the Reformation established itself in Germany.

The Reformation. The Reformation presents the historian with an acute instance of the general problem of scholarly interpretation-namely, whether events are shaped primarily by individuals or by the net of historical circumstances enmeshing them. The phenomenon that became the Protestant Reformation is unthinkable without the sense of mission and compelling personality of Martin Luther. But in social and intellectual conditions less conducive to drastic change, Luther's voice would have gone unheard and his actions been forgotten. Among the preconditions-which are the deeper causes of the Reformation-the following stand out: (1) Everyone agreed that the Roman Catholic church was in need of correction. The lack of spirituality in high places, the blatant fiscalism, of which the unrestrained hawking of indulgences-the actual trigger of the Reformation-was a galling example, and the embroilment in political affairs were symptoms of corruption long overdue for purgation. While the church continued to be accepted as the only legitimate mediator of divine grace, denunciations of its abuses, perceived or actual, became more strident in the decades before 1517. (2) A subtle change, moreover, had been occurring in people's religious needs and expectations, leading to demands for a more personal experience of the divine. Failing to meet this aspiration, the church was widely, if diffusely, rebuked for its unresponsiveness. (3) More focused criticism came from the Christian humanists, an influential group of scholars bent on restoring the fundamental texts of Western Christianity. Led by Desiderius Erasmus, the most renowned biblical scholar of the time, these men held the Catholic church up to the spiritual ideals for which it claimed to stand and, finding it wanting, set the principle of Evangelicalism against the church's secular-

Causes of the Reformation

These, then, were the forces driving events toward a crisis. In the first decade of the 16th century they coalesced into a powerful surge of religious, social, and political agitation, for which "reform" (of church and society) was the code word. Fornically, Luther, who was to channel this agitation into the Reformation, had, until his emergence as a national figure in the 1520s, nothing to do with it. For him one issue alone mattered: the imperative of faith. His personal path to the Reformation was an inner search for religious truth, to which his conscience was his guide.

When he wrote his Ninety-five Theses against indulgences in October 1517, Luther was an Augustinian friar, a preacher in the Saxon city of Wittenberg, and a theology professor at the university founded there in 1502 by the elector of Saxony, Frederick III, called "the Wise." His ambitious father had pushed him toward a career in law, but in 1505 the fervently devout Martin entered a monastic house. His order, that of the Augustinian eremites, was a strict reform congregation dedicated to prayer, study, and the ascetic life. Deeply troubled by the question of justification-of how a human being, a sinner, may be justified (saved) in God's sight-Luther found no comfort in monastic routine and turned to an exploration of the sources of the Christian faith, notably St. Paul and St. Augustine. His intellectual promise having been recognized, he was sent by his order to study theology at Erfurt and Wittenberg. He gained his doctorate in 1512 and commenced his teaching of the Bible in Wittenberg that same year. According to his own account, it was during his close reading of Paul's Epistle to the Romans, while preparing to give a course of lectures on that text, that he discovered what struck him as the solution to the problem posed by the huge gap between human sin and divine grace. Justification is not earned as a reward for human effort through good works (a position Luther now attributed to a misguided and misguiding Roman church). To the contrary, human beings are justified without any merit of their own by God's freely given and prevenient (i.e., coming before any worthy human deeds) grace, through faith, which is a gift of God. This is the meaning Luther found in the crucial passage in Romans 1:17: "For in it [i.e., the gospel] the righteousness of God is revealed through faith for faith: as it is written, 'He who through faith is righteous shall live." "Righteousness"-justitia in Latin-does not refer, Luther now saw, to God's activity as judge but to the justifying righteous condition he effects in the human sinner, a condition expressing itself as faith. The momentous consequences of this theological insight, which Luther appears to have taken as a unique discovery but which had in fact been espoused by a score of theologians before him.

were not then apparent to him. They asserted themselves powerfully, however, once he began to lecture and present on the—for him—paramount themes of salvation by faith alone (sola fade) and exclusive reliance on Scripture (size ascriptura). It was the indulgence controversy of October 1517 that brought it all into the open.

Few other issues could so clearly have exposed the gulf that separated this ardent friar from an urbane and pragmatic church. The indulgence offered in Saxony in 1517 had its origin in two purely financial arrangements. First, Popes Julius II and Leo X needed funds for rebuilding Saint Peter's Basilica in Rome; second, Bishop Albert of Hohenzollern, forced to buy papal dispensations in order to gain the archbishoprics of Mainz and Halberstadt. agreed to promote indulgences in his domains, half the income from which was to go to Rome, the other half to him and his bankers. For Luther, the issue turned not so much on the outrageous venality of this deal as on the indulgence itself. Truly contrite sinners do not desire relief through an indulgence (which is a remission of temporal punishment to be performed following absolution); they crave penance. This is the gist of Luther's argument in the Ninety-five Theses, which he sent to his ecclesiastical superiors to persuade them to abandon the indulgence sale. (The story that he nailed a copy of the theses to the door of the castle church in Wittenberg may be the invention of a later time.)

Luther intended no defiance with this action. He intervened as a priest on behalf of his flock and as a conscientious theologian against a corrupting church. But the public reaction to the theses (he had written them in Latin, but they were soon translated and printed) made it evident that he had touched a nerve. Encouraged by expressions of support and goaded by opponents, Luther became more outspoken, harsher in his criticism of the church, and more focused in his attacks on the papacy. By 1520 he was well on his way to becoming the spokesman for Germany's grievances against Rome. A pamphlet he published that year, "Address to the Christian Nobility of the German Nation," urged the empire's secular rulers to reform a church that would not set its own house in order. Popes and prelates are not sacrosanct, he argued; they may be brought to justice. As every Christian can read the Bible for himself, papal claims to interpretive authority are a vain boast. Luther prodded the German princes to consider the state of the church and to reform it for the sake of the faith. In this way Luther drew out, albeit reluctantly, the full consequences of his principle of "salvation by faith alone." No church was needed to act as God's agent; grace was available without mediation. No priest, not even the pope, has special powers, for, so Luther argued, all human beings are priests, made so by their faith. It is scarcely surprising that a bull of excommunication against him (Exsurge domine) issued from Rome

Imperial election of 1519 and the Diet of Worms. At any other time the Lutheran matter would probably have ended there. But 1521 was no ordinary moment in the empire's history. When he died in 1519, Maximilian had not succeeded in having his grandson and heir, Charles, designated his successor. King of Castile and Aragon since 1516, and suzerain also over Habsburg apanages in the Netherlands, Naples, and central and eastern Europe-not to mention the Spanish possessions in the New World-Charles posed a formidable problem for the electors. Should they choose a man whose vast resources might well empower him to centralize authority in the empire when this would limit their hard-won autonomy? Should they elect a prince whose international commitments would entangle Germany in European conflicts? The only other viable candidate was the king of France, Francis I, who recognized in the rapidly growing Habsburg ascendancy a serious threat to his own power. But, though Francis made tempting promises, the electors, in the end, opted for Charles-not, however, without drawing from him a 36point "electoral capitulation" in which he swore to uphold the estates' prerogatives. While in so choosing the electors strove to secure their own privileges, the German public tended to see in the new monarch a fulfillment of national

Martin Luther acquiring the features of a national cause.

The Diet

of 1521

of Worms

Delayed by disturbances in his Spanish domains, Charles reached Germany late in 1520. He was crowned king in Aachen, assuming at the same time the title of Roman emperor elect. He then proceeded to Worms, where he was to meet with the German estates in early 1521. By then no other issue counted as much on the agenda as the Lutheran affair. Acting out of what appears to be a blend of conviction and political expediency, the estates' leaders, prompted by Frederick the Wise, demanded that the diet reopen Luther's case by allowing the excommunicated friar to speak before the estates. Unable to resist, the emperor issued a safe-conduct, and Luther traveled to Worms, treated on his way to so extravagant a public acclaim that he must have felt like a national hero. On April 17 and 18 he stood before the emperor and representatives of the estates. He refused to revoke his views on justification and other points of theology, reiterated his denial of ultimate authority to pope and church councils, andwhen pressed-asserted the principle of individual responsibility in matters of faith: "As long as my conscience is held captive by the words of God, I cannot and will not revoke anything, for it is dangerous, and a great peril to salvation, to act against conscience, God help me, Amen." These words, and all else that transpired, were broadcast to the country in scores of pamphlets in which Luther was cast in the role of the man sent by God to cleanse the German church. While an imperial edict condemned his teachings and placed him and his adherents under the ban, Luther himself was offered a refuge in Frederick the Wise's castle in the Thuringian forests, the Wartburg,

gained momentum.

Analysis of what happened at Worms reveals the first signs of what was to become a fateful split in the self-perception of this movement. The estates saw it as a means of promoting ecclesiastical reform; on questions of faith, they were willing to compromise. Luther, on the contrary, tolerated no distinction between points of faith and aspects of church practice, and on his understanding of the former he stood rock solid. He and his political patrons were trus pursuing different ends; for the present, however, his support in official circles was, for whatever reason, substantial.

There, fretting over his enforced absence from events, he

turned to the translation of the New Testament, while the

movement, of which he was now the acknowledged head,

Luther's hold on the general public was even more impressive than his hold on the political leadership. Historians are not unanimous in explaining how this friar from the German east, utterly obscure only five years earlier, could have gained such a following by 1521 that few governments would enforce the ban against him, knowing that they would face strong resistance if they tried to do so. It is not clear whether the general population, still largely illiterate, understood the doctrine of solifidianism well enough to make it the object of informed choice. More likely, the German populace took Luther not as the preeminently religious prophet he was but saw in him their best hope of achieving an amelioration of the many troubles vexing them in their respective stations, not only in religion but also, and perhaps mainly, in their social condition. Against these conditions, the products of deeply rooted legal and institutional structures, Luther-or so people seem to have understood him-raised the standard of evangelical morality: all things were to be judged by Scripture and God's law.

Scholars have often pointed out that this view is less attributable to the Wittenberg reformer than to another theologian and preacher then beginning to be active in the Swiss city of Zürich, Huldrych Zwingli. Luther explicitly rejected the use of the—to him purely spiritual—New Testament as a norm for social reform. But Zwingli affirmed it. On the other hand, Luther's vehemence and forceful reterior were so compelling that, rightly or wrongly, his

name came to be fused with the general hope of improvement in human affairs. His partisans, proficient in their use of the media of print and woodcut illustration, helped shape this conviction by furnishing propaganda for a strong popular drive toward Lutheranism. This drive from below, further nourished by traditional anticlerical sentiments, was met from above by the eagenress of territorial and urban governments to utilize Lutheran ideas as legitimation for the extension of political control over the church. Thus, by the mid-1520s, a number of German cities and states had formally turned Lutheran, meaning that they had severed their legal and administrative ties to Rome and its prelates and were building new ecclesiastical institutions and framing new doctrines.

The revolution of 1525. The events of the revolutionary years 1524-25 underscored the urgent need to establish Lutheran church organizations. In its own time, and often since then, these events were labeled a "peasant rebellion"; but modern scholarship has made it clear that the insurrection was far more than a series of uprisings by rural bands. The tens of thousands of peasants drawn into the movement, some of them massed in major military actions, were a symptom of the general unrest that had gripped Germany since the middle of the 15th century. This unrest was ultimately caused by demographic pressures with attendant economic and political dislocations. The particular demands pressed in the 1520s-mitigation of fiscal and labour burdens imposed on peasants by their lords, autonomy for village communes, and relief from high taxes-had been voiced before. New was the linkage of these demands with the grievances of restive urban groups also protesting exploitation and disenfranchisement and their formulation as an agenda of social reform on the principle of Christian communitarianism. This ideological redirection of old patterns of resistance could not have occurred without the impetus of the Reformation, specifically the incendiary preaching in towns and villages of evangelical pastors who represented Lutheran and Zwinglian ideas as solutions to the problems at hand. The clearest evidence of the Reformation's impact on the shaping of what some modern scholars call "the revolution of the common man" are the Twelve Articles drawn up for the Swabian peasantry by an evangelical cleric and associate of Zwingli's. Article three of this document asserts that "The Bible proves that we are free, and we want to be free," while another article claims for every congregation the right to choose its minister; these articles are a strong indication of how vital the principle of Biblicism had become to people preeminently concerned with worldly life. In the regions involved-Franconia, Swabia, the Upper

Rhine and Alsace, Thuringia, and Tirol-large forces of peasants attacked castles, monasteries, and some cities. News of these actions encouraged discontented urban groups to rise against their oligarchic town governments, and for a while it looked as though a united revolutionary front of ordinary-i.e., nonprivileged-people might be forged. Manifestos and lists of articles abounded; there was talk everywhere of judging things by "God's law" (meaning the gospel), and some groups even laid plans for a "Christian association" across regional and towncountry lines. But before long the forces of authority won the upper hand, and the insurrectionaries were put down with the ferocity customary in those days. The war's final stage was dominated by Thomas Müntzer, a visionary theologian with a message of social deliverance for and by the poor. The defeat of his forces at Frankenhausen in May 1525 marks the final victory of the old order over the would-be new dispensation.

the would-be new aspensation. Luther was heavily implicated in this turnabout. Realizing that his words and deeds had served to encourage popular action against legitimate rulers, he sought to separate himself drastically from the movement, going so far as to urge the rulers' warriors to "cut [the peasants] down, hit them, choke them wherever you can." His brush with revolution confirmed Luther in the rigorous segregation he made between "two realms," the worldly and the spiritual, the respective laws and ideals of which must not be confounded, as, he claimed, the revolutionaries had done. The gospel, he said, cannot be used as a standard

Thomas Müntzer

The issue of social reform

for governing in the world, which has its own rules and ways of justice, many of them, he acknowledged, unfair and blameworthy. Luther's separation of worldly and evangelical values, soon made binding law by Lutheran governments, brought an abrupt end to the early phase of the Reformation, during which events seemed to many to be moving toward a sweeping transformation of social, as well as religious, structures. At the same time, Lutheran governments read 1525 as a lesson on the need to control subjects, concluding that preaching in particular, and religious behaviour generally, must be controlled. To accomplish this purpose, new laws and bureaucracies were set up everywhere.

Lutheran church organization and confessionalization. The 1525 revolution was but one of several upheavals worrying the authorities. Three years earlier a group of imperial knights led by Franz von Sickingen had declared feud on the archbishop of Trier, claiming to derive from Scripture their right to despoil Roman Catholic prelates. The ensuing "Knights' War" was quickly crushed. But about the same time a disturbance broke out in Wittenberg where, during Luther's exile in the Wartburg, a group of reforming Spiritualist activists forced the city council to abolish many traditional Catholic practices. Upset by this rash move, Luther intervened to reverse it. But this incident, and the knights' attack, caused consternation among the heads of government, who feared loss of control. Their anxiety was deepened by the spread from Switzerland in the mid-1520s of Anabaptism, a radical religious movement whose most distinctive tenet was adult baptism. The events of 1525 thus strengthened a long-ripening resolution that firm structures and clear doctrines were needed to reassert authority in a situation of drift.

The ability of Lutheran states to act on this resolution was facilitated by the impact of foreign affairs on the empire's internal politics. Far from seeing to the execution of the 1521 edict against Luther, Charles V left his brother Ferdinand in charge of imperial affairs and departed from Germany after the Worms diet to deal with the many problems besetting his far-flung interests. The most perilous of these was the war with France, which implicated the emperor in a constantly shifting balance of alliances with other powers and in a see-saw of military actions in which now he, now Francis I, was in the ascendant. Charles's victory at Pavia in 1525 led in turn to the formation of a coalition against him (the so-called "Holy League of Cognac"), intended to forestall Habsburg hegemony in Europe (a scenario to be replayed many times in the following two centuries). In 1526, therefore, Charles was in no position to dictate to the German estates on the Lutheran matter. Within a year, however, the situation turned in his favour. Spanish troops captured and plundered Rome in 1527, and by 1529 Charles was dominant once more, though it had become clear that neither warring party could bring the other to its knees. At the same time a potentially fatal danger loomed in the east where the Turks, under Süleyman I the Magnificent, began to aim their path of conquest at the Balkans and Hungary. The death of King Louis II at the Battle of Mohács in 1526 put Ferdinand of Habsburg (Charles V's brother) in line for the Bohemian and Hungarian crowns, thereby exposing the already overextended Habsburgs on a new front. By 1529 the Turks were moving toward Buda (captured in September of that year) and Vienna. Facing these perils, Charles concluded peace with France, sealing his triumph in the west with his coronation as emperor at Bologna. He then returned to Germany

The events just described formed the larger political frame in which Lutheran church organization took place. Forced to solicit military aid from the estates in 1526. Ferdinand postponed implementation of the Worms edict, accepting a declaration by the Diet of Speyer of that year to the effect that every estate "will, with its subjects, act, live, and govern in matters touching the Worms edict in a way each can justify before God and his Imperial Majesty." This declaration gave Lutheran rulers the signal to proceed with their intended legal, administrative, financial, and liturgical reforms, and the years following 1526 saw the construction in every Lutheran territory of what

amounted to a state church, headed by the ruling prince. In 1529 this process was interrupted when, following the emperor's military successes, Ferdinand demanded at a diet, also held in Speyer, that, pending a general council to decide the religious issue, Lutherans should end their separation. (It was the "protest" of a number of princes and cities against this abrogation of the earlier Spever decree that attached to Lutherans the name "Protestants.") By then, Protestants were no longer a united party. Luther and Zwingli had met at Marburg in 1529 in an attempt to iron out differences, but they could not agree on the question of Christ's real presence in the Eucharist, While a few Lutheran princes prepared for military action, a compromise-minded group led by the humanist Philipp Melanchthon, who dreaded the prospect of fragmentation within Protestantism, drew up a moderate outline of Lutheran positions. These were presented for discussion at the Diet of Augsburg in 1530, which was attended by the emperor. The Augsburg Confession, which became a fundamental statement of Lutheran belief, assumed that reconciliation with the Catholics was still possible. This view was shared by Charles, who was pushing the pope toward the summoning of a general council to mend the religious split. Negotiations among theologians and politicians, however, came to nothing, and the end result was that, with the Augsburg Confession rejected. Lutheranism was outlawed again. The militant Protestant faction, led by Philip, landgrave of Hesse, now established a formal organization of resistance, the Schmalkaldic League (1531). and the empire moved toward armed conflict as Lutherans passed beyond the formation of a political party and became a military force as well.

Around this time much more rigid standards of religious orthodoxy and conformity were imposed. This development has been called "confessionalization," a concept used by some historians to define developments in the empire during the second half of the 16th century. Confessionalization completed the process, under way since the late Middle Ages, of meshing religious and church politics with the objectives of the state. Central to this process was the institution of a territorial religion that was based on an authorized declaration of doctrines (a "Confession") binding on all subjects and implemented by an established church responsible to the ruler (or, in city states, to the magistrates). Tending toward exclusiveness and therefore intolerance, this system contributed to the warlike turn taken by events after 1530. More important in the long run, confessionalism promoted a social drive, also long under way, toward the inculcation of discipline and order in public and private as well as in religious and civic affairs. Through catechisms, schooling, family and welfare legislation, norms for work, and standards for personal life, state and church attempted to restructure society in accordance with the goals of what has since been called the Protestant temperament. Success was slow in coming and never more than partial. But there is no doubt that, through the confessional process, Protestantism left a deep imprint on the German character.

Religious war and the Peace of Augsburg. After the diet of 1530 Charles left Germany for more than a decade, occupied with troubles in the Mediterranean, the Netherlands, and, once again, France. In 1535 he campaigned against Tunis to subdue the Barbary pirates who, as the naval arm of the Ottomans and as corsairs and privateers, had been making navigation unsafe. Renewed war with France was temporarily halted in 1538 by a treaty meant to last 10 years, but in 1542 France struck again, allied now with major European powers, including the duke of Guelders and Cleves, whose lands were claimed by Charles as part of his Burgundian inheritance. The emperor's conquest of this duchy in 1543, which considerably broadened his power base, and the peace he concluded with France in 1544 (Peace of Crepy), followed by an armistice in 1545 with the Ottoman Empire, left him free at last to deal decisively with the German Protestants.

The emperor's policy toward religious deviants was guided by his concept of empire. The universal realm over which he hoped to reign faced external and internal threats; its mission of unity and order was assaulted by

Confessionaliza-

Turkish advance infidels from without and by national rivalries and heresy from within. He had dealt with the first and second threats: now he turned his attention to the third. Protestantism had spread rapidly in Germany. More than a religion, it was, by the 1540s, a full-fledged political movement with a growing military capacity. The number of Protestant territories had recently grown to include, among others, Brandenburg, the Palatinate, Albertine Saxony, and the bishoprics of Cologne, Münster, Osnabrück, Naumburg, and Merseburg. In Philip of Hesse the Lutherans had an able political strategist. At least provisionally, pending the settlement of all religious issues by a general council, the Protestants had won grudging recognition of their right to exist. Such a council was actually summoned by Pope Paul III-though only upon repeated prodding by the emperor-but there were few signs that the Protestant states would submit. In 1545, therefore, Charles decided on war. He found a pretext in the capture, by Lutheran princes, of the duke of Braunschweig-Wolfenbüttel, a Catholic who had tried to reconquer the lands from which he had been expelled by his Lutheran subjects. Claiming that this capture violated imperial law, Charles opened the conflict in 1546, in which he was joined by Maurice, duke of Saxony, an ambitious Lutheran prince to whom Charles had secretly promised the Saxon electorship. The ensuing war fell into two phases, the first of which saw the emperor victorious (Battle of Mühlberg, 1547). Capitalizing on this strong position, Charles in 1548 forced the estates to accept an Interim, a temporary religious settlement on the emperor's terms. It was the political concessions Charles demanded from the estates, however-concessions that would have permanently limited their autonomy-that led to a resumption of war. Among the Protestants the lead was now taken by Maurice of Saxony, who had abandoned the emperor and had obtained material support from the new French king, Henry II, for fighting on the Protestant side. The resulting "Princes' War" was brief (1552-53) and inconclusive, and in 1555 a peace was signed at an imperial diet held, again, in Augsburg.

The Peace of Augsburg closed one epoch of German history and opened another. It decided the religious issue but did so in a way bound to occasion future problems. It reinforced the princes' authority over their territories but failed to settle their relations with the emperor. Most important, it legalized Lutheranism, laying down the rule, later epitomized in the phrase cuius regio, eius religio ("he who governs the territory decides its religion"), that each estate-i.e., each prince or city-could opt for either the Roman Catholic or the Lutheran religion (jus reformandi) and that this choice was binding on everyone under that ruler's jurisdiction. Only one faith could legitimately exist in a given state, and that faith had to be the ruler's and could be only Catholicism or Lutheranism; Calvinism, Zwinglianism, and Anabaptism were excluded. A subject unwilling to live by this choice was free to emigrate and take his belongings with him (a provision considered liberal at the time). Confiscated church properties could be kept by the governments that had taken them. An Ecclesiastical Reservation prevented ruling prelates from converting their lands along with them. These terms make it clear that the real winners of the war, and of the entire Reformation period, were the territorial princes, whose authority and power, which now encompassed the church, were greatly increased. It scarcely needs to be said that Luther, who had died in 1546, would not have approved of this outcome. As for the emperor, he abdicated in frustration and retired to a monastery in Spain, leaving his Spanish and Burgundian crowns to his son Philip and the empire to his brother Ferdinand. These two men, as Philip II and Ferdinand I, strong-minded Catholics both, were to play prominent roles in the period of Counter-Reformation and confessionalism that dominated Europe after 1555.

THE CONFESSIONAL AGE: 1555-1648

German society in the later 1500s. The changes caused by state building and the Reformation bestowed little real benefit on the lives of ordinary people. Histonians agree that the later 16th century was, for many, a time of economic hardship and social stress. Rapid increase in population (the European population rose by more than half between 1500 and 1700) and, secondarily, the influx of precious metals from the New World were the main causes of an inflationary trend that spanned the entire century and reached painful stages in Germany in the 1590s and early 1600s. Grain prices were especially affected, with the result that an ever smaller share of the ordinary person's budget was available for the purchase of other products. This had several effects, which, at least in outline, are well documented. The quality of nutrition for all but the wealthiest became much worse than it had been in the late Middle Ages, when meat consumption was at an all-time high. Illness and epidemic disease were frequent as the nutritional deficiency was aggravated by a series of bad harvests, perhaps caused by unusually severe winters in the decades after 1560.

Cities and towns suffered loss of income as the market for their manufactured wares declined. In consequence, municipal guilds lost ground, not only economically but also politically, owing to the curtailment of their participation in urban policy-making. There were exceptions to this trend. Craftsmen specializing in the manufacture of luxury cloths and arms found lucrative markets at princely courts; but overall the position of artisans declined. Journymen could no longer anticipate becoming masters. Artisans employed in traditional handiwork felt the pressure of the putting-out system favoured by early capitalism, whereby much production was moved from the town to the countryside. Division of labour was introduced, gradually transforming self-employed craftsmen into dependent workers.

In the agricultural sector, high grain prices and rising land values improved the lot of peasant proprietors, but the real beneficiaries were landowning nobles and urban patricians with investments in agriculture. Society was polarized by these developments. A minority of rich peasants lived amid struggling smallholders hard-pressed by land-lords who maximized their profits by increasing labour and tax burdens (the period has been spoken of as that of a "second serfdom"), and in the cities an upper crust of merchants and landed aristocrats faced a proletariat, whole sections of which were pauperized by the end of the century. The populous cities, once the glory of Germany, began to play a smaller role, as economic troubles and the centralizing policies of territorial princes decreased their prosperity and sapped their political strength.

The highly visible contrast between rich and poor and the animosity of the weak against the wielders of influence created tensions among groups and classes. Political and economic power was more concentrated than ever before. Its new centres in Germany were the splendid courts of secular and ecclesiastical princes, whence it was distributed to favoured groups: the nobility, rising in importance again but finding its function limited to the service of rulers, and the upper bourgeoisie, shifting its loyalty from guild hall to palace. For ordinary people, administrative centralization and politically sanctioned Reformation had the effect of making their lives more rigid. A host of mandates flowed from centres of government, seeking to promote an ethic of order, productivity, and morality by shaping working and domestic activities as well as private habits and attitudes. These inroads caused resentment, and there is evidence of widespread resistance, most of it passive. Under these circumstances, the evangelical Reformation seems to have made but slight impact on the populace at large, whose effective religion continued to be a mixture of traditional Christianity and folk magic.

Must people were worse off near the end of the 16th century than at its beginning. The lot of women, in particular, had deteriorated. Around 1500 many German women had been at work in numerous urban occupations. But a century later they had been crowded out of all but the most demeaning trades as economic pressures, reinforcing ancient prejudices, eliminated them wherever they offered competition to male craftsmen. In this light, it is not surprising that the period from the 1580s to the 1620s also witnessed a surge of persecutions for witchcraft in Germany (mainly in the southwest and Bavaria). As

elsewhere, the witch craze in the empire seems to have been a reaction to the strains of a time of troubles, the actual causes of which, fairly clear now to historians, were hidden from contemperature.

hidden from contemporaries. Religion and politics: 1555-1618. Four forces contended for supremacy in the Holy Roman Empire in the aftermath of the Peace of Augsburg, Lutherans-that is to say, Lutheran estates and governments-sought to extend the rights they had won in 1555 to parts of Germany still Roman Catholic, Calvinists, having been excluded from the Augsburg settlement, strove for recognition and made major territorial gains in the 1560s and '70s. Adherents of the old faith, invigorated by the Catholic Reformation issuing from Spain and Rome, attempted to turn back the Protestant advance by making common cause with strong governments. Habsburg emperors tried to serve the Catholic cause by weakening Protestant princes wherever possible and by holding the line against Protestantism in their dynastic lands. Political conflicts were constant under these circumstances and wars frequent, the empire's institutions being powerless to neutralize or channel these competing endeavours. Maximilian II from 1564, Rudolf II from 1576, and Matthias from 1612, though ardent Catholics, were preoccupied with the intertwined problems of retaining the loyalty of their dynastic lands and securing the eastern borders against the Turks. They had, in any case, been stripped of the ability to maintain order in the empire, as the Augsburg terms had placed public security under the supervision of the empire's administrative districts, which were controlled by the estates. The period leading up to the Thirty Years' War was therefore one of more or less constant strife in nearly all parts

The second half of the 16th century introduced two new agents of change to this scene. The Catholic Reformation. operating mainly through the Council of Trent (1545-63) and the Society of Jesus, brought about major changes in Roman Catholicism. Trent produced authoritative definitions of dogma for the first time in the long history of the church, declared tradition to be, with the Bible, a source of revelation, reaffirmed the sacraments as mediators of grace, declared the church to be a hierarchical institution headed by the pope (against Luther's formulation of the "priesthood of all believers"), and issued a large number of reform mandates to meet, at last, the age-old charges of laxness and corruption. After the 1560s the Catholic Reformation's chief energies went to the implementation of the Trent decrees. Most effective in this endeavour were the Jesuits, a militant order founded by Ignatius of Loyola in 1534, pledged to strict obedience to the pope and to acting as the church's instrument for regaining ground lost to Protestantism. Germany was a major area of Jesuit activity; the order settled in Cologne in 1544 and later in Vienna, Ingolstadt, and Prague. In close collaboration with Catholic rulers, often as their confessors, the Jesuits embodied the activist phase of Catholic reform that goes under the name of Counter-Reformation.

On the Protestant side, this activism was represented by the Calvinists, who made so forceful an impact on German society in these decades that some historians have called their appearance a "Second Reformation." The Palatine Electorate went Calvinist when its ruler converted; later the "Reformed" creed (as its partisans named it, denying to other Protestant denominations the claim to have truly reformed the faith) established itself, among other places, in the electorates of Brandenburg and (for a time) Saxony, the territories of Hessen-Kassel, Nassau, Durlach, and Anhalt, and the cities of Bremen, Emden, and Münster. Unlike Genevan Calvinism, the Reformed religion in Germany coexisted easily with the autocratic territorial church; German princes, for their part, saw Calvinism as a far more aggressive theological and political weapon with which to wage the struggle for Protestant supremacy in the empire. Calvinist theology, with its emphasis on action in the world and its association of success with sanctification, even with election, was well suited, in the use made of it by German state churches, to act as an aggressive creed of social discipline; it also inspired the formation of militant parties pressing for recognition of Calvinism as a

legitimate religion under the cuius regio, eius religio rule With the religious situation thus more inflamed than ever and the confessional and political issues inextricably intertwined, any incident might have triggered renewed conflict, which-given the competition for power in Europe among the Habsburg dynasties. France, England and the Netherlands-was likely to lead to a general war. A series of incidents moved events toward the brink. In 1582 the archbishop-elector of Cologne, having converted to Calvinism, challenged the Ecclesiastical Reservation of the 1555 Augsburg treaty by holding on to his title, thus threatening to throw the majority vote in the College of Electors to the Protestants. In the "Cologne War" of 1583 he was expelled by Spanish troops, and Duke Ernst of Bavaria was chosen as his successor. Throughout the 1590s the incorporation of church properties by Protestant governments was a cause of litigation before the empire's courts, as Roman Catholic authorities sought to compel the return of everything confiscated since 1555; Protestant estates, in turn, made support for the emperor's war

against the Turks dependent on further concessions. The Habsburgs, meanwhile, were hampered in their advancement of the Roman Catholic cause by the growing mental incapacity of Rudolf II; indeed, much of the direction of affairs was transferred to his brother Matthias, who eventually succeeded him in 1612. A more serious undermining of Habsburg imperial power occurred in the dynastic lands. Rigorous Catholic reform occasioned peasant uprisings in Austria and resistance by nobles in Hungary and Bohemia (where Calvinism had made inroads among the ruling classes). In Hungary a nationalist party under István Bocskay forged an alliance with Lutheran princes and obtained support from the Turks. In Bohemia, in 1609, the estates extracted from the emperor a guarantee of religious freedom, the so-called Letter of Majesty.

At about the same time the city of Donauworth was ocupled by Bavarian troops, Duke Maximilian of Bavaria
having been empowered by the emperor to "protect" the
Roman Catholic minority there. Seeing this "Donauworth
incident" as a straw in the wind, Lutheran and Calvinis
rulers formed a Protestant Union (1608), the answer to
which was the Catholic League (1609), headed by Maximilian, the most resolute Catholic prince in the empire.
Each party organized an army and allied itself with foreign powers, the Protestants with France and Bohemia,
the Catholics with Spain. In this way the German struggle

was both militarized and internationalized.
General war nearly broke out in 1609-10 over the Jülich-Cleves succession crisis. When the Roman Catholic ruler of these counties, which formed the strategically most important block of territories on the lower Rhine, died without issue, two Protestant claimants occupied his lands, aided not only by the German Protestant Union but also by France and England; they were, however, militantly opposed by Spain and the emperor. The assassination of Henry IV of France, who had been about to launch an invasion in support of the Protestant claimants, defused the crisis in 1610.

Peace was preserved, although not for long. The Bohemian situation finally precipitated the war. Because neither Rudolf II nor Matthias left legitimate heirs, the governance of the Habsburg dynastic lands fell to Archduke Ferdinand of Styria (later Emperor Ferdinand II), a ruthless counter-reformer who reduced the religious liberties granted to Bohemians under the Letter of Majesty. In response, the Bohemian estates in May 1618 mounted a protest in Hradčany (Prague Castle), which prompted a militant faction of deputies to throw two imperial councillors from a castle window ("defenestration" being a traditional Bohemian gesture of defiance). Ferdinand now prepared military action, while the Bohemian estates elected a Calvinist, Frederick V of the Palatinate, to be their king. As the alliances fell into place on each side, the stage was set for the sequence of large-scale military actions that constituted the Thirty Years' War

The Thirty Years' War and the Peace of Westphalia. The Bohemian problem was resolved swiftly. Two Roman Catholic armies, the emperor's and the League's, converged on the kingdom, routing Frederick at the White The Jülich-Cleves succession

Defenestration of Prague But this impressive strengthening of the sovereign's power in the empire brought his foreign and domestic enemies together once more, the latter including now not only Protestants but also Roman Catholic estates concerned about their liberties. Subsidized by the Dutch and by France and allied with Saxony, Sweden entered the conflict in 1630, winning commanding victories at Breitenfeld (1631) and Lützen (1632) but suffering defeat at Nördlingen in 1634. This phase of the war was marked by unprecedented brutality; for example, in 1631, imperial troops massacred two-thirds of the population of Magdeburg, a city of 20,000 that had withstood a long siege.

A way out of the long conflict appeared in 1635 when Saxony, Brandenburg, and other Protestant estates seeking to end foreign intervention joined the emperor in the Peace of Prague, which included the revocation of the Edict of Restitution. But in this, the war's final phase, the initiative passed to France, which, seeking to forestall Spanish preponderance on the Continent, offered large subsidies to Sweden and to German princes to enable them to fight on. Combined Swedish-French campaigns commenced in 1638, and a decade later foreign armies operated as far south as Bavaria, while the French held Lorraine and Alsace, which was important to France to prevent construction of a Spanish land bridge from the Netherlands to Italy.

By then most belligerents were exhausted. Several German princes had quit the war. Since 1644, representatives of the powers had been talking about terms, although military operations continued in hopes of improving bargaining positions. In 1648, finally, treaties were signed in Münster and Osnabrück (both in Westphalia) by agents of the emperor, the German estates, Sweden, and France as well as between Spain and the Netherlands. Fighting continued for some years—France and Spain did not conclude peace until 1659—but the war was at last winding down.

The Peace of Westphalia brought territorial gains to Sweden and France, awarded an electoral seat to Bavaria, and secured for Protestant rulers the church properties they had confiscated, based on the status quo of 1624. More important, it brought Calvinists into the religious settlement and established the independence of the Netherland from Spain and of Switzerland from the empire. Most significant of all, it guaranteed the nearly unlimited terri-

torial sovereignty of German princes, bringing to an end the last effort (until the 19th century) to turn the empire into a centrally ruled "modern" state. In this way 1648 scaled the fragmentation of the Holy Roman Empire into hundreds of autonomous political entities, most of them small. At the same time, it brought to an end the last major conflict in continental Europe in which religion was a salient issue; indeed, the war itself had demonstrated that reason of state was a stronger determinant of policy than faith. In declaring the religious situation fixed as of 1624, the treaty eliminated the jus reformand as a cause for confessional change; if a prince converted, his land no longer converted with him. Religious pluralism and—albeit grudgingly—coexistence were now the norm.

The war's social and economic ost is difficult to gauge, modern scholarship having greatly modified original claims of vast humar losses and near-total economic ruin. Nonetheless, in the most embattled realms, such as Württemberg, more than 50 percent of the people died or disappeared; elsewhere, the loss was less severe. Most historians agree that an overall population decline of 15 to 20 percent (from c. 20 million to 16 or 17 million) occurred during the war and the ensuing epidoxines. In addition, historians agree that in theatres of war rural impovershment and displacement of people were widespread, while economic regression happened nearly everywhere. For German society overall, the war was a traumatic experience; it is rivaled in the national consciousness only by the 1939–45 war as a time of unmitigated disaster.

To gain perspective on these calamities, their wider European aspects must be considered. Wars, uprisings, and political turmoil had occurred in many countries during the first half of the 17th century. The Fronde-a series of civil wars in France between 1648 and 1653 whose goal, at least in part, was to halt the growing power of royal government-and the Civil War in England (1642 to 1651) are only the most famous of these disturbances. Turmoil had occurred also in Catalonia, Portugal, Naples, Ireland, Scotland, Sweden, and Russia. Historians have referred to these events, including the numerous local manifestations of the Thirty Years' War, as parts of a general crisis in the fabric of European society, the causes of which range from a worsening of the climate (Little Ice Age) to plagues, often spread by the armies roaming Europe almost continuously at that time. But the most destabilizing factor burdening society was the centralizing monarchy with its expanding bureaucracy, extravagant courts, swollen armies, and incessant wars, all of them supported by heavy taxation. No social group, or estate, was unaffected by the effort of monarchs to alter in their favour traditional ways of distributing power and influence. Resentment of this and of its social cost was widespread; hence the proliferation and the scale of rebellions.

TERRITORIAL STATES IN THE AGE OF ABSOLUTISM

The empire after Westphalia. The empire was an awkward structure. German historians of an older, nationalistic generation deplored the fact that the empire lacked any of the attributes of a great power and lamented its victimization by more unified foreign states. Such critics always quote the 17th-century legal scholar Samuel Pufendorf, who called the empire a "monstrosity," and interpret this term as a value judgment rather than an expression indicating the inapplicability of standard categories of political classification. Recent scholars have been more appreciative of the post-1648 empire as a loose-jointed but not ineffective constitutional edifice within which could coexist 300 large and small, secular and ecclesiastical principalities, 51 imperial (i.e., immediate to the empire) cities, and nearly 2,000 imperial counts and knights, each of whom possessed the same territorial sovereignty as an elector or a duke. The empire proved a working federation for the varied interests of these distinct sovereign entities, some of them large and powerful (like Saxony, whose electors were also kings of Poland from 1697 to 1763, or Brandenburg, whose prince was also king in Prussia) and some laughably tiny (such as the Abbey of Baindt in Swabia, a fully independent territory of a few hundred acres inhabited by 29 nuns and governed by a princess-abbess).

The Magdeburg massacre

The Treaties of Westphalia

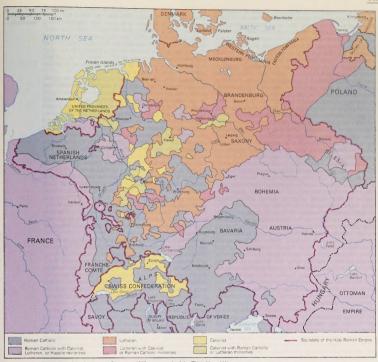

Germany in 1648

The empire's administrative organs, especially the districts (Kreise), protected the small and weak from the predatory aims of the strong. Because most constituent members were vulnerable, there was no general inclination, despite disunity among the estates on matters of taxation and religious parity, to break the frame that guarded the status quo. The emperor's suzerainty over the entire realm went unchallenged, but virtually no real power adhered to his title, executive authority having been thoroughly particularized between 1555 and 1648. To prevent a resurgence of imperial power, princes formed alliances among themselves, such as the League of the Rhine (Rheinbund), tied in 1658 to France and Sweden. In the princely territories authority fell increasingly to the princes (exceptions were Württemberg and Mecklenburg), while territorial estates dwindled in political importance. In each of the empire's constituent units, estates served mainly to uphold established hierarchies and traditions, as did the empire as a whole. It was an inherently conservative system.

The consolidation of Brandenburg-Prussia and Austria. Against an overall tendency among the empire's constituent units to keep things as they were, the larger

territories pursued an insistent policy of dynastic and personal aggrandizement. A number of factors favoured state building in the post-1618 era. General economic exhaustion made central direction of, and active intervention in, commerce and industry seem to be the only way out of stagnation. War taxes, raised to a steep level during the French wars of the 1670s (see below), greatly increased the financial might of rulers, who came to control an unprecedented share of society's wealth by preparing for and engaging in military conflict. Because territorial assemblies opposed this siphoning process—whose proceeds, augmented by subsidies from abroad, served mostly to create standing armies and a supporting state apparatusrulers attempted to reduce even further the estates' role in policymaking. The nobility, growing economically dependent on princely service, adapted itself to an essentially ancillary function at court. In society at large the view gained ground that the country's welfare was safest with the ruler-a view vigorously promoted by official propaganda. Two of the empire's territories, Brandenburg-Prussia and Austria, profited above all others from these developments.

The range of confessions in Germany, 1650, as a result of the Thirty Years' War.

Frederick William, the "Great Elector"

The story of Brandenburg-Prussia has always been read as exemplifying the triumph of political skill and audacity over unfavourable conditions. Sparsely populated and deficient in resources, Brandenburg in 1648 was a patchwork of scattered territories. Its ruler, Frederick William (1640-88), later called for his achievements the "Great Elector," faced the problem of integrating and defending widely separated possessions, which included the duchy of Prussia, inherited in 1619 but remaining under Polish suzerainty and geographically separated from the electorate; the counties of Cleves, Mark, and Ravensberg in the Rhine and Westphalia regions, gained in 1614, also distant from Brandenburg and not contiguous with each other; and eastern Pomerania and various small lands and bishoprics acquired in the Treaty of 1648. Through nimble diplomatic maneuvering, such as changing sides several times between Sweden and Poland and beweeen France and the emperor, he augmented and solidified his realm and his authority within it; he won direct rule over Prussia as its duke and acquired the important episcopal territory of Magdeburg.

Frederick William's instrument in the attainment of these and subsequent prizes was the army, a permanent force of 30,000 disciplined professionals, the adequate financial support of which dictated every aspect of his government. Large revenues from taxes required a flourishing economy, the stimulation and direction of which by mercantilist

principles was a main undertaking. Economic growth was further accelerated late in the Great Elector's reign by the influx of nearly 20,000 skilled Huguenot refugees following the revocation of the Edict of Nantes by Louis XIV in 1685 and by the resettlement of Dutch colonists. A territorywide system of state administration undergirded this economic and fiscal effort and resulted in the creation of a professional bureaucracy that permitted the Great Elector to govern essentially without estate participation. The land-owning nobility supported their prince in exchange for the freedom to exploit their peasants as they saw fit. In these ways Frederick William laid the foundation for what was to become an autocratically ruled state, enabled by its strong economy, tightly run administration, efficient fiscal organization, and powerful army to play a prominent role in the empire's and Europe's affairs.

The Great Elector's efforts were rewarded in 1701 when his successor. Frederick III (1688–1713), obtained from the emperor (who needed the Brandenburg army for the impending War of the Spanish Succession) the right to style himself "King in Prussia." The title, recognized internationally upon the conclusion of the war in 1713, was of considerable importance to Brandenburg in its competition with Saxony, whose ruler had become king of Poland in 1697, for preemience in north Germany. But it was Frederick's son, Frederick William I (1713–40; Prussian rulers renumbered themselves upon bestowal of the royal

"King in Prussia"

title) who perfected the combination of statist structure, productive energy, and ethical drive that came to be identified with modern Prussia. Known as the "soldier-king," Frederick William built his standing army into a force of more than 80,000 men. It was the fourth largest army in Europe (after those of France, Russia, and Austria) in a country only thirteenth in population, superbly drilled and equipped but serving mainly defensive purposes. Only peasants and journeymen served in the ranks, many of whom were impressed abroad, while the middle classes were safe from the draft but obliged to quarter soldiers in their homes. A huge war chest obviated foreign subsidies, and reliable revenues, more than 70 percent of which went to the army, provided ample support,

To continue to draw high taxes without ruining land and people, the country's level of wealth had to be raised. Frederick William therefore pursued an aggressive mercantilist policy of stimulating agriculture and manufacturing while reducing unnecessary expenditures; even his court was stripped of many of its royal trappings. Export bans preserved raw materials, and sumptuary laws limited indulgence in luxuries. Town governments ceded authority to royal commissioners, whose powers included supervision of urban production. A work ethos suffused society from the top; the king's ascetic Calvinism, which dictated to him a life of hard work and personal engagement, was spread to his Lutheran subjects by a Pietist clergy who instilled in their flocks habits of intense labour, frugal living, and dutiful subservience to the state.

Organizationally, Frederick William completed the centralizing process begun by the Great Elector, its capstone being the General Directory, set up in 1723. Tied to regional and local organs by a network of commissioners, this supreme body of state policy and administration directed industry, trade, finance, internal affairs, and military matters in all the state's territories. Upper-level bureaucrats came entirely from the nobility, as did the army's officer corps; in this way nobles were bound more closely than ever to the state. Ruling, not merely reigning, over the entire edifice was the king-elector in his "cabinet," a small circle of close advisers and trusted secretaries. So successful were these measures in lifting the state to influence and prestige that by 1740 Prussia counted as a full-fledged member of Europe's concert of great powers. In Austria, the ruling Habsburg house's lasting conflict

with France and the Ottoman Empire dominated all questions of statecraft. With their powers as emperors greatly diminished, Leopold I (1658-1705), his son Joseph I (1705-11), and Joseph's brother Charles VI (1711-40) bent all their efforts to the consolidation of their dynastic and crown lands in central and eastern Europe. Although they failed to achieve Prussian-style streamlining, they raised Austria to the rank of a major state. The Habsburgs' conglomeration of territories included the Austrian duchies (Austria, Styria, Carinthia, Krain, and the county of Tirol), the Bohemian provinces (kingdom of Bohemia, Moravia, Silesia), the kingdom of Hungary, and-after 1714, following the War of the Spanish Succession-the southern Netherlands (Brabant, Luxembourg, Flanders) and the duchy of Milan.

These disparate lands were held together only by the Habsburg monarchy, but the monarchs were distracted from the task of integrating them. They were preoccupied by imperial concerns and by dynastic complications, notably the succession question. Until the reforms of Maria Theresa's reign (1740-80) Austrian administration never became effective. Finances were especially muddled, because tax administration remained with the estates of the various territories, along with control over other sources of revenue. The army of 100,000 men, though the third largest in Europe, was barely adequate for the defense of so large and scattered a realm. A supreme war council and a central financial chamber overlapped with special commissions created by the emperor's privy council, which also handled military and fiscal affairs. Nonetheless, the realm held together.

The prospect of a succession without a male heir, however, presented the severest test to the realm's cohesion. It became the chief enterprise of Charles VI to persuade the estates of his territories to accept an order of succession known as the "Pragmatic Sanction," by which the Habsburg lands were declared indivisible and Charles's oldest daughter, Maria Theresa, was to inherit them. The other European powers assented, because splitting the Habsburg complex would have thrown the European balance into disarray and played into the hands of France; the Sanction was proclaimed a basic law in 1713. By then Austria had met successfully a series of Turkish incursions from the east and French invasions in the west.

The age of Louis XIV. For the empire as a whole, the half century following the Peace of Westphalia was almost entirely shaped by the dominant political figure of the time, King Louis XIV of France. The response of the empire and its members to the aggressive undertakings of this monarch, whose aim from his assumption of power in 1661 to his death in 1715 it was to make France the mightiest state in Europe, was largely reactive (for a different interpretation, see the article FRANCE: The age of Louis XIV: Foreign affairs). Only in its struggles against Louis's ally in the east, the Ottoman Turks, did the empire show some initiative. After a Polish relief army had helped imperial, Bavarian, and Saxon troops to lift a three months' Turkish siege of Vienna in 1683 in the Battle of Kahlenberg, imperial armies took the offensive. winning battles at Ofen (1686), Mohács (1687), and, most notably, Zenta (1697). In the Treaty of Carlowitz (1699) Austria gained parts of Hungary, Transylvania, Slavonia, and Croatia, all of them formerly occupied by the Turks. The eastern wars resumed in the early and mid-18th century, but the Turks were never again a threat to Europe, since Russia became the chief bulwark against Ottoman expansionism.

Matters were different on the empire's western and southern fronts. The overriding political question in Europe in the second half of the 17th century was the future of Spain and its vast holdings in the southern Netherlands, Italy, and America, because it was expected that the Spanish Habsburg line would die out with the feeble Charles II Contenders for the Spanish inheritance were the Habsburg emperor, Leopold I, husband of a younger Spanish princess, and Louis XIV. The French monarch, son of the eldest daughter of Philip III, had further strengthened his claim to the Spanish throne in 1659 when, in accordance with the Peace of the Pyrenees, which had ended the long conflict between Spain and France, he had married the Spanish infanta.

While waiting for the Spanish throne to become vacant, Louis pursued an aggressive expansionist policy. He pushed his forces toward Germany to make the Rhine River France's new eastern border. In 1667 he occupied Flanders and in 1670 Lorraine; in 1672 he attacked Cleves and invaded the United Provinces of the Netherlands. his main antagonist in the wars that followed. In 1679 he began to penetrate Alsace, occupying the imperial city of Strassburg (Strasbourg) in 1681. Lacking the military power to bring the whole empire to its knees, Louis resorted to the lure of money; at one time or another almost every German state was in his pocket, either serving as ally or remaining neutral. Though not incapable of acting on national impulses, German princes-the Great Elector being a case in point-always served territorial interests first. This prevented the emperor, himself at times allied with Louis, from forging a solid front against France.

Leadership of the anti-France coalition passed to the Netherlands. William of Orange, as stadtholder of Holland and captain general of the United Provinces, emerged as the most determined opponent of French aggression. Upon becoming king of England in 1689, he changed the direction of English politics, which had been pro-French under the last Stuart king. The threat of a French universal monarchy arose dramatically as the death of the last Habsburg in Spain approached (Charles II died in 1700) and Louis's plans for a French claim on the entire Spanish inheritance swung into place. A Grand Alliance now formed against him (it was formally concluded in 1701), consisting of the empire (except Bavaria and the electorate of Cologne), the Netherlands, England, Sweden, Brandenburg-Prussia, and Savoy. Its aim was to restore

War of the Snanish Succession

the European balance to the status of 1648 and 1659 by ejecting Louis from his conquests and by splitting the Spanish empire.

The first phase of the ensuing struggle, known in Germany as the Palatine War, was fought in Germany. It led to savage destruction in the Palatinate and in Swabia but to no decisive victories on either side. A temporary peace (Riiswijk, 1697) forced Louis to make concessions and perhaps to realize the limits of his strength; his revocation of the Edict of Nantes in 1685 had set Protestants everywhere against him. The long-prepared War of the Spanish Succession broke out in 1701. The empire played a minor role in this conflict, Louis having failed in his diplomatic effort to enlarge the simultaneous Northern War of Sweden against Denmark, Russia, and Saxony into an attack on Brandenburg-Prussia. Austria, however, proved a major antagonist in this last attempt by the grand monarque to gain the upper hand. While Austrian and English troops operated in Italy, French and Bavarian forces fought in southern Germany. Neither side won clear victories, but the alliance gradually gained the advantage, until the death of emperor Joseph I in 1711 placed his brother Charles, who had been proclaimed Spanish king, on the imperial throne as Charles VI (1711-40). This raised the spectre of a Habsburg reunion of the Holy Roman and Spanish empires, which was no more agreeable to European powers than the prospect of French overlordship. Thus the alliance severed

Peace negotiations began in 1712, resulting in a number of treaties, signed at Utrecht and Rastatt in 1713-14. The Spanish empire was partitioned, with the Spanish Netherlands, Milan, Naples, and Sicily going to Austria and Spain itself coming under the rule of Philip V of Bourbon, a grandson of Louis XIV. The alliance's original aim, to prevent French hegemony, had been achieved, though in the follow-up War of the Polish Succession (1733-35) France acquired control of Lorraine. Austria profited substantially in territorial terms, and a few other German rulers profited as well, albeit less so. As for the empire itself, it had gained no real benefits from more than half a century of intermittent warfare.

German society, however, was deeply affected. Economic stagnation and slow demographic recovery after the Thirty Years' War made Germany dependent on governmental intervention as a means of stimulating recovery. This left the country exposed to foreign influences, which reached land and people by way of the many princely courts and the elites clustered there.

German cultural life took its cues from abroad: Baroque art-the preeminent expression of monarchical power and of Roman Catholic resurgence after the Reformationcame from Spain and Italy, opera from Italy, and polite language and manners from France. The style of this period took French patterns as its model, from elaborately coded court ceremonials to dress, social conventions, food, and conversation. French absolutism not only became the political model, however scaled down, for the governance of all states in the empire, but every German prince and princeling imitated the lavish display with which Louis XIV created his aura of majesty and outshone his rivals. This started up a lively domestic market in luxuries, not to mention splendid works of architecture and decoration. But the cost of these luxuries was prohibitive (in 1719 the Palatine court consumed 50 percent of the territory's revenues) and represented an enormous burden on the people, especially when added to the cost of large armies and proliferating bureaucracies. Not only did this conspicuous consumption widen the social division between the court-oriented elite and the bulk of the urban and rural population but the culture's foreign provenance of the goods also inhibited creative impulses at home.

In the second half of the 17th century German energies were to a large extent still focused on religion. The confessional pluralism legitimized by the settlement of 1648 encouraged emphasis on theological distinctions, exacerbating the move toward religious orthodoxy under way in each denomination since the 16th century. The one genuinely German product of this religious preoccupation was Pietism. It was a religious movement within Lutheranism that opposed rigid dogmatism and promoted instead a subjective, mystical devoutness and an emphasis on a pious life guided by love of one's neighbour as well as of God. Influenced by English Puritanism, Pietism was shaped in its theology by Philipp Jakob Spener (1635-1705) and in its organization by his disciple August Hermann Francke (1663-1727), who established a centre for its promulgation in the Brandenburg city of Halle. There he founded schools, orphanages, medical facilities, and a printing house for publishing cheap Bibles and devotional works, which made of Pietism a widely influential program of evangelical activism. The intensely emotional and mystical flavour of Pietist poetry is preserved in the cantata texts set to music by Johann Sebastian Bach, in whose deeply spiritual church music Protestant chorale singing, another indigenous German product, reached its apogee

The contest between Prussia and Austria. In 1740 the death of the Habsburg emperor Charles VI without male heir unleashed the most embittered conflict in Germany since the wars of Louis XIV. The question of who would ascend the Austrian throne had occupied statesmen for decades. Rival claimants disputed the right-by the terms of the Pragmatic Sanction (1713)-of Charles's daughter Maria Theresa to succeed; France supported them, its aim being, as before, the fragmentation of the Austrian state. But it was the new Prussian king, Frederick II (1740-86), who began the conflict. To understand what follows, the modern reader should remember that few observers, even in the enlightened 18th century, disputed a ruler's right to do what he wished with his state. Dynastic aggrandizement, territorial expansion, prestige, honour, power, and princely glory were legitimate grounds for war and sound reasons for demanding the sacrifices necessary to wage it. The only position from which to oppose this arrogation was the Christian ethic, but to do so had proved futile when last tried by Erasmus and Sir Thomas More in the 16th century. No checks-philosophical, moral, or political-therefore restrained kings from indulging their taste for conquests.

Soon after taking control of affairs, Frederick reversed his father's cautious policy of building and hoarding, rather than consuming, Brandenburg-Prussia's military potential. He attacked Silesia, a province in the kingdom of Bohemia and thus part of the Habsburg monarchy, which Prussia had long desired for its populousness, mineral resources, and advanced economy. In exchange for an Austrian cession of Silesia he offered to accept the Pragmatic Sanction (formally recognized by his predecessor in the Treaty of Berlin in 1728) and support the candidacy of Maria Theresa's husband, Francis Stephan, as emperor, But the resolute woman who now headed the Austrian Habsburgs (1740-80) decided to defend the integrity of her realm. and war began in 1740. Austria was helped only by a Hungarian army, though financial support came from Austria's ally, England. Prussia was joined by Bavaria and Saxony in the empire as well as by France and Spain. The Prussian armies, though greatly outnumbered against forces that included troops from Russia and Sweden, revealed themselves as by far the best as well as the best led. In the Treaty of Hubertusburg of 1763 Prussia kept Silesia but could not hold on to Saxony, which Frederick had invaded in 1756 and which he coveted as a way of rounding out his state.

In a sense, the War of the Austrian Succession (1740-48) was another of the many internal struggles over the constitutional balance in the empire in which territorial states opposed imperial authority. But it was also part of an international struggle, with France and England fighting out their rivalry in western and southern Europe, America, and India. Thus it blended into the worldwide Seven Years' War (1756-63), the latter being preceded by a "Diplomatic Revolution" in which England switched its support to Prussia and France allied itself with its traditional foe. Austria (a part of this agreement was the marriage, in 1770, of the Austrian princess Marie Antoinette to the future Louis XVI). The real significance of the Seven Years' War lay in the Peace of Paris of 1763, which concluded for a time the maritime and colonial conflict between France and England.

War of the Austrian Succession

Austria having survived the war and Prussia having increased in size and immeasurably in prestige, these two powers now dominated German affairs in a condition of tension usually called "the German dualism," meaning that each had become so powerful that only the other could keen it in some sort of check. The monarchs of both realms carried out important internal reforms. Guided by her interior minister. Count Friederich Wilhelm Haugwitz, Maria Theresa streamlined the Austrian administrative structure on the Prussian model, thus drawing together, to the extent possible, the multiethnic and polyglot regions of the far-flung Habsburg empire. The remaining powers of the estates were curtailed everywhere and centralization institutionalized in absolutist fashion but without attaining the full integration of the Prussian system. Maria Theresa's son, Joseph II (1765-90), completed this program of modernization

In Prussia, Frederick II further tightened his control of all aspects of public life in his far-flung kingdom. But in accordance with his personal commitment to rational tolerance and free-thinking skepticism he also undertook extensive legal reforms; he virtually abolished judicial torture, lifted some of the tax burden from the poorest of his subjects, established religious tolerance as a policy of his state, and encouraged scientific and scholarly activity in the Prussian Academy. Like his father, he was a vigorous promoter of economic development and colonization. His taste for French Enlightenment thought and his own prolific creativity in letters and music lent to his reign the flavour of an era shaped by a philosopher-king, albeit one with the instincts of a ruthless power politician. His successes in war and peace earned him a place as national hero as well as the title "the Great." (Ge.St.)

Germany from c. 1760 to 1871

GERMANY TO 1815

Germany in the middle of the 18th century was a country that had been drifting in the backwaters of European politics for more than a hundred years. The decisive roles in the affairs of the Continent were played by those great powers-such as France, England, and Spain-whose economic resources and commercial connections provided a solid foundation for their military might. The states of central Europe, on the other hand, floundered in a morass of provincialism and particularism. All the forces that had contributed to the rise of powerful national monarchies west of the Rhine were lacking in the east. In the Holy Roman Empire the central government was losing rather than gaining strength, the princes were enlarging their authority at the expense of the crown, and business initiative was being discouraged by the lack of political unity and by the remoteness of the major trade routes.

Civic power became increasingly concentrated in the hands of local governments controlled by aristocratic overlords, ecclesiastical dignitaries, or municipal oligarchs. The history of Germany between the Thirty Years' War and the French Revolution is largely the sum total of the histories of dozens upon dozens of small political units, each enjoying virtually full rights of sovereignty. The rulers of these gingerbread principalities, copying the example of the royal court of France or Austria, built costly imitations of the palaces of Versailles and Schönbrunn, which today are the delight of tourists but which were once the curse of an impoverished peasantry. The tradition of princely authority, an instrument of national greatness in western Europe, encouraged national divisiveness in central Europe. The petty rulers of Germany legislated at will, levied taxes, concluded alliances, and waged wars against each other and against the emperor. Policies pursued in Munich, Stuttgart, Dresden, or Darmstadt reflected policies originating in Paris, Vienna, London, or Madrid but without seeking a goal greater than the promotion of particularistic interests.

Political institutions designed theoretically to express the will of the nation continued to function, yet they had become an empty shell. The Holy Roman emperor was still elected in accordance with a time-honoured ritual that proclaimed him to be the successor of Caesar and Augus-

tus. The splendid coronation ceremony in Frankfurt am Main, however, could not disguise the fact that the office conferred on its holder little more than prestige. Since all the emperors except Charles VII were Habsburgs by birth or marriage, they enjoyed an authority that had to be respected. But that authority rested not on the prerogative of the imperial crown but on the possession of hereditary lands stretching from Antwerp in the west to Debrecen in the east. The sovereigns of the Holy Roman Empire in other words, were able to play an important role in German affairs by virtue of their non-German resources. And, since Germany was not the main source of their strength, Germany was not the main object of their concern. The emperors tended to regard the dignity bestowed upon them as a means of furthering the interests of their dynastic holdings. The Imperial Diet meeting in Regensburg had also become an instrument for the promotion of particularistic advantage rather than national welfare. It continued in theory to express the will of the estates of the realm meeting in solemn deliberation. In fact it had degenerated into a debating society without authority or influence. The princes had ceased to attend the sessions. so that only diplomatic representatives were left to discuss questions for which they were powerless to provide answers. The other central institutions of the empire, such as the imperial cameral tribunal in Wetzlar, languished in indolence. Constitutionally and politically, Germany in about 1760 resembled Poland in that a once vigorous and proud state had become weakened by internal conflict to the point that it invited the intervention of its more powerful neighbours.

What saved Germany from the fate of Poland was the ability of one of the member states to defend the empire against aggression. For 200 years Austria acted as the bulwark of central Europe against French expansion. Its possessions, forming a chain of protective bases extending between the North Sea and the Danube, had time and again borne the brunt of attacks by Bourbon armies. The frontiers of France kept moving closer to the Rhine, but the Holy Roman Empire was at least spared the tragedy of partition that befell the Polish state. It was partly in recognition of the vital role that the Habsburgs played in the defense of Germany that the electors chose them as emperors with such regularity. The Austrian monarchy, moreover, endowed with resources comparable to those of the western nations, was able to pursue a policy of political rationalization with greater success than the principalities. The rulers in Vienna succeeded in improving the administration, strengthening the economy, and centralizing the government. Until the middle of the 18th century, Austria remained the only great power east of the Rhine.

Further rise of Prussia and the Hohenzollerns. emergence of the Hohenzollerns as rivals of the Habsburgs and the beginning of the Austro-Prussian dualism created the possibility of reversing the process of civic decentralization that had prevailed in central Europe since the late Middle Ages. The interests of the territorial princes of the Holy Roman Empire inclined them toward a policy of particularism, while the government of Austria, with its Flemish, Italian, Slavic, and Magyar territories, could not perforce become the instrument of German unification. Prussia, on the other hand, was militarily strong enough and ethnically homogeneous enough to make national consolidation the main object of statecraft. But, though the creation of a united Germany became its mission, this mission was not from the outset one that it accepted willingly or even consciously. The intention of Frederick the Great and of his successors Frederick William II and Frederick William III was to pursue dynastic rather than national objectives. Like the lesser princes of central Europe, all they sought was to maintain and enlarge their authority against the claim of imperial supremacy. Far from wanting to end the disunity of Germany, they hoped to prolong and exploit it. The patriotic Prussophile historians, who a hundred years later argued that what Bismarck had achieved was the consummation of what Frederick had sought, were letting the present distort their understanding of the past. In fact, the greatest of the Hohenzollerns had remained as indifferent to the glaring

The traditional role of the Austrian Habsburgs

The Holy Roman Empire

political weaknesses of his nation as to its great cultural achievements. His attitude toward the constitutional system of the Holy Roman Empire was similar to that of the self-seeking princelings who were his neighbours and from whom he was distinguishable only by talent and power. He may have scorned their sybaritic way of life, but politically he wanted what they wanted-namely, the freedom to seek the advantage of his dynasty without regard for the interests of Germany as a whole.

His preoccupation with the welfare of his state rather than with that of his nation is apparent in the strategy by which he tried to check Habsburg ambitions after the Seven Years' War (1756-63). During the first half of his reign he had relied primarily on military force to restrict and undermine imperial authority. In the second half he preferred to employ the weapons of diplomacy to achieve the same end. In 1777 the ruling dynasty of Bavaria came to an end with the death of Maximilian Joseph. The elector of the Palatinate, Charles Theodore, now became ruler over the territories of both branches of the house of Wittelsbach. Without legitimate offspring to whom to leave his state and without affection for his newly acquired eastern possessions, he agreed to a plan proposed by Emperor Joseph II according to which part of the Bayarian lands would be ceded to Austria. But any increase in the strength of the Habsburgs was unacceptable to Frederick the Great. With the tacit approval of most of the princes of the empire, he declared war against Austria in 1778, hoping that other states within and outside central Europe would join him. In this expectation he was disappointed. Yet Joseph also became discouraged by the difficulties encountered in what he had believed would be an easy success. The War of the Bavarian Succession dragged on from the summer of 1778 to the spring of 1779, with neither side enhancing its reputation for prowess on the field of battle. There was much marching back and forth. while hungry soldiers scrounged for food in what came to be called the "Potato War." The upshot was the Treaty of Teschen (May 1779), by which the Austrian government abandoned all claims to Bavarian territory except for a small strip along the Inn River. The conflict had brought Frederick no significant military victories, but he had succeeded in frustrating Habsburg ambition.

The War

Bayarian

Succession

of the

Joseph II, however, was a stubborn adversary. In 1785 he once again advanced a plan for the acquisition of Wittelsbach lands, this time on an even more ambitious scale. He suggested to Charles Theodore nothing less than an outright exchange of the Austrian Netherlands for all of Bayaria. The emperor, in other words, proposed to surrender his distant possessions on the North Sea, which were difficult to defend, for a territory that was contiguous and a population that was assimilable. The scheme went far beyond that which Prussia had defeated seven years before, and Frederick opposed it with equal determination. He hoped to enlist the diplomatic aid of France and Russia against what he regarded as an attempt to upset the balance of power in central Europe. But, more than that, he succeeded in forming an Association of Princes, which 17 of the more important rulers in Germany joined. The members pledged themselves to maintain the fundamental law of the empire and to defend the possessions of the governments included within its boundaries. The growing opposition to the absorption of Bavaria by Austria persuaded Joseph that the risks inherent in his plan outweighed its advantages. The proposed exchange of territories was dropped, and Frederick could celebrate yet another triumph of his statecraft, the last of an illustrious career. But the association of princes that he founded did not survive its author. Its sole purpose had been the protection of princely prerogative against imperial authority. Once the danger had passed, it lost the only justification for its existence. Those nationalists who later maintained that it foreshadowed the creation of the German Empire misunderstood its origins and objectives. It was never more than a weapon in the struggle for the preservation of a decentralized form of government in central Europe.

The subordination by the Hohenzollerns of national to dynastic interests was even more apparent in the role they played during the partitions of Poland. Frederick the Great was the chief architect of the first partition, that of 1772, by which the ill-starred kingdom lost about a fifth of its inhabitants and a fourth of its territory to Prussia, Russia, and Austria. His successor, Frederick William II. helped to complete the destruction of the Polish state by the partitions of 1793 (between Prussia and Russia) and 1795 (between Prussia, Russia, and Austria). The result was bound to be an enhancement of Prussia's role in Europe but also a diminution of its role in Germany. The Hohenzollerns willingly embarked on a course that would in time have transformed their kingdom into a binational state comparable to the Habsburg empire. The German population in the old provinces would have been counterbalanced by the Slavic population in the new; the Protestant faith of the Prussians would have had to share its influence with the Roman Catholicism of the Poles; the capital city of Berlin would have found a competitor in the capital city of Warsaw. In short, the centre of gravity of the state would have shifted eastward, away from the problems and interests of the Holy Roman Empire. Yet the rulers of Prussia did not shrink from a policy that was likely to have such far-reaching consequences. They never contemplated sacrificing the advantage that their state would gain from an enlargement of its resources in order to assume the role of unifiers of their nation. Such a political attitude would have been an anachronism during the age of princely absolutism in central Europe. It was not design but accident that before long led to the abandonment by Prussia of most of its Polish possessions and that thereby allowed it to continue to play a vital part in that thereby the thereby the affairs of Germany.

The cultural scene. Whereas in England the great liter-

ary epoch of Queen Elizabeth I had coincided with commercial and naval expansion, and in France the golden age of classicism had added lustre to the military glory of Louis XIV, German arts and letters flourished amid tiny principalities and somnolent towns that could only envy the powerful national monarchies west of the Rhine. Moreover, whereas in France and England, where public opinion could exert a significant influence on government. the debate over issues of state and society was conducted with a vigour that reflected its importance, in Germany the debate was bound to remain purely theoretical. No Voltaires, Rousseaus, or Burkes were likely to emerge out of such an environment. The thinkers of central Europe tended to emphasize introspection and spirituality. Culture became an escape from the narrow world of princely absolutism. Intellectual energies that could not reform the community fought to emancipate the individual through

self-purification and self-perfection.

This was the background of German idealism, a philosophical movement seeking to liberate ethics and aesthetics from the shackles of empirical knowledge. Armed with the weapons of Kantian thought, it attempted to prove that there was a realm of experience lying beyond the categories of scientific investigation: the realm of the good, the true, and the beautiful. There were realities of the spirit and the mind, in other words, that were inaccessible to the practicality of the British empiricists or the intellectualism of the French rationalists. The disciples of idealism hoped to transcend the barriers created by nation, class, and religion. They spoke in the name of humanity as a whole, which manifested its underlying harmony through the infinite variety of its political, social, and theological categories. Gotthold Ephraim Lessing pleaded for religious toleration on the basis of a common system of ethical values to which all men of goodwill could subscribe. Johann Gottfried Herder preached that the unique character and meaning of each culture contributed to the richness of common humanity that defied state boundaries. Johann Joachim Winckelmann deified the classical ideal of beauty that he found in Greek art as an eternal standard, immune to the vicissitudes of time and history. These were views that offered an escape from the narrowness of everyday life. Men who found no scope for their talents in the petty world of princely authority could turn to the liberating spirituality of the idealist philosophy. Thought in central Europe gradually acquired a metaphysical coloration that distinguished it from the more robust pragmatism of phi-

und Drang

movement

losophy in the west. It was during the second half of the 18th century that the Germans began to consider their country "the land of thinkers and poets."

The literary revival of the age displayed the same quality of introspective idealism as the philosophical movement. Johann Wolfgang von Goethe, the greatest genius of German letters, willingly accepted the existing system of civic and social values. He regarded the disunity of his nation as an expression of its historic character and defended the authority of the petty princes as an instrument of good government. He urged his countrymen to seek greatness not in collective action but in individual perfectibility. After a period of youthful rebellion against traditional canons of literary propriety, he turned to a classicism in which a serene acceptance of life harmonized with his own sympathy for the established order. Friedrich Schiller, a man of more turbulent temperament, felt a sense of resentment against political injustice and weakness. In his plays and poems there are occasional outbursts of indignation and appeals for reform. Yet there is also a pessimistic mood of resignation induced by the burden of civic ineffectualness that history had imposed on his people. Ultimately, he too sought refuge from the world in the poet's private vision. The Sturm und Drang ("Storm and Stress") was a movement of literary innovation through which a group of young writers in the last decades of the 18th century sought to throw off the voke of accepted standards of composition, but it remained confined to problems of prosody and taste, refusing to grapple with political or social issues.

The cultural achievements could not alter the harsh realities of national fragmentation and princely autocracy. They supported, however, the ideals of rational reform and social progress that the Enlightenment had introduced throughout the Continent. In Germany as elsewhere the 18th century became the age when the monarchical principle advanced the loftiest justification of its claim to power. The authority of the prince, so the argument went, was to be exercised not for his private advantage or gratification but for the greatness of his state and the welfare of his people. His power had to be unrestricted so that his benevolence might be unlimited. Absolute government was the only effective instrument for achieving the general good. Impressed by the scientific discoveries and material advances that they saw about them, men began to believe that the prejudices and injustices that had plagued society would gradually disappear before the steady march of reason.

Enlightened reform and benevolent despotism. The main source of enlightened reform was to be the crown. but many well-intentioned people of means and education also began to apply a new standard of conduct in their dealings with their fellow man. This change in attitude was apparent in the decline of religious resentments and discriminations. Never before had the relationship between Roman Catholics and Protestants among the well-to-do classes of central Europe been as free of rancor as on the eve of the French Revolution. It was at this time also that the Jews first began to emerge from the isolation to which a deep-seated intolerance had consigned them. The idea of assimilation held out to them the prospect of escape from the ghetto on the condition that they identify themselves in thought, speech, and attitude with the Christian society in which they lived. That prospect was to attract the Jewish minority in Germany more and more during the next 150 years. Religious toleration, however, was not the only article of faith of the Enlightenment. Its vision of a happier future included the reformation of education, the abolition of poverty, the alleviation of sickness, and the elimination of injustice. Men of goodwill established schools, founded orphanages, built hospitals, improved farming methods, modernized industrial techniques, and tried to raise the standard of living of the masses. While the hopes of the enlightened reformers of the 18th century far outstripped their accomplishments, the practical results of their efforts should not be underestimated.

According to the doctrines of benevolent despotism, however, the chief instrumentality for the improvement of society was not private philanthropy but government action. The state had the primary responsibility for preparing

the way for that golden age which, in the opinion of many intellectuals, awaited humankind. The extent to which official policy conformed to rationalist theory depended, in central Europe as elsewhere, on the personality and ability of the ruler. Both of the leading powers of the Holy Roman Empire followed the teachings of benevolent despotism but with substantially different results. The emperor Joseph II a well-meaning though doctrinaire reformer, attempted to initiate a revolution from above against the opposition of powerful forces that continued to cling to tradition. In the course of a single decade he tried to centralize the government of his far-flung domains, reduce the influence of the church, introduce religious toleration, and ease the burden of serfdom. His uncompromising program of innovation however, alienated the landed aristocracy, whose support was essential for the effective operation of the government. The emperor encountered mounting unrest that did not end until his death in 1790 and the subsequent abandonment of most of the reforms that he had promulgated. Frederick the Great was more successful as an enlightened autocrat, but only because he was more cautious. His reorganization of the government was not as drastic, his belief in religious toleration remained less profound, and his assistance to the peasants did not go beyond a prohibition against the absorption of their holdings by the nobility. He invited settlers to cultivate reclaimed lands, and he encouraged entrepreneurs to increase the industrial capacity of Prussia. Among his most important accomplishments. although it was not completed until after his death, was the Prussian Legal Code, which defined the principles and practices of an absolute government and a corporative society. Yet Frederick was also convinced that the Prussian landed noblemen, the Junkers, were the backbone of the state, and he continued accordingly to uphold the alliance between crown and aristocracy on which his kingdom had been built.

The achievements of benevolent despotism among the minor states of the Holy Roman Empire varied considerably. Some princes employed their inherited authority in a serious effort to improve the lot of their subjects. Charles Frederick of Baden, for example, devoted himself to the improvement of education in his margravate, and he even abolished serfdom, though without eliminating manorial obligations. Charles Augustus of Saxe-Weimar-Eisenach was a hardworking administrator of his small Thuringian principality, whose capital he transformed into the cultural centre of Germany. Charles Eugene of Württemberg, on the other hand, led a life of profligacy and licentiousness in defiance of protests by the estates of the duchy. Frederick II of Hesse-Kassel was another princely prodigal whose love of pleasure impoverished his subjects and forced his soldiers into mercenary service for England. The record of enlightened autocracy in central Europe was as uneven as in western Europe. Yet the ideas of the Enlightenment even at their best were unable to transform the basis of political life in the Holy Roman Empire. They could palliate, reform, and improve, but they could not alter a system of particularistic sovereignty and absolutistic authority resting on a hierarchical structure of society. They could not become an instrument of national consolidation or representative government. Only some great creative disruption of existing civic institutions could break through the crust of habit and tradition sanctified by history. Germany lacked the vital energies required for a process of political reconstruction. The galvanizing forces of rejuvenation and regeneration were to come from the outside.

The French Revolutionary and Napoleonic era. The French Revolution, transforming the Bourbon kingdom into a constitutional state, aroused intense excitement east of the Rhine. Most German intellectuals were at first in sympathy with the new order in France, hoping that the defeat of royal absolutism in western Europe would lead to its decline in central Europe as well. The princes, on the other hand, were from the outset fearful of the Revolution, which they regarded as a serious danger, for the example of unpunished insubordination by the French might encourage demands for reform among the Germans. The result was a growing hostility between the government in Paris and the rulers of the Holy Roman

Attempts at social and political reform

The end of the old

order

Empire, which led in the spring of 1792 to the outbreak of war (the War of the First Coalition, 1792-97). The immediate occasion of the conflict was a quarrel over the rights of German princes with holdings in France and over the propagandistic activities of French émigrés in Germany. But the underlying cause was the clash of two incompatible principles of authority divided by profound differences regarding the nature of political and social justice. The course of hostilities soon revealed that the civic ideals and military tactics of the French Revolution were more than a match for the decrepit Holy Roman Empire. After 1793 the left bank of the Rhine remained under the control of France, and for the next 20 years its inhabitants were governed from Paris. Yet there is no evidence that they were dissatisfied with French rule or at least that they strongly opposed it. Devoid of a sense of nationalism and accustomed to submission to authority, they accepted their new status with the same equanimity with which they regarded a succession to the throne or a change in the dynasty. The Prussians, moreover, discouraged by defeats in the west and eager for Polish spoils in the east, concluded a separate peace at Basel in 1795 by which they in effect recognized the French acquisition of the Rhineland. The Austrians held out two years longer, but the brilliant successes of the young Napoleon Bonaparte forced them to accept the loss of the left bank in the Treaty of Campo Formio (Oct. 17, 1797).

End of the Holy Roman Empire. The peace proved short-lived, however, for at the end of 1798 a new coalition directed against France was formed (the War of the Second Coalition, 1798-1802). This time Prussia remained neutral. Frederick William III, a conscientious and modest but ineffectual ruler, was distinguishable from his father by private morality rather than political skill. The government in Berlin drifted back and forth, dabbling in minor economic and administrative reforms without introducing a significant improvement in the structure of the state. A decade of neutrality was frittered away while the army commanders rested on the laurels of Frederick the Great, Austria, on the other hand, played the same leading role in the War of the Second Coalition as in the War of the First Coalition, with the same unfortunate result. The French victories at Marengo (June 14, 1800) and Hohenlinden (Dec. 3, 1800) forced Emperor Francis II to agree to the Treaty of Lunéville (Feb. 9, 1801), which confirmed the cession of the Rhineland. More than that, those rulers who lost their possessions on the left bank under the terms of the peace were to receive compensation elsewhere in the empire. In order to carry out this redistribution of territory, the Imperial Diet entrusted a committee of princes, the Reichsdeputation, with the task of drawing a new map of central Europe. The major influence over its deliberations, however, was exercised by France. Napoleon had resolved to utilize the settlement of territorial claims to achieve a fundamental alteration in the structure of the Holy Roman Empire. The result was that the Final Recess (Hauptschluss) of the Reichsdeputation of February 1803 marked the end of the old order in Germany. In their attempt to establish a chain of satellite states east of the Rhine, the French diplomats brought about the elimination of the smallest and least viable of the political components of central Europe. They thereby also furthered the process of national consolidation, since the fragmentation of civic authority in the empire had been a mainstay of particularism. That it was not Napoleon's intention to encourage unity among his neighbours goes without saying. Yet he unwittingly prepared the way for a program of centralization in Germany that helped to frustrate his own

The chief victims of the Final Recess were the free cities and the ecclesiastical territories. They fell by the dozens. Too weak to be useful allies of Napoleon, they were destroyed by the ambition of their French conquerors and by the greed of their German neighbours. They could still boast of their ancient history as sovereign members of the Holy Roman Empire, but their continued existence had become incompatible with the establishment of effective government in central Europe. The principal heirs to their holdings were the larger secondary states. To be

plans for the future aggrandizement of France.

sure, Napoleon could not keep Austria and Prussia from making some gains in the general scramble for territory that they had helped make possible. But he was especially solicitous for the welfare of those German rulers, most of them in the south, who were strong enough to be valuable vassals but not strong enough to be potential threats. Bavaria, Württemberg, Baden, Hesse-Darmstadt, and Nassau were the big winners in the competition for booty that had been the main object of the negotiations. Napoleon's strategy had been in the classic tradition of French diplomacy, the tradition of Richelieu and Mazarin. The princes had been pitted against the emperor to enhance the role that Paris could play in the affairs of central Europe. Yet neither the states that gained nor those that lost territory felt resentment at being used as pawns in a political game to promote the interests of a foreign power. Whatever objections they raised against the settlement of 1803 were based on expediency and opportunism. The most serious indictment of the old order was that in the hour of its imminent collapse none of the rulers attempted to defend it in the name of the general welfare of Germany

The Final Recess was the next to the last act in the fall of the Holy Roman Empire. The end came three years later In 1805 Austria joined the third coalition of Great Powers determined to reduce the preponderance of France (the War of the Third Coalition, 1805-07). The outcome was even more disastrous than its participation in the first and the second coalitions. Napoleon forced the main Habsburg army in Germany to surrender at Ulm (Oct. 17, 1805); then he descended on Vienna, occupying the proud capital of his enemy; and finally he inflicted a crushing defeat on the combined Russian and Austrian armies at Austerlitz in Moravia (Dec. 2, 1805). Before the year was out Francis II had been forced to sign the humiliating Treaty of Pressburg (December 26), which signified the end of the dominant role his dynasty had played in the affairs of central Europe. He had to surrender his possessions in western Germany to Württemberg and Baden, and the province of Tirol to Bavaria. Napoleon's strategy of playing off princely against imperial ambitions had proved a brilliant success. The rulers of the secondary states in the south had supported him in the war against Austria, and in the peace that ensued they were richly rewarded. Not only did they share in the booty seized from the Habsburgs but they also were permitted to absorb the remaining free cities, petty principalities, and ecclesiastical territories. Finally, in an assertion of the rights of full sovereignty, the rulers of Bavaria and Württemberg assumed the title of king, while the rulers of Baden and Hesse-Darmstadt contented themselves with the more modest rank of grand duke. The last vestiges of the imperial constitution had now been destroyed, and central Europe was ready to receive a new form of political organization reflecting the power relationship created by the force of arms.

In the summer of 1806, 16 of the secondary states, encouraged and prodded by Paris, announced that they were forming a separate association to be known as the Confederation of the Rhine. Archbishop Karl Theodor von Dalberg was to preside over the new union as the "prince primate," while future deliberations among the members were to establish a college of kings and a college of princes as common legislative bodies. There was even talk of a "fundamental statute" that would serve as the constitution of a rejuvenated Germany. Yet all these brave plans were never more than a facade for the harsh reality of alien hegemony in central Europe. Napoleon was proclaimed the "protector" of the Confederation of the Rhine, and a permanent alliance between the member states and the French Empire obliged the former to maintain substantial military forces for the purpose of mutual defense. There could be no doubt whose interests these troops would serve. The secondary rulers of Germany were expected to pay a handsome tribute to Paris for their newly acquired sham sovereignty. On August 1 the confederated states proclaimed their secession from the empire, and a week later, on Aug. 6, 1806, Francis II announced that he was laying down the imperial crown. The Holy Roman Empire thus came officially to an end after a history of a thousand years.

Confederation of the Rhine French Empire. He carved out the kingdom of Westphalia

for his brother Jérôme and the grand duchy of Berg for his brother-in-law Joachim Murat. He was the undisputed

master of all of middle Germany.

After the formation of the Confederation of the Rhine, there was only one state in central Europe that had not yet been forced to submit to France. But the leaders of Prussia hesitated and wavered in their policy until they lost the opportunity of profiting from the War of the Third Coalition. Had they joined Austria and Russia against Napoleon, they might have kept him from gaining hegemony over Germany. Or had they become the allies of Napoleon, they might have established a sphere of influence in the region north of the Main River. As it was, they waited until they fell between two stools. They finally declared war against the French in October 1806, after Austria had been forced to surrender, Russia had decided to retreat, and the secondary states had become the vassals of Paris. Yet public opinion in the Prussian capital remained confident that the army of Frederick the Great would prove a match for the conqueror of Europe. The result of such self-deception was a military disaster of unparalleled magnitude. In the two simultaneous battles of Jena and Auerstädt (Oct. 14, 1806) the Hohenzollern armies were completely routed, and the road to Berlin lay open before the French invaders. The city was occupied on October 27.

More disastrous than the military defeat, however, was the moral collapse of a state that had taught its citizens that obedience to authority was the supreme political virtue. The civilian population never thought of offering resistance to the advancing enemy. Even many army officers were so disheartened by Napoleon's success that they surrendered one fortified position after another without a fight. Frederick William III had to pay a terrible price for the policy of his ancestors, who had built efficient government at the expense of civic initiative. He tried to hold out in East Prussia, hoping that the Russian armies, which were still at war with Napoleon, would help him regain the rest of his kingdom. But when in July 1807 Alexander I concluded peace with France at Tilsit, the unfortunate Hohenzollern had no choice but to follow suit. The treaty that he was forced to sign was a catastrophe, Prussia lost almost half its territory and population, including most of the Polish possessions in the east as well as all of the territories west of the Elbe. Subsequent agreements, moreover, imposed a heavy indemnity, a military occupation, and a reduction in the size of the army. The proud monarchy of Frederick the Great had been reduced to a secondary state in Germany.

Central Europe remained under the dominant influence of France for more than a decade. That influence was at first limited and indirect, then pervasive and overpowering. Yet it was during this period of alien preponderance that Germany for the first time felt the stirrings of liberalism and nationalism. The regions that had become part of the French Empire experienced at first hand the advantages of efficient centralized government in which equality before the law and freedom of opportunity were accepted principles. Those states that retained a pseudo-

Germany in 1807 after reconstruction by Napoleon.

independence as satellites of Napoleon, moreover, sought to imitate the example of their master, partly in order to gain his favour, partly in order to emulate his success. One government after another began to remove religious disabilities, relax economic restrictions, eliminate servile obligations, and centralize administrative functions. Above all, constitutional rule and popular representation ceased to seem Utopian to men of property and education who had witnessed the stirring events of the years since 1789. The French hegemony also led to the birth of nationalism in central Europe. For one thing, the achievement of political unity became a distinct possibility, once the territorial fragmentation of the Holy Roman Empire had come to an end. The presence of foreign invaders, furthermorearrogant, overbearing, and avaricious-aroused among the Germans a sense of nationality that they had never felt in the tranquil days of the old order. Finally, an example of what great deeds the love of fatherland could inspire lay before all who admired or envied the triumphs of Napoleon. The ideal of cosmopolitan individualism that had been generally accepted in the 18th century began to give way before a growing consciousness of national identity. Yet the fact that the concepts of constitutional freedom and national unity were not indigenous but arose in response to foreign domination had an important effect on the form they assumed in central Europe.

Once to fill they assumed in central Europe.

Every German state felt the influence of the new principles of government and economy that the period of French hegemony had introduced, but nowhere was that influence more profound or fruitful than in Prussia. For only in the hour of deepest humiliation did the Hohenzollern kingdom finally make an effort to adapt its structure to the changing political and social conditions that if had stubbornly ignored during the years of greatness. Between 1806 and 1813 the statesmen in Berlin initiated a revolution from above in order to transform a rigid deepotism into a popular monarchy supported by the loyalty of a free citizenry. Out of the disasters of Jena and Tlisti emerged a group of gifted reformers who sought to

The subjection of Prussia

The Prussian reformers: Stein and Hardenberg

prepare the way for the regeneration of their country. The leading figures in this movement for civic reconstruction were the civil servants Karl vom Stein and Karl August von Hardenberg and the military commanders Gerhard von Scharnhorst and August Neithardt von Gneisenau. Among their most important achievements was the abolition of serfdom, a measure designed to create citizens out of human beasts of burden. Yet, while it gave the peasant personal freedom, the government failed to provide him with economic independence. Most of the land remained in the hands of the aristocracy, which therefore continued to dominate the countryside politically as well as socially. More successful was the law establishing municipal selfgovernment. Thereafter, the cities of the kingdom were to be administered by officials chosen not by the central bureaucracy but by the propertied inhabitants of the cities themselves. The autonomy of the cities, it was hoped, would help train a politically conscious and active middle class. The most effective reforms, however, were those introduced in the armed forces. After the officers who had shown themselves incompetent during the war were dismissed or retired, the high command carried out a thorough reorganization of the military system. Discipline became more humane, promotion was made a reward for merit, the method of recruitment was improved, and the training in tactics was modernized. Most important, the army's leaders sought to instill in the soldiers a new spirit rooted in inner conviction rather than unquestioning obedience. Defeat had changed Prussia from a garrison state into a centre of political and intellectual ferment.

Liberalism and nationalism became increasingly vehement in Germany as the burden of French domination grew progressively heavier. The financial sacrifices occasioned by the subordination to Napoleon reinforced the personal resentments aroused by his ruthless statecraft. Before long a network of secret organizations had sprung up in central Europe seeking the expulsion of the foreign invaders. Yet it would be a mistake to think that all Germans regarded the hegemony of France as an unmitigated evil. There were in fact wide differences of opinion among them. The rulers of the secondary states and their supporters in the army and the bureaucracy saw in Napoleon the instrumentality of their new importance. Many reformers in the south-the Bavarian statesman Maximilian von Montgelas, for example-believed that only French influence had made possible the modernization of government in Germany. Some publicists continued to argue, moreover, that the political disunity of central Europe was a natural result of its historic experience and reflected its essential character. To be sure, those who opposed alien domination outnumbered those who accepted it. But even among the former there was no agreement regarding the future political structure of the nation. Many of them dreamed of a liberal and united fatherland that would take its place among the great powers of Europe. Others were willing to settle for a loose association of governments, similar to the Confederation of the Rhine, which could safeguard the interests of the secondary states against Prussia and Austria. Still others hoped for a complete restoration of the old order in which they had grown up and to which they longed to return. And then there were the broad masses of the population of central Europe, exploited, illiterate, and uninformed. They remained by and large indifferent to the crosscurrents of political thought, seeking nothing more than an improvement in their standard of living and the preservation of their way of life. Germany was beginning to move toward new norms of civic and social value, but the transformation of political attitudes was gradual and intermittent.

That the growth of the ideals of unity and freedom " was slow became apparent during the first serious effort to throw off the yoke of foreign domination in central Europe. The Austrian government concluded in 1809 that the reverses that Napoleon had been encountering in Spain presaged a general uprising against the French hegemony on the Continent. The result was an ill-fated attempt at a war of liberation, in which the Habsburg troops challenged Napoleon for the fourth time, only to go down in defeat once again. Appeals from Vienna to the people of Germany found little response except in Tirol and among a few nationalist hotspurs in the north. The princes refused to risk French wrath until they could be sure of ultimate victory, while their subjects refused to rise against French oppression without princely approval. The result was that the war in central Europe, unlike the one in the Iberian Peninsula, was waged primarily by regular forces rather than by guerrilla bands. Archduke Charles gained important successes for the Austrian army at Aspern and Essling (May 21-22, 1809), an indication that the strategic mastery of the French was drawing to a close. But at Wagram (July 5-6) Napoleon was able to work the last of his military miracles. Vienna had to sue for peace once more, the Treaty of Schönbrunn (October 14) ceding Salzburg to Bavaria, West Galicia to the grand duchy of Warsaw, and the Adriatic coastland to France The defeat finally persuaded the emperor, who had exchanged the title Francis II of the Holy Roman Empire for Francis I of the Austrian Empire, that resistance would be as futile in the future as it had been in the past. He therefore adopted a policy of collaboration with France signalized by the marriage of his daughter Marie-Louise to Napoleon. Germany continued to languish in the grip of foreign domination.

The wars of liberation. A new struggle for liberation opened three years later with the defeat of Napoleon's grande armée in Russia. As the tsarist armies began to cross their western frontiers in December 1812, the crucial question became what reception they would find among the rulers and the inhabitants of central Europe. The first state to cut its ties to Paris was Prussia. It was not the king, however, but one of his generals, Ludwig Yorck von Wartenburg, who decided on his own initiative to cooperate with the Russians. Only hesitatingly and fearfully did Frederick William III then agree in February 1813 to a war against France, although public opinion in his kingdom greeted the outbreak of the conflict with enthusiasm. The other rulers of central Europe refused initially to follow the Prussian example. The members of the Confederation of the Rhine were still convinced of Napoleon's invincibility. while Austria preferred to see the combatants exhaust each other to the point at which it could play the role of mediator and arbiter. The foreign minister in Vienna, Clemens Lothar von Metternich, was afraid that the hegemony of France in central Europe might be replaced by that of Russia. He tried, therefore, to pursue a strategy of armed neutrality, hoping that he could persuade the opposing sides to accept a compromise by which an equilibrium would be maintained between Alexander I and Napoleon. This plan failed because of the obstinacy of the latter, who feared that concessions in foreign affairs would weaken his control over internal politics in France. The upshot was that in August 1813 Austria entered the conflict on the side of Russia and Prussia, and the balance of military power shifted in favour of the anti-French coalition. The faith of the secondary states in Napoleon's star began to weaken, and Bavaria became the first member to secede from the Confederation of the Rhine (October 8). One great allied victory would now suffice to bring all of Germany into the struggle against France.

That victory came on Oct. 16-19, 1813, at the Battle of Leipzig. After four days of bitter fighting, the French army was forced to retreat, and its domination of central Europe was finally at an end. Before the year was out. Napoleon had withdrawn across the Rhine. Of all his conquests in Germany, only the left bank was still under the effective control of Paris. The Confederation of the Rhine promptly collapsed, as its members rushed to go over to the winning side before it was too late. The Rhineland was also reconquered early in 1814, after the allies had launched their invasion of France. In the course of the spring the capture of Paris, the restoration of the Bourbons, and the conclusion of peace in the first Treaty of Paris (May 30) ended the war of liberation except for the episode of the Hundred Days, when Napoleon briefly returned to power and was ultimately and finally beaten at Waterloo. The western frontier of central Europe was to remain essentially the same as at the time of the initial outbreak of hostilities more than 20 years before. New

The anti-French alliance of Russia. Prussia, and Austria

The defeat of Austria

Results of the Congress of Vienna. The men who, in the nine months from September 1814 to June 1815, redrew the map of Europe were diplomats of the old school, Francis I and Prince von Metternich of Austria, Frederick William III and Prince von Hardenberg of Prussia, Alexander I of Russia, Viscount Castlereagh of England, Talleyrand of France, and the representatives of the secondary states were all intellectual heirs of the 18th century. They feared the principles of the French Revolution, they scorned the theories of democratic government, and they opposed the doctrines of national self-determination. But they recognized that the boundaries and governments of 1789 could not be restored without modification or compromise. There had been too many changes in attitudes and loyalties that the rigid dogmas of legitimism were powerless to undo. The task before the peacemakers was thus the establishment of a sound balance between necessary reform and valid tradition capable of preserving the tranquillity that Europe desperately needed. The decisions regarding Germany reached during the deliberations in Vienna followed a middle course between innovation and reaction, avoiding extreme fragmentation as well as rigid centralization. The Confederation of the Rhine was not maintained, but neither was the Holy Roman Empire restored. Although the reforms introduced during the period of foreign domination were partly revoked, the practices of enlightened despotism were not entirely reestablished. Despite the complaints of unbending legitimists and the dire predictions of disappointed reformers, the peacemakers succeeded in creating a new political order in central Europe that endured for half a century. The long years of war and unrest that had convulsed Europe during the era of the French Revolution and Napoleon were followed by even longer years of stability and tranquillity.

The Germany that emerged in 1815 from the Congress of Vienna included 39 states ranging in size from the two great powers, Austria and Prussia, through the minor kingdoms of Bavaria, Württemberg, Saxony, and Hannover; through smaller duchies such as Baden, Nassau, Oldenburg, and Hesse-Darmstadt; through tiny principalities such as Schaumburg-Lippe, Schwarzburg-Sondershausen, and Reuss-Schleiz-Gera; to the free cities of Hamburg, Bremen, Lübeck, and Frankfurt am Main. The new boundaries in central Europe bore little resemblance to the bewildering territorial mosaic that had been maintained under the Holy Roman Empire, but there were still many fragments, subdivisions, enclaves, and exclaves. too many for the taste of ardent nationalists. Yet the overall pattern of state frontiers represented a significant improvement over the chaotic patchwork of sovereignties and jurisdictions that had characterized the old order. The peacemakers not only created more integrated and viable political entities but also altered the role that these entities were to play in the affairs of the nation. Without design or even awareness on the part of Frederick William III, his kingdom of Prussia assumed a pivotal position in Germany. The victorious powers, on guard against a revival of French aggression, decided to make Berlin the defender of the western boundary of central Europe. The Rhineland and Westphalia, a region destined to develop into the greatest industrial centre on the Continent, became Hohenzollern provinces. More than that, the king agreed at the urging of Alexander I to cede the bulk of his Polish possessions to Russia in return for a substantial part of Saxony. Prussia, which at the end of the 18th century had been in the process of becoming a binational state, was thrust back into Germany and given a strategic position on both frontiers of the nation. The centre of gravity of Austria, on the other hand, shifted eastward. Francis I had decided to abandon the historic role of his state as protector of the Holy Roman Empire against the Bourbons for the sake of greater geographic compactness and military defensibility. The possessions in southern and western Germany were surrendered along with the Austrian Netherlands in return for Venetian territory on the Adriatic. The Habsburg empire thus became less German in composition and outlook as its focus shifted in the direction of Italy and the Balkans. The consequences of this territorial rearrangement were to be far-reaching.

The German Confederation, 1815.

THE AGE OF METTERNICH AND THE ERA OF UNIFICATION: 1815-71

Reform and reaction. In place of the Holy Roman Empire the peacemakers of the Congress of Vienna had established a new organization of states of central Europe, the German Confederation. This was a loose political association in which most of the rights of sovereignty remained in the hands of the member governments. There was no central executive or judiciary, only a federal Diet meeting in Frankfurt am Main to consider common legislation. The delegates who participated in its deliberations were representatives appointed by and responsible to the rulers whom they served. The confederation was in theory empowered to adopt measures strengthening the political and economic bonds of the nation. In fact it remained a stronghold of particularism, unwilling to sacrifice local autonomy in order to establish centralized authority. It was designed essentially to defend the interests of the secondary states and the Habsburgs. The former, jealously guarding the independence and importance they had gained during the period of French hegemony, were opposed to any reform that might limit their sovereignty. The latter believed that only a decentralized form of political union in Germany would give them enough freedom of action to pursue their non-German objectives. The confederation was thus from the outset an ally of localism and traditionalism. To the nationalists, whose hopes had

Germanic Prussia and the polyglot Austrian Empire

Major flaw of the German Confederation

risen so high during the war of liberation, it seemed to be an instrument of blind reaction. Yet the truth is that the confederal system established in 1815 accurately reflected the slow development of civic consciousness and economic integration in central Europe. The militant reformers who demanded the centralization of government were a vocal but small minority. The lower classes accepted the territorial and constitutional decisions of the Congress of Vienna without a murmur of protest. The weakness of the peace settlement was not its failure to embody present realities but its inability to adjust to future changes. What had been a reasonable adaptation to the political needs of an agrarian and rural society became a hopeless anachronism 50 years later in the age of factories and railroads. This was the fatal flaw in the German Confederation.

Yet the reform movement that had begun under the impact of the French hegemony did not end with the downfall of Napoleon. It continued to exert influence over affairs of state for another few years, before the forces of authoritarianism and particularism crushed it. That influence was strongest in southern Germany, where the political example of western Europe had made the deepest impression. There, many civil servants, court officials, army officers, and even aristocratic landowners came to believe that the future of the state depended on its readiness to reform civic institutions in accordance with liberal theories. In the years following Waterloo, one government in the south after another promulgated a constitution: Bavaria and Baden in 1818, Württemberg in 1819, and Hesse-Darmstadt in 1820. These constitutions established representative assemblies, elected by the propertied citizens, whose assent was required for the enactment of legislation. Their purpose was not only to win for the crown the support of the educated classes of society but also to engender a sense of unity in a heterogeneous population that still had diverse allegiances and traditions. To the north there were also persistent echoes of the reform movement.

The followers of Karl vom Stein were still influential in the councils of state, and Frederick William III of Prussia at first seriously considered ways of fulfilling the promise he had made in 1815 to establish constitutional government. The agitation for political reorganization was loudest, however, among university students, who formed patriotic groups known as Burschenschaften. They demanded the abandonment of the confederal system, the establishment of greater unity, and the achievement of national power. Gathering in 1817 at the Wartburg, a castle near Eisenach, they listened to veiled denunciations of the existing order and consigned to flames various symbols of traditional authority. The rulers of Germany began to stir uneasily at this bold display of defiance of legitimate government.

The chief strategist of the forces hostile to reform was Metternich. Not only did he reject the teachings of liberalism and nationalism in principle, but also, as the leading statesman of the Habsburg empire, he recognized that the establishment of centralized authority in Germany would seriously impede the policies his government was pursuing in Hungary, Italy, and the Balkans. When on March 23, 1819, an unbalanced student, Karl Ludwig Sand, assassinated the conservative playwright and publicist August von Kotzebue, Vienna persuaded the princes of the German Confederation that they were facing a dangerous attempt to overthrow the established order in central Europe. The result was a series of repressive measures called the Carlsbad Decrees, which the federal Diet adopted on Sept. 20, 1819. General censorship was introduced, and the Burschenschaften were outlawed. This first major success of the conservative counteroffensive had an important effect on the struggle within the state governments between the advocates and the opponents of reform. In Prussia the liberal members of the ministry were forced to resign, and the plan to promulgate a constitution for the kingdom was rejected. This shift to the right by Berlin encouraged authoritarian tendencies among the secondary states of the north, which soon abandoned their own constitutional projects. By the end of 1820 the reform movement, which had begun some 15 years before, came to a complete halt.

It had succeeded in altering the political and economic structure of society, but it had been unable to establish a tradition of liberal government and national lovalty in central Europe. The forces of particularism and legitimism, deriving their chief support from the landowning nobility and the conservative peasantry, remained strong. The foundation of bourgeois civic consciousness and material prosperity on which England and France had built their representative institutions was still lacking beyond the Rhine. The ideal of free government was introduced in Germany not as the fruit of an industrial or a political revolution but as the imitation of a foreign example and the reaction against a foreign oppression.

The established order was once again threatened briefly in the wake of the July days of 1830 in France. The news that there had been a successful insurrection against the Bourbons in Paris had an electrifying effect throughout the Continent. In central Europe there were sympathetic uprisings in some of the secondary states of the north. The rulers of Brunswick, Saxony, Hannover, and Hesse-Kassel. seeking to forestall more extreme demands, agreed to promulgate liberal constitutions. A mass meeting of southern radicals at Hambach Castle in the Palatinate (May 1832). moreover, expressed its approval of national unification republican government, and popular sovereignty. A group of militant students even launched a foolhardy attempt to seize the city of Frankfurt am Main, dissolve the federal Diet, and proclaim a German republic. The effect of such harebrained schemes was predictable. As the princes of the German Confederation gradually recovered from their initial fear of the revolutionary movement, they began to oppose with increasing vigour plans to alter the existing system of government. Again, Metternich took the lead in the effort to crush liberalism and nationalism. Under his direction the federal Diet adopted additional repressive measures reinforcing the position of the crown in state politics, limiting the power of the legislature, restricting the right of assembly, enlarging the authority of the police, and intensifying the censorship. Within a few years the opposition had been subdued, and the German Confederation could continue to vegetate in its cozy provincialism. Not until the middle years of the century did a new and more violent outburst of political disaffection shake the foundations of the system of authority that the Congress of Vienna had erected.

Evolution of parties and ideologies. Although the critics of the established order could be defeated, they could not be silenced. The struggle between the supporters and the adversaries of the existing form of government led to the emergence of a rudimentary party system in the German Confederation. In the legislative assemblies of the secondary states the proponents of reform began to meet, plan, organize, and propagandize. The defenders of legitimism were thereby forced in turn to concert their strategy and to publicize their program. Even in Prussia and Austria, where there were as vet no constitutions or parliaments. political criticism could be expressed obliquely through clubs, meetings, newspapers, pamphlets, and petitions, The result was the gradual development of amorphous civic associations held together by common convictions regarding the nature of state and society. These primitive groupings were only the raw material out of which disciplined political parties were slowly fashioned in the course of the century. They still lacked a clear sense of purpose and the systematic propagation of belief characteristic of a fully mature system of parliamentary politics. Yet they became the instrumentalities by which disaffected groups in the community could express their opposition to the established order. They reflected the fact that the civic attitudes of the period of the Restoration were no longer those of the age of enlightened despotism. There were men in central Europe now who refused to submit without question to princely authority, seeking freedom only in the inner recesses of the soul. The change in the form of economy and the structure of society produced by the beginnings of industrialization led to an alternation in the system and organization of politics.

The most important opponents of legitimism and particularism were the liberals or moderates. Deriving their sup-

> liberals or moderates

which the states' rights would be curtailed but not de-

stroyed by a central government and a federal parliament. Farther to the left stood the democrats or radicals, whose following was made up largely of small businessmen, petty shopkeepers, skilled workers, independent farmers, publicists, journalists, lawyers, and physicians. They looked with scorn on the golden mean between autocracy and anarchy that the liberals were seeking. They preferred an egalitarian form of authority in which not parliamentary plutocracy but popular sovereignty would be the underlying principle of government. Their supporters drew inspiration from the French rather than the English or the American Revolution. Their ideal of petty bourgeois democracy was the Jacobin republic of 1793 as an instrument to shape the energies and aspirations of the people into a disciplined force for political and social reform. The spokesmen of this ideal could not openly demand the overthrow of monarchical institutions without risking imprisonment. Yet, while they were forced to accept the crown as a political institution, they sought to transfer its power to a parliament elected by equal manhood suffrage. The masses would thereby become the ultimate arbiter of politics. The democrats were also willing to accept government regulation of business activity as a means of improving the economic position of the lower classes, although their belief in the sanctity of private property was as firm as that of the liberals. In their advocacy of national unification, however, they were less solicitous about royal prerogatives and state rights. While not as numerous as the moderates, the radicals remained an important source of opposition to the established order.

The growth of criticism directed against the political system of the Restoration forced its supporters to define their ideological position with greater precision. The old theories of monarchy by divine right or despotic benevolence offered little protection against the assaults of liberalism and democracy. Legitimism, whose defenders came mostly from the landed nobility, the court aristocracy, the officer corps, the upper bureaucracy, and the established church, began therefore to advance new arguments based on conservative assumptions about the nature of man and society. The relationship between the individual and government, so the reasoning went, cannot be determined by paper constitutions founded on a doctrinaire individualism. Human actions are not motivated solely by rational considerations but by habit, feeling, instinct, and tradition as well. The impractical theories of visionary reformers fail to take into account the historic forces of organic development by which the past and the present shape the future. To assert that all men are equal is to ignore differences in rights and duties expressing differences in birth, class, background, education, and tradition. The dogmas

of constitutional authority and parliamentary government are merely a facade behind which a self-seeking bourgeoisie seeks to disguise its lust for power. An enduring form of government can be built only on the traditional institutions of society: the throne, the church, the nobility, and the army. Only a system of authority legitimated by law and history can protect the worker against exploitation, the believer against godlessness, and the citizen against revolution. According to these tenets, the political institutions of the German Confederation were valid, because they represented fundamental convictions deeply embedded in the snirit of the nation.

Economic changes and the Zollverein. The struggle of parties and ideologies during the Restoration reflected farreaching changes in the structure of the economy and the community. The most significant of these changes was the rise of large-scale industry in central Europe. Techniques of mechanization, introduced in textile mills and coal mines, spread to other branches of manufacture and exerted pressures that influenced the entire economic life of the nation. The transportation network improved with the construction of railroads, steamships, bigger highways, and better canals. Banking institutions and private investors began to transfer their funds from government bonds and commercial ventures to manufacturing enterprises, Millowners, ironmasters, railroaders, financiers, and stockbrokers gradually formed a new middle class whose wealth was derived primarily from industrial activity and whose growing economic importance encouraged among its members a demand for greater political influence. Skilled handicraftsmen, constituting the bulk of the urban working class, could not compete successfully with the factories. The conflict between industrial and preindustrial forms of output was aggravated, moreover, by important demographic changes in the period following the Congress of Vienna. Population began to shift from country to city, although a majority of the inhabitants of the German Confederation continued to live in rural

Agriculture also went through as difficult a period of reorganization and rationalization as industry. The end of serfdom had led in the regions east of the Elbe to the expansion of large estates belonging to aristocratic landowners but cultivated by a propertyless rural proletariat. Peasant emancipation in Prussia allowed the Junkers to enlarge their lands by absorbing the holdings of small farmers. The result was the continuing economic, social, and political domination of the village by the nobility in the eastern provinces of the Hohenzollern kingdom. The squirearchy entrenched in Pomerania, Brandenburg, Silesia, and East Prussia controlled agriculture, commanded the army, directed the bureaucracy, and influenced the court. It constituted a powerful force for conservatism and

West of the Elbe the basic problem was not landlessness but overpropulation. The aristocracy along the Rhine and the Danube was often willing to give the peasantry possession of the soil in return for a substantial payment. The farmer was thereby saddled with heavy financial obligations. Many rustics tried to escape poverty by emigrating to the New World; those who remained faced swift demographic expansion and often had to subdivide small holdings until they yielded no profit. Civil discontent mounted among impoverished villagers who lacked employment in industry.

The system of authority in the German Confederation was thus being undermined by the struggle of artisans against industrial mechanization, by the disaffection of peasants hungry for land, and above all by the criticism of businessmen groaning under the shackles of particularism. Industrialists and financiers had to overcome the barriers created by a variety of monetary systems, commercial regulations, excise taxes, and state boundaries. It is little wonder that the bourgeoise of central Europe turned increasingly to the teachings of liberalism and nationalism. Yet the established order did make a major attempt to met the needs of the business community. Before long, several of the more important secondary governments

concluded agreements with Berlin by which a sizable free

The growth of the German Zollverein.

The Zollverein trade area was established in the heart of central Europe. In 1834 the Zollverein, or Customs Union, including most of the states of the German Confederation, came into existence. Only Austria and the northwest coastland remained aloof. The industrialists of the Habsburg empire, who wanted their products protected against outside competition, felt that the tariff rates of the new association were too low for their needs, whereas the merchants and bankers of the coastal region, who depended on imports thought that they were too high. Yet for some 25 million Germans the Zollverein meant in effect the achievement of commercial unification without the aid of political unification. The Prussian government, moreover, acquired a powerful new weapon in the struggle against Austria for the dominant position in central Europe. Still, although the Zollverein helped meet the most pressing demands of the middle class for economic consolidation, it could not surmount all the material disadvantages of a particularistic form of government. People of means and education continued to grumble about the confederal system under which they lived, while the masses became increasingly restless under the pressure of social dislocation.

The revolutions of 1848-49. The hard times that swept over the Continent in the late 1840s transformed widespread popular discontent in the German Confederation into a full-blown revolution. After the middle of the decade a severe business depression halted industrial expansion and aggravated urban unemployment. At the same time, serious crop failures led to a major famine in the entire area from the Irish Sea to Russian Poland. In central Europe the hungry '40s drove the lower classes, which had long been suffering from the economic effects of industrial and agricultural rationalization, to the point of open rebellion. There were sporadic hunger riots and violent disturbances in several of the states, but the signal for a concerted uprising did not come until early in 1848 with the exciting news that the regime of the bourgeois king Louis-Philippe had been overthrown by an insurrection in Paris (February 22-24). The result was a series of sympathetic revolutions against the governments of the German Confederation, most of them mild but a few, as in the case of the fighting in Berlin, bitter and bloody. When on March 13 Metternich, the proud symbol of the established order, was forced to resign his position in the Austrian Cabinet, the princes hastened to make peace with the opposition in order to forestall republican and socialist experiments like those in France. Prominent liberals were appointed to the state ministries, and civic reforms were introduced safeguarding the rights of the citizens and the powers of the legislature. But even more important was the attempt to achieve political unification through a national assembly representing all of Germany, Elections were held soon after the spring uprising had subsided, and on May 18 the Frankfurt National Assembly met to prepare the constitution for a free and united fatherland. Its convocation represented the realization of the hopes that nationalists had cherished for more than a generation. Within the space of a few weeks, those who had fought against the particularistic system of the Restoration for so long suddenly found themselves in power with a popular mandate to rebuild the foundations of political and social life in central Europe. It was an intoxicating moment.

The forces that had defeated the establishment order, however, soon discovered that they were in disagreement regarding the use to be made of their common victory. There were, first of all, sharp differences between the liberals and the democrats. While the former had comfortable majorities in most of the state legislatures as well as in the Frankfurt parliament, the latter continued to plead, agitate, and conspire for a more radical course of action. There were also bitter disputes over the form that national unification should assume. The Grossdeutsch (Great German) movement maintained that only Austria, the state whose rulers had worn the crown of the Holy Roman Empire for 400 years, could successfully guide the united fatherland. The Kleindeutsch (Little German) party, on the other hand, argued that the Habsburgs had too many Slavic, Magyar, and Italian interests to work single-mindedly for the greatness of Germany. The natural leader of the nation was Prussia, whose political vigour and geographic position would provide efficient government and military security for central Europe. Finally, there was a basic conflict between the proletariat, which wanted protection against mechanized production and rural impoverishment, and the bourgeoisie, which sought to use the political power it had gained in order to promote an industrial capitalism based on freedom of enterprise. Once the spring uprising was over, the parties and classes that had participated in it began to quarrel about the nature of the new order that was to take the place of the old. Popular support for the revolution, which had made the defeat of legitimism during the March days possible, began to dwindle, discouraged by the realization that the liberals would do no more to solve the problems of the masses

Frankfurt National Assembly

Suppres-

sion of the

revolutions

than the conservatives had done. While the Frankfurt parliament was debating the constitution under which Germany would be governed, its following diminished and its authority declined. The forces of the right, recovering from the demoralization into which they had been plunged by the revolution, began to plan a counterrevolution.

Their first major victory came in Austria, where the young emperor Francis Joseph found an able successor to Metternich in his prime minister Prince Felix zu Schwarzenberg. In the course of the summer of 1848 the Habsburg armies crushed the uprising in Bohemia and checked the insurrection in Italy. By the end of October they subjugated Vienna itself, the centre of the revolutionary movement, and now only Hungary was still in arms against the imperial government. At the same time, in Prussia the irresolute Frederick William IV had been gradually persuaded by the conservatives to embark on a course of piecemeal reaction. Early in December he dissolved the constituent assembly that had been meeting in Berlin, promulgated by his own authority a middleof-the-road constitution for the kingdom, and proceeded little by little to reassert the prerogatives of the crown. Among the secondary states there was also a noticeable shift to the right, as particularist princes and legitimist aristocrats began to regain their courage. By the time the Frankfurt parliament completed its deliberations in the spring of 1849, the revolution was everywhere at ebb tide. The constitution that the National Assembly had drafted provided for the creation of a federal union at the head of which was to stand a hereditary emperor with powers limited by a popularly elected legislature. Since the Austrian government had already indicated that it would oppose the establishment of a centralized system in Germany, the imperial crown was offered to the king of Prussia, Frederick William IV hesitated, brooded, and agonized, but in the end he refused the dignity whose authority was in his opinion too restricted. This rejection of political consolidation under a liberal constitution destroyed the last chance of the revolutionary movement for success. The moderates, admitting failure, went home to mourn the defeat of their hopes and labours. The radicals, on the other hand, sought to attain their objectives by inciting a new wave of insurrections. Their appeals for a mass uprising, however, were answered mostly by visionary intellectuals, enthusiastic students, radical politicians, and professional revolutionaries. The lower classes remained by and large indifferent. There was sporadic violence, especially in the southwest, but troops loyal to princely authority had little difficulty in defeating petty bourgeois democracy. By the summer of 1849 the revolution, which had begun a year earlier amid such extravagant expectations, was completely crushed.

The 1850s: years of political reaction and economic growth. The attempt to achieve national unification through liberal reform was followed by an attempt to achieve it through conservative statesmanship. Frederick William IV had refused to accept an imperial crown vitiated by parliamentary government, but he was willing to become the head of a national federation in which the royal prerogative remained unimpaired. While the Austrian armies were still engaged in the campaign against the revolution in Hungary, Berlin began to exert diplomatic pressure on the secondary governments to join in the formation of a new federal league known as the Prussian Union. If Frederick William IV had acted with enough determination, he might have been able to reach his goal before Francis Joseph could intervene effectively in the affairs of Germany. But he allowed his opportunity to slip away. Though he succeeded through threats and promises in persuading most of the princes to accept his proposals, no irrevocable commitments had been made by the time the Hungarians were defeated in August 1849. Vienna could now proceed to woo the secondary governments, which had in most cases submitted to Prussia only out of weakness and fear. Basically they remained opposed to sacrificing their sovereignty in order to exalt the Hohenzollern dynasty. When Schwarzenberg suggested the reestablishment of the old federal Diet, he won the support of many rulers who had agreed to follow Berlin against

their will. The nation was now divided into two camps. the Prussian Union on one side and the revived German Confederation on the other. It was only a question of time before they would clash. When both Austria and Prussia decided to intervene in Hesse-Kassel, where there was a conflict between the supporters and the opponents of the prince, Germany stood on the brink of civil war. But Frederick William IV decided at the last moment to back down. His fear overcame his pride, especially after Nicholas I of Russia indicated that he supported Vienna in the controversy. By the Punctation of Olmütz of Nov. 29, 1850, the Prussians agreed to the restoration of the German Confederation, and the old order was fully

reestablished in all its weakness and inadequacy. The years that followed were a period of unmitigated reaction. Those who had dared to defy royal authority were forced to pay the penalty of harassment, exile, imprisonment, or even death. Many of the political concessions made earlier, under the pressure of popular turmoil. were now restricted or abrogated. In Austria, for example, the constitution that had been promulgated in 1849 was revoked, and legitimacy, centralization, and clericalism became the guiding principles of government. While in Prussia the constitution granted by the king remained in force, its effectiveness was reduced through the introduction of a complicated system of election by which the ballots were weighted in accordance with the income of the voters. The consequence was that well-to-do conservatives controlled the legislature. The secondary states returned to the policies of legitimism and particularism that they had pursued before the revolution. In Frankfurt am Main, where the federal Diet now resumed its sessions, diplomats continued to guard the prerogatives of princely authority and state sovereignty. The restoration of the confederal system also served the interests of the Habsburgs, who stood at the pinnacle of their prestige as the saviours of the established order. In Berlin, on the other hand, the prevailing mood was one of confusion and discouragement. The king, increasingly gloomy and withdrawn, came under the influence of ultraconservative advisers who preached legitimism in politics and orthodoxy in religion. The government, smarting under the humiliation suffered at the hands of Austria, was as timid in foreign as it was oppressive in domestic affairs. The people, tired of insurrection and cowed by repression, were politically apathetic. The German Confederation as a whole, rigid and unvielding, remained during these last years of its existence blind to the need for reform that the revolution had made clear.

Yet the 1850s, so barren in politics, were of the highest importance in economics, for it was during this period that the great breakthrough of industrial capitalism occurred in central Europe. The national energies, frustrated in the effort to achieve civic reform, turned to the attainment of material progress. The victory of the reaction was followed by an economic expansion as the business community began to recover from its fear of mob violence and social upheaval. The influx of gold from America and Australia, moreover, generated an inflationary tendency, which in turn encouraged a speculative boom. Not only did the value of industrial production and foreign trade in the Zollverein more than double in the course of the decade, but also new investment banks based on the joint-stock principle were founded to provide risk capital for factories and railroads. The bubble burst in 1857 in a financial crash that affected the entire Continent. For many investors the price of overoptimism and speculation turned out to be misfortune and bankruptcy. Yet Germany had now crossed the dividing line between a preindustrial and an industrial form of economy. Although the rural population still outnumbered the urban, the tendency toward industrialization and urbanization had become irreversible. And this in turn had a profound effect on the direction of politics. For, as wealth continued to shift from farming to manufacturing, from the country to the city, and from the aristocracy to the bourgeoisie, the pressure for a redistribution of political power also gained strength. While the reactionaries were solemnly proclaiming the sanctity of traditional institutions, economic change was undermining the foundation of those institutions. By the

Revival of the German Confedera-

Industrial capitalism end of the decade a new struggle between the forces of liberalism and conservatism was in the making.

The 1860s and the triumphs of Bismarck. The revival of the movement for liberal reform and national unification at the end of the 1850s came to be known as the "new era." Its coming was heralded by scattered but distinct indications that the days of the reaction were numbered. In 1859 the defeat of Austria in the war against France and Piedmont had a profound effect on central Europe. For one thing, the maintenance of the authoritarian regime in Vienna depended on respect for its military strength. Now that the Habsburg armies had shown themselves to be vulnerable, popular unrest in the empire began to increase. Since autocracy was no longer an effective principle of government, Francis Joseph decided to experiment with a parliamentary form of authority. On Oct. 20, 1860, he promulgated a constitution (the October Diploma) for his domains, setting up a bicameral legislature with an electoral system favouring the bourgeoisie, and Austria ceased to be an absolutist state. The achievement of political consolidation in Italy, moreover, aroused hope and envy north of the Alps. If the Italians could overcome the obstacles of conservatism and particularism, why not the Germans? National sentiment in central Europe, dormant since the revolution, suddenly awoke. Patriotic organizations like the Nationalverein (National Union) and the Reformverein (Reform Union) initiated an agitation for a new federal union, the former advocating Prussian, the latter Austrian, leadership. Liberal publicists and politicians began to advance plans for the reconstruction of the German Confederation. Some of the states, detecting a shift in the trend of public opinion, decided to change their course accordingly. Here and there the conservative ministers of the reaction were retired or dismissed, and their place was taken by statesmen with more moderate views.

The most significant portent of a new age in politics. however, appeared in Prussia. In 1857 Frederick William IV, crushed by memories of the mass insurrections and diplomatic defeats that he had been forced to endure, suffered a mental breakdown. A year later his brother became regent, and the government in Berlin immediately began altering the direction of its policy. Prince William, although a man of conservative inclination, had little sympathy with the mystical visions and pious dogmas prevailing at the court during the period of reaction. He dismissed the Cabinet that had served his predecessor, announced a program of cautious reform in Prussian as well as German affairs, and won a popular endorsement of his course in the elections that gave the liberals control of the legislature. After a long period of discouragement, the advocates of civic reconstruction could once again look to

the future with hope and expectation.

Yet there was an important difference between the political attitude of the liberals in 1858-59 from that of 1848-49. They came to feel during the new era that their defeat 10 years before had been due to an excess of idealism and exuberance. The fatal mistake of the revolution, they reasoned, had been the assumption that enthusiasm and selflessness could be translated into power and substituted for statesmanship. Now a more calculating policy, a policy of realpolitik, must be adopted. Not theory and rhetoric but negotiation and compromise would lead to the attainment of unity and freedom. The liberals therefore pursued at first a strategy of conciliation, anxious not to frighten the established order into blind resistance against all reform. In Prussia, for example, they waited patiently for the regent to move against the forces of disunity and oppression, confident that if they only gave him enough time he would obtain for them by royal authority what they could not seize through revolutionary violence. Yet it gradually became apparent that their hopes would not be realized. Prince William, who in 1861 became king in his own right, was a moderate conservative but a conservative nevertheless. As the advocates of reform grew increasingly restless, the more militant among them formed the Progressive Party, which sought to hasten the introduction of liberal legislation by exerting pressure on the government. The monarch, afraid that he was being pushed farther to the left than he wanted to go, became more adamant

and uncompromising. Sooner or later a conflict between crown and parliament was bound to arise.

It came in connection with the question of army reform, although, if that issue had not developed, there would undoubtedly have been another. The king wanted to strengthen the armed forces by increasing the number of line regiments and decreasing the size of the popular militia. The legislature, reluctant to enhance the power of the conservative officer corps, demanded a modification of the plan. The king refused, convinced that the politicians were attempting to gain control of the army, which he considered subject only to royal authority. The legislature responded by withholding approval of the budget to pay for the cost of army reform. A complete deadlock ensued. In the spring of 1862 the liberal ministers who had been appointed after the establishment of the regency were dismissed, and a conservative Cabinet took office. But the new leaders of the government were as unsuccessful as the old in resolving the crisis. William I began to think about abdicating in favour of his son, who was believed to have political views close to those of the parliamentary opposition. He was persuaded however, to consider first the possibility of naming a new ministry led by Otto von Bismarck, the Prussian ambassador to Paris. There was a momentous interview between the monarch and the envoy, as a result of which the former abandoned all thought of retirement, and the latter became head of a Cabinet pledged to continue the struggle against the legislature. The battle between crown and parliament, which the liberals had been on the point of winning, was now to be waged without regard for constitutional provisions concerning the budget. On Sept. 23, 1862, the nation was startled by the news that a statesman with a reputation for unyielding conservatism had become the prime minister of Prussia. It meant that the established order, having successfully defended its interests against the forces of reform after 1815 and after 1848, was determined to fight to the bitter end against the new challenge to its predominance.

The constitutional conflict in the Hohenzollern kingdom continued for another four years. The legislature refused to approve the budget until its wishes concerning military reform had been met. Bismarck's government, after carrying out the controversial reorganization of the army, continued to collect taxes and disburse funds without regard for parliamentary authorization. The liberals condemned the prime minister as a violator of the law, while the prime minister denounced the liberals as blindly doctrinaire. Although the electorate remained on the side of the opposition, the Cabinet declared that it would not be swayed by party politics or parliamentary majorities. The broad masses of the population, it maintained, were still loyal to the crown. And so the struggle went on without prospect of alleviation or resolution. There were even dark prophecies of a violent uprising against a regime that was so indifferent to its constitutional obligations. Yet in fact Bismarck was not blind to the need for a reconciliation between crown and bourgeoisie. Despite his reputation as a fire-eating legitimist, he had a supple mind and recognized that the political principles of Frederick the Great could not solve the problems facing William I. He hoped, therefore, for an eventual reconciliation between the government and the legislature, but a reconciliation in which the prerogative of the monarch and the influence of the

nobility would remain undiminished. What Bismarck sought in essence was an alteration in the form of government that would create a facade of parliamentary institutions disguising the continuation of authoritarian policies. The middle class wanted to end the domination of the traditional forces in society, he calculated, but it also wanted to achieve national unification in central Europe. Here was the key to a solution of the constitutional conflict. Unity could be used to restrict freedom: nationalism could become the means of taming liberalism. Bismarck had concluded that the political integration of Germany was, in the long run, inevitable. If the established order did not effect it, the reformers, democrats, and revolutionaries would. Thus, it was in the interest of conservatism to take the task of centralization in hand, bring it to a successful conclusion, and create a Advent of Otto von Rismarck

The Prussian policy of realpolitik The

Danish

War and

Holstein

Schleswig-

new system of authority compatible with the preservation of royal and aristocratic preponderance. Such a policy would make possible a compromise between crown and bourgeoisie by which the latter obtained the benefits of economic consolidation while the former retained the advantages of political domination. Through this strategy the prime minister hoped to end the constitutional conflict.

The defeat of Austria. The international situation was favourable to a program of unification in the German Confederation, Since its defeat in the Crimean War (1853-56), Russia had ceased to play a decisive role in the affairs of the Continent, England remained preoccupied with the problems of domestic reform, And Napoleon III was not unwilling to see a civil war east of the Rhine that he might eventually use to enlarge the boundaries of France. Bismarck could thus prepare for a struggle against Austria without the imminent danger of foreign intervention that had faced Frederick William IV. His first great opportunity came in connection with the duchies of Schleswig and Holstein, which were ruled by the king of Denmark but which were politically and ethnically tied to Germany. When the government in Copenhagen sought to make Schleswig an integral part of the Danish state in 1863, nationalist sentiment in central Europe was outraged. William I proposed to Francis Joseph that the two leading powers of the German Confederation should occupy the duchies in order to prevent the violation of an international agreement that had guaranteed their separate status. Afraid to let the Prussians act on their own, the emperor agreed, and in 1864 there was a brief war against Denmark that demonstrated the strength of the reorganized army of the Hohenzollerns. Danish hopes for foreign assistance proved illusory, and by the Peace of Vienna (October 30) the duchies became the joint possession of Prussia and Austria.

The easy victory of the allies, however, was only the prelude to a bitter conflict between them. Vienna would have liked to see Schleswig-Holstein become an independent secondary state in the German Confederation, committed to a policy of particularism. Berlin, on the other hand, hoped for the outright annexation of the duchies or at least the indirect control of their government. Even more important than the disposition of the spoils of war however, was the mounting rivalry between the two great powers for hegemony in central Europe. Bismarck would probably have been willing to collaborate with Austria in the division of Germany into two spheres of influence, a northern under the Hohenzollerns and a southern under the Habsburgs, but Francis Joseph was reluctant to restrict his authority and ambition to the region below the Main River. The result was a steady deterioration of relations between Vienna and Berlin. In 1865 their differences were papered over by the Convention of Gastein, which placed Schleswig under Prussian and Holstein under Austrian administration but which also reaffirmed the joint sovereignty of the two governments over the duchies. Still, this was only a temporary solution, and before long the danger of civil war in the German Confederation began to grow once again.

In the course of the spring of 1866 both sides stepped up their preparations for a military solution to the Austro-Prussian dualism. Bismarck concluded an alliance with Italy by which the latter was to receive Venetia as a reward for participating in a war against the Habsburg empire. He also sought to gain the support of public opinion in the German Confederation by introducing a motion in the federal Diet for the convocation of a national parliament elected by equal manhood suffrage. The Austrians in the meantime secured a promise of French neutrality in the event of hostilities and tried to win the adherence of the secondary states in the impending struggle. The last desperate attempts to preserve peace collapsed in June. Vienna announced that it would submit the question of the duchies to the federal Diet. Berlin, condemning this step as a violation of the Convention of Gastein, ordered its troops in Schleswig to expel the Austrians from Holstein. Francis Joseph in reply called on the other states of the confederation to mobilize their armies against the Prussian threat to domestic tranquillity, and central Eu-

rope trembled on the verge of civil war. The only question now was what the position of the secondary states would be. Most of them lined up behind Austria, which they regarded as the defender of their independence against the ambitions of Berlin Bismarck's attempt to enlist the aid of the national movement by advocating reform of the confederal system thus failed. It alarmed the particularists without propitiating the centralists. Public opinion remained frightened and confused, distrusting one side and fearing the other. The future of the nation was decided not by popular insurrections or parliamentary deliberations but by the force of arms.

The Seven Weeks' War between Prussia and Austria (June-August) produced a diplomatic revolution in Europe, destroying the balance of power that had been established 50 years before by the Congress of Vienna. Yet this momentous alteration in the international equilibrium was accomplished so swiftly that foreign diplomats had barely begun to grasp its implications before the struggle for hegemony in Germany ended. The Hohenzollern armies had a brilliant strategist in Helmuth von Moltke and a deadly weapon in the breech-loading needle gun. The Austrian high command, on the other hand, became irresolute and demoralized before a decisive encounter had even taken place. The Prussians succeeded in dividing and defeating the forces of the secondary states, and on July 3 they routed the Habsburg troops as well at the Battle of Königgrätz (Sadowa). The war was thus decided within a few weeks after its outbreak. Bismarck, refusing to be dazzled by the brilliance of the victory, urged the swift conclusion of an honourable peace. Not only did he feel that the preservation of a strong Austria was essential for the maintenance of stability on the Continent, but he also feared that a prolongation of hostilities would enable Napoleon III to intervene in the affairs of Germany. By the preliminary Peace of Nikolsburg (July 26) and the definitive Treaty of Prague (August 23), Francis Joseph was permitted to retain all of his possessions except Venetia, which had been promised to the Italians. There was to be no occupation and only a modest indemnity. The emperor had to acquiesce, however, in the Prussian annexation of Hanover, Nassau, Hesse-Kassel, Schleswig-Holstein, and Frankfurt am Main, in the dissolution of the German Confederation, and in the formation under Hohenzollern leadership of a new federal union north of the Main River. The contest between Berlin and Vienna that had determined the history of central Europe for more than a century was now over.

Bismarck's national policies: the restriction of liberalism. Bismarck's triumph in the military struggle led directly to his victory in the constitutional conflict. Before the outbreak of hostilities he had tried to reach an understanding with the liberal opposition, but the liberals hesitated to make peace with a statesman who had so flagrantly violated the fundamental law of the kingdom. The defeat of Austria changed all that. While the war was still in progress, general elections resulted in important gains for the right. Many voters, elated over the successes of the Prussian armies, expressed their confidence in the government by supporting its adherents at the polls. Some of the ultraconservatives hoped that the Cabinet would now capitalize on its triumph by suspending the constitution and establishing an authoritarian regime. Yet the prime minister recognized that such reactionary schemes would prove futile in the long run. What he wanted was not the suppression of liberalism but an accommodation with it. As soon as peace was concluded, he introduced in the legislature a bill of indemnity granting the government retroactive approval for its conduct of affairs of state without a legal budget. The consequence, as Bismarck had foreseen, was a split in the ranks of his adversaries. Those who argued that there could be no compromise with the principle of constitutional government rejected a reconciliation between crown and parliament based on mutual concessions, but many members of the opposition, who eventually formed the National Liberal Party, decided to accept the settlement offered by the prime minister. Their reasoning was that an obstinate resistance against the Cabinet would only condemn them to sterile dogmaThe Seven Weeks

tism, whereas a willingness to accept what could not be prevented would enable them to influence official policy in the direction of greater freedom. This view prevailed, and on Sept. 3, 1866, the legislature approved the Bill of Indemnity, 230 to 75. By dividing the forces of reform and weakening their sense of purpose, Bismarck won as important a success in domestic affairs as the victory on the field of battle.

His subjugation of liberalism was made possible by the triumph of nationalism. It had long been the prime minister's belief that the achievement of unity could appease the demand for freedom. The success of the Prussian armies provided him with an opportunity to test this assumption. Once Austria had been subdued, he cajoled and bullied the secondary governments above the Main into joining Berlin in the establishment of the North German Confederation. It was the union of a giant and 21 pygmies, for the Hohenzollern kingdom constituted about four-fifths of the territory and population of the confederation. Executive authority was vested in a presidency held in accordance with hereditary right by the rulers of Prussia, who were to exercise the powers of their office with the assistance of a chancellor responsible only to them. The legislature was composed of a federal council, or Bundesrat, whose members were appointed by the state governments, and a lower house, or Reichstag, elected by equal manhood suffrage. Since Berlin had 17 votes out of 43 in the Bundesrat, it could easily control the proceedings with the support of a few of its satellites among the small principalities. Although the Reichstag could theoretically exercise considerable influence over legislation by granting or withholding its approval, parliamentary authority and party initiative were weak and untested, and Bismarck had little difficulty in piecing together a workable majority for his program by a strategy of divide and rule. His support came largely from a combination of moderate liberals and moderate conservatives willing to sacrifice theory for expediency. The federal constitution provided no bill of rights, no ministerial responsibility, and no civilian supervision over military affairs. But it introduced uniformity in currency, weights, measures, commercial practices, industrial laws, and financial regulations. In short, it created the economic unity that the middle class had long demanded and that helped reconcile it to the defeat of its hopes for greater political freedom.

The North

Confedera-

German

tion

Franco-German conflict and the new German Reich. The Seven Weeks' War, by creating a powerful new state in the heart of central Europe, abruptly altered the system of international relations on the Continent. Every government now had to reexamine its diplomatic and military position in the light of the establishment of the North German Confederation. No nation, however, was affected by the victory of the Hohenzollern armies as directly as France, Emperor Napoleon III had encouraged the outbreak of hostilities between Austria and Prussia on the assumption that both combatants would emerge from the struggle exhausted and that the Second Empire of France could then expand eastward against little resistance. The outcome of the war revealed how shortsighted such calculations had been. Instead of profiting from the conflict between Francis Joseph and William I, Paris suddenly confronted a strong and united German state that presented a serious threat to French interests. The imperial government was bound to regard this turn of events with suspicion and hostility. It sought to mitigate its discomfiture by seeking compensation in the Rhineland, Luxembourg, or Belgium. But Berlin succeeded in frustrating these plans, and the conviction began to grow in France that sooner or later a struggle with Germany would be unavoidable. The prospect of a new armed conflict was not unwelcome to Bismarck. He wanted to see national unification consummated by the entry of the southern states into the North German Confederation. Yet public opinion below the Main remained distrustful. Only a common patriotic struggle against foreign aggression might overcome the reluctance of the south to unite politically with the north. Thus in Berlin as well as in Paris there were reasons for seeking a test of strength. The immediate occasion came in the spring of 1870 with the candidacy of Prince Leopold, a relative of William I, for the throne of Spain. The ensuing controversy was cleverly exploited by Bismarck to provoke the French into initiating hostilities which both sides had wanted but for which the French government received the blame.

When France learned of Leopold's acceptance of the offer of the Spanish crown, there were wild protests in Paris and an immediate demand that Leopold be ordered to withdraw. On July 12 Leopold's father renounced the Spanish candidature on his behalf. This was not enough for the French government; it insisted that William I, as head of the Hohenzollern family, should promise that the candidature would never be renewed. This demand was presented to William at Ems by the French ambassador. Though William refused to give a promise, he dismissed the ambassador in a friendly enough way. But when the "Ems telegram," a report of what was happening, reached Bismarck, he shortened it for publication in such a way as to imply that William had refused to see the French ambassador again. The French used this as an excuse to

declare war on Prussia on July 19.

Bismarck's calculation that a struggle waged ostensibly against the expansionist designs of Napoleon III would overcome particularism below the Main proved correct. The southern states joined the north in the Franco-German War, and the sense of unity engendered by the brotherhood of arms was soon enhanced by the intoxication of victory. The German troops won one battle after another in hard fighting along the frontier, until on September 2 they forced a large French army, headed by the emperor himself, to surrender at Sedan. The result was the establishment of a republican government in France, which continued to wage the struggle in the name of the old revolutionary ideals of 1793. The generalship of Moltke, however, was too much for the fierce determination of the new regime. Paris capitulated on Jan. 28, 1871, after a long and bitter siege, and on May 10 the Treaty of Frankfurt brought the war officially to a close. The Third Republic had to cede Alsace-Lorraine, pay an indemnity of five billion francs, and accept an army of occupation. It was a Carthaginian peace designed to crush a dangerous rival. The work of national unification in Germany, in the meantime, was successfully completed even before hostilities had ended. Bismarck had entered into negotiations with the southern states soon after the outbreak of war, determined to use patriotic fervour as an instrument for achieving political consolidation. The enthusiasm aroused in central Europe by the victory over France proved too much for the defenders of particularism. On January 18, while Prussian guns bombarded Paris, William I was proclaimed emperor of a united nation at military headquarters in Versailles. The governments below the Main joined the North German Confederation to form a powerful new Reich under the Hohenzollerns. Within a single lifetime, central Europe had completed the transition from cosmopolitanism to nationalism, from serfdom to industrialization, from division to union, from weakness to preponderance, from the Holy Roman Empire to the German Empire.

Rismarck's unification of Germany

Germany from 1871 to 1945

THE GERMAN EMPIRE, 1871-1918

The German Empire was founded on Jan. 18, 1871, in the aftermath of three successful wars by the north German state of Prussia. Within a seven-year period Denmark, the Habsburg monarchy, and France were vanquished in short, decisive conflicts. The empire was forged not as the result of an outpouring of nationalist feeling from the masses but from traditional cabinet diplomacy and agreement by the leaders of the states in the North German Confederation with the hereditary rulers of Bavaria, Baden, Hesse, and Württemberg. Prussia, occupying more than three-fifths of the area of Germany and having approximately three-fifths of the population, remained the dominant force in the empire until its demise at the end of another war in 1918.

At its birth Germany occupied an area of 208,825 square miles and had a population of more than 41 million, which The Con-

etitution

of 1867

was to grow to 67 million by 1914. The religious makeup was 63 percent Protestant, 36 percent Roman Catholic, and one percent Jewish. The nation was ethnically homogeneous apart from a modest-sized Polish minority and smaller Danish and French populations. Approximately 67 percent lived in villages and the remainder in towns and cities. Literacy was close to universal because of compulsory education laws dating to the 1820s and '30s.

Domestic concerns. From its origins in 1871, the empire was governed under the constitution designed four years earlier by Otto von Bismarck, the Prussian prime minister, for the North German Confederation. This constitution reflected the predominantly rural nature of Germany in 1867 and the authoritarian proclivities of Bismarck, who was a member of the Junker landowning elite. There were two houses: the Reichstag, to represent the people, and the Bundesrat, to represent the 25 states. The former was composed of 397 members elected by universal manhood suffrage and a secret ballot. The constituencies established in 1867 and 1871 were never altered to reflect population shifts, giving rural areas a vastly disproportionate share of power as urbanization progressed. In theory the Reichstag's ability to reject any bill seemed to make it an important reservoir of power; in practice, however, the power of the lower house was circumscribed by the government's reliance on indirect taxes and the Reichstag's limited right to approve the military budget once every seven years. All legislative proposals were submitted to the Bundesrat first and to the Reichstag only if they were approved by the upper house. In addition, the legislative bodies were rarely consulted about foreign policy. Imperial ministers were chosen by and were responsible to the emperor rather than to the legislature. In comparison with the lower houses of the French and British parliamentary systems of the period, the Reichstag was a relatively impotent body.

A problem that was to plague the empire throughout its existence was the disparity between the Prussian and imperial political systems. In Prussia the lower house was elected under a restricted three-class suffrage system, a propertied franchise that allowed 15 percent of the male population to choose approximately 85 percent of the delegates. A conservative majority was always assured in Prussia, whereas the imperial franchise resulted in increasing majorities for the political centre and left-wing parties. William I (1797-1888) was both German emperor and king of Prussia. Apart from two brief instances the imperial chancellor was simultaneously prime minister of Prussia. Thus, the executives had to seek majorities from two separate legislatures elected by radically different franchises. A further problem was that government ministers were generally selected from the civil service or the military. They often had little experience with parliamentary government or foreign affairs.

The constitution had been designed by Bismarck to give the chancellor and monarch primary decision-making power. Universal suffrage had been proposed because of Bismarck's belief that the rural population would vote for either the Conservative or Free Conservative parties. The Progressives, a left-wing liberal party, were expected to do poorly in the two-thirds of Germany that was rural. Bismarck had not counted on new parties such as the Centre Party, a Roman Catholic confessional party, or the Social Democrats (SPD), both of which began participating in imperial and Prussian elections in the early 1870s. The Centre generally received 20-25 percent of the total vote in all elections. The SPD grew from 2 seats in the first imperial election to 35 by 1890, in which year the SPD actually gained a plurality of votes. Bismarck termed the Centre and SPD along with the Progressives Reichsfeinde or enemies of the empire, because they sought each in its own way to change the fundamental conservative political character of the empire.

Beginning in 1871 he launched the Kulturkampf, a campaign in concert with German liberals against political Catholicism, Bismarck's aim was clearly to destroy the Centre Party. Liberals saw the Roman Catholic church as politically reactionary and feared the appeal of a clerical party to the one-third of Germans who professed Roman Catholicism. Both doubted the loyalty of the Catholic population to the Prussian-centred and, therefore, primarily Protestant nation. In Prussia, the minister of ecclesiastical affairs and education, Adalbert Falk, introduced a series of bills establishing civil marriage, limiting the movement of the clergy, and dissolving religious orders. All church appointments were to be approved by the state. As a result hundreds of parishes and several bishoprics were left without incumbents. Clerical civil servants were purged from the Prussian administration,

The Kulturkampf failed to achieve its goals and, if anything, convinced the Roman Catholic minority that their fear of persecution was real and that a confessional party to represent their interests was essential. By the late Kulturkampf

The German Empire, 1871-1918

1870s Bismarck abandoned the battle as a failure. He now launched a campaign against the SPD in concert with the two conservative parties and many National Liberals. Fearing the potential of the Social Democrats in a rapidly industrializing Germany, Bismarck found a majority to outlaw the party from 1878 to 1890, although it could not constitutionally be forbidden to participate in elections. Party offices and newspapers were closed down and meetings prohibited. Many socialists fled to Switzerland and sought to keep the party alive in exile. During the 1880s Bismarck also sought to win the workers away from socialism by introducing legislation granting them modest pensions, accident insurance, and a national system of medical coverage. Like the Kulturkampf, the campaign against the SPD was a failure, and when the 1890 elections showed enormous gains for the Reichsfeinde, Bismarck began to consider having the German princes reconvene, as in 1867, to draw up a new constitution. The new emperor, William II (1859-1941), saw no reason to begin his reign with a potential bloodbath and asked for the 74-year-old chancellor's resignation. Thus, Bismarck, the architect of German unity, left the scene in a humiliating fashion, believing that his creation was fatally flawed. Indeed, his policy of supporting rapid social and economic modernization while seeking to avoid any reform of the authoritarian political system did lead to an atmosphere of persistent crisis.

The economy 1870-90. The empire was founded toward the end of two decades of rapid economic expansion, which saw the German states surpass France in steel production and railway building. By 1914 Germany was an industrial giant second only to the United States. After the establishment of the North German Confederation (1867) the impediments to economic growth were quickly removed. The usury laws and fetters on internal migration disappeared. A uniform currency based on gold was adopted by Bismarck and his National Liberal allies, An imperial state bank was created, and the tough regulations hindering the incorporation of joint stock ventures fell by the wayside. Combined with the euphoria over unification, these changes led to an unprecedented boom between 1870 and 1873. The Gründerjahre, as the years after unification were called, saw 857 new companies founded with a capital of 1.4 billion talers-or more new companies and investment in the private sector than in the previous 20 years. Dividends reached an astounding 12.4 percent. The railway system almost doubled in size between 1865 and 1875. Tens of thousands of Germans invested in stock for the first time to demonstrate both their patriotism and their faith in the future of the new German Empire.

The

jahre

Gründer-

These halcyon years came to an abrupt end with the onset of a worldwide depression in 1873. The prices for agricultural and industrial goods fell precipitously; for six successive years the net national product declined. A sharp decline in profits and investment opportunities persisted until the mid-1890s. About 20 percent of the recently founded joint stock companies went bankrupt.

In agriculture, the deeply indebted Junker elite now faced severe competition as surplus American and Russian grain flooded the German market. Among the more immediate consequences of the crash was a burst of emigration from the overpopulated provinces of rural Prussia. During the 1870s some 600,000 people departed for North and South America; this number more than doubled in the 1880s. As a result of the depression social and economic questions increasingly preoccupied the Reichstag, while constitutional and political issues were put on the back burner.

It would be incorrect to draw the conclusion that the economy remained in the doldrums for an entire generation. While the 1870s and early 1890s were depressed periods, the 1880s saw significant recovery in industry, if not in agriculture. The British, who paid scant attention to Germany's emergence as an industrial power, began to respect their competitor during this decade.

In adjusting to the "Great Depression," Germany's leaders chose to return to a regulated or administered economy, after a generation of increasingly free trade. The hallmark of the new age was concentration; Germany became the land of big industry, big agriculture, big banks, and big government. The two areas in which the trend toward a controlled economy was most evident were tariff policy and cartelization. Cartel agreements, which were Cartelsanctioned by the state, apportioned markets, set standards for manufactured goods, and fixed prices. It is not coincidental that Germany, where the guild system prevailed into the 19th century, should have given birth to the cartel. Cartels arose rapidly in the steel, coal, glass, cement, potash, and chemical industries. Between 1882 and 1895 the total number of business enterprises grew by 4.6 percent, but the number employing more than 50 workers grew by 90 percent.

In 1878-79 Bismarck initiated a significant change in German economic policy, which coincided with his new alliance with the two conservative parties at the expense of the National Liberals. Tariffs were introduced on iron as well as on the major agricultural grains; the latter were raised in 1885 and again in 1887. This departure from liberal economic policy was necessitated by complaints from industrialists, estate owners, and peasants about the terrible impact the depression was having on their respective incomes. Only Britain held out against the protectionist tide that swept Europe in the 1880s, Bismarck's shift, nevertheless, had serious political implications. It signified his opposition to any further evolution in the direction of political democracy. The grain tariffs provided the Junker estate owners of Prussia, who constituted the main opposition to full political emancipation, with subventions that insulated them somewhat from the international market. Thus, the landed elite, major industrialists, the military, and the higher civil service formed an alliance to forestall the rise of social democracy, prevent further political liberalization, and make sure that the uncertainties of the market did not weaken the elites.

Foreign policy 1870-90. Until his resignation in 1890 Bismarck had a relatively free hand in the conduct of foreign policy. After three successful wars he saw his task as promoting peace and gaining time so that a powerful German Empire in the middle of Europe would come to be accepted as natural rather than as an interloper. The Prussian victories had led to great insecurity among the continental powers, who now adopted universal military service in imitation of Germany and maneuvered for defensive alliances so they would not find themselves isolated in the event of war. Bismarck's two areas of concern were the Balkans, where the disintegration of the Turkish Empire could easily lead to conflict between the Habsburg Monarchy and Russia, and France, which nurtured a desire for revenge against the German victors. Each might spark a general European conflagration that would inevitably involve Germany.

Although Bismarck is considered the foremost practitioner of realpolitik, his policies reflected a preference for dealing with monarchies and a disdain for parliamentary governments. In 1873 he negotiated the Three Emperors' League with Russia and Austria-Hungary. The league collapsed in the mid-1870s when rebellion broke out in Turkey's Slavic provinces. In 1877 Russia declared war on Turkey, leading both Britain and Austria-Hungary to express serious concern about Russia's expansionist war aims. When Russia imposed an annexationist peace on Turkey in the Treaty of San Stefano, Bismarck called for an international conference to reconsider the peace treaty and to forestall another military conflict. At the Congress of Berlin in 1878 Bismarck played the role of honest broker among the powers. Russia reluctantly accepted more modest gains and tensions dissipated.

But a conflagration had barely been avoided. Soon after the conference Bismarck negotiated an alliance with the Habsburg Monarchy (1879), which remained in effect through World War I. Thus he tied the fate of the youthful German Empire to the aged multinational empire that faced continuous problems from its many ethnic minorities. The chancellor had clearly opted for the Dual Monarchy over Russia should a war break out. The alliance gave him leverage in Vienna, and he steadfastly used it to prevent a war over the Balkans. His choice of the Habsburg Monarchy resulted from his fear that its dissolution would

The Dual Alliance

hated Centre Party.

Having a solid ally, Bismarck demonstrated his virtuosity by negotiating a revived Three Emperors' League in 1881. He now had influence in St. Petersburg as well as in Vienna to prevent a conflict over the Balkans. In 1882 Italy, fearing French hostility, joined the Dual Alliance with Austria-Hungary, making it into the Triple Alliance. On the surface Bismarck had triumphed. France had no allies for a war of revenge, and the alliance with the Habsburgs and Russia at once gave him influence with the two major adversaries in the Balkans.

The transient nature of this artistry soon became apparent, A crisis in Bulgaria inflamed Russo-Austrian relations, leading to the breakup of the revived league. Once again a war was avoided with Bismarck's intervention, but the Habsburgs and the Romanovs could no longer patch up their differences. Bismarck negotiated a separate Reinsurance Treaty with the tsar in 1887. Nevertheless, France and Russia bean courtine each other before Bis-

marck left office.

Between 1870 and 1890 Bismarck earned the respect of European leaders for his pecific policies. Apart from a few colonial additions in the mid-1880s, Germany under his guidance acted as a satiated power. The question remained whether this burgeoning industrial power led by the Junker and industrial elites would continue this policy while the other Western powers carved out world empires.

Politics 1890-1914. The political structure established by Bismarck in 1867 remained with scant change until the empire's demise in 1918. Leo von Caprivi, Bismarck's successor, was a political neophyte, having spent his entire career in the military. Given the disjuncture between the Prussian and German political systems (see above), Caprivi, surprisingly, sought to work with the parties of the centre and left, Bismarck's Reichsfeinde. With their support he reduced the grain tariffs and negotiated longterm trade treaties with Russia, the Dual Monarchy, and Romania. Food prices fell as a result, and industry flourished. National wealth rose rapidly, as did the standard of living of the industrial labour force. The Junker elite were outraged at Caprivi's willingness to sacrifice their interests in behalf of industry and labour. Utilizing their political power in Prussia and their access to the emperor, they were able to force his resignation in 1894, making his chancellorship the shortest before the war. After his resignation, the former general wrote to a friend, "In regard to the 'Junker agrarians' I see only evil, and it appears to me that a revolution by the agrarians is not impossible and for the moment more dangerous than a Social Democratic revolution."

Succeeding chancellors learned from Caprivi's fall that opposition to the landed elite was fraught with peril. Bernhard von Bülow, chancellor from 1900 to 1909, abandoned Caprivi's trade policy and resurrected the alliance of the agrarian and industrial elites.

To many observers the empire was edging toward a monumental crisis as it entered the 20th century. While its authoritarian political system was marked by paralysis, its economy was the most dynamic in Europe. With each election the increasingly urban electorate returned Social Democrats in growing numbers. By 1890 the Social Democrats (who had adopted a Marxist program of revolution at their Erfurt congress in 1891) received more votes than any other party, although four other parties won more seats. By 1912 they had more voters supporting them than the two next-largest parties combined. Both the Centre and Social Democrats were able to create parties with a mass base in German society. The Conservatives, National Liberals, and Progressives were more traditional parties, led by notables who were ill at ease in the world of populist politics. All three were declining, especially the Conservatives, who, despite flirting with anti-Semitism after 1893 by becoming a Christian party, fell to less than 15 percent of the vote by 1912. Many contemporary observers thought that a major crisis was impending between

the recalcitrant elites and the increasing number of Germans who desired political emancipation similar to that of Britain and France.

The rise

groups

of interest

While the Liberals and Conservatives declined in the Reichstag, a new phenomenon on the political scene was the rise of single-issue extraparliamentary interest groups. For the most part organizations such as the Pan-German League, the Navy League, the Farmers League. and the Colonial League were authoritarian in their politics and aggressively expansionist in foreign policy. Their constituencies were overwhelmingly middle-class and educated (except for the Farmers League), and they sought to influence the decision-making process both directly, by impressing the ministers with their strength, and indirectly, by supporting parties that adhered to their goals. Given the wealth and high status of their membership (professors were highly visible as leaders), they were unusually effective in achieving their goals. One of the striking characteristics of the empire was the support it received from the educated strata of the population, despite its elitist

In the last election during the empire (1912) the Social Democrats scored a great victory, capturing 34.8 percent of the vote and 110 seats. On the local level they had begun to cooperate with the Progressives and occasionally with the Centre Party. Southern states such as Württemberg were moving toward full parliamentary government, and Alsace-Lorraine was given a surprising degree of selfgovernment. Thus, there were some indications that the empire was evolving into a representative democracy. On the other hand, the states of Saxony and Hamburg adopted even more restrictive franchises than Prussia in the years before World War I. Above all Prussia and its Junker, military, and bureaucratic elites, supported by much of the professoriat, stood firm in opposition to any further democratization. Some historians have viewed the outbreak of the war in 1914 as an attempt by these elites to shore up their sagging position by a successful war and annexations, as Bismarck had done in the 1860s when the authoritarian Prussian state was besieged by a liberal opposition.

Economy 1890-1914. The speed of Germany's advance to industrial maturity after 1890 was breathtaking. The years from 1895 to 1907 witnessed a doubling of the number of workers engaged in machine building, from slightly more than one-half million to well over a million. An immediate consequence of expanding industrial employment was a sharp drop in emigration; from an average of 130,000 people a year in the 1880s, the outflow dropped to 20,000 a year in the mid-1890s. The surplus population continued to leave Prussia's eastern provinces, but the destination was the growing and multiplying factories of the Ruhr rather than the Americas. Earlier British fears of German competition now came to fruition. Only onethird of German exports in 1873 had been finished goods; the percentage rose to 63 percent by 1913. Germany came to dominate all the major continental markets except France.

The focus of national wealth as well as population shifted to the urban industrial sector by 1900. Only 40 percent of Germans lived in villages by 1910, a drop from 67 percent at the birth of the empire. Cities of more than 100,000 inhabitants accounted for one-fithh of the population in 1914, compared to one-twentieth at the time of unification. The application of intensive agricultural techniques led to a doubling in the value of all farm products despite a sharp decline in the rural population. Industry accounted for 60 percent of the gross national product in 1913.

The German working class grew rapidly in the Wilhelmian era. Total union methership reached 3.7 million in 1912, of which 2.5 million were affiliated with the socialist union Sismarck's welfare legislation covered some 13.2 million workers by 1911. Although German employers were extremely authoritarian and hostile to collective bargaining, the labour force did make significant economic gains. Between 1867 and 1913 the number of hours worked per year declined by 14 percent. Nearly every study of real income shows a rapid rise until 1902 and then a modest increase yearly thereafter. National income

Leo von Caprivi per capita rose from 352 marks to 728 during the life of the empire. Despite these advances industrial workers lacked full political rights, which led a large number of them, including many Roman Catholic workers, to vote for the revolutionary socialist party.

While industrialization was rapid, it occurred only in certain sectors of the economy; other areas were only marginally affected. Some two million Germans persisted in traditional artisanal enterprises as the nation became an industrial colossus. While Germany was characterized by large Junker estates and cartels, it was also the nation of dwarf-sized farms (60 percent of farmers owned less than five acres) and the small workshop. German factories were larger and more modern than their British and French counterparts, but the preindustrial sector was more backward. During depressions those in the traditional trades often turned to anti-Semitism as an ideology that was at once patriotic and anticapitalist.

Foreign policy 1890-1914. Bismarck's successors rapidly abandoned the premises of his foreign policy. The Reinsurance Treaty of 1887 with Russia was dropped. leaving the empire more firmly tied to the Dual Monarchy and Russia free to conclude an alliance with France in 1894. Within four years Friederich von Holstein, a councillor in the political division of the foreign office, had weakened Germany's influence in the Balkans and allowed France to end its isolation. German overtures to

Britain remained nugatory.

In 1895 the brilliant young sociologist Max Weber gave an inaugural lecture in Freiburg in which he pointed out that while Germany was establishing a nation-state belatedly the other powers had been founding world empires in Africa and Asia. Weber admonished his audience that Germany had to follow suit or become another Switzerland. Weber's contemporaries needed little convincing. From 1897 to 1912 William II, with his politically astute naval adviser, Alfred von Tirpitz, launched a policy of Weltpolitik. Germany's naval power went from being negligible to being second only to Britain's in little more than a decade. Nor did Germany build a navy simply to defend its coastline; rather, the new battleships were capable of challenging the other naval powers on the oceans. Tirpitz was a master of publicity, able to win much of the commercial and industrial middle class to his vision of a mighty empire, whose shipping lanes would be guarded by his fleet. The fleet was also expected to make the monarchy more popular and stem the growth of the left-wing parties. Weltpolitik proved to be a colossal failure. Germany came on the imperial scene late, when the choicest territories had already been occupied. Togo, part of New Guinea, and southwest Africa hardly seemed to justify the enormous expenditures on the navy. Moreover, Tirpitz's plans alienated Britain. Germany already had the most powerful army in the world when it fastened on becoming a great naval power. The British found this threatening and negotiated an alliance with Japan in 1902 and another one with France in 1904. In 1907 Britain settled its differences with Russia, and the Triple Entente (including France) was established. Germany now found itself surrounded by three major powers.

The more established powers found Germany meddling everywhere. This was particularly striking, because it followed two decades of Bismarck's policy of avoiding conflict. The Japanese objected to Germany's involvement in China in the 1890s. Russia watched as German power and influence were established in Turkey, its hereditary enemy. The French, of course, still harboured dreams of undoing their defeat in 1870. With Britain also alienated, Bismarck's nightmare of a coalition against the young upstart power, Germany, had become a reality. Bismarck had cre ated a system designed for his extraordinary talents; neither his successors nor the unstable young emperor, William II, shared the master's gifts. Parliament was more or less ignored, although some insightful critiques of Weltpolitik were to be heard in the Reichstag. Twice Germany's rulers sought to break up the alliance that was forming against the empire. In 1905 and 1911 Germany created crises over French penetration of Morocco. In each case the British and Russians stood firm, and, even though Germany gained concessions, the Triple Entente remained solid In 1912 the chancellor, Theobold Bethmann Hollweg, and his ministers reassessed the decade and a half of Wellpolitik and judged it a failure. The army, which had not been expanded since 1894, once again became the pride of the regime. Eastern Europe and the Balkans were now considered the most likely areas for German economic and political penetration. Since Italy had become unreliable, Austria-Hungary was the only ally to be counted on in the event of war. Any threat to the stability of the Dual Monarchy could leave Germany totally isolated.

The assassination of the Austrian heir to the throne. Archduke Francis Ferdinand, by Serbian terrorists in June 1914 augured poorly for the future of Austria-Hungary unless it showed resolve in dealing with the provocation. William II and Bethmann Hollweg urged strong measures against Serbia and reasserted their unconditional loyalty if war should eventuate. With Russia industrializing and the Dual Monarchy increasingly threatened by the aspirations of its minorities, time appeared to be on the side of the Triple Entente. Thus, if war was inevitable, the sooner it came the better. A localized conflict between Austria-Hungary and Serbia with a quick victory for the former would be desirable. If Russia chose to intervene to help its Slavic brother, Serbia, then a general European conflict would ensue. This was acceptable to the German government both because of its pessimism about the long-term strength of the Central Powers (i.e., the German Empire and Austria-Hungary) and because the civilian population could be expected to rally to the war effort if tsarist Russia appeared to bear much of the responsibility. War, which inevitably gives the state increased power over civil society and demands sacrifices for the existing regime, may also have been attractive to elites fearing the growing strength of Germany's socialist movement.

World War I. During the first days of World War I Germans experienced a sense of bonding that had eluded them since the founding of the empire. Differences of class, religion, and politics were transcended as Germans flocked to their city centres to show their enthusiastic support for the impending conflict. Overwhelmingly, the parties, including the Social Democrats, voted for war credits. The euphoria of the early days masked Germany's dangerous situation. The Triple Entente commanded the seas, outnumbered Germany in population by three to one, and had access to the world's natural resources through their empires and close contact with the United States, Germany was immediately blockaded and had to rely on its own resources and those of contiguous nonbelligerents like The Netherlands, Denmark, and Switzerland. The Central Powers did have interior lines of transit, which was valuable in a two-front war. They also had a unified command structure-in contrast to the Triple Entente, where rivalries resulted in three different wars being fought simultaneously with little coordination.

General Alfred von Schlieffen, chief of the German general staff, had recognized Germany's vulnerability in a two-front war and saw the best hope in an overwhelming attack against France through Belgium. If all went according to plan, France's industrial region would be occupied in six to eight weeks and Paris itself surrounded. The slow-moving Russians would occupy Prussia's eastern rural provinces, facing only a modest-sized German military force. After France's concession of defeat following the occupation of its capital, whole armies would be shifted to the eastern front to drive the Russians out. Schlieffen died in 1913, and the plan was put in motion by General Helmuth von Moltke. As often happens in history, the plans of men may go awry in ironic ways. The western armies of Germany did, indeed, move through neutral Belgium but were stopped at the Battle of the Marne (September 1914) in northern France. Meanwhile, Paul von Hindenburg was reactivated at age 67 and sent with Major General Erich Ludendorff to halt the Russian advance into East Prussia. There the Germans unexpectedly defeated two large Russian armies at the Battle of Tannenberg (August 1914).

The western front turned into a war of attrition as the two sides built opposing trenches from the Swiss border to the English Channel. For three and a half years neither

Weltpolitik

Schlieffen

side moved more than 30 miles despite titanic battles at Verdun, the Somme, and Ypres. In the east the outmanned German forces, with the help of the Austrians, inflicted a series of costly military defeats on Russia, but, given the vast plains of eastern Europe, the Central Powers were unable to knock Russia out of the war until after the seizure of power by Lenin in the October Revolution of 1917. In 1916 Ludendorff and Hindenburg became joint heads of all German land forces and recognized, as had their predecessor Erich von Falkenhavn, that the war would be won or lost on the western front. With Italy (1915) and Romania (1916) entering the war on the side of the Triple Entente, the Central Powers faced an almost impossible situation in a war of attrition. The two generals became de-facto rulers of Germany and sought the mobilization of the whole society for total war. More than 11 million men, some 18 percent of the population, were in uniform, of whom almost two million were ultimately killed. Germany was unable to feed itself, and after the severe winter of 1916-17 malnutrition and even starvation were not uncommon.

On the diplomatic front the elites ruling Germany planned for vast annexations of Russian, Belgian, and French territory as well as for an African empire. The war costs were to be paid by the defeated powers of the Triple Entente. At no time during the war did the German government engage in serious negotiations to restore the sovereignty of Belgium or to return to the status quo ante. Nor were the allies very interested in a negotiated peace, but their situation was not as desperate as Germany's.

Ludendorff and Hindenburg adopted an all-or-nothing policy in regard to victory. They created an independent state of Poland in 1916, which prevented serious negotiations with Russia for a separate peace. They adopted submarine warfare in 1917, despite the knowledge that it would bring the United States into the war, because it offered a slim hope of quick victory if Triple Entente ships carrying men and supplies could be prevented from reaching France. Ludendorff also mounted a major offensive in April 1918, ignoring Woodrow Wilson's proposal of Fourteen Points for a future peace and failing to offer any peace terms of his own. When asked what would happen if the offensive failed, he replied, "Then, Germany will be destroved."

In 1917 the Reichstag, following the lead of the Centre Party, passed a peace resolution based on an annexations. Social Democratis and Progressives rallied to support the resolution. The military and civilian leadership ignored the resolution and enforced a draconian peace on Russia and Romania in 1917–18. When the major battle in the west was brewing in April 1918, there were more than a million soldiers in the east to enforce the Treaty of Brest Litowsk with Russia.

Clearly, the military, agrarian, and industrial elites who ruled Germany viewed themselves as involved in two wars simultaneously, one against the Triple Entente and the other against the aspirations of the German people for full political emancipation. The latter conflict dictated victory at all costs on the military front. Defeat or a compromise peace on the battlefield would inevitably lead to democratization because of the sacrifices endured by many millions of workers, farmers, and artisans. In November 1914 Alfred Hugenberg, the major industrialist and subsequent ally of Hitler, told German entrepreneurs, "The consequences of the war will be unfavourable to employers and industry in many ways. One will probably have to count on a very increased sense of power on the part of the workers and labour unions, which will find expression in increased demands on the employer for legislation. It would, therefore, be well advised in order to avoid internal difficulties to distract the attention of the people and to give fantasies concerning the extension of German territory room to play." William II felt compelled to promise an eventual end to the restrictive Prussian franchise in his Easter message of 1917. Shortly thereafter the Fatherland Party was established with enormous support from the elites. Its program included a Carthaginian peace and maintenance of the Prusso-German political system. The Ludendorff offensive of April 1918 made great

breakthroughs in the west. But the effects of four years of attrition were apparent. The military did not have the reserves to take advantage of the initial gains. With almost a million fresh American troops in France, the Allies launched a counterattack that quickly gave them the initiative. Slowly the German forces began retreating. On August 8 the German army suffered a severe defeat in northern France, and not long thereafter William II installed a new, more liberal, government in Berlin, headed by Prince Max von Baden. The new ministers were informed that the war was virtually lost, and they were advised to seek an immediate armistice. Before the negotiations were successful, revolution broke out in the German navy and spread to the military and urban workers William II was forced to abdicate as emperor of Germany and king of Prussia. The Social Democrats took power at this appalling moment of defeat, while the former military and civilian leaders sought to escape responsibility for the calamity. A civilian, Matthias Erzberger of the Centre Party, signed the armistice, which took effect Nov. 11, 1918. (For further discussion of World War I, see the article WORLD WARS, THE.)

THE GERMAN REPUBLIC, 1918-33

The republic proclaimed early in the afternoon of Saturday, Nov. 9, 1918, is often called the "accidental republic." When Friedrich Ebert, the leader of the so-called Majority Socialists, accepted the imperial chancellorship from Maximilian, Prince of Baden, it was with the understanding that he would do his utmost to save the imperial system from revolution. Ebert believed that the only way to accomplish this would be by transforming Germany into a constitutional monarchy. Elections would have to be held for a constitution and work of the deformance of the constitution was not constitution.

Defeat of revolutionaries, 1918-19. Ebert, however, was faced with a precarious situation. The dangers confronting him were mounting all over the country. Four and a half years of war and sacrifice were giving way to a war-weariness that was leaving the imperial system, as well as its emperor, discredited. Shortages of food and fuel had rendered the population vulnerable to the influenza epidemic sweeping Europe. On October 18 alone Berlin authorities had reported 1,700 influenza deaths. Independent Socialists in Munich had forced the abdication on November 8 of Bavaria's King Ludwig III and proclaimed a Bavarian socialist republic. The port cities along the North Sea and the Baltic Sea were falling into the hands of sailors' and workers' and soldiers' councils (Räte) in the wake of the naval mutiny at Kiel in early November. Berlin's radical leaders, Karl Liebknecht and Rosa Luxemburg, were eager to transform Germany into a republic of workers' and soldiers' councils (a Räterepublik) in imitation of the soviet republic being established by the Bolshevik leaders in Russia. As Ebert was accepting the reins of government in the Reichstag building on November 9, Liebknecht was addressing a rally of his own followers in front of the deserted Royal Palace about a mile away. Among Marxist revolutionaries the view was widespread that the Bolshevik revolution was merely the spark that would set off the worldwide proletarian revolution predicted by Karl Marx. Inevitably, that revolution would have to spread to Germany. Given this ideologically charged scenario, Liebknecht confidently anticipated his destiny to become the German Lenin.

While the Liebknecht rally was proceeding in front of the Royal Palace, an angry crowd was gathering before the governmental headquarters in the Reichstag building. Because Ebert had just left the building, his friend and fellow Majority Socialist Philipp Scheidemann felt called upon to address the crowd. To meet its inevitable demands for change and to forestall whatever Liebknecht might be telling his followers, Scheidemann in his speech used he phrase "Long live the German Republic" Once said, the proclamation of a republic could not be withdrawn. Ebert was furious when he learned of Scheidemann's "accidental" proclamation, but he realized that there was no turning back. He spent the afternoon seeking partners to form a provisional government to run the newly pro-

claimed republic. By nightfall he managed to persuade the Independent Socialists, a party that in 1917 had split from the Majority Socialists over the continuation of the war, to provide three members of a provisional government. To gain their cooperation, Ebert had to agree to naming the provisional government the Council of Peoples' Commissars and to transforming Germany into a vaguely defined social republic. This promise notwithstanding, Ebert still hoped that elections to a constituent assembly would lead to the creation of a moderate democratic republic. The Independent Socialists, however, though not as radical as Liebknecht, held to their vision of a socialist Räterepublik. They hoped that workers and soldiers would elect a multitude of councils across the entire nation during the next weeks, which they assumed would establish the foundation for a genuinely socialist republic.

For the time being, however, Majority and Independent Socialists were joined in providing provisional governance for the defeated German nation, which everywhere seemed on the verge of collapse. Although the armistice of November 11 ended the fighting, it did not end the Allied blockade. The winter of 1918–19 brought no relief in the shortages of food and fuel, and the flu epidemic showed no signs of abatement. Soldiers returning from the military fronts by the hundreds of thousands were left stranded, jobless, hungry, and bitter—grist for the mill

of revolution.

The push for revolution, led by an enthusiastic Liebknecht and a more reluctant Luxemburg, came on Jan. 6, 1919, encouraged by Soviet Russia and further prompted by fear that Ebert's plans for the election of a constituent assembly, scheduled for January 19, might stabilize the German situation. The Spartacists, now officially the Communist Party of Germany, initiated massive demonstrations in Berlin and quickly seized key government and communications centres.

The events of "Spartacist Week," as the radical attempt at revolution came to be known, demonstrated that Germany was not nearly as ripe for revolution as its leaders had thought it to be. As Luxemburg had feared, mass support among German workers for communism did not exist; most of them remained loval to the Independent Socialists or to Ebert's more moderate and democratic vision of socialism. The German Army, moreover, had recovered its nerve and was determined to prevent a further move to the left. In December the army had begun secretly to train volunteer units drawn from the sea of soldiers returning from the front. These so-called Freikorps ("free corps") units became the basis for the dozens of small right-wing armies that during the next years roamed the country, looking for revolutionary activity to suppress. The Spartacist revolt, which was confined largely to Berlin, was put down within a week by some 3,000 Freikorps men. When Liebknecht and Luxemburg were captured on January 15, they were both shot at the initiative of Freikorps officers. Although sporadic revolutionary activity continued elsewhere in Germany during the next months, its failure in Berlin clearly marked its doom. The proclamation on April 4, 1919, of a Räterepublik in Bavaria revived radical fortunes only briefly; Freikorps units put down the radical Bavarian republic by the end of the month.

The collapse of the Spartacist revolt greatly enhanced the chances for Ebert's vision of Germany's future to prevail. Moreover, the meeting of a national congress of workers' and soldiers' councils in mid-December 1918, upon which the Independent Socialists had pinned their own hopes for creating a socialist republic, proved to be far less radical than expected; it did nothing to interfere with Ebert's plans to elect an assembly to draw up a democratic constitution. The elections on Jan. 19, 1919, which for the first time included women, produced a resounding victory for Ebert's conception of democracy. Three of every four voters gave their support to political parties that favoured turning Germany into a democracy. After months of turmoil Germany was to become a democratic republic. The assembly began its deliberations on Feb. 6, 1919, choosing to meet in Weimar, where it believed itself less vulnerable to radical political interference than in Berlin.

On Jan. 18, 1919, representatives of the powers victorious over Germany began the deliberations in Paris that would establish a European peace settlement. Germany's new democratic leaders placed high hopes in the prospects for this settlement. Woodrow Wilson's Fourteen Points seemed to promise Germans national self-determination as well as to encourage the efforts to transform Germany into a democracy. When the German constituent assembly met in Weimar for the first time on February 6, it immediately declared itself sovereign over all Germany. It selected a provisional government—with Ebert as president and Scheidemann as chancellor—whose first major task was to prepare for the expected invitation to Paris to negotiate a treaty of peace with the empire's former enemies.

But the invitation for a German delegation to come to Paris did not arrive until early April. Rather than being treated as a fellow—if fledgling—democracy, Germans soon learned that they were still viewed as the "bad boys" of Europe. Wilson's idealism had been forced to yield to still-fresh wartime resentments being articulated by the leaders of the French, British, and Italian delegations. There were to be no negotiations about a peace treaty. Germany would simply be handed a treaty and told to

sign.

The Treaty of Versailles. The treaty in its final form contained many provisions that the Germans had fully expected. That Alsace-Lorraine was to be handed back to France was no surprise; nor were the small territorial adjustments along the border with Belgium. The plebiscite allowing the Danish population of northern Schleswig to choose between joining Denmark or remaining with Germany was unarguably consistent with the principle of national self-determination. But this principle, the Germans expected, would also justify a union between Germany and the Germans of what now remained of Austria after the collapse of the previous November. More serious to Germany was the stipulation that its coal-rich Saar region was to be taken over by the League of Nations and the coal given to France to aid its postwar reconstruction. Eventually a plebiscite was to allow Saarlanders to choose whether or not they wished to be returned to Germany.

On its eastern frontier Germany was forced to cede to the newly restored Poland the province of West Prussia, thereby granting Poland access to the Baltic Sea while losing land access to the province of East Prussia. Danzig was declared a Free City under the permanent governance of the League of Nations. Much of the province of Posen, which, like West Prussia, had been acquired by Prussia in the late 18th-century partitions of Poland, was likewise granted to the restored Polish state. Also lost to Germany as the result of a later plebiscite was a significant portion

of coal-rich Upper Silesia.

Overseas, Germany was forced to yield control of its colonies. Although these colonies had proven to be economic liabilities, they had also been symbols of the world-power status Germany had gained in the 1880s and '90s. More immediately serious were the treaty's commercial clauses that took from Germany most of its foreign financial holdings and reduced its merchant carrier fleet to

roughly one-tenth of its prewar size.

The treaty's provisions for disarming Germany were to be, the Allied leaders promised, merely the first step in a worldwide process of disarmament. To insure that Germany would not revive as a military power, its army was to be reduced to 100,000 men and would not be allowed to produce tanks, poison gas, or military planes. Moreover, Germany's frontier with France was to be permanently demilitarized; German military forces were to remain behind a line 31 miles east of the Rhine. The treaty also called for the dissolution of the German General Staff, the military command structure of the German Army, which the Allies believed to be the engine of German aggression. The navy, too, was to be dismantled and limited to 15,000 men, a half-dozen battleships, and 30 smaller ships. A prohibition on the building of submarines was absolute. Germany's compliance with the treaty's terms was to be assured by an Allied occupation of the Rhineland and the presence of the Inter-Allied Commissions of Control.

The most resented terms of the treaty, however, were the

The Spartacist revolt

so-called honour clauses: Articles 227 through 230 gave the Allies the right to try individual Germans, including the former emperor, as war criminals; Article 231, often called the war-guilt clause, provided the justification for Article 232, setting up a commission to collect reparation payments, the total of which was eventually set at 132 billion goldmarks (about 32 billion gold dollars). German bitterness over these honour clauses was nearly universal. Almost no German believed his country responsible for the outbreak of war in 1914, Technically, Article 231 did not declare Germany to be solely responsible for causing the war, merely "for causing all the loss and damage" suffered by the Allies in the war "imposed upon them by the aggression of Germany and her allies," Germans read it as an accusation of guilt, however, and understood it as the cynical product of victors' justice.

The German provisional government in Weimar was thrown into upheaval when it learned of the treaty's full terms. "What hand would not wither that binds itself and us in these fetters?" Scheidemann asked, and he resigned rather than accept the treaty. Army chief Paul von Hindenburg did the same, after declaring the army unable to resume the war under any circumstances. Only an ultimatum from the Allies finally brought a German delegation to Paris to sign the treaty on June 28, 1919, five years to the day since the assassination of Archduke

Francis Ferdinand.

The Weimar Constitution. During the month following the signing of the treaty, the Weimar constituent assembly completed its drafting of a constitution for the new republic. The result was widely hailed as the most modern democratic constitution of its day. The document provided for a popularly elected president who was given considerable power over foreign policy and the armed forces. In Article 48 he was also given emergency decree powers to protect the republic from crises initiated by its opponents from either the left or the right. The president was empowered to nominate the chancellor, whose government required the confidence of the lower house of the parliament, the Reichstag, elected by universal suffrage and a system of proportional representation. An upper house, the Reichsrat, was composed of delegates appointed by the governments of the federal states, the Länder.

The most modern features of the Weimar constitution, the provisions for popular initiative and referendum, were designed to enable the electorate on its own initiative, by way of petition, to introduce bills into the Reichstag and to force the body to a vote on the proposal. If the bill was voted down, a national referendum was to be held to allow the electorate to pass the bill into law against the wishes of the Reichstag. Never again could a government

afford to ignore the wishes of the voters.

The Weimar constitution was promulgated formally on Aug. 11, 1919, ending the provisional status of government in Germany that had begun with Scheidemann's proclamation of a republic the previous November. In September the government, judging the situation sufficiently safe in Berlin, returned to the capital. But it did not yet consider it sufficiently safe to risk the national elections for president or for a Reichstag to replace the constituent assembly. Instead the assembly prolonged Ebert's provisional term as president for three years; elections for the Reichstag were delayed until June 1920.

Years of crisis, 1920-23. In its early years the new German democracy was beset by continuing turnoil. The Treaty of Versailles, quickly labeled "the Diktar" by the German public, galvanized the resentment that had accumulated during the war, much of which was turned back on the republic itself. Its enemies began to put the blame for the hated treaty upon the republic's socialist and democratic progenitors, whom they accused of having undermined Germany's efforts in the final stages of the war. A revived and radicalized right wing asked whether the German Army might not have been stabbed in the back by traitors on the home front. Resist circles took seriously the notionous Protocols of the Learned Elders of Zion, a fraudulent document fabricated in Russia in 1895 and published in Germany in 1920. It allowed the conclusion that all of recent history, including World War

I, was the product of a conspiracy of Jews seeking to control the world. Roying Freikorps units contributed to the brutalization of German political life. In March 1920 one of these units, under the command of the former naval captain Hermann Ehrhardt, succeeded in briefly establishing its control of the government in Berlin. This socalled Kapp Putsch, named after the conservative politician Wolfgang Kapp, who had planned it, was put down not by the army but by a general strike of Berlin's socialist and communist workers. A similar right-wing putsch in Bavaria was successful, however, and from that point forward radical groups of the right found protection and a degree of nurture in this south German state. By the end of 1922 there had been nearly 400 political assassinations, the vast majority of them traceable to the right wing. The victims included prominent politicians such as Matthias Erzberger, a signatory to the Armistice of 1918. and Walther Rathenau, the foreign minister.

The difficulties in which the new democracy found itself were already reflected in the June 1920 elections to the first Reichstag. The Weimar coalition parties, the SPD (socialist), the Centre Party (Roman Catholic), and the Democrats, which in January 1919 had received over 75 percent of the vote, this time managed to win only 43.5 percent. Contributing to the problems Weimar faced in the early 1920s was the escalating rate of inflation that was eventually to destroy the German mark. Although the inflation was rooted in the huge debt that Germany had amassed in financing the world war, the hyperinflation of 1923 was triggered by the French-Belgian military occupation in January 1923 of the German industrial district in the Ruhr valley. The occupation occurred in retaliation for Germany's having fallen behind in its reparation payments and was intended to force German industry to provide compensation for the French and Belgian losses. Rather than accede quietly to the humiliation of occupation, the German government urged workers and employers to close down the factories. Idle workers were paid for the next months with a currency inflating so rapidly that printers gave up trying to print numbers on bills. By mid-1923 the German mark was losing value by the minute. A loaf of bread that cost 20,000 marks in the morning would cost 5,000,000 marks by nightfall. Restaurant prices went up while customers were eating. Workers were paid twice a day. On November 15, when the collapse came, it took 4.2 trillion German marks to buy a single American dollar.

The social and political cost of the hyperinflation was high. Scholars note that the inflation did more to undermine the middle classes than the presumably socialist revolution of 1918. A lifetime of savings would no longer buy a subway ticket. Pensions planned for a lifetime were wiped out completely. Politically, the hyperinflation fueled radicalism on both the left and the right. The Communists, badly set back by their failure in January 1919, believed the prospects for a successful revolution to be greatly improved. In Munich the leader of the small National Socialist German Workers' Party, Adolf Hitler, used the turmoil to fashion an alliance with other rightwing groups and attempt a coup in November 1923 that sought to use Bavaria as a base for a nationalist march on Berlin. His hope was to overthrow the democratic system of Weimar that he believed was responsible for Germany's political and economic humiliation. Neither the radicals of the right nor those of the left succeeded in imposing their will. In the short run they did not succeed because of ineptitude and miscalculation; in the long run they failed because the government sponsored a currency reform that led to a restabilization of the mark and also decided to end its policy of passive resistance in the Ruhr in exchange for an end to the occupation and a rescheduling of the reparation payments it owed to the Allies.

The Weimar Renaissance. Amid the political and economic turmoil of the early 1920s Germany's cultural and intellectual life was flowering. The so-called Weimar Renaissance brought to Germany the fulfillment of the Modernist revolution, which in the late 19th century had begun to transform the European aesthetic sensibility. The Modernist rejection of tradition seemed to suit perfectly the need of many Germans for new meanings and values Kapp

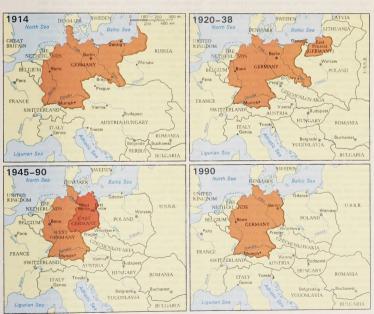

The hyperinflation of 1923 to replace those destroyed by the war. "A world has been destroyed; we must seek a radical solution," said the young architect Walter Gropius upon his return from the front in laté 1918. In 1919 Gropius became the founder and first director of the Bauhaus school of design in Weimar, the most important institution in Germany for the expression of Modernism's aesthetic and cultural vision. Bauhaus artists believed themselves to be creating a new world through their painting, poetry, musical compositions, theatrical productions, and architectural constructions. The legacy of German Modernism in general, and of the Bauhaus in particular, is most immediately evident in the stark steel-and-glass high-rise buildings whose clear and clean lines have come to dominate the skylines of the world's cities. Moreover, the paintings and the sculptures decorating them, as well as the design of the furniture and the lighting fixtures, are heavily influenced by the aesthetic principles articulated in Weimar during the 1920s.

Bevond the Bauhaus, painters like George Grosz, Max Beckmann, and Otto Dix pursued an artistic objective described as Expressionism; i.e., they were interested in depicting their emotional responses to reality rather than reality itself. In music the rejection of tonality by composers such as Armold Schoenberg, Anton von Webern, and Alban Berg broke a centuries-old tradition in music. At the juncture between popular and serious music the composer Kurt Weill collaborated with the poet Berolit Brecht to create in 1928 The Threepenny Opera, a bitterly sattire musical play in which the world of modern capitalism was equated with that of underworld gangsterism. In films such as The Cabinet of Dr. Caligari, distorted sets and unusual camera angles probed for disturbing truths behind the surface appearances of reality.

Not everyone was pleased by the Modernist attack on tradition. Opera performances and theatrical productions were often interrupted by angry audiences. Siegfried Wagner, the son of the composer Richard Wagner, deplored a Modernist version of his father's The Flying Dutchman, calling the production an example of "cultural bolshewism." Other artists, the novelist Thomas Mann, for example, chose to remain above the fray in the Olympian heights of German Kultur, an effort for which Mann in 1929 won the Nobel Prize for Literature.

Years of economic and political stabilization. The financial recovery that began with the restabilization of the German currency in late 1923 was undergirded in 1924 when the Allies agreed to end their occupation of the Ruhr and to grant the German government a more realistic payment schedule on reparations. A committee of the Allied Reparations Commission headed by the American financier and soon-to-be vice president Charles Dawes had recommended these changes as well as urged the Allies to grant sizable loans to Germany to assist its economic recovery. The Dawes Plan marked a significant step in the upswing of the German economy that lasted until the onset of the Great Depression. The 800 million gold marks in foreign loans had by 1927 enabled German industrial production to regain its 1913 prewar high. That same year the Reichstag contributed to the vital need for social and class reconciliation by voting for a compulsory unemployment insurance plan. Reconciliation on the political level seemed achieved in 1925 when the 77-year-old Hindenburg was elected to succeed the deceased Friedrich Ebert as president. Although no democrat, the aged field marshal took seriously his duty to support the constitution and the republic.

The Dawes

Changes in Germany's territory and internal status from 1914 to 1990

The guiding spirit in German foreign policy from 1924 through 1929 was the foreign minister, Gustav Stresemann, who firmly believed that Germany was more likely to gain relief from the harshness of Versailles by trying to fulfill its terms than by stubbornly continuing to resist them. Stresemann's efforts ushered in what came to be known as "the era of fulfillment." It began in December 1925 when Germany signed the Locarno treaties, in which it guaranteed to maintain the new postwar boundaries with France and Belgium and to submit to international arbitration any boundary disputes that might arise in the east with Poland or Czechoslovakia. Germany was formally readmitted into the family of nations by being granted membership in the League of Nations in September 1926. In 1928 Germany became party to the most dramatic symbolic gesture of postwar reconciliation, the Kellogg-Briand Pact, which promised to outlaw the resort to aggressive war; this agreement was signed by nearly all the world's major countries during the next year.

The economic and political stabilization of the German republic seemed to be reflected in the May 1928 elections to the Reichstag. The antirepublican parties of the left and right together received only 13 percent of the total vote, with the Communists receiving 10.6 percent and the Nazis taking only 2.6 percent. Germany's reintegration into the international political structure was reflected also in the decision in early 1929 by the Allied Reparations Commission to make a final disposition of the reparations question. The committee appointed to make recommendations in this matter was headed by Owen D. Young, an American business executive. The Young Committee proposed that German reparations be reduced to about 37 billion gold marks, less than one-third of the 1921 total, and that payments be stretched until 1988. It also called for the dissolution of the Reparations Commission and for an immediate end to what remained of the Allied

occupation of the Rhineland.

The German government, seeing the obvious advantages in the Young Plan, officially accepted its terms in August 1929. Right-wing parties of the opposition, however, saw the plan as nothing less than a renewal of Germany's humiliation. Led by the German National Peoples' Party (DNVP) and its leader Alfred Hugenberg, the press and movie-industry lord, the nationalist opposition seized upon the constitutional processes for popular initiative and referendum in order to force the government to reverse its acceptance of the plan. To run the opposition's anti-Young Plan campaign, Hugenberg engaged Adolf Hitler, the leader of the apparently moribund NSDAP (National Socialist German Workers' Party). The objective was to force the German government into a repudiation of the reparations debt as well as of the war-guilt clause of Versailles upon which the debt rested. German signatories to the Young Plan, moreover, were to become liable to the charge of treason. The right wing's initiative did force the Reichstag into reconsidering its approval of the Young Plan, but to no avail. The national plebiscite that necessarily followed found only 13.8 percent of the voters favouring the objectives of the right wing. The bitterness of the campaign, however, may have contributed to the illness and death during the campaign of Stresemann.

The end of the republic. An unintended effect of the anti-Young Plan campaign was to give widespread public exposure to the little-known Adolf Hitler. Hitler used his access to the Hugenberg-owned press empire and to its weekly movie newsreels to give himself and his Nazi movement national publicity. An additional assist to Hitler's career came on Oct. 29, 1929, with the stock market crash on Wall Street, an event that signaled the onset of what quickly became a worldwide depression. The crash had an immediate effect in Germany as American investors, anxious about their financial position, began withdrawing their loans to Germany. German indebtedness to these investors had by 1929 reached nearly 15 billion marks. Prices on the German stock exchanges fell drastically during the last month of the year. Business failures multiplied. Early in 1930 Germany's second-largest insurance firm collapsed. Unemployment rose to three million during the course of the year. By the winter of 1932 it reached six

million. Germany's industry was working at no more than 50 percent of its capacity, and the volume of German foreign trade fell by two-thirds between 1929 and 1932.

The first critically important political effect of the economic crisis came in March 1930 when the government coalition fell apart over the rising cost of maintaining the unemployment program adopted in 1927. The SPD, representing labour, and the Peoples' Party (VP), representing business, were unable to agree on the size of the government's contribution to the fund, and therewith the government fell. When a new coalition could not be found. parliamentary democracy in Germany came to an end.

President Hindenburg was forced by the situation to invoke his emergency powers (Article 48), which he used to appoint Heinrich Bruning of the Catholic Centre Party as chancellor. For the next two years, until May 30, 1932. Brüning governed without a parliamentary majority, deriving his authority from the powers residing in the office of President Hindenburg. However well-intentioned, Brüning's deflationary economic policies were unable to stem the tide either of the depression or of its social and political ravages. His fateful decision to call for Reichstag elections in September 1930, moreover, inadvertently opened the door for the enemies of Weimar democracy. Together the Nazis and the Communists gained nearly one of every three votes cast. The 18 percent acquired by the Nazis represented seven times the total number of votes they had received in 1928; the 13 percent won by the Communists represented a healthy gain over the 10 percent of 1928.

Although bitterly opposed to each other, the Nazis and Communists during the next two years succeeded in mobilizing the political and economic resentments generated by the depression. Hitler's charismatic appeal and the youthful energies of his movement were attractive to large segments of a populace fearful of being ruined by economic and social disaster. Hitler's record as a war veteran lent authority to the hypernationalism he expressed in racist terms. His identification of the Jew as the enemy responsible for all of Germany's ills, be it the defeat of 1918, the Treaty of Versailles, the reparations, the inflation, or now the depression, seemed plausible to many eager to find a scapegoat. The power of Hitler's appeal was reflected in the party's growing membership lists (1929: 170,000 members; 1932: 1,378,000 members) and in the swelling ranks of the party's paramilitary SA (Sturmabteilung), the infamous storm troopers.

The Communists, unlike Hitler, found it difficult to extend their support beyond the German working classes. Their political flexibility, moreover, was limited by the fact that they increasingly fell under the control of Stalin. Nonetheless, their self-confidence was greatly enhanced because the depression seemingly confirmed their analysis of the inevitable collapse of capitalism. Hitler and National Socialism they perceived merely as products of the

last phase of capitalism.

The winter of 1931-32 witnessed the depression at its depths. Unemployment was still rising; the succession of business failures resembled rows of falling dominoes. Brüning, helpless in the face of these problems, was dubbed "the hunger chancellor" by his critics. Some hope of breaking through the political impasse was offered by the series of critical state legislative elections scheduled for the spring of 1932 and by the presidential election required at the expiration of Hindenburg's first term. The 84-year-old Hindenburg was with great difficulty prevailed upon to seek a second term. The year 1932 was to be one of continuous election campaigning.

Hitler chose to challenge Hindenburg for the presidency. Although Hindenburg was eventually reelected, a runoff was necessary, and Hitler was able to take 37 percent of the popular vote. His larger aim, however, had been to make himself the leading, or only, candidate for Brüning's position as chancellor. Hindenburg did choose to replace Brüning in May 1932, but rather than Hitler he named the political dilettante Franz von Papen. Desperate to find for himself a base in parliament, Papen called for Reichstag elections in July. The result was a disaster for Papen and another triumph for the Nazis, who took 37 percent

Heinrich Brüning

The stock market crash of

of the vote, the largest total they were ever to acquire in a free election. The Communists won 15 percent of the vote. Thus the two parties dedicated to destroying German democracy held a majority in the Reichstag. Still, Hitler did not get the chancellorship. In November Papen called for another Reichstag election in the hope of gaining parliamentary backing. Again he failed, although the Nazi vote fell by 4 percent. The Communist vote, on the other hand, rose to nearly 17 percent. In early December, when Hindenburg decided to replace Papen, he again ignored Hitler, choosing instead a friend from the army, General Kurt von Schleicher.

In the Nazi camp there was bitter frustration at the end of 1932. The party was deeply in debt and demoralized by the year's endless campaigning. Putschist elements in the party, never persuaded that elections could bring the party to power, were growing increasingly restive. So deep was the frustration that on December 7 Gregor Strasser, second only to Hiller in the party, broke with the Nazis and retired from politics.

THE THIRD REICH, 1933-45

The Nazi revolution. When Hitler finally became chancellor on Jan. 30, 1933, it was not on the crest of a wave of popular support but as the result of backroom political intrigue by Schleicher, Papen, and the president's son, Oskar von Hindenburg, Only Hitler, they believed, could bring together a coalition with Hugenberg's DNVP and possibly the Centre Party that could command a majority in the Reichstag. They assured the reluctant president that Hitler's radical tendencies would be checked by the fact that Papen would hold the vice-chancellorship and that other conservatives would control the crucial ministries, such as those of war, foreign affairs, and economics. The Nazis themselves were restricted to holding the chancellorship and the powerless ministry of the interior. As a sop to the Nazis, Hermann Göring was granted ministerial status but given no portfolio; yet, significantly, he became interior minister in the state of Prussia, which gave him control over the largest police force in Germany

The Nazis brought with them an ideology that purported to champion the common man, whom they portrayed as victimized in a world controlled by Jews. Anti-Semitism and notions of German racial superiority were at the core of this ideology, which, in its particulars, was also a catalog of resentments that had accumulated in German society since November 1918. Heading the list were the humilitations associated with Versailles, but not far behind were resentments of big business, big banks, big department stores, and big labour, as well as resentments of the divisiveness and inefficiencies seemingly being fostered by political particle.

Neither the 25-point party program (1920) nor Hitler's autobiographical Mein Kampf (1925) contained clear conceptions of how the German world would be structured under the Nazis, but Hitler and his propagandists had communicated clearly that the changes would be fundamental and come at the expense of Germany's racial enemies. Racially superior Germans were to be gathered into a tightly knit Volksgemeinschaft, or racial community, in which divisions of party and class would be transcended in a spirit of racial harmony, a harmony that would necessarily exclude people of inferior blood. The logic of this construct required a solution to what the Nazis called "the Jewish problem." At the very least it called for a reversal of the trend, more than a century old, of Jewish assimilation into the allegedly superior German nation and into German cultural and economic life. As for Germany's position in international affairs, Hitler had long spoken of Germany's need for living space (Lebensraum) in the east. First, however, there was the continued need to break the chains of the hated Treaty of Versailles.

Whether the Nazis would ever get a chance to implement their ideological objectives depended, when Hilter became chancellor, upon whether they would be able to tighten their initially tenuous hold on the reins of power. Liberals, socialists, and communists remained bitterly opposed to Hilter, important segments of business, the army, and the churches were to varying degrees suspicious of the measures he might take. It was a combination, finally, of Hitler's daring and brutality, of the weaknesses of his opponents, and of numerous instances of extraordinary good luck that allowed him to establish his totalitarian dictatorship. When the Centre Party refused to join the Nazi-DNVP coalition in January 1933, Hitler demanded elections for a new Reichstag. The elections of March 5 1933, were preceded by a brutal and violent campaign in which Nazi storm troopers under the command of Ernst Röhm figured prominently. Hitler was also able to take advantage of the Reichstag fire (probably the work of a lone and deranged Dutch communist) of February 27 to suspend civil liberties and arrest Communist as well as other opposition leaders. Despite this campaign of terror the Nazis did not win a majority, gaining only 43.9 percent of the total. The 8 percent acquired by the DNVP, however, was sufficient for the two parties to wield a majority in the Reichstag. At its first meeting on March 23 this Reichstag, under great pressure from the SA and Heinrich Himmler's SS (Schutzstaffel; "Protective Echelon"), voted in favour of an Enabling Act that gave Hitler power to ignore the constitution and to give his decrees the power of law

The decree powers were the pseudolegal base from which Hitler carried out the first steps of the National Socialist revolution. Within two weeks of the passing of the Enabling Act, Nazi governors were sent out to bring the federal states into line, and a few months later the states themselves were abolished. On April 7, 1933, the civil service, including the universities, began to be purged of socialists, democrats, and Jews. On May 2 the trade unitions were disbanded and replaced by what the Nazis called a Labour Front. In the meantime Göring had begun refashioning the political arm of the Prussian police into a secret political police (Gestapo [Geheime Statspolizei]) to serve the Nazi cause, a process that was being duplicated by Himmler with the Bavarian police.

The brutality with which Hitler proved willing to meet any presumed challenge to his authority became dramatically evident in his ordering the June 30, 1934, murders of the SA leadership. Röhm's storm trooper street thugs had provided useful muscle during the party's long years of struggle, but their continuing penchant for unruliness, Hitler feared, could invite the army's intervention and therewith his own overthrow. To head off this possibility, Hitler engaged the loyal Himmler, who used his SS during the so-called Night of Long Knives to purge the SA of dozens of its top leaders, including Hitler's longtime friend Ernst Röhm. The penultimate step in Hitler's seizure of power came on Aug. 2, 1934, when, upon the death of President Hindenburg, he appropriated for himself the powers of the presidency and combined them with his own as chancellor. The final step came in February 1938 when Hitler took personal command over the three branches of the German armed forces.

The totalitarian state. The main purpose of the Nazi revolution, the goal to which power was to be put, was the establishment of the Volksgemeinschaft. Its creation required the purification and increase of the German race as well as its biological separation from the Jews, whose infusion of evil into the German bloodstream, the Nazis said, served to pollute and undermine Germany's wellbeing. Nazi efforts to purify the German race found a degree of scientific respectability from the new science of eugenics, the racial hygiene movement that flourished widely in the early decades of the 20th century. Nazi leaders spoke of their efforts to "reconstruct the German race." A Law for the Protection of Hereditary Health (July 14, 1933) allowed for the eventual sterilization of as many as two million people deemed unworthy of propagating. A Marriage Subsidy Law of July 1933 was calculated to stimulate the birth rate by granting loans to newly married couples; these loans would be forgiven incrementally with the birth of each additional child. The Nazi idealization of mothers and the celebration of motherhood as a special service to the Reich had the same objective. Hitler spoke of an eventual doubling of the German population through these measures. The most notorious of the steps taken to purify the German race was also a milestone

Krietall.

nacht

in the anti-Jewish legislation promulgated by the Nazis: the infamous Nürnberg Laws of September 1935, which forbade marriage or sexual relations between Jews and Germans and assigned to Jews a lower class of citizenship.

Nazi efforts to solve the "Jewish problem" were ultimately products of a vicious anti-Semitism that propelled the Nazi system toward increasingly extreme measures of persecution. SA terrorism, legislation expelling Jews from the civil service and universities, boycotts of Jewish businesses and professional people, and the eventual expropriation of Jewish-owned properties had by 1938 led to the emigration of roughly half of the 1933 Jewish population of 500,000 people. Until the massive display of violence against Jews and Jewish property known as Kristallnacht (Night of Broken Glass), during the night of Nov. 9-10, 1938, it still seemed possible for some Jews to remain in Germany, albeit in severely circumscribed circumstances. With Kristallnacht the Nazis ushered in a new level of persecution. In its aftermath Hitler put Hermann Göring in charge of Jewish policy. It became Göring's job to coordinate the numerous party and governmental agencies competing for control over-and profit from-the persecutions of the Jews.

To exclude Jews from the Volksgemeinschaft was as critical a need as attracting the German working classes to it, thereby undoing the long-standing alienation of the largely socialist-minded German worker from the nationalist consensus. Any success in this effort depended heavily upon the Nazis' ability to provide employment for the millions of jobless whom they inherited in 1933. Public spending on rearmament and on public works projects such as the superhighway, or autobahn, network helped create many of the jobs so desperately needed. By 1937 Germany was beginning to suffer from a labour shortage. It was equally important to inculcate workers with a sense of being an integral part of a racially based national community. For this the Nazis devised an elaborate program of subsidies for leisure-time activities for workers, Called "Strength through Joy," the program subsidized workers' vacations: it made possible excursions to mountain or seaside resorts and offered the possibility of cruises in the Mediterranean or the Baltic Sea. By providing leisure activities for the workers until then reserved for their economic and social superiors, the government attempted to integrate them into the Volksgemeinshaft. Workers were also given the opportunity to purchase an automobile, the Volkswagen. a symbol of wealth and status still largely reserved in the early 1930s for the upper classes. Hitler once said that Henry Ford had done more than anyone else to obliterate class differences in America.

Foreign policy. Hitler kept tight control over foreign affairs, formulating himself both the strategy and the tactics calculated to achieve his goals. The immediate objective was to reestablish Germany's position in world affairs; by this Hitler meant ending the humiliations attending the Treaty of Versailles, such as the demilitarized Rhineland and the limitations on German armaments. The chains of that treaty needed to fall with a loud clang, he said. The larger objective, the one he had spoken about since his entry into politics in the early 1920s, was the conquest for Germany of Lebensraum. Hitler believed that this space needed to be acquired in the east, at the expense of the Soviets, so as to secure for Germany the Ukrainian "breadbasket" and open up vast territories for German colonization. Hitler found justification for such conquests in his notions of German racial superiority over the Slavic peoples who inhabited the lands he coveted. Furthermore, he saw the Bolsheviks who now controlled Russia as the vanguard of the world Jewish conspiracy. Control of this territory was to become the foundation for Germany's economic and military domination of Europe and eventually, perhaps, of the world.

No such domination or expansion was possible without war, of course, and Hitler did not shrink from its implications. His rearming of Germany, begun in secret in 1933, was made public in March 1935 when he announced the creation of an air force and the reintroduction of general military conscription to provide the manpower for 36 new divisions in the army. In June of that same year he signed

an agreement with the British that allowed a German naval buildup of up to 35 percent of Britain's surface naval strength and up to 45 percent of list tonnage in submarines. On March 7, 1936, he moved German forces into the demilitarized Rhineland. Versailles was dead. Neither the British nor the French had lifted a finger in its defense, choosing instead to sign agreements expressly negating the terms of Versailles. By 1936 Hitter was spending 10.2 billion marks on rearmament, and Göring was placed in charge of a so-called Four-Year Plan to prepare the German economy for war. On Nov. S, 1937, Hitter gathered his general staff and admonished them to be prepared for war in the east no later than 1942 or 1943.

As a cover for his true intentions during the first years of power. Hitler spoke long and often of his desire for peace. All he wanted, he said, was a Germany allowed its rightful place in world affairs. As evidence of his pacific intentions he signed in January 1934 a 10-year nonaggression pact with Poland. A truer picture of his intentions became evident in July 1934, however, when Hitler encouraged the Nazi party in Austria to attempt an overthrow of the government of Chancellor Engelbert Dollfuss. Doll-fuss was shot and killed, but the coup attempt was badly managed. Benito Mussolini's movement of Italian troops to the Austrian border forced Hitler to back away from supporting his Austrian partners.

It was from behind a cloak of anti-Bolshevism, carefully maintained by Propaganda Minister Joseph Goebbels, that Hitler managed to delude France and Britain, as well as the United States, leery of being drawn into another European quarrel, into accepting his claim to be the West's last bulwark against Bolshevik expansion. His agreement with the Japanese in 1936, the Anti-Comintern Pact, was directed against the Third Communist International. A year later Mussolini, after a year of German-Italian cooperation in aiding General Francisco Franco's rebel forces in the Spanish Civil War, added his signature to the pact.

Hitler made two dramatic foreign policy moves in 1938 that helped clarify to the world the extent of his less-thanpacific intentions. In March he annexed Austria to the Reich, justifying the move as a fulfillment of the principle of German national self-determination. Britain and France stood by quietly at this additional repudiation of the Versailles treaty. Next, Hitler engineered a diplomatic crisis with Czechoslovakia, claiming Czech mistreatment of its German minority in the Sudetenland. Against considerable opposition from his own military, Hitler was determined to go to war with the Czechs. Only through the intervention of Britain's Prime Minister Neville Chamberlain, who offered to come to Germany to appease Hitler and who managed to persuade the Czechs to yield to all of Hitler's demands, was war avoided. Chamberlain's intervention resulted in a four-power conference at Munich in late September 1938, at which the Italians, the French, and the British ceremoniously handed the Sudetenland over to Hitler. In diplomatic parlance ever since, the word "Munich" has come to symbolize caving in to the demands of a dictator.

Certain that Britain and France would do nothing to stop him, Hitler, after Munich, decided to move up his timetable for conquests in the east. On March 15, 1939, Hitler seized what remained of Czechoslovakia, reshaping its pieces into a Bohemian and Moravian protectorate and a nominally independent state of Slovakia. Within a week he annexed from Lithuania the city of Memel and the surrounding countryside, territory lost to Germany as a consequence of Versailles. When Britain and France countered these moves by issuing their guarantee to Poland, clearly next on Hitler's agenda, a furious Hitler ordered his military to prepare an invasion of Poland. Poland was critical to Hitler's long-range strategy for the conquest of Lebensraum in the east; any invasion of the Soviet Union required that Polish territory be available as a staging area. Until the British-French guarantee he had hoped to enlist Poland, mostly through bombast and threat, as an ally in an attack on the Soviet Union. After the defeat of the Soviet Union, he believed Poland could be dealt with summarily. When Poland refused to play the role he had assigned it, Hitler began looking for allies in his resolution

Annexation of Austria Soviets for a few years. Thus prepared, on Sept. 1, 1939, Hitler launched his invasion of Poland. Two days later Britain and France declared war on Germany.

World War II. World War II is appropriately called "Hitler's war." The first two years were so extraordinarily successful that Hitler came close to realizing his aim of establishing a German hegemony in Europe. But his victories did not prove to be the essential components of a strategic conception that secured victory in the long run. Nonetheless, the early successes were spectacular. After the defeat of Poland within a month, Hitler turned his attention westward. He believed that it was necessary to defeat Britain and France before he could again turn eastward to the territories that were to become the "living space" for his new empire. The attack on the western front began in the spring of 1940. Hitler took Denmark and Norway during the course of a few days in April, and on May 10 he attacked France, along with Luxembourg, Belgium, and The Netherlands. Once again his armies achieved lightning victories; Luxembourg, Belgium, and The Netherlands were overrun in a few days, and France capitulated on June 21. Only the British, now alone, obstructed Hitler's path to total victory in the west.

Britain, Hitler determined, could be taken out of the war with air power. German bombers began their attack in August 1940, but the British proved intractable. The vaunted German air force failed to bring Britain to its knees partly because of the strength of the British air force, partly because the German air force was ill-equipped for the task, and partly because the British had been able since February 1940 to read German code. Yet Hitler had been so confident of a quick victory that even before the attack began he had ordered his military planners to draw up plans for an invasion of the Soviet Union. The date he

set for the invasion was May 15, 1941.

Although the defeat of the Soviet Union was central to Hitler's strategic objective, he twice during the early months of 1941 allowed himself to be sidetracked into conflicts that delayed his invasion. In both instances he felt obliged to rescue his ally Mussolini from military difficulties. Mussolini had invaded Greece in October 1940, despite the fact that he was already in difficulty in North Africa, where he was unable to cut off Britain's Mediterranean lifeline in Egypt. In February 1941 Hitler decided to reinforce Mussolini in North Africa by sending an armoured division under the command of General Erwin Rommel. When Mussolini's invasion of Greece also bogged down, Hitler again decided to send reinforcements. To reach Greece, German troops had to be sent through the Balkan countries, all of them officially neutral. Hitler managed to bully these countries into accepting the passage of German troops, but on March 27 a coup in Yugoslavia overthrew the government, and the new rulers reneged on the agreement. In retaliation Hitler launched what he called Operation Punishment against the Yugoslavs. Yugoslav resistance collapsed quickly, but the effect was to delay for another month the planned invasion of the Soviet Union.

When the invasion of the Soviet Union finally came, on June 22, 1941, it did so with both campaigns against the Briish, across the English Channel and in the Mediterranean, still incomplete. Hitler was prepared to take the risk that fighting on multiple fronts entailed because he was convinced that the war against the Soviet Union would be over by the onset of the Russian winter. The spectacular German advances during the first weeks of the invasion seemed proof of Hitler's calculation. On July 3 his army chief of staff wrote in his war diary that the war had been won. The German Army Group North was

approaching Leningrad; Army Group Centre had broken through the Soviet defenses and was rushing toward Moscow; and Army Group South had already captured vast reaches of the Ukraine. The prospect of capturing the summer harvest of the Ukraine along with the oil fields of the Caucasus led Hitler to transfer troops driving toward Moscow to reinforce those operating in the south.

Moscow to reinforce those operating in the south. Hitler's generals later considered this decision a turning point in the war. The effect was to delay until October the drive toward Moscow. By then an early winter had set in, greatly impeding the German advance and finally bringing it to a hall at the outskirts of Moscow in early December. Then, on December 6, the Soviets, having had time to regroup, launched a massive counteroffensive to relieve their capital city. On the following day the Japanese, norminally Germany's ally, launched their attack on the U.S. naval base at Pearl Harbor in Hawaii. Although they had not bothered to inform Hitler of their intentions, he was jubilant when he heard the news. "Now it is impossible for us to lose the war," he told his aides. On December 11 he declared war on the United States.

Though his plans for a quick defeat of the Soviet Union had not been realized, Hitler's troops at the end of 1941 controlled virtually all of the European territory of the Soviet Union. They stood at the outskirts of Leningrad and Moscow and were in control of the entire Ukraine. To prepare for what would now have to be the campaign of 1942, Hitler dismissed a number of generals and assumed himself the strategic and operational command of

the armies on the eastern front.

At the high point of Hitler's military successes in the Soviet Union, members of the Nazi leadership were, with Hitler's understanding, feverishly planning for the new order they intended to impose on the conquered territories. Its realization called both for the removal of obstacles to German settlements and for a solution to the "Jewish problem." Nazi planners were drafting an elaborate scheme, General Plan East, for the future reorganization of eastern Europe and the western Soviet Union which called for the elimination of 30 million or more Slavs and the settlement of their territories by German overlords who would control and eventually repopulate the area with Germans. During the fall of 1941 Heinrich Himmler's SS expanded and refurbished with gas chambers and crematoriums an old Austrian army barracks near the Polish rail junction at Auschwitz. Here was to continue, with greater efficiency, the mass murder of Jews that had begun with the June invasion, when SS murder squads began rounding up Jews and shooting them by the thousands. The assurance of victory in the east, the heartland of European Jewry, gave Nazis the confidence that the "Jewish problem" could be rendered amenable to a "final solution." Experts suggest that ultimately somewhere between five and six million Jews were murdered in the death factories of eastern Europe. At least an equal number of non-Jews died of murder and starvation in places like Auschwitz, including two and a half million Soviet prisoners of war and countless others from the eastern European nationalities.

The success of Nazi armies until the end of 1941 had made it possible to spare German civilians on the home front from the misery and sacrifices demanded of them during World War I. Hitler's imagination, however, was haunted by the memory of the collapse of the home front in 1918, and to avoid a repetition the Nazis undertook to loot the occupied territories of food and raw materials as well as labour. Food shortages in Germany were not serious until late in the war. Women were allowed to stay at home, and the energies of the German work force were not stretched to their limits because eventually some seven million foreign slave labourers were used to keep the war effort goine.

Through much of 1942 an ultimate German victory still seemed possible. The renewed offensive in the Soviet Union in the spring at first continued the successes of the previous year. Once again Hitler chose to concentrate on the capture of the Caucasu and its oil at the expense of the Moscow front. The decision made inevitable a major battle over the industrial centre at Stalingrad (now Volgograd). Elsewhere, by midsummer of 1942, Rommel's

Invasion of the Soviet Union Afrika Korps advanced to within 65 miles of Alexandria in Egypt. In the naval battle for control of the Atlantic sea lanes, German submarines were able to maintain their ability to intercept Allied shipping into mid-1943.

By early 1943, however, the tide had clearly begun to turn. The great winter battle at Stalingrad brought Hitler his first major defeat. His entire Sixth Army was killed or captured. In North Africa Rommel's long success ended in late 1942 when the British broke through at El Alamein. At the same time a joint British-American force landed in northwestern Africa on the coast of Morocco and Algeria. By May 1943 the German and Italian forces in North Africa were ready to surrender. That same summer the Allies broke the back of the German submarine campaign in the Atlantic. On July 10 the Allies landed in Sicily. Two weeks later Mussolini was overthrown, and in early September the Italians withdrew from the war.

The addition of an Italian front made the rollback of German forces on all fronts that much more likely. In the Soviet Union, German forces were stretched across 2,500 miles. They had lost their air superiority when Allied bombing raids on German cities forced the withdrawal of large numbers of fighter planes. Allied bombings reached a high point in midsummer when a raid on Hamburg killed 40,000 of its inhabitants. Other cities suffered similar raids. Shortages of food, clothing, and housing began to afflict German cities as inevitably as did the Allied bombers

The rollback of German forces continued inexorably during 1944. On June 6 the Allies in the west launched their invasion of France across the English Channel. In the east the Soviet Army was advancing along the entire 2,500-mile front. By the end of the year it stood poised on the eastern frontiers of prewar Germany. In the west, British and American troops stood ready to attack across the western borders.

On the German home front, 1944 became a year of acute suffering. On July 20 an officers' plot, part of a long-simmering opposition to Hitler from within German military and civilian circles, was carried out, but Hitler managed to escape the dramatic attempt on his life practically unharmed. He attributed his survival to his having been selected by fate to succeed in his mission of restoring Germany to greatness.

Fate did not again intervene on Hitler's behalf. In mid-January of 1945 he withdrew underground into his bunker in Berlin where he remained until his suicide on April 30. By that time Soviet soldiers were streaming into Berlin. All that remained of the Reich was a narrow wedge of territory running southward from Berlin into Austria, (For further discussion of World War II, see WORLD WARS, THE.)

With the Soviet army in control of Berlin and the western Allies within striking distance to the west and the south. there was no prospect of dividing them. Nonetheless, when Hitler's successor, Grand Admiral Karl Dönitz, sought to open negotiations for a surrender a few days after Hitler's death, he still hoped that a separate surrender to the British and Americans in the west might allow the Reich to rescue something from the Soviets in the east. The western Allies, fearful of any move that might feed the suspicions of Stalin, refused to consider the German proposal, insisting that a German surrender be signed with all of the Allies at the same time. Early in the morning of May 7, 1945, a German delegation came to U.S. General Dwight D. Eisenhower's headquarters in Rheims, Fr., and at 2:41 AM signed the surrender documents. Despite the fact that a Soviet major general signed for the Soviet Union, Stalin insisted that a second surrender ceremony be arranged in Soviet-occupied Berlin. This second surrender was signed in a Berlin suburb the following afternoon. (KASC)

The era of partition

As a legacy of unconditional surrender at the end of World War II, a truncated Germany was divided into four zones of Allied military occupation; Berlin, the capital between 1871 and 1945 of the unified German Reich, was similarly divided. In 1949 the zones of occupation of France, the United Kingdom, and the United States were merged to form the Federal Republic of Germany (Bundesrepublik

Deutschland: commonly known as West Germany), with its capital at Bonn. The three western sectors of Berlin also had a separate administration, beginning in 1948, constituting West Berlin, West Berlin's political affiliation was with West Germany, although it was a detached exclave of territory at a distance of 110 miles (180 kilometres). Also in 1949 the Soviet zone became the German Democratic Republic (Deutsche Demokratische Republik; commonly known as East Germany), with its capital in the former Soviet sector of Berlin (i.e., East Berlin).

West Germany's recovery from total economic and political prostration and the devastation of its cities and capital industries at the end of World War II was of such dramatic proportions as to become a modern legend. The Wirtschaftswunder ("economic miracle") of the 1950s and '60s made it the world's fourth largest economy after the United States, the Soviet Union, and Japan and one of the world's largest trading nations.

West German recovery

Germany, 1952-90.

Domestically, the West German state grew into one of the most stable of Western democracies, with three major political parties competing peacefully for power. In large measure because of the 5 percent of votes required for representation in the federal parliament (Bundestag) and provincial diets, extremist parties of the right and left did not succeed in West German politics. The West Germans as citizens moved from their accustomed political apathy to becoming intensely involved and well-informed on the issues that affected their lives.

East Germany was established as a socialist state of the Stalinist type and became a member of the Council for Mutual Economic Assistance (Comecon) and of the Warsaw Pact military alliance. It had the most advanced economy and the highest living standards of all the Sovietbloc states, but industrially it lagged behind the Western level. To outside observers, the centralized and dictatorial regime of the Socialist Unity Party (a forced union of the Social Democratic Party with the Communists), buttressed by the omnipresent State Security Police (Stasi), appeared unassailable. But the precarious nature of this foundation was demonstrated by the East German government's swift and unforeseen collapse under popular pressure in late 1989, most strikingly symbolized by the opening of the Berlin Wall on November 9. At free elections on March 18, 1990, the majority of East Germans, by voting for the counterpart of the West German Christian Democratic Union, signaled their wish to join the Federal Republic at the earliest possible moment (see below, The reunification of Germany). (T.H.El./G.H.K./Ed.)

OF THE TWO GERMANIES, 1945-49

Following the German military leaders' unconditional surrender in May 1945, the country lay prostrate. The German state ceased to exist, and sovereign authority passed to the victorious Allied powers. The physical devastation from Allied bombing campaigns and from ground battles was enormous: an estimated one-quarter of the nation's housing was destroyed or damaged beyond use, and in many cities the toll exceeded 50 percent. Germany's economic infrastructure had largely collapsed as factories and transportation systems ceased to function. Rampant inflation was undermining the value of the currency, and an acute shortage of food reduced the diet of many city dwellers to the level of malnutrition. These difficulties were compounded by the presence of millions of homeless German refugees from the east. The end of the war came to be remembered as "zero hour," a low point from which virtually everything had to be rebuilt anew from the ground up.

For purposes of occupation, the Americans, British, French, and Soviets divided Germany into four zones. The American, British, and French zones together made up the western two-thirds of Germany, while the Soviet zone comprised the eastern third, Berlin, the former capital, was placed under joint four-power authority but was partitioned into four sectors for administrative purposes. An Allied Control Council was to exercise overall joint

Allied

zones of

occupation

Not all of prewar Germany was included in these arrangements. The Soviets unilaterally severed the German territories east of the Oder and Neisse rivers and placed these under the direct administrative authority of the Soviet Union and Poland, with the larger share going to the Poles as compensation for territory they lost to the Soviet Union. The former provinces of East Prussia, Pomerania. and Silesia were thus stripped from Germany. Since virtually the entire German population of some 9.5 million in these and adjacent regions was expelled westward, this amounted to a de facto annexation of one-quarter of Germany's territory as of 1937, the year prior to the beginning of German expansion under Hitler. The Western Allies acquiesced in these actions by the Soviets, taking consolation in the expectation that their postwar territorial dispositions were merely temporary expedients that would quickly be superseded by the final peace terms.

As a result of irreconcilable differences among the Allied powers, however, no peace conference was ever held. The issue of German reparations proved particularly divisive. The Soviet Union, whose population and territory had suffered terribly at the hands of the Germans, demanded large-scale material compensation. The Western Allies initially agreed to extract reparations but soon came to resent the Soviets' seizures of entire German factories as well as current production. Under the terms of inter-Allied agreements, the Soviet zone of occupation, which encompassed much of German agriculture and was less densely populated than those of the other Allies, was to supply foodstuffs to the rest of Germany in return for a share of reparations from the western occupation zones. But when the Soviets failed to deliver the requisite food, the Western Allies found themselves forced to feed the German population in their zones at the expense of their own taxpayers. The Americans and British therefore came to favour a revival of German industry so as to enable the Germans to feed themselves, a step the Soviets opposed. When the Western powers refused in 1946 to permit the Soviets to claim further reparations from their zones, cooperation among the wartime allies deteriorated sharply.

During the postwar years two quite different economic and social systems took shape. In the western zones the Allies permitted a market economy based on private property to reemerge, though at the outset under extensive regulation. The emergence of a free and pluralistic press was also fostered. In carrying out the policy of de-Nazification agreed upon by all four Allied powers, the Western occupation authorities sought to punish those Germans who had been deeply involved in the Nazi regime while levying lighter penalties on those less implicated. The Soviets proceeded against former Nazis in their occupation zone more summarily and with little attempt at differentiating among degrees of complicity. They subjected the press and all other means of communication in their zone to increasingly close censorship. In the economic sphere they nationalized most industries without compensation for the previous owners, and they effected a sweeping agrarian reform by expropriating large estates and distributing the land among small farmers.

Beginning in the summer of 1945, the occupation authorities permitted the formation of German political parties preparatory to elections for new local and regional representative assemblies. Two of the major leftist parties of the Postwar Weimar era quickly revived: the moderate Social Demo-political cratic Party (SPD) and the German Communist Party (KPD), which was loyal to the Soviet Union. These were soon joined by a new creation, the Christian Democratic Union (CDU), with its Bayarian sister party, the Christian Social Union (CSU). The leaders of this Christian Democratic coalition had for the most part been active in the moderate parties of the Weimar Republic, especially the Catholic Centre Party. They sought to win popular support on the basis of a nondenominational commitment to Christian ethics and democratic institutions. Liberalminded Germans who favoured a secular state and laissezfaire economic policies formed a new Free Democratic Party in the western zones and a Liberal Democratic Party in the Soviet zone. Numerous smaller parties were also

launched in the western zones.

In April 1946, under pressure from the occupation authorities, the Social Democratic leaders in the Soviet zone agreed to merge with the Communists, a step denounced by the Social Democrats in the western zones. The resulting Socialist Unity Party (SED) swept to victory with the ill-concealed aid of the Soviets in the first elections for local and regional assemblies in the Soviet zone. However. when in October 1946 elections were held under fairer conditions in Berlin, which was under four-power occupation, the SED tallied fewer than half as many votes as the Social Democratic Party, which had managed to preserve its independence in the old capital. Thereafter, the SED, which increasingly fell under communist domination as Social Democrats were systematically purged from its leadership ranks, avoided free, competitive elections by forcing all other parties to join a permanent coalition

under its leadership.

The occupying powers soon approved the formation of regional organs of self-administration called Länder (singular Land), or "states." By 1947 those Länder established in the western zones had freely elected parliamentary assemblies. Institutional developments followed a superficially similar pattern in the Soviet zone, but there the political process remained less than free because of the dominance of the Soviet-backed SED.

When it had become apparent by 1947 that the Soviet Union would not permit free, multiparty elections throughout the whole of Germany, the Americans and British amalgamated the German administrative organs in their occupation zones in order to foster economic recovery. The resulting unit, called Bizonia, operated through a set of German institutions located in the city of Frankfurt am Main. Its federative structure would later serve as the

model for the West German state.

In the politics of Bizonia, the Social Democrats and the Christian Democrats quickly established themselves as the major political parties. The Social Democrats held to their long-standing commitment to nationalization of basic industries and extensive government control over other aspects of the economy. The Christian Democrats, after initially inclining to a vaguely conceived "Christian socialism," swung to espousal of a basically free-enterprise orientation. In March 1948 they joined with the laissezfaire Free Democrats to install as architect of Bizonia's economy Ludwig Erhard, a previously obscure economist who advocated freeing the economy from government control.

When repeated meetings with the Soviets failed to produce four-power cooperation, the Western occupying powers decided in the spring of 1948 to move on their own.

Creation of West Germany

The Soviets responded angrily to the currency reform, which was undertaken without their approval. When the new Deutsche Mark was introduced into Berlin, they protested vigorously and boycotted the Allied Control Council. Then, in June 1948 they blockaded the western sectors of the old capital, which were surrounded by territory occupied by the Soviet Red Army and lay about 100 miles from the nearest Western-occupied area. By sealing off the railways, highways, and canals used to deliver food and fuel, as well as the raw materials needed for the factories of a city of more than two million people, the Soviets sought to paralyze West Berlin and drive out their erstwhile allies. They were thwarted, however, when the Western powers mounted an around-the-clock airlift that supplied the West Berliners with food and fuel throughout the bleak winter of 1948-49. In May 1949 the Soviets relented and lifted the blockade.

Formation of the Federal Republic of Germany. Instead of halting progress toward the political integration of the western zones, as the Soviets apparently intended, the Berlin blockade accelerated it. In April 1949 the French began to merge their zone into Bizonia, which became Trizonia. That September a Parliamentary Council of 65 members chosen by the parliaments of the Länder began drafting a constitution for a West German government, Twenty-seven seats each in this council were held by the Social Democrats and the Christian Democrats, five by the Free Democrats, and the rest by smaller parties, including two by the Communists. The Council completed its work in the spring of 1949, and the Federal Republic of Germany came into being in May 1949 after all the Länder except Bavaria had ratified the Basic Law (Grundgesetz), as the constitution was designated to underline the provisional nature of the new state. This document specified that it was designed only for temporary use until a constitution had been freely adopted by the German people as a whole.

The Basic Law was approved by the Western Allied military governors with certain reservations, notably the exclusion of West Berlin, which had been proposed as the 12th Land of the federation. The 11 constituent Lander of West Germany, then, were Bavaria, Bremen, Hamburg, Hesse, Lower Saxony, North Rhine-Westphalia, Rhineland-Palatinate, Schleswig-Holstein, Baden, Württemberg-Baden, and Württemberg-Hohenzollern (the last three were merged in 1952 to form Baden-Württemberg, and in 1957 Saarland became the 10th Land).

By the terms of the Basic Law, the Federal Republic of Germany was established with its provisional capital in the small university city of Bonn. The West German state took shape as a federal form of parliamentary democracy. An extensive bill of rights guaranteed the civil and political freedoms of the citizenry. In keeping with German traditions, many spheres of governmental authority were reserved for the individual Länder. The key locus of power on the federal level lay in the lower legislative chamber, the Bundestag, elections for which had to take place at least every four years. The deputies were chosen by a voting procedure known as "personalized proportionality" that combined proportional representation with single-seat constituencies by according each voter two ballots-one for a party and one for a specific candidate. The composition of the chamber was ultimately determined by the percentage of the national vote each party received. But half the seats were filled by candidates who commanded the most votes in the constituencies, thereby giving the citizenry local advocates in the legislature. In order to minimize the proliferation of smaller political parties that had helped to discredit democracy in the Weimar Republic, a party had to win a minimum of 5 percent of the overall vote to gain representation in the Bundestag. All citizens 18 years of age and older were eligible to vote (until 1971 the minimum age was 21).

The Bundestag elected the head of government, the federal chancellor. Once installed, the chancellor chose members of the Cabinet, who presided over the ministries, and the chancellor determined and assumed responsibility for general policy. To rule out the instability that characterized the Cabinets of the Weimar Republic, the Basic Law introduced a novel provision designed to strengthen the constitutional position of the chancellor. It required that a majority vote of no-confidence in the Bundestag could unseat the chancellor and his Cabinet only if it was accompanied by a positive majority in favour of a substitute candidate for the chancellorship.

Whereas the chancellor headed the government, a federal president stood at the head of the state. Because of the misuse of presidential power in the Weimar Republic, the powers of this office were greatly reduced by the Basic Law, The president was not directly elected, as in Weimar. by popular vote, but instead was chosen indirectly by a federal convention. Half of that body, which came into being solely to select a president, was composed of members of the Bundestag, and the other half was chosen by the parliaments of the Länder. The president represented the Federal Republic in its formal dealings with other countries, accrediting and receiving envoys. In domestic affairs, presidential authority was limited to nominating candidates for the chancellorship and dissolving the Bundestag to make way for new elections in the event that no majority could be found to install a chancellor.

The Lânder were represented in the upper legislative chamber, the Bundesra. Its members were not elected but rather designated by the governments of the Lânder, the number varying according to the states' populations. Constitutional changes required a two-thirds vote in both the Bundesrat and the Bundestag. On all legislation affecting the rights of the Lânder the Bundesrat and an absolute veto. On other legislation a majority of the Bundesrat veto. On other legislation a majority of the Bundesrat by what is known as a "suspensive veto." If the margin in the Bundesrat was a simple majority, this could be overridden by a majority vote in the Bundestag, but if the margin was two thirds, a similar vote was necessary to override.

The final key institution of the Federal Republic was the Federal Constitutional Court. Independent of both the legislative and executive branches, it successfully introduced into German practice for the first time the American principle of judicial review of legislation. Half of its members were named by the Bundestag, the other half by the Bundesrat, each for a nonrenewable term of 12 years. Its seat was in the city of Karlsruhe.

Initially, the Federal Republic was not a sovereign state. Its powers were circumscribed by an Occupation Statute drawn up by the American, British, and French governments in 1949. That document reserved to those powers ultimate authority over such matters as foreign relations, foreign trade, the level of industrial production, and all questions relating to military security. Only with the permission of the Western occupation powers could the Federal Republic legislate or otherwise take action in those spheres. Alterations in the Basic Law required the unanimous consent of the three Western powers, and they reserved veto power over any legislation they deemed unconstitutional or at variance with occupation policies. In the event of an emergency that endangered the new West German government, the Western Allies retained the right to resume their full authority as occupying powers.

Formation of the German Democratic Republic. When it became clear that a West German government would be established, a so-called election for a People's Congress was held in the Soviet occupation zone in May 1949. But instead of choosing among candidates, voters were allowed only the choice of approving or rejecting—usually

Berlin blockade

West German governmental structure in less-than-secret circumstances-"unity lists" of candidates drawn from all parties, as well as representatives of mass organizations controlled by the communist-dominated SED. Two additional parties, a Democratic Farmers' Party and a National Democratic Party, designed to attract support, respectively, from farmers and from former Nazis, were added with the blessing of the SED. By ensuring that communists predominated in these unity lists, the SED determined in advance the composition of the new People's Congress. According to the official results, about two-thirds of the voters approved the unity lists. In subsequent elections, favourable margins in excess of 99 percent were routinely announced.

In October 1949, following the formation of the Federal Republic, a constitution ratified by the People's Congress went into effect in the Soviet zone, which became the German Democratic Republic (East Germany), with its capital in the Soviet sector of Berlin. The People's Congress was renamed the People's Chamber, and this body, together with a second chamber composed of officials of the five Länder of the Soviet zone (which were abolished in 1952 in favour of centralized authority), designated the communist Wilhelm Pieck of the SED as president of the German Democratic Republic on Oct. 11, 1949. The next day, the People's Chamber installed the former Social Democrat Otto Grotewohl as premier at the head of a Cabinet that was nominally responsible to the chamber. Although the German Democratic Republic was constitutionally a parliamentary democracy, decisive power actually lay with the SED and its boss, the veteran communist functionary Walter Ulbricht, who held only the obscure position of deputy premier in the government. In East Germany, as in the Soviet Union, the government served merely as the agent of an all-powerful communist-controlled party, which was in turn ruled from above by a self-selecting Politburo.

POLITICAL CONSOLIDATION AND ECONOMIC GROWTH, 1949-69

The government that emerged from the Federal Republic's first general election in August 1949 was based on a coalition of the Christian Democrats with the Free Democrats. Konrad Adenauer of the Christian Democratic Union, a veteran Roman Catholic politician from the Rhineland, was elected the country's first chancellor by a narrow margin in the Bundestag, Because of his advanced age of 73. Adenauer was expected by many to serve only as an interim officeholder, but in fact he retained the chancellorship for 14 years. Elected as West Germany's first president was Theodor Heuss of the Free Democratic Party. As economics minister in the Adenauer Cabinet, Ludwig Erhard launched the Federal Republic on a phenomenally successful course of economic revival under the formula of "social market economics," or welfare-state capitalism. His policies left the means of production in private hands and allowed market mechanisms to set price and wage levels. Social justice was served by means of government measures designed to ensure an equitable distribution of the wealth generated by the pursuit of profit. So successful were these modified free-market policies that West Germany soon abolished all rationing and became renowned for its "economic miracle" as industrial output rapidly recovered and living standards steadily rose.

One of the most urgent internal problems for Adenauer's first administration was the resettlement of refugees. By 1950 the Federal Republic had become the new home of 4.5 million Germans from the territory east of the Oder-Neisse line; 3.4 million ethnic Germans from Czechoslovakia, prewar Poland, and other eastern European countries; and 1.5 million from the German Democratic Republic. The presence of these refugees put a heavy social burden on the Federal Republic, but their assimilation proved surprisingly easy. Many of the refugees were skilled, enterprising, and adaptable, and their labour proved an important factor in West Germany's economic recovery.

In the German Democratic Republic, the SED regime accorded priority to building a viable economy in a territory that lacked rich natural resources, was less than onehalf the size of the Federal Republic, and had a population (17 million) only one-third as large. The regime used its centralized control over a planned economy to invest heavily in the construction of basic industries at the expense of the production of consumer goods. Moreover, war reparations required that much productive capacity be diverted to Soviet needs. Despite an impressive rate of industrial growth, the standard of living remained low. lagging far behind that of West Germany. Even food was a problem, as thousands of farmers fled to West Germany each year rather than give in to mounting pressure to merge their land (which many had only recently obtained through the postwar agrarian reform) into the collective farms favoured by the communist regime. Food rationing had to be continued long after it had ended in West Germany. The resulting material hardships, along with relentless ideological indoctrination, repression of dissent. and harassment of churches by a militantly atheistic regime prompted many thousands of East Germans to flee to West Germany every year. In 1952 East Germany sealed its borders with West Germany, but East Germans continued to leave through Berlin, where free movement still prevailed between the four separate occupation sectors of the city.

In the Federal Republic, Adenauer followed a resolute policy of linking the new West German state closely with the Western democracies, even at the cost of perpetuating Germany's division for the time being. In 1951 the chancellor succeeded in gaining membership for West Germany in the European Coal and Steel Community, which later served as the core of the European Communities (EC). In that same year the Americans, British, and French agreed to a revision of the Occupation Statute that substantially increased the internal authority of the Federal Republic. Skillfully exploiting the Western fears of a communist assault on Europe that had been awakened by the Korean War, Adenauer gained further concessions from the Western occupying powers in return for his agreement to rearm West Germany within the context of a western European defense system. In 1955 the Federal Republic became a full member of the North Atlantic Treaty Organization (NATO) and gained sovereignty over its foreign relations as the Occupation Statute expired. In 1957 it became one of the charter members of the European Economic Community.

With West Germany's economic recovery continuing impressively, the voters confirmed the policies of the Adenauer government: in the Bundestag election of 1953, the coalition of the Christian and Free Democrats increased its previously thin majority. In the election of 1957, the chancellor's party achieved the first absolute majority ever recorded by a German party in a free general election. The Free Democrats, who had left the government in 1956 because of policy disputes, remained in opposition thereafter, along with the Social Democrats.

Mounting dissatisfaction with the SED regime in East Germany led to the first popular uprising in the postwar Soviet bloc when workers in East Berlin, the seat of government, went on strike on June 17, 1953, to protest against increased production quotas. When the regime failed to respond, the workers took to the streets and demanded a change in government. The rebellion quickly spread throughout East Germany and was quelled only when Soviet troops intervened, killing at least 21 people and wounding hundreds of others. A wave of retribution followed, as some 1,300 were sentenced to prison for taking part in the uprising, which the East German government portrayed as a plot on the part of West Germany and the United States.

In the wake of the uprising, Joseph Stalin's successors in the leadership of the Soviet Union upgraded the status of the German Democratic Republic. In 1954 reparations to the Soviet Union were halted, and Moscow proclaimed East Germany a sovereign state. In 1955 East Germany became a charter member of the Warsaw Pact, the Soviet bloc's military alliance. The SED leadership loosened ideological controls on artistic and intellectual activities somewhat, and the production of consumer goods was increased. Pressure on farmers to enter collective farms was also relaxed. Agricultural yields improved, and the

last food rationing was ended in 1958. Within a few years, however, the government resumed its repressive measures and again shifted its economic priorities to favour the collectivization of agriculture and investment in heavy industry at the expense of consumer goods. The flight of refugees through Berlin continued, with a high proportion of technicians, managers, and professionals among them.

In 1961 the flow of refugees to West Germany through Berlin increased dramatically, bringing the total number of East Germans who had fled since the war to some three million. On Aug. 13, 1961, the East German government surprised the world by sealing off East Berlin from West Berlin, first by barbed wire and later by construction of a concrete wall through the middle of the city. No one was thenceforth permitted to go to the West through the tightly guarded crossing points without official permission. which was rarely granted. East Germans who sought to escape by climbing over the wall risked being shot by East German guards under orders to kill, if need be, to prevent the crime of "flight from the republic." By thus imprisoning the population, the SED regime stabilized the economy of East Germany, which eventually became the most prosperous of the Soviet bloc but which nevertheless continued to lag behind that of West Germany in both the quantity and quality of its consumer goods. Under party boss Ulbricht, the East German government also tightened the repressive policies of what had become a totalitarian communist dictatorship. Upon the death of President Pieck in 1960, Ulbricht had assumed the powers of the presidency as head of a newly created Council of State. In 1968 he imposed a new constitution on East Germany that sharply curtailed civil and political rights. In the Federal Republic's Bundestag election of 1961 the Christian Democrats suffered losses for the first time. The Social Democratic Party, which had broadened its appeal by jettisoning the last remnants of its Marxist past and accepting the existing economic system in its Bad Godesberg program of 1959, scored impressive gains. Adenauer managed to retain the chancellorship by forming another coalition with the Free Democrats, but his position was weakened. He had tarnished his image in 1959 when he announced his candidacy for the presidency only to withdraw in favour of the election of a lacklustre party colleague, Heinrich Lübke, when he realized that under the Basic Law the president had little power. The elderly chancellor was further weakened when in 1962 his defense minister, Franz Josef Strauss of the Bavarian Christian Social Union, adopted high-handed methods in bringing about the arrest of journalists of the popular weekly news magazine Der Spiegel in connection with an alleged security leak. At the insistence of the Free Democrats, Adenauer relinquished the chancellorship in October 1963 to Erhard. Although the Erhard Cabinet held its own in the election of 1965, the architect of the "economic miracle" himself fell from power in November 1966 when the Free Democrats withdrew their support because of disagreements over how to respond to a recession. For the next three years the Federal Republic was governed by a grand coalition of the two largest parties, the Christian Democrats and the Social Democrats, with Christian Democrat Kurt Georg Kiesinger as chancellor and Social Democrat Willy Brandt as foreign minister.

OSTPOLITIK AND RECONCILIATION, 1969-89

When the Social Democrats scored impressive gains in the Bundestag election of 1969 and also captured the presidency for their candidate, Gustav Heinemann, West Germany underwent its first full-scale change of government. After 20 years of Christian Democratic domination, the Social Democrats captured the chancellorship for Brandt in coalition with the Free Democrats, whose leader Walter Scheel became foreign minister. This so-called socialliberal coalition carried through a number of domestic reforms, but its principal impact was on the Federal Republic's relations with East Germany and the communistruled countries of eastern Europe. While confirming West Germany's commitment to the Western alliance, the new government embarked upon a bold new "eastern policy," or Ostpolitik.

Previously, the Federal Republic had refused to recognize even the existence of the East German government. And by the terms of the so-called Hallstein doctrine (named for one of Adenauer's key foreign policy aides, Walter Hallstein) the Bonn authorities had refused to maintain diplomatic relations with all those countries (other than the Soviet Union) that recognized the German Democratic Republic. Now the Brandt-Scheel Cabinet reversed these policies by opening direct negotiations with East Germany in 1970 for the purpose of normalizing relations between the two German states

In 1970 the social-liberal Cabinet entered into treaties Brandt's with the Soviet Union and Poland that required Bonn to recognize the Oder-Neisse line as Germany's eastern boundary. After the Soviet Union joined in 1971 with the Americans, British, and French in a Four Power Agreement which regularized Berlin's status and opened the way for an easing of the West Berliners' lot, the Brandt-Scheel Cabinet reached agreement in 1972 with East Germany on the Basic Treaty, designed to regularize the relations of the two German states. By its terms each side recognized. and agreed to respect, the other's authority and independence. Each foreswore any title to represent the other internationally, which meant West Germany's abandonment of its long-standing claim to be the sole legitimate spokesman of the German people. The two agreed to exchange "permanent missions," which meant that their relations stopped short of full diplomatic recognition.

The new Ostpolitik met with bitter resistance within West Germany from the Christian Democrats, who denounced it as a surrender on many points that should await settlement by a peace treaty, including the status of the eastern territories severed from Germany in 1945. The Christian Democrats were especially offended by the prospect of the Federal Republic's according legitimacy to a dictatorial German Democratic Republic that refused to allow free elections, maintained the Berlin Wall, and ordered its border guards to shoot fleeing citizens. The Christian Democrats therefore pledged not to ratify the Basic Treaty if they were returned to power in the Bundestag election of November 1972. The voters endorsed the Brandt government's Ostpolitik, however, by making the Social Democrats the largest party in the Bundestag (for the first time) and by strengthening their coalition partner, the Free Democrats, as well. The Basic Treaty was signed at the end of 1972, and the following year both German states gained admission to the United Nations.

When West Germany's original overtures toward East Germany had met with resistance from Ulbricht, the path for negotiations had been cleared by a withdrawal of Soviet support that led to Ulbricht's replacement as East German leader in 1971 by another communist functionary, Erich Honecker. In his last years, Ulbricht had experimented with a decentralization of economic decision making, but under Honecker the German Democratic Republic re-

verted to Soviet-style centralized planning. East Germany benefited greatly from the Basic Treaty with the Federal Republic. Once Bonn had accorded East Germany recognition, the Western democracies followed suit, so that the East German state at last enjoyed the international acceptance it had so long sought. Economically, too, the Basic Treaty proved a boon to East Germany. Spurred by West German credits, trade between the two German states increased, yielding valuable West German currency for East Germany. The latter derived further income from annual fees paid to it by West Germany for western travelers' use of the highways through East Germany to Berlin, and from ransoms paid by West Germany for the release of political prisoners held in East Germany. The larger number of West Germans allowed to visit East Germany also brought in hard currency. Each year the East German government reported impressive leaps in productivity which, after that regime's collapse, proved to be largely fictional. In actuality, the material gap between the two parts of Germany widened. The East German government neglected to maintain the country's infrastructure in order to concentrate its resources on industrial production for export purposes; the results of this became increasingly apparent as East Germany's roads,

Ostpolitik

The Basic Treaty

Growing East-West contacts

railways, and buildings deteriorated. An acute housing shortage also persisted. Waiting periods of years were still required for the purchase of major consumer items such as automobiles, which continued to be crudely manufactured according to standards of the early postwar period, while those of West Germany ranked high in the world for quality and advanced design.

The benefits of international recognition were offset by the dangers posed to the dictatorial East German government by increased visits by West Germans to the east, In an effort to deal with the subversive effects of such contacts, the East German government repeatedly sought to reduce the influx of West German visitors by raising the fees it charged for visas. It classified some two million of its citizens as "bearers of secrets" and forbade them personal contact with Westerners. To stifle dissent at home, the government tightened its already repressive ideological controls on artists and intellectuals, imprisoning some and stripping others of their citizenship and banishing them to West Germany. To emphasize the distinctness of the German Democratic Republic, the amended constitution of 1974 minimized the use of the word "German" and stressed the socialist nature of the East German state and its irrevocable links with the Soviet Union

In West Germany, Brandt resigned in 1974 after one of his trusted aides was unmasked as a spy for East Germany. Brandt's successor as chancellor was the Social Democrat Helmut Schmidt, who continued the coalition of the Social Democrats with the Free Democrats. Walter Scheel, a Free Democrat, was elected federal president in 1974. Recause laissez-faire elements in the Free Democratic Party resisted increases in the government's role in the economy, the Social Democrats were able to achieve little of their program

for expanding the welfare state.

The social-liberal coalition came to an end in October 1982 when the Free Democrats, who had been suffering losses in local and regional elections, defected and formed a new coalition with the Christian Democrats. The new chancellor was the veteran Christian Democrat Helmut Kohl. The 1983 Bundestag election yielded sizable gains for the Christian Democrats but heavy losses for their coalition partners, the Free Democrats, many of whose former voters preferred collaboration with the Social Democrats. The Social Democrats also suffered heavy losses, most of which went to the new ecological party, the Greens, who entered the Bundestag only a few years after their movement had formed to protest environmental pollution, sexism, and authoritarianism. In 1984 Richard von Weizsäcker of the Christian Democrats took office as West Germany's sixth federal president.

Faced with mounting dissent at home, the East German government under the leadership of Honecker sought to enhance its legitimacy by seeking further recognition from West Germany. It was therefore buoyed when Chancellor Schmidt paid an often-postponed official visit to the German Democratic Republic in 1981. Schmidt ignored Honecker's demand that Bonn treat East Germans as foreigners and cease to bestow West German citizenship

automatically on those who fled to the West.

Nevertheless, after Schmidt's visit East Germany began making it easier for its citizens to visit West Germany. By 1986 nearly 250,000 East Germans were visiting West Germany each year. Only one family member at a time was permitted to go, so that virtually all returned home. The East German government also began granting some of its dissatisfied citizens permission to emigrate to the West. In return, West Germany guaranteed several large Western bank loans to East Germany. In 1987 the East German government realized a long-held ambition when, after many postponements, Honecker was received in Bonn with full state honours, seemingly confirming West Germany's acceptance of the permanence of the German Democratic Republic.

But behind the Honecker government's facade of stability, East Germany was losing its legitimacy in the eyes of the majority of its citizenry. Particularly among younger East Germans, the new opportunities for travel to West Germany produced discontent rather than satisfaction.

There, they experienced a much more advanced, consumer-oriented society that provided its citizens with an abundance of far higher-quality goods than were available at home. While in West Germany, they chafed at having to depend materially on Western relatives because their own currency was virtually worthless outside the German Democratic Republic. They also experienced freedom of expression and an open marketplace of ideas and opinions that contrasted sharply with the rigid censorship and repression of deviant views at home. Once these Fast Germans had traveled or even heard of others' travel, the Berlin Wall and the other border fortifications designed to restrict their movements seemed more onerous than ever. In protest against the East German government's indifference to the damage its outdated industries were inflicting on the environment, a clandestine ecological movement arose, and an underground peace movement opposed the regime's manipulation of the cause of peace for propaganda purposes. Both of these movements found sanctuary in the churches of predominantly Protestant East

The reunification of Germany

The swift and unexpected downfall of the German Democratic Republic was triggered by the decay of the other communist regimes in eastern Europe and the Soviet Union. The liberalizing reforms of President Mikhail S. Gorbachev in the Soviet Union appalled the Honecker regime, which in desperation was by 1988 forbidding the circulation within East Germany of Soviet publications it viewed as dangerously subversive. The Berlin Wall was in effect breached in the summer of 1989 when a reformist Hungarian government began allowing East Germans to escape to the West through Hungary's newly opened border with Austria, By the fall, thousands of East Germans had followed this route, while thousands of others sought asylum in the West German embassies in Prague and Warsaw to obtain passage to the Federal Republic. Mass demonstrations in the streets of Leipzig and other East German cities defied the authorities and demanded re-

In an effort to halt the deterioration of its position, the SED Politburo replaced Honecker in mid-October with another hard-line communist, Egon Krenz. Under Krenz the Politburo sought to end the embarrassing flow of refugees to the West German embassies in neighbouring countries. It intended to allow direct travel to West Germany with a permit issued by the East German government. However, when an official announced on television that the government was permitting travel to West Germany "immediately," crowds gathered at the Berlin Wall demanding to pass into West Berlin, Unprepared, the border guards let them go. In a night of revelry, tens of thousands of East Germans poured through the crossing points in the wall and celebrated their new freedom with rejoicing West Berliners. The opening of the Berlin Wall proved fatal for the Ger-

man Democratic Republic. Ever-larger demonstrations demanded a voice in government for the people, and in mid-November Krenz was replaced by a reform-minded communist, Hans Modrow, who promised free, multiparty elections. When the balloting took place in March 1990 the SED, now renamed the Party of Democratic Socialism (PDS), suffered a crushing defeat. The eastern counterpart of Kohl's Christian Democratic Union, which had pledged a speedy reunification of Germany, emerged as the largest political party in East Germany's first democratically elected People's Chamber. A new East German government headed by Lothar de Maizière, a long-time member of the eastern Christian Democratic Union, and backed initially by a broad coalition including the Social Democrats and Free Democrats, began negotiations for a treaty of unification. A surging tide of refugees from East to West Germany that threatened to cripple the German Democratic Republic added urgency to those negotiations. In July that tide

was somewhat stemmed by a monetary union of the two

Germanies that gave East Germans the hard currency of

the Federal Republic.

Fall of the Berlin Wall The final obstacle to reunification was removed in July 1990 when Kohl prevailed upon Gorbachev to drop his objections to a unified Germany within the NATO alliance in return for sizable (West) German financial aid to the Soviet Union. A unification treaty was ratified by the Bundestag and the People's Chamber in September and went into effect on Oct. 3, 1990. The German Democratic Republic joined the Federal Republic as five additional Lânder, and the two parts of divided Berlin became one Land. (The five new Lânder were Brandenburg, Mecklenburg-West Pomerania, Saxony, Saxony-Anhalt, and Thuringia) After 45 years of division, Germany was once again a united nation.

In December 1990 the first all-German free election since the 1930s conferred an expanded majority on the coalition government led by Kohl. (H.A.T.)

Unification soon faced a series of difficulties. Like most of Europe, Germany in the 1990s confronted increased global competition and stubborn unemployment, especially in its traditional industrial sector. However, it also faced the staggering expense of unifying the former east and west. The monetary union of East and West Germany, which had involved a one-to-one exchange of East German for West German marks, priced most East German goods and services well above their market value. Under these conditions, only a handful of eastern firms could compete on the world market. As a result the former East German economy collapsed, leaving hundreds of thousands of easterners facing unemployment. Moreover, the east became heavily dependent on subsidies from the federal government. Meanwhile, the infrastructure-roads, rail lines, and telephones-required massive capital investment. Unemployment, social dislocation, and disappointment continued to haunt the former east into the 21st century.

Many easterners resented economic hardship and perceived western domination, while many westerners chafed at the heavy taxation that financed the rebuilding of the east. The PDS became the political voice of eastern discontent. Meanwhile, there was the problem of resolving the legacies of 40 years of dictatorship. East Germany's large and effective State Security Police (Staatssicherheitspolizei, or Stasi) had employed a wide network of professional and amateur informants. When the files of this organization were made public, eastern German discovered that many of their most prominent citizens, as well as some of their friends, neighbours, and even family members, had been on the Stasi payroll.

Despite the problems attending unification and a series of scandals in his own party, Kohl won a narrow victory in the 1994 elections. Earlier that year, Roman Herzog had assumed the presidency. In 1996 Kohl became the longest-serving German chancellor since Bismarck. Nevertheless, his popularity was clearly ebbing. Some members of Kohl's party hoped that he would step saide in favour of a new candidate in the 1998 elections. Instead, the chancellor ran again and lost to Gerhard Schröder, the pragmatic and photogenic Social Democratic candidate, who formed a coalition with the Greens.

Schröder's government was largely concerned with reducing Germany's high unemployment and reviving the country's stagnant economy. In 1999 Schröder deployed troops to Kosovo to stop ethnic cleansing there, and he also sent forces to Afghanistan in 2001 as part of an international effort against terrorism after the attacks against the United States on September 11 of that year. However, despite the implementation of various domestic economic reforms, by 2002 unemployment remained stubbornly high, and the worldwide economic downturn continued to dampen the return to economic growth. Nonetheless, aided by his response to historic floods in Germany and his opposition to U.S. military action against Iraq, Schröder's SPD-Green coalition narrowly won reelection in Septem-

At the start of the new millennium, Germany remained the most powerful country in Europe. For more than 50 years, Germans had played an important role in the creation of European institutions. German support remained essential to the success both of the European Union's ambitious program of economic and political integration and

of European efforts to supplement or replace Cold War institutions such as NATO with new security arrangements.

For later developments in the history of Germany, see the BRITANNICA BOOK OF THE YEAR.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 912, 921, 923, 961, 963, and 972, and the *Index*.

BIBLIOGRAPHY

Geography. A simple but useful portrayal of Germany in maps is BERNHARD SCHÄFERS et al., The State of Germany Atlas (1998; originally published in German, 1997). W. TIETZE et al. (eds.), Geographie Deutschlands: Bundesrepublik Deutschland (1990), is a massive, comprehensive, and authoritative geographic survey. Other useful sources include ELMAR KULKE, Wirtschaftsgeographie Deutschlands (1998), on economic geography; and HERBERT LIEDTKE and JOACHIM MARCINEK (eds.), Physische Geographie Deutschlands (1994), on physical geography. LUIGI BARZINI, The Impossible Europeans (1983), discusses the nation in the context of the European federation. ERIC OWEN SMITH, The German Economy (1994), provides an overview of West and East Germany's economies as well as the economy of united Germany, Sources of recent information on Germany include the periodicals Country Profile: Germany (annual), Country Report: Germany (quarterly), and OECD Economic Surveys: Germany (annual). The current economic policies and perspectives of the German federal government are outlined in annual economic reports, such as The German Government's Economic Report for 2000: Economic and Financial Reports: Creating Jobs— Strengthening Germany's Economic Future (2000). Recent publications that provide an overview of population issues in Germany and Europe include RAINER MÜNZ and MYRON WEIN-ER (eds.), Migrants, Refugees, and Foreign Policy: U.S. and German Policies Toward Countries of Origin (1997); and HEINZ FASSMANN and RAINER MÜNZ (cds.), European Migration in the Late Twentieth Century: Historical Patterns, Actual Trends, and Social Implications (1994). (Wm.H.B.)

The administrative and political structure of former West Germany are covered in PETER 1. KATZENSTEN, POIG: and Politics in West Germany: The Growth of a Semi-Sovereign State (1987); and IAN DEBENSITIER, Politics in West Germany, rev. 2nd ed. (1991). Sources on intellectual life, arts, and culture in former West Germany include GORDON A. CRAIG, The Germans (1982, eprinted 1991); K. STLART PARKES, Writers and Politics in West German (1982, exprinted 1993).

History. Ancient Germany. HERBERT SCHUTZ, The Privition yof Germanic Humpe (1983), offers a good, well-litter state question and count of the early period. THM CORNELL and 1919. MATTHEWS, Alfas of the Roman World (1982, crissed 1987), employs maps and illustrations to clarify the social and economic background of Roman-German interaction. MALCIOM, 7000. The Northern Barbarians, 100 BC-4D 300, rev. ed. (1987), is another useful source on prehistory and early history. EDWARD JAMES, The Franks (1988, reissued 1991), discusses one of the more important Germanic peoples.

Difficulties attending unification

Merovingians and Carolingians: PATRICK J. GEARY, Before France and Germany: The Creation and Transformation of the Merovingian World (1988), examines the period from the perspective of the unity of late antiquity. ROSAMOND MCKITTERICK, The Frankish Kingdoms Under the Carolingians, 751-987 (1983), presents a general survey of Carolingian Europe. TIMO-THY REUTER (ed. and trans.), The Medieval Nobility: Studies on the Ruling Classes of France and Germany from the Sixth to the Twelfth Century (1979), contains important essays on early German and Frankish society,

Medieval Germany to 1250: G. BARRACLOUGH, The Origins of Modern Germany, 3rd ed. (1988), is a good analysis of medieval German history. General surveys include HORST FUHRMANN, Germany in the High Middle Ages, c. 1050-1200 (1986; originally published in German, 1978), covering such fundamentals as economy and cultural horizons; ALFRED HAVERKAMP, Me-dieval Germany, 1056-1273, 2nd ed. (1992; originally published in German, 1984), providing an informative though mainly German bibliography; and TIMOTHY REUTER, Germany in the Early Middle Ages, c. 800-1056 (1991), presenting a good synthesis of more recent scholarship. K.J. LEYSER, Rule and Conflict in an Early Medieval Society: Ottonian Saxony (1979, reissued 1989), explores the main forces of development of the Saxon empire and its society from 900 to 1024, and Medieval Germany and Its Neighbours, 900-1250 (1982), studies warfare, the nobility, and German-Byzantine and German-English relations. BENJAMIN ARNOLD, German Knighthood, 1050-1300 (1985), is a fine study of knights and ministeriales. (K.I.I.)

From 1250 to 1493: A valuable source on this period is F.R.H. DU BOULAY, Germany in the Later Middle Ages (1983). HER-MANN KELLENBENZ, Von den Anfängen bis zum Ende des 18. Jahrhunderts (1977), vol. 1 of Deutsche Wirtschaftsgeschichte, surveys medieval and early modern economic history. The collection of GERHART HOFFMEISTER (ed.). The Renaissance and Reformation in Germany: An Introduction (1977), offers a fine overview of intellectual life; and on the extraordinary flowering of German sculpture there are two masterly works by MICHAEL BAXANDALL, South German Sculpture, 1480-1530 (1974), and The Limewood Sculptors of Renaissance Germany (1980)

From 1493 to c. 1760: The best guide to this period is THOMAS A. BRADY, JR., HEIKO A. OBERMAN, and JAMES D. TRACY (eds.), Handbook of European History, 1400-1600. Late Middle Ages, Renaissance, and Reformation, 2 vols, (1994-95), BOB SCRIBNER and SHEILAGH OGILVIE (eds.), Germany: A New Social and Economic History, 2 vols. (1996), is a good collection on the society and economy of the Renaissance and Reformation, HAJO HOLBORN, A History of Modern Germany: The Reformation (1959, reprinted 1982), is a comprehensive general account, with emphasis on political events. PETER BLICKLE, The Revolution of 1525: The German Peasants' War from a New Perspective (1981, reissued 1985; originally published in German, 1975), stresses the common grievances that brought peasants and the urban poor together in a widespread uprising, THOMAS A, BRADY, JR., The Politics of the Reformation in Germany: Jacob Sturm (1489-1553) of Strasbourg (1997), tells the story of Reformation politics from the perspective of an important Protestant statesman, MERRY E. WIESNER, Working Women in Renaissance Germany (1986). offers a pioneering examination of the changing situation of women engaged in trades and professions between 1500 and 1600. GEOFFREY PARKER (ed.), The Thirty Years' War, 2nd rev. ed. (1997), surveys the military, political, social, and cultural aspects of the war. JOHN G. GAGLIARDO, Reich and Nation: The Holy Roman Empire as Idea and Reality, 1763-1806 (1980), is an examination of the empire's efforts and failure to survive in the age of the French Revolution, R.J.W. EVANS, The Making of the Habsburg Monarchy, 1550-1700: An Interpretation (1979, reprinted 1991), analyzes the events leading to the construction of the Austrian empire. RUDOLF VIERHAUS, Germany in the Age of Absolutism (1988; originally published in German, 1978), discusses the German principalities in the late 17th and 18th centuries. (Ge.St./ J.J.Sh.)

From c. 1760 to 1871: A good survey of the period as a whole is JAMES J. SHEEHAN, German History, 1770-1866 (1989, reissued 1993). DAVID BLACKBOURN, The Long Nineteenth Century. A History of Germany, 1780–1918 (also published as Fontana History of Germany, 1780–1918: The Long Nineteenth Century: 1997), covers Germany's emergence as a nation-state. The best account of Germany's place in the international system is PAUL W. SCHROEDER, The Transformation of European Politics, 1763-1848 (1994, reissued 1996). The most comprehensive source on German social history is the monumental HANS-ULRICH WEHLER, Deutsche Gesellschaftsgeschichte, (1987-C.B.A. BEHRENS, Society, Government, and the Enlightenment: The Experiences of Eighteenth-Century France and Prussia (1985), is a comparative history of the events and developments that led to revolution in France and stabilization in Germany. T.C.W. BLANNING, The French Revolution in Germany: Occupa tion and Resistance in the Rhineland, 1792-1802 (1983), is a reexamination of this period of German history. ENNO KRAEHE, Metternich's German Policy, 2 vol. (1963-83), describes the War of Liberation: while HAROLD NICOLSON. The Congress of Vien. na: A Study in Allied Unity, 1812-1822 (1946, reissued 2000), deals with the reconstruction of Europe. A balanced and up-todate overview of the period of the German Confederation is THOMAS NIPPERDEY, Germany from Napoleon to Bismarck, 1800-1866 (1996; originally published in German, 1983). JONATHAN SPERBER, Rhineland Radicals: The Democratic Movement and the Revolution of 1848-1849 (1991, reprinted 1993), provides a good analysis of the revolution's social origins and political meaning in western Germany. OTTO PFLANZE, Bismarck and the Development of Germany, 2nd ed., 3 vol. (1990), portrays the architect of the new Germany and his impact on the European balance of power. (T.S.H./J.J.Sh./Ed.)

From 1871 to 1918: General historical surveys include GOR-DON A. CRAIG, Germany, 1866-1945 (1978, reissued 1981). which is particularly good on politics and culture; and HANS-ULRICH WEHLER, The German Empire, 1871-1918 (1985, reissued 1997; originally published in German, 1973), which stresses the continuity between the empire and the Nazi era. DAVID BLACKBOURN and GEOFF ELEY, The Peculiarities of German History: Bourgeois Society and Politics in Nineteenth-Century Ger many (1984), explores the connection between economics and politics in the German Empire, MARGARET LAVINIA ANDERSON, Practicing Democracy: Elections and Political Culture in Imperi al Germany (2000), examines the relationship between political participation and authority from 1867 to 1914. The history of German socialism is detailed in GARY P. STEENSON, "Not One Man! Not One Penny!": German Social Democracy, 1863-1914 (1981), a comprehensive treatment of the Social Democratic Party from its origins to the war, ROGER CHICKERING (ed.). Imperial Germany: A Historiographical Companion (1996), is a useful guide to further reading. A valuable source on developments leading to World War I is V.R. BERGHAHN, Germany and the Approach of War in 1914, 2nd ed. (1993). A good introduction to Germany at war is ROGER CHICKERING, Imperial Germany and the Great War, 1914-1918 (1998). JÜRGEN KOCKA, Facing Total War: German Society, 1914-1918 (1984; originally published in German, 1973), examines the effects of World War I on different social groups. UTE FREVERT, Women in German History: From Bourgeois Emancipation to Sexual Liberation (1989, reissued 1993; originally published in German, 1986), is a fine survey of this important area of research. (Ke.B./ J.J.Sh.)

From 1918 to 1945: DIETRICH ORLOW, A History of Modern Germany: 1871 to Present, 4th ed. (1999), offers a good survey of Germany's troubled 20th century. A.J. RYDER, The German Revolution of 1918: A Study of German Socialism in War and Revolt (1967), treats both the democratic and revolutionary socialists in 1918 and 1919 along with their conflicting visions for change. HANS MOMMSEN, The Rise and Fall of Weimar Democracy, trans. by ELBORG FORSTER and LARRY EUGENE JONES (1996; originally published in German, 1989), is a fine synthesis of the republic's tragic history. The definitive study of the German inflation is GERALD D. FELDMAN, The Great Disorder: Politics, Economics, and Society in the German Inflation, 1914–1924 (1993, reissued 1997). PETER GAY, Weimar Culture: The Outsider as Insider (1968, reprinted 1988), provides a stimulating introduction to the cultural and intellectual brilliance of Germany during the 1920s. An excellent guide to further reading on Weimar culture is ANTON KAES, MARTIN JAY, and EDWARD DI-Weimar Culture is Anton Kaes, Martin JAY, and Edward Di-Mendberg (eds.), *The Weimar Republic Sourcebook* (1994). IAN KERSHAW, *Hitler*, 1889–1936: *Hubris* (1998, reissued 2000), and *Hitler*, 1936–45: *Nemesis* (2000), together constitute the definitive biography of the dictator. A comprehensive study of National Socialism emphasizing the totalitarian nature of the regime is available in KARL DIETRICH BRACHER, The German Dictatorship: The Origins, Structure, and Effects of National Socialism (1970, reissued 1980; originally published in German, 1969). One of the best single-volume treatments of World War II is GER-HARD L. WEINBERG, A World at Arms: A Global History of World War II (1994). RAUL HILBERG, The Destruction of the European Jews, rev. ed., 3 vol. (1985), remains the standard and most comprehensive study of the efforts by the Nazis to exterminate the Jewish people; SAUL FRIEDLÄNDER, Nazi Germany and the Jews (1997-), is an important newer study. EARL R. BECK, Under the Bombs: The German Home Front, 1942-1945 (1986), explores German civilian life during the war.

(K.A.Sc./L.J.Sh./Ed.)

After 1945: Surveys of the history of both German states include HENRY ASHBY TURNER, JR., The Two Germanies Since 1945 (1987); and A. JAMES MCADAMS, Germany Divided: From the Wall to Reunification (1993). V.R. BERGHAHN, Modern Germany: Society, Economy, and Politics in the Twentieth Century, 2nd ed. (1987, reissued 1993), is a comparative history. A more

detailed account of West Germany's development is DENNIS L.
BARK and DAVID B. CRESS, A HISTORY of West Germany. 2nd ed.,
2.0d. (1993). PETR IN. MERKL, The Origin of the West German
Republic (1983, reprinted 1982), focuses on West Germany She
ginnings, and ROGER MORGAN, The United States and West Germany, 1945–1973. A Study in Alliance Political (1974), treats its
relations with the United States. FREINY LEAMAN, The Political
Economy of West Germany, 1945–1974. See Jahr Introduction (1988),
surveys the West German economy, A good account of the Soviet role in East Germany is NORMAN IN ARMARK, The Rus-

sians in Germany: A History of the Soviet Zone of Occupation, 1945–1949 (1995). Other sources on the history of East Germany include MARY FULBROOK, Anatomy of a Dictatorship: Inside the GDR, 1949–1989 (1995, reissued 1997); and DAVID CHILDS (ed.). The best single-volume treatment of the collapse of East Germany is CHARLES S. MAIER, Dissolution: The Crisis of Communism and the End of East Germany (1997, reissued 1999). KONRAD H. JARAUSCH, The Rush to German Unity (1994), is also useful.

(H.A.T./J.J.Sh.)

Globalization and Culture

lobalization is the process by which the experience of everyday life, marked by the diffusion of commodities and ideas, is becoming standardized around the world. An extreme interpretation of this process, often referred to as globalism, sees advanced capitalism, boosted by wireless and Internet communications and electronic business transactions, destroying local traditions and regional distinctions, creating in their place a ho-

mogenized world culture. According to this view, human experience everywhere is in jeopardy of becoming essentially the same. This appears, however, to be an overstatement of the phenomenon. Although homogenizing influences do indeed exist, people are far from creating a single overarching world culture. The actual process of globalization has been fitful, chaotic, and slow.

This article is divided into the following sections:

Emergence of global subcultures 133

"Davos" culture

The international "faculty club"

Nongovernmental organizations Transnational workers

The persistence of local culture 133

Experiencing globalization 134 The collapse of time and space The standardization of experience Political consequences of globalization 136 Challenges to national sovereignty and identity Anti-globalism movements and the Internet The illusion of global culture 137 Localized responses

Borrowing and "translating" popular culture Subjectivity of meaning-the case of Titanic

The ties that still bind 137 Bibliography 137

EMERGENCE OF GLOBAL SUBCULTURES

Some observers argue that a rudimentary version of world culture is already taking shape among certain individuals who share similar values, aspirations, or lifestyles. The result is a collection of elite groups whose unifying ideals transcend geographical limitations.

"Davos" culture. One such cadre, according to political scientist Samuel Huntington in The Clash of Civilizations (1998), comprises an elite group of highly educated people who operate in the rarefied domains of international finance, media, and diplomacy. Named after the Swiss town that hosts annual meetings of the World Economic Forum, these "Davos" insiders share common beliefs about individualism, democracy, and market economics. They are said to follow a recognizable lifestyle, are instantly identifiable anywhere in the world, and feel more comfortable in each other's presence than they do among their lesssophisticated compatriots.

The international "faculty club." The globalization of cultural subgroups is not limited to the upper classes, however. Expanding on the concept of Davos culture, sociologist Peter L. Berger observes that the globalization of Euro-American academic agendas and lifestyles has created a worldwide "faculty club"-an international network of people who share similar values, attitudes, and research goals. Although they are not as wealthy or privileged as their Davos counterparts, members of this international faculty club wield tremendous influence through their association with educational institutions worldwide and have been instrumental in promoting feminism, environmentalism, and human rights as global issues. Berger cites the antismoking movement as a case in point: the movement began as a singular North American preoccupation in the 1970s and subsequently spread to other parts of the world, traveling along the contours of academe's global network.

Nongovernmental organizations. Another global subgroup comprises "cosmopolitans" who nurture an intellectual appreciation for local cultures. As pointed out by Swedish anthropologist Ulf Hannerz, this group advocates a view of global culture based not on the "replication of uniformity" but on the "organization of diversity." Often promoting this view are nongovernmental organizations (NGOs) that lead efforts to preserve cultural diversity in the developing world. By the turn of the 21st century, institutions such as Cultural Survival were operating on a world scale, drawing attention to indigenous groups who are encouraged to see themselves as "first peoples"-a new global designation emphasizing common experiences of exploitation among indigenous inhabitants of all lands. By sharpening such identities, these NGOs have globalized the movement to preserve indigenous world cultures.

Transnational workers. Another group stems from the rise of a transnational workforce. Indian-born Arjun Appadurai, an American anthropologist, studied Englishspeaking professionals who trace their origins to South Asia but who live and work elsewhere. They circulate in a social world that has multiple home bases, and they have gained access to a unique network of individuals and opportunities. For example, many software engineers and Internet entrepreneurs who live and work in Silicon Valley. California, in the United States, maintain homes in-and strong social ties to -Indian states such as Maharashtra and Punjab.

THE PERSISTENCE OF LOCAL CULTURE

Underlying these various visions of globalization is a reluctance to define exactly what is meant by the term culture. During most of the 20th century, anthropologists defined culture as a shared set of beliefs, customs, and ideas that held people together in recognizable, self-identified groups. Scholars in many disciplines challenged this notion of cultural coherence, especially as it became evident that members of close-knit groups held radically different visions of their social worlds. As a result, many social scientists now treat culture as a set of ideas, attributes, and expectations that change as people react to changing circumstances. Indeed, at the turn of the 21st century, the collapse of barriers enforced by Soviet socialism and the rise of electronic commerce have increased the perceived speed of social change everywhere.

The term local culture is commonly used to characterize the experience of everyday life in specific, identifiable localities. It reflects ordinary peoples' feelings of appropriateness, comfort, and correctness-attributes that define personal preferences and changing tastes. Given the strength of local cultures, it is difficult to argue that an overarching global culture actually exists. Jet-setting sophisticates may feel comfortable operating in a global network disengaged from specific localities, but these people constitute a very small minority; their numbers are insufficient to sustain a coherent cultural system. It is more important to ask where these global operators maintain their families, what kind of kinship networks they rely upon, if any, and if theirs is a transitory lifestyle or a permanent condition. For most people, place and locality still matter. Even the transnational workers discussed by Appadurai are rooted in local communities bound by common perceptions of what represents an appropriate and fulfilling lifestyle.

Place and location still matter EXPERIENCING GLOBALIZATION

Research on globalization has shown that it is not an omninotent, unidirectional force leveling everything in its path. Because a global culture does not exist, any search for it will be futile. It is more fruitful to focus on particular aspects of life that are indeed affected by the globalizing process.

The collapse of time and space. The breakdown of time and space is best illustrated by the influential "global village" thesis by Marshall McLuhan in Gutenberg Galaxy (1962). Instantaneous communication, predicted McLuhan, would soon destroy geographically based power imbalances and create a global village. Later, geographer David Harvey argued that the postmodern condition is characterized by a "time-space compression" that arises from inexpensive air travel and the ever-present use of telephones, fax, and, more recently, E-mail.

There can be little doubt that people perceive the world today as a smaller place than it appeared to their grandparents. In the 1960s and '70s immigrant workers in London relied on postal systems and personally delivered letters to send news back to their home villages in India, China, and elsewhere: it could take two months to receive a reply. The telephone was not an option, even in dire emergencies. By the late 1990s, the grandchildren of these first-generation migrants were carrying cellular phones that linked them instantaneously to cousins in Calcutta, Singa-

pore, or Shanghai.

Live global news coverage

McLuhan's notion of the global village presupposed the worldwide spread of television, which brings distant events into the homes of viewers everywhere. Building on this concept, McLuhan claimed that accelerated communications produce an "implosion" of personal experience-that is, distant events are brought to the immediate attention of people halfway around the world.

The spectacular growth of Cable News Network (CNN) is a case in point. CNN became an icon of globalization through its U.S.-style news programming broadcast throughout the world, 24 hours a day. Live coverage of the fall of the Berlin Wall in 1989 and the Gulf War in 1991 illustrated the power of television to influence world opinion. Some governments have responded to such advances by attempting to restrict international broadcasting, but satellite technology makes these restrictions increasingly unenforceable.

The standardization of experience. Travel. Since the mid-1960s, the cost of international flights has declined, and foreign travel has become a routine experience for millions of middle- and working-class people. Diplomats, businesspeople, and ordinary tourists can feel "at home" in any city, anywhere in the world. Foreign travel need no longer involve the challenge of adapting to unfamiliar food and living arrangements. Western-style beds, toilets, showers, fitness centres, and restaurants now constitute the global standard, and CNN has been an essential feature of the standardized hotel experience since at least the 1990s. These developments are linked to the technology of climate control. In fact, the very idea of routine global travel was inconceivable prior to the universalization of air-conditioning. An experience of this nature would have been nearly impossible in the 1960s, when the weather, aroma, and noise of the local society pervaded one's hotel room. Modes of dress can disguise an amazing array Clothing. of cultural diversity behind a facade of uniformity. The man's business suit, with coloured tie and buttoned shirt, is now "universal" in the sense that it is worn just about everywhere-even in parts of the world that work to avoid global trends, such as Saudi Arabia and Iran. Iranian parliamentarians wear the "Western" suit but forgo the tie, while Saudi diplomats alternate "traditional" Bedouin robes with tailored business suits, depending upon the occasion. At the turn of the 21st century, North Korea and Afghanistan appeared to be among the few societies holding out against these globalizing trends.

The emergence of women's "power suits" in the 1980s signified another form of global conformity. Stylized trouser-suits, with silk scarves and colourful blouses (analogues of the male business suit), are now worldwide symbols of modernity, independence, and competence, Moreover, the export of used clothing from Western countries to developing nations has accelerated the adoption of Western-style dress around the world.

Entertainment. The power of media conglomerates and the ubiquity of entertainment programming has globalized television's impact and made it a logical target for accusations of cultural imperialism. Critics cite a 1999 anthropological study that linked the appearance of anorexia in Fiji to the popularity of American television programs, notably Melrose Place and Beverly Hills 90210. Both series feature the exploits of slender young actresses who, it was claimed. led Fijian women (who are typically fuller-figured) to question indigenous notions of the ideal body.

Anti-globalism activists contend that American television shows have corrosive effects on local cultures by highlighting Western notions of beauty, individualism, and sexuality. Although many of the titles exported are considered second-tier shows in America, there is no dispute that these programs are part of the daily fare for viewers around the world. Television access is widespread, even if receivers are not present in every household. In the small towns of Guatemala, the villages of Jiangxi province in China, or the hill settlements of Borneo, for instance, one television set-often a satellite system powered by a gasoline generator-may serve two or three dozen viewers, each paying a small fee. Collective viewing in bars, restaurants, and teahouses was common during the early stages of television broadcasting in Indonesia, Japan, Kenya, and many other countries. By the 1980s, video-viewing parlours had become ubiquitous in all but the poorest regions of the globe. Live sports programs continue to draw the largest global

audiences. The 1998 World Cup football (soccer) final between Brazil and France was watched by an estimated two billion people. After the 1992 Olympic Games, when the American "Dream Team" of National Basketball Association (NBA) stars electrified viewers who had never seen the sport played to U.S. professional standards, NBA games were broadcast in Australia, Israel, Japan, China, Germany, and Britain.

Hollywood has had a similar influence, much to the chagrin of some countries. In early 2000, Canadian government regulators ordered the Canadian Broadcasting Corporation (CBC) to reduce the showing of Hollywood films during prime time and feature more Canadian-made programming. CBC executives protested that their viewers would stop watching Canadian television stations and turn to satellite reception for international entertainment. Such objections were well grounded, given that 79 percent of English-speaking Canadians named a U.S. program when asked to identify their favourite television show in 1998,

Hollywood, however, does not hold a monopoly on entertainment programming. The world's most prolific film industry is in Bombay, India ("Bollywood"), where as many as 1,000 feature films are produced annually in all of India's major languages. Primarily love stories with heavy doses of singing and dancing, Bollywood movies are popular throughout Southeast Asia and the Middle East. State censors in Islāmic countries often find the modest dress and subdued sexuality of Indian film stars acceptable for their audiences. Although the local appeal of Bollywood movies remains strong, exposure to Hollywood films such as Jurassic Park (1993) and Speed (1994) has caused young Indian moviegoers to develop an appreciation for the special effects and computer graphics that are hall-

marks of most American films. Food. It is not mass media but food that is the oldest global carrier of culture. In fact, food has always been a driving force for globalization, especially during earlier phases of European trade and colonial expansion. The hot red pepper was introduced to the Spanish court by Christopher Columbus in 1493. It spread rapidly throughout the colonial world, transforming cuisines and farming practices in Africa, Asia, and the Middle East. It might be difficult to imagine Korean cuisine without red pepper paste or Szechuan food without its fiery hot sauce, but both are relatively recent innovations-probably from the 17th century. Other New World crops, such as corn (maize), cassava, sweet potatoes, and peanuts (groundnuts), were responsible for agricultural revolutions in Asia and Africa,

Popularity of the Indian film industry

opening up terrain that had previously been unproductive. One century after the sweet potato was introduced into south China, it had become a dominant crop and was largely responsible for a population explosion that created what today is called Cantonese culture. It is the sweet potato, not the more celebrated white rice, that sustained generations of southern Chinese farmers. These are the experiences that cause cultural meaning to be attached to particular foods. Today the descendants of Cantonese, Hokkien, and Hakka pioneers disdain the sweet potato as a "poverty food" that conjures up images of past hardships. In Taiwan, by contrast, independence activists (affluent members of the new Taiwanese middle class) have embraced the sweet potato as an emblem of identity, reviving old recipes and celebrating their cultural distinctions from rice-eating mainlanders."

The global food trade

While the global distribution of foods originated with the pursuit of exotic spices (such as black pepper, cinnamon, and cloves), contemporary food trading features more prosaic commodities such as soybeans, bananas, and oranges. Green beans are now grown in Burkina Faso in Central Africa and shipped by express air cargo to Paris, where they end up on the plates of diners in five-star restaurants. This particular exchange system is based on a "nontraditional" crop that was not grown in Burkina Faso until the mid-1990s, when the World Bank encouraged its cultivation as a means of promoting economic development. The country soon became Africa's second-largest exporter of green beans. Central African farmers consequently find themselves in direct competition with other "counter-season" producers of green beans in Brazil and Florida. African bananas, Chilean grapes, and California oranges have helped to transform consumer expectations about the availability of fresh produce everywhere in the world.

The average daily diet has also undergone tremendous change, with all nations converging on a diet high in meat, dairy products, and processed sugars. Correlating closely to a worldwide rise in affluence, the new "global diet" is not necessarily a beneficial trend, as it can increase the risk of obesity and diabetes. Now viewed as a global health threat, obesity has been dubbed "globesity" by the World Health Organization. To many observers, the homogenization of human diet appears to be unstoppable. Vegetarians, environmental activists, and organic food enthusiasts have organized rearguard actions to reintroduce "traditional" and more wholesome dietary practices, but these efforts are concentrated among educated elites in industrial nations.

Western corporations are often blamed for these dietary trends. McDonald's, KFC (Kentucky Fried Chicken), and Coca-Cola are primary targets of anti-globalism demonstrators (who are themselves organized into global networks, via the Internet). Food and beverage companies attract attention because they cater to the most elemental form of human consumption. We are what we eat; when diet changes, notions of national and ethnic identity are affected. McDonald's has become a symbol of globalism for obvious reasons: On an average day in 2001, the company served nearly 45 million customers at more than 25,000 restaurants in 120 countries. It succeeds in part by adjusting its menu to local needs. In India, for example, no beef products are sold.

The influences of fast food restaurants are not limited to dietary changes. In Japan, for instance, using one's hands to eat prepared foods was considered a gross breach of etiquette. The popularization of McDonald's hamburgers has had such a dramatic impact on popular etiquette that it is now common to see Tokyo commuters eating in public, without chopsticks or spoons. In late-Soviet Russia, rudeness had become a high art form among service personnel. Today customers expect polite, friendly service when they visit Moscow restaurants-a social revolution initiated by McDonald's and its employee indoctrination programs.

The social atmosphere in colonial Hong Kong of the 1960s was anything but genteel. Cashing a check, boarding a bus, or buying a train ticket required brute force. When McDonald's opened in 1975, customers clumped around the cash registers, shouting orders and waving money over the heads of people in front of them. McDonald's responded by introducing queue monitors-young women

Growing up with fast food: young girls attending a birthday party at a McDonald's restaurant, Shenzhen, China,

who channeled customers into orderly lines. Queuing subsequently became a hallmark of Hong Kong's cosmopolitan, middle-class culture. Older residents credit Mc-Donald's for introducing the queue, a critical element in this social transition. In some cultures of Asia, Latin America, and Europe, another innovation was the provision of clean toilets and washrooms. McDonald's was instrumental in setting new cleanliness standards (thereby raising consumer expectations) in cities that had never offered public facilities.

The introduction of fast food has been particularly influential on children who are often the direct targets of television advertising. The symbolic impact of fast food makes it a powerful force for dietary and social change, and a meal at these restaurants will introduce practices that younger consumers may not experience at home-most notably, the chance to choose one's own food. The concept of personal choice is symbolic of Western consumer culture. Visits to McDonald's and KFC have become signal events for children who approach fast food restaurants with a heady sense of empowerment.

Religion. Central to Huntington's thesis in The Clash of Civilizations is the assumption that the post-Cold War world would regroup into regional alliances based on religious beliefs and historical attachments to various "civilizations." Identifying three prominent groupings-Western Christianity (Catholicism and Protestantism), Orthodox Christianity (Russian and Greek), and Islām, with additional influence from Hinduism and Confucianism-he predicted that the progress of globalization would be severely constrained by religio-political barriers. The result would be a "multipolar world." This view is quite different from the prophesies of a standardized, homogenized global culture.

There is, however, considerable ethnographic evidence, gathered by anthropologists and sociologists, that refutes this model of civilizational clash and points instead to a rapid diffusion of religious and cultural systems throughout the world. Islam is an excellent case in point, given that it constitutes one of the fastest-growing religions in the United States, France, and Germany-supposed bastions of the Christian West. At the turn of the 21st century, entire districts (arrondisements) of Paris were dominated by Muslims, the majority of them French citizens born and reared in France. Thirty-five percent of students in the suburban Dearborn, Mich., public school system were Muslim in 2001; the provision of halāl ("lawful" under Islām) meals at lunchtime became a hot issue in local politics. Meanwhile Muslims of Turkish origin constituted the fastestgrowing sector of Berlin's population, and, in northern England, the old industrial cities of Bradford and Newcastle were revitalized by descendants of Pakistani and Indian Muslims who immigrated during the 1950s and '60s.

From its inception, Christianity has been an aggressively proselytizing religion with a globalizing agenda. Indeed, the Roman Catholic church was arguably the first global Diffusion of religious cultural systems

institution, spreading rapidly throughout the European colonial world and beyond. Today, perhaps the fastestgrowing religion is evangelical Christianity. Stressing the individual's personal experience of divinity, evangelism has wide appeal in developing regions such as Latin America and sub-Saharan Africa, presenting serious challenges to established Catholic churches, Following the collapse of Soviet power in 1991, the Russian Orthodox church began the process of rebuilding after more than seven decades of repression. At the same time, evangelical missionaries from the United States and Europe shifted much of their attention from Latin America and Africa to Russia, alarming Russian Orthodox leaders. By 1997, under pressure from Orthodox clergy, the Russian government promoted legislation to restrict the activities of religious organizations that had operated in Russia for less than 15 years, effectively banning Western evangelical missionaries. The debate over Russian religious unity continues, however, and such legislation could have little long-term effect.

Sociologists such as Berger confirm the resurgence, since the late 20th century, of conservative religion among faiths such as Islam, Hinduism, Buddhism, and even Shinto (in Japan) and Sikhism (in India). The social and political connotations of these conservative unsurges are unique to each culture and religion. According to Berger, evangelicalism can be seen as a carrier of modernization; its emphasis on the Bible encourages literacy, while involvement in church activities can teach administrative skills that are

applicable to work environments.

POLITICAL CONSEQUENCES OF GLOBALIZATION

Challenges to national sovereignty and identity. Antiglobalism activists often depict the McDonald's, Disney, and Coca-Cola corporations as agents of globalism or cultural imperialism, a new form of economic and political domination. Critics of globalism argue that any business enterprise capable of manipulating personal tastes will thrive, whereas state authorities everywhere will lose control over the distribution of goods and services. According to this view of world power, military force is perceived as hopelessly out of step or even powerless; the control of culture (and its production) is seen as far more important than the control of political and geographic borders. Certainly, it is true that national boundaries are increasingly permeable and any effort by nations to exclude global pop culture usually makes the banned objects all the more irresistible.

The commodities involved in the exchange of popular culture are related to lifestyle, especially as experienced by young people; pop music, film, video, comics, fashion, fast foods, beverages, home decorations, entertainment systems, and exercise equipment. Millions of people obtain the unobtainable by using the Internet to breach computer security systems and import barriers. "Information wants to be free" was the clarion call of software designers and aficionados of the World Wide Web in the 1990s. This code of ethics takes its most creative form in societies where governments try hardest to control the flow of information (e.g., China and Iran). In 1999, when Serbian officials shut down the operations of Radio B92, the independent station continued its coverage of events in the former republic of

Yugoslavia by moving its broadcasts to the Internet. The idea of a borderless world is reflected in theories of the "virtual state," a new system of world politics that is said to reflect the essential chaos of 21st-century capitalism. In Out of Control (1994), Kevin Kelly predicted that the Internet would gradually erode the power of governments to control citizens; advances in digital technology would instead allow people to follow their own interests and form trans-state coalitions. Similarly, Richard Rosecrance, in The Rise of the Virtual State (1999), wrote that military conflicts would be superseded by the flow of information, capital, technology, and manpower among states. Taking a countervailing approach, Martin Wolf wrote, in the January 2001 issue of Foreign Affairs, that the state was unlikely to disappear and could continue to be an effective basis of governance.

Arguments regarding the erosion of state sovereignty are particularly unsettling for nations that have become consumers rather than producers of digital technology. PostSoviet Russia, post-Maoist China, and post-Gaullist France are but three examples of Cold War giants that face uncertain futures in the emerging global system. French intellectuals and politicians have seized upon anti-globalism as an organizing ideology in the absence of other unifying themes. In Les cartes de la France à l'heure de la mondialisation (2000; "France's Assets in the Era of Globalization"), French Foreign Minister Hubert Vedrine denounced the United States as a "hyperpower" that promotes "uniformity" and "unilateralism." Speaking for the French intelligentsia, he argued that France should take the lead in building a "multipolar world,"

Globaliza-

tion as a

threat to

national

identity

Ordinary French citizens also were concerned about losing their national identity, particularly as the regulatory power of the European Union began to affect everyday life. Sixty percent of respondents in a 1999 L'Expansion poll agreed that globalization represented the greatest threat to the French way of life, Food, especially haute cuisine, is commonly regarded as the core of French culture. Yet, by the end of 2000 there were 857 McDonald's restaurants in France, collectively employing more than 30,000 people. The Big Mac may be a reviled symbol of cultural imperialism for French intellectuals, but the steady growth of fast food chains demonstrates that anti-globalism attitudes do not always affect economic behaviour, even in societies (such as France) where such sentiments are nearly universal. Like their counterparts in the United States, French workers are increasingly pressed for time. Fast food is convenient. The two-and-a-half-hour lunch is a thing of the past for most Parisians.

Anti-globalism movements and the Internet. Anti-globalism organizers are found throughout the world, not least in many management organizations. They are often among the world's most creative and sophisticated users of Internet technology. This is doubly ironic, for NGOs, as stated earlier, exhibit many of the characteristics of a global. transnational subculture; the Internet, moreover, is one of the principal tools that makes globalization feasible and organized protests against it possible. For example, Greenpeace, an environmentalist NGO, has orchestrated worldwide protests against genetically modified (GM) foods. Highly organized demonstrations appeared, seemingly overnight, in many parts of the world, denouncing GM products as "Frankenfoods" that pose unknown (and undocumented) dangers to people and to the environment. The bioengineering industry, supported by various scientific organizations, launched its own Internet-based counterattack, but the response was too late and too disorganized to outflank Greenpeace and its NGO allies. Sensational media coverage had already turned consumer sentiment against GM foods before the scientific community even entered the debate.

The anti-GM food movement demonstrates the immense power of the Internet to mobilize political protests. This power derives from the ability of a few determined activists

Demonstrators marching to protest against genetically modified organisms (GMOs), Montreal, January 2000.

Questioning the future role of governments

to communicate with thousands (indeed millions) of potential allies in an instant. The Internet's power as an organizing tool became evident during the World Trade Organization (WTO) protests in Seattle, Wash., in 1999, in which thousands of activists converged on the city, disrupting the WTO meetings and drawing the world's attention to criticisms of global trade practices. The Seattle protests set the stage for similar types of activism in succeeding years.

THE ILLUSION OF GLOBAL CULTURE

Localized responses. For hundreds of millions of urban people the experience of everyday life has become increasingly standardized since the 1960s. Household appliances. utilities, and transportation facilities are increasingly universal. Technological "marvels" that North Americans and Europeans take for granted have had even more profound effects on the quality of life for billions of people in the less developed world. Everyday life is changed by the availability of cold beverages, hot water, frozen fish, screened windows, bottled cooking-gas, or the refrigerator.

It is difficult to argue, however, that the globalization of technologies is making the world everywhere the same The "sameness" hypothesis is only sustainable if one ignores the internal meanings that people assign to cultural

innovations.

Internal

meanings

Borrowing and "translating" popular culture. The domain of popular music illustrates how difficult it is to unravel cultural systems in the contemporary world: Is rock music a universal language? Do reggae and ska have the same meaning to young people everywhere? American-inspired hip-hop (rap) swept through Brazil, Britain, France, China, and Japan in the 1990s. Yet Japanese rappers developed their own, localized versions of this art form. Much of the music of hip-hop, grounded in urban African American experience, is defiantly antiestablishment, but the Japanese lyric content is decidedly mild, celebrating youthful solidarity and exuberance. Similar "translations" between form and content have occurred in the pop music of Indonesia, Mexico, and Korea. It is also obvious to any casual listener of U.S. radio that Brazilian, South African, Indian, and Cuban forms have had profound effects on the contemporary American pop scene. The flow of popular culture is rarely, if ever, unidirectional.

Subjectivity of meaning-the case of Titanic. A cultural phenomenon does not convey the same meaning everywhere. In 1998, the drama and special effects of the American movie Titanic created a sensation among Chinese fans. Scores of middle-aged Chinese returned to the theatres over and over-crying their way through the film. Enterprising hawkers began selling packages of facial tissue outside Shanghai theatres. The theme song of Titanic became a best-selling CD in China. Chinese consumers purchased more than 25 million pirated (and 300,000

legitimate) video copies of the film.

One might ask why middle-aged Chinese moviegoers found themselves so emotionally involved with the story told in Titanic. Interviews among older residents of Shanghai revealed that many people had projected their own, long-suppressed experiences of lost youth onto the film. From 1966 to 1976 the Cultural Revolution convulsed China, destroying any possibility of educational or career advancement for millions of people. At that time, Communist authorities had also discouraged romantic love and promoted politically correct marriages based on class background and revolutionary commitment. Improbable as it might seem to Western observers, the story of lost love on a sinking cruise ship hit a responsive chord among the veterans of the Cultural Revolution. Their passionate, emotional response had virtually nothing to do with the Western cultural system that framed the film. In China, then, Titanic served as a socially acceptable vehicle for the public expression of regret by a generation of aging revolutionaries who had devoted their lives to building a form of socialism that had long since disappeared.

Chinese President Jiang Zemin invited the entire Politburo of the Chinese Communist Party to a private screening of Titanic, cautioning that Titanic could be seen as a Trojan horse, carrying within it the seeds of American cultural imperialism. Chinese authorities are not alone in their mistrust of Hollywood. There are those who suggest, as did Jiang, that exposure to films such as Titanic will cause people everywhere to become more like Americans. Yet anthropologists are wary of such suggestions, emphasizing instead the particular ways in which consumers use popular entertainment. The process of globalization looks far from hegemonic when one focuses on ordinary viewers and their efforts to make sense of what they see.

Another case in point is anthropologist Daniel Miller's study of television viewing in Trinidad, which demonstrated that viewers are not passive observers. In 1988, 70 percent of Trinidadians who had access to a television watched daily episodes of The Young and the Restless, a series that emphasized family problems, sexual intrigue, and gossip. Miller discovered that Trinidadians had no trouble relating to the personal dramas portrayed in American soap operas, even though the lifestyles and material circumstances differed radically from life in Trinidad. Local people actively reinterpreted the episodes to fit their own experience, seeing the televised dramas as commentaries on contemporary life in Trinidad. The portrayal of American material culture, notably women's fashions, was a secondary attraction. In other words, it is a mistake to treat television viewers as passive.

THE TIES THAT STILL BIND

Local culture remains a powerful influence in daily life. People are tied to places, and those places continue to shape particular norms and values. The fact that residents of Moscow, Beijing, and New Delhi occasionally eat at Mc-Donald's, watch Hollywood films, and wear Nike athletic shoes (or copies of them) does not make them "global." Outward appearances do not reveal the internal meanings that people assign to a cultural innovation. True, the standardization of everyday life will likely accelerate as digital technology comes to approximate the toaster in "userfriendliness." But technological breakthroughs are not enough to create a world culture. Studies in globalization show that people everywhere have an unquenchable desire to partake of the fruits of globalization while celebrating the inherent distinctiveness of their own cultures.

Goethe

oet, novelist, playwright, and natural philosopher, Goethe is the greatest figure of the German Romantic period and of German literature as a whole. He was perhaps the last European to achieve the many-sidedness of the great Renaissance personalities: critic, journalist, painter, theatre manager, statesman, educationist, natural philosopher. The bulk and diversity of his output are phenomenal; his writings on science alone fill about 14 volumes.

asy of the Bayerische Staatsgemalde

Goethe, oil painting by Joseph Karl Stieler. 1828. In the Neue Pinakothek, Munich.

Early life and influences. Johann Wolfgang von Goethe was born on Aug. 28, 1749, in Frankfurt am Main. He came of middle-class stock, the Bürgertum that he praised as a breeding ground of the finest culture. His father, a retired lawyer, was able to lead a life of cultured leisure. Goethe's mother was the daughter of a Bürgermeister (mayor) of Frankfurt. Of eight children, only Wolfgang, the firstborn, and his sister, Cornelia, survived. In his autobiography, Dichtung und Wahrheit (1811-32; Poetry and Truth from My Own Life), Goethe left an unforgettable picture of a happy childhood.

In October 1765 Goethe was sent to study law at his father's alma mater, the University of Leipzig, where a world of elegance and fashion daunted the young provincial. The Frenchifying influence of the critic J.C. Gottsched still dominated the theatre and provided a repertory of the best plays of contemporary Europe. But C.F. Gellert, poet and author of fables and hymns, presented the new sensibility of Edward Young, Laurence Sterne, and Samuel Richardson. Gellert's literary influence was reinforced by the robust elegance and ironic sagacity of the works of C.M. Wieland.

The literary harvest of Goethe's Leipzig period manifested itself in a songbook written in the prevailing Rococo mode-songs praising love and wine in the manner of the Greek poet Anacreon. Appropriately titled Das Leipziger Liederbuch (1770; The Leipzig Song Book), it was ostensibly but not passionately inspired by the daughter of the wine merchant at whose tavern he took his midday meal. The same note is struck in two verse plays, Die Laune des Verliebten (1767, printed 1806; "The Mood of the Beloved") and a more sombre farce, Die Mitschuldigen (1768, printed 1787; "The Accomplices"), which foreshadows the psychological preoccupations of later works. From then on, the Rococo was to reappear in the setting of Torquato Tasso (1790) and Die Wahlverwandtschaften (1809; Elective Affinities); he paid tribute to its charm in Anakreons Grab (1806; "Anacreon's Grave") and amalgamated it with Eastern influence in the enchanting poems of his West-östlicher Divan (1819; Poems of the West and the East).

Works of the storm and stress period. Goethe's stay in Leipzig was cut short in 1768 by severe illness. A long convalescence at home fostered introspection and religious mysticism. On his recovery it was decided that he should pursue legal studies in Strassburg. In this German capital of a French province, he experienced a reaction against the cosmopolitan atmosphere of Leipzig and under the impact of the great cathedral proclaimed his conversion to the Gothic German ideal. More decisive still was the influence of J.G. Herder, who spent the winter of 1770-71 there undergoing treatment for his eyes. From him Goethe learned a new view of the artist as a creator fashioning forms expressive of feeling; a new theory of poetry as the original and most vital human language; the virtues of a new style. that of the Volkslied (folk song) and the poetry of "primitive" peoples as enshrined in the Bible, the epics of Homer, and the poems attributed (falsely) to Ossian, a 3rd-century Celtic poet.

In writing the Geschichte Gottfriedens von Berlichingen mit der eisernen Hand dramatisiert (1771: "The Dramatized History of Gottfried von Berlichingen of the Iron Hand"), Goethe was deliberately vving with Shakespeare. With the publication in 1773 of Götz von Berlichingen, a radically tautened version of that "History," the Shakespeare cult was launched, and the Sturm und Drang (storm and stress) movement was provided with its first major work of genius. The manifesto of the movement-"Von deutscher Art und Kunst" ("Concerning German Nature and Art")-was heralded by Goethe's enthusiastic Rede zum Schakespears Tag ("Conversation from Shakespeare's Day"). It appeared after Goethe's return to Frankfurt in August 1771.

Literature soon won the day over law, and Goethe's impassioned yet self-ironic ode in free verse, "Wandrers Sturmlied" ("Wanderer's Storm Song"), is testimony both to a recently inspired admiration for Pindar and to a hesitant certainty that he himself might be destined for greatness. And he experienced a new passion, Charlotte Buff, who was engaged to be married. She was enshrined in Die Leiden des jungen Werthers (1774; The Sorrows of Young Werther). But the real theme of Werther is what the 18th century called Enthusiasm: the fatal effects of a predilection for absolutes. The title has been trivialized in translation: Sorrows (instead of "Sufferings"), which obscures the allusion to the Passion of Christ and individualizes what Goethe himself thought of as a "general confession," in a tradition going back to St. Augustine.

Besides Werther and Götz, the period 1771-75 saw the appearance of a number of magnificent hymns, including "Der Wandrer" ("The Wanderer"); the inception of Egmont (1788) and Faust (this so-called Urfaust, or "original" version of Faust, was discovered by a lucky chance in 1887); the completion of Clavigo (1774), a play of more "regular" form on a theme of the French playwright Beaumarchais, and of Stella (1775), with its conciliatory ending of a mariage à trois, subsequently conventionalized into tragedy. Two operettas, Erwin und Elmire (1775) and Claudine von Villa Bella (1776), reflect a return to the elegance of Rococo inspired by Goethe's short-lived betrothal to Lili Schönemann, daughter of a banker.

The mature years at Weimar. In 1775 Goethe went to Weimar on a visit to the reigning duke, the major turning point of his life. Weimar remained his home-despite Napoleon's invitation to Paris-until his death there on March 22, 1832. From now on, mastery of life became his chief concern; and Wilhelm Meisters Lehrjahre (1795-96; Wilhelm Meister's Apprenticeship), the title he eventually gave his next novel, suggests the long apprenticeship such

The Sturm und Drang movement Journey

to Italy

mastery involves. (Thomas Carlyle, the Scottish historian and essayist, did a distinguished translation of the novel.) Goethe developed a passionate devotion to the wife of a court official, Charlotte von Stein. The sublimation she increasingly enforced on him, though irksome, could inspire works ranging from the almost psychoanalytical probings of "Warum gabst du uns die tiefen Blicke?" ("Why did you give us the deep glances?") to such well-loved lyrics as "An den Mond" ("To the Moon") and the two exquisite "Wandrers Nachtlieder" ("Wanderer's Night Songs"). In these and other poems of this period, nature has ceased to be a mere reflection of man's moods and has become something existing in its own right. This new "objectivity" is in tune with Goethe's growing scientific preoccupations. Yet such is his versatility that he could, when he chose, compose ballads such as "Erlkönig" ("Elf King"), in which na-

ture bears the projection of unconscious forces. In September 1786, in dramatic secrecy, Goethe set out on a long-postponed Italian journey-recounted in Italienische Reise (1816-17), which was translated in the 20th century as Italian Journey 1786-88 by the poet W.H. Auden and Elizabeth Mayer. Goethe sought among other things a key to the world of Homer, which he recaptured in a glorious dramatic fragment, Nausikaa (1787). He sought and found the Urmensch, or archetypal man, in the forms of Greek antiquity, and in these landscapes there also came to his mind the extension of this idea to plants as well. In his literary work these pursuits led to the creation of beings who are individual manifestations but of a clearly discernible type; to themes that are universal and timeless but treated in a highly differentiated way; to the measured cadences of verse that are yet vibrant with personal passion.

This new conception of form is apparent in the revision of the four plays he had taken with him to Italy, Faust, Ein Fragment ("Faust, a Fragment"), published in 1790, is quite clearly a step in the direction of the stupendous cultural symbol the play would eventually become. Egmont, though not actually east into verse, is raised to the level of poetic drama by a thickening of the verbal texture, so that when music finally takes over it seems the inevitable culmination of a gradual convergence and sudden contraction of themes.

In Torquato Tasso such linguistic density is carried to lengths possible only in verse. The tragic conflict in this play about a poet arises from misunderstandings about the various modes of language, and the temperamental clashes are presented as concomitants of this. By placing the poet in a society that, far from being indifferent or hostile, cherishes him and values his work, Goethe has thrown into sharpest relief the incurable "discrepancy" between poet and world.

But it was perhaps Iphigenie auf Tauris (1787) that benefitted most from Goethe's encounter with classical antiquity, though Schiller was right in calling it "astonishingly modern and un-Greek." Like Tasso, it treats of the problems of communication. But it also concerns man's power to free himself from his myths by recognizing them as projections of his own unconscious, his power to break the chain of events that seems to determine his present (symbolized in the monotonously regular crime sequence of the race of Tantalus) by a reorientation of outlook. In its synthesis of Greek and Christian values, its elevation of the physical to the spiritual through the identification of Iphigenie with the divine sister, Diana, this play represents the highest achievement of 18th-century humanism.

The chief lyrical product of the Italian journey was the Römische Elegien (written 1788-89, published 1795; Roman Elegies and Other Poems). The inspiration for these elegies was Christiane Vulpius, daughter of a humble official, with whom Goethe had begun living soon after his return from Italy, although he did not marry her until 1806. Christiane bore him several children.

A return visit to Italy in 1790 brought nothing but disappointment, and a restlessness aggravated by the revolutionary events in the outer world. The Venezianische Epigramme (1790; published in Roman Elegies and Venetian Epigrams) reflect something of this discontent. In 1792 Goethe accompanied his duke on the disastrous campaign into France and wrote up his experiences in two still very readable war books, Campagne in Frankreich 1792 and Die Belagerung von Mainz 1793 (both 1822; published in Miscellaneous Travels of J.W. Goethe). The French Revolution forms the background of his Homeric treatment of the refugee problem, Hermann und Dorothea (1797), and it fills the whole canvas of Die Natürliche Tochter (1804; "The Natural Daughter").

Schiller and the Classical ideal. The human and spiritual isolation in which Goethe found himself on his return from Italy was unexpectedly relieved by the development of a friendship with Friedrich von Schiller. Some of the works Goethe produced during the next few years are embodiments of the Classical ideal espoused by Schiller (and by Goethe). Hermann und Dorothea, one of the best loved. is Goethe's attempt to "produce a Greece from within. The characters are types-except for the hero and heroine, they have no proper names, and even the hero's and hereine's are symbolic-and like those of the Odyssey they vindicate peace and home and the domestic virtues. Yet, as always in Goethe's works, these are shown as never secure for long, as constantly in need of being fostered by the efforts to be human and humane. In the Helena act of Faust, Part II (1832), in which the meeting and mating of Faust and Helen of Troy marks the synthesis of paganism and Christianity, of Greece and Germany, he captured the Greek spirit so successfully that competent critics hold that if translated into Attic Greek it might well pass for a lost fragment of the Athenian stage. A never completed epic, Achilleis (1808), is his last attempt to "be a Greek after his own fashion."

Other works of this period are in tune with Schiller's growing conviction that the only future for literature in a world that increasingly clamoured for the naturalistic and the tendentious lay in a hermetic closing of the poetic world by a frank introduction of symbolic devices, Wilhelm Meisters Theatralische Sendung (Wilhelm Meister's Theatrical Mission; a manuscript of this version turned up in 1910) is now widened to a vocation for life and is wholly in tune with Goethe and Schiller's conviction that art. though not the handmaid of either truth or morality, has nevertheless its own peculiar part to play in making better men and better citizens. (Selections from their correspondence can be found in Correspondence between Goethe and Schiller, 1994.)

It was Schiller, too, who turned Goethe's thoughts to the continuation of Faust and discerned the difficulties involved in reconciling this "barbarous composition" with their Classical ideal, in blending the evident seriousness of its "idea" with that element of "play" that was the prerequisite of the art of the future. By his insistence on such problems, he inspired the fictional framework of Faust's "Prelude on the Stage" no less than the philosophical framework of the "Prologue in Heaven."

Goethe's relation to the Romantics. With Schiller's death in 1805, Goethe felt he had lost "the half of his existence," and he wrote a magnificent tribute to his great friend in Epilog zu Schillers Glocke (1805; "Epilogue to Schiller's Bells"). His intellectual loneliness was eased by his relations to the new school of Romantics then flourishing in Jena, for they had much in common. In Die Wahlverwandtschaften he drew heavily for his thematic material

upon their preoccupation with "the night side of nature." By their translations the Romantics were opening up the literary treasures of the world, and Weltliteratur was to become one of Goethe's most treasured concepts. Its aim was, as he put it, to advance civilization by encouraging mutual understanding and respect whether through translation or criticism (his own attempts to interpret Serbian poetry to the Germans is an excellent example of the latter) or through the blending of different literary traditions. Two great ballads, "Der Gott und die Bajadere" ("The God and the Dancing Girl") and "Paria" ("Outcast"), and two exquisite cycles, the late and lesser known Chinesisch-Deutsche Jahres- und Tageszeiten (1830; "Chinese-German Hours and Seasons") and the West-östlicher Divan, are his own outstanding attempts to marry East with West

The last decade. In his last years, Goethe found himself a world figure, and little Weimar drew a constant stream Schiller

Faust

of pilgrims. Goethe's continued openness to the world around him and its possibilities is nowhere more apparent than in Wilhelm Meisters Wanderjahre (1821-29; Wilhelm Meister's Years of Travel), with its commitment to social and technological progress, to a type of education better adapted to modern specialization than the old humanistic studies, to a world no longer centred wholly in Europe-a major "complication" of his plot is a resettlement plan for emigrants in the land of the future ("Amerika, du hast es besser!" ["America, you are better off!"]).

Faust, like Wilhelm Meisters Wanderjahre, is often decried as formless. The array of lyric, epic, dramatic, operatic, and balletic elements, of almost every known metre, of styles ranging from Greek tragedy through medieval mystery, Baroque allegory, Renaissance masque, commedia dell'arte, and the "temerities of the English stage," to something akin to the modern revue, all suggest a deliberate attempt to make these various forms a vehicle of cultural comment rather than any failure to create a coherent form. And the content with which Goethe invests his forms bears this out. He draws on an immense variety of cultural material-theological, mythological, philosophical, political, economic, scientific, aesthetic, musical, literary-for the more realistic Part I no less than for the more symbolic Part II (first published posthumously in 1832): if Faust's wooing of Helena in the "Classic-Romantic Phantasmagoria" (as the first publication of the scene in 1827 called it) is accomplished by teaching her the unfamiliar delights of rhymed verse, his seduction of Gretchen is firmly set in the long tradition of erotic mysticism going back to the Song of Solomon. The Faust myth is here made the medium of a profoundly serious but highly ironic commentary on our cultural heritage, presented as a drama of the diverse potentialities that coexist in Western civilization. This Faust, unlike his creator, is the very type of Western man, with two souls warring within his breast and a restlessly inquiring spirit. If the seal of approval is set on a spirit that has eluded Mephisto's every effort to lull him into sloth, the evil into which it led him is not condoned. Indeed, none of Goethe's conciliatory endings, except that of Iphigenie, really removes the sting of tragedy.

Similarly, Goethe was profoundly aware of the dual nature of music and as suspicious as Plato of its orgiastic power. As in every art he looked for the taming of the Dionysian by the Apollonian, nowhere more movingly symbolized than by the taming of the lion through the piping of the little child in his Novelle of 1828, Increasingly he turned to music for assuagement of his own suffering. His Trilogie der Leidenschaft (1823-27; "Trilogy of Passion") is at once the lyrical precipitate of an old man's anguished love for a girl of 18 and a tribute to the cathartic effect of this "heavenly art," which restores to life even as it soothes. His Zauberflöte, Zweiter Teil (1794) is a tribute to his favourite Mozart's Magic Flute: Mozart would, he

thought, have been the ideal composer for Faust. By common consent, Faust is one of the supreme, if as yet unclassified, achievements of literature. But there were moments when Goethe rated his scientific work higher than all his poetry. The usefulness of the Psycho-Physiological Section of his Farbenlehre (1805-10; Goethe's Colour Theory), together with his study Entoptische Farben ("Entoptic Colours"), is generally acknowledged, while the Historical Section is something of a pioneer work in the writing of the history of science. His work in botany and biology is less controversial. His Metamorphose der Pflanzen (1790; The Metamorphosis of Plants) is a model of presentation, and the drawings in it are a botanist's delight. His main thesis, that all the parts of the plant are modifications of a type-leaf, has met with a measure of acceptance, though his categorical neglect of the root is regarded as an unscientific exclusion of a possible area of relevance. His discovery in 1784, arrived at independently even if he was not the first to make it, of a recognizable os intermaxillare (the premaxilla of modern anatomists) in the human species was yet another result of his sustained

quest for unity and continuity in nature and caused Charles Darwin to hail him as a forerunner.

Scrupulous awareness of his own mental operations was of paramount importance in morphology, the science Goethe founded and named. Morphology, as he understood it, was the systematic study of formation and transformation-whether of rocks, clouds, colours, plants, animals, or the cultural phenomena of human society-as these present themselves to sentient experience. Goethe was aiming at an understanding of nature in all its qualitative manifestations; and one of his most impassioned pleas is for a concert of all the sciences, a cooperation of all types of method and mind.

This impulse to find a scientific as well as an aesthetic corrective to the inevitably esoteric tendencies of specialization, is nowhere more apparent than in his two elegies on plant and animal metamorphosis in which he tries to present to imagination and feeling what has been understood by the mind. They eventually took their place in a cycle of philosophical poems entitled Gott und Welt ("God and World"). Goethe was and remained a grateful heir of the Christian tradition-bibelfest, rooted in the Bible. From this centre he extended sympathetic understanding to all other religions, "Panentheism" has been proposed as a more exact term for his belief in a divinity at once immanent and transcendent.

Assessment. Goethe's Werther knew that the realities of existence are rarely to be grasped by Either-Or. And the reality of Goethe himself certainly eludes any such attempt. He was, as befits a son of the Enlightenment, wholly committed to the adventure of science; but he stood in awe and reverence before the mystery of the universe. Goethe nowhere formulated a system of thought. He was as impatient of the sterilities of logic chopping as of the inflations of metaphysics, though he acknowledged his indebtedness to many philosophers, including Immanuel Kant. But here again he was not to be confined. Truth for him lay not in compromise but in the embracing of opposites. And this is expressed in the form of his Maximen ("maxims"), which, together with his Gespräche ("conversations"), contain the sum of his wisdom. As with proverbs, one can always find among them a twin that expresses the complementary opposite. And they have something of the banality of proverbs, too. But it is, as André Gide observed, "une banalité supérieure." What makes it "superior" is that the thought has been felt and lived and that its formulation betravs this. Not an ascetic, a mystic, a saint, or a recluse, not a Don Juan or a poet's poet but a man who to the best of his ability had tried to achieve the highest form of l'homme moyen sensuel-which is perhaps what Napoleon sensed when after their meeting in Erfurt he uttered his famous "Voilà un homme!"

Truth as the embracing of opposites

BIBLIOGRAPHY. English translations of representative works from his oeuvre are in Goethe's Collected Works, 12 vol. (1983-89, reissued 1994-95), published by Suhrkamp; and Goethe's Works, 14 vol. (1848-90), in Bohn's Standard Library. Bibliographic details are available in EUGEN OSWALD, Goethe in England and America, 2nd ed., rev. and enlarged by LINA OS-WALD and ELLA OSWALD (1909).

The best introduction in English to Goethe's life is GEORGE H. LEWES, The Life and Works of Goethe, with Sketches of His Age and Contemporaries from Published and Unpublished Sources, 2 vol. (1855; also published as Life of Goethe), available also in later editions and printings. Also of interest are NICHOLAS BOYLE, Goethe: The Poet and the Age (1991-); BENEDETTO CROCE, Goethe, trans. by EMILY ANDERSON (1923, reprinted 1973; originally published in Italian, 1919); and GEORGE BRANDES, Wolfgang Goethe, trans. by ALLEN W. PORTERFIELD, 2 vol. (1924, reissued 2 vol. in 1, 1936; originally published in Danish, 1915). Critical analyses of his works are found in THOMAS MANN, Three Essays, trans. from German by H.T. LOWE-PORTER (1929, reissued 1932); ELIZABETH M. WILKINSON and LEONARD A. WILLOUGHBY, Goethe: Poet and Thinker (1962); and RONALD PEACOCK, Goethe's Major Plays (1959, reprinted 1966). Other studies include GEORG LUKÁCS (GYÖRGY LUKÁCS), Goethe and His Age (1968, reprinted 1979; originally published in German, 1947). (E.M.Wn./Ed.)

The Forms of Government: Their Historical Development

ost of the key words commonly used to describe governments, words such as monarchy, oligarchy, and democracy, are of Greek or Roman origin. They have been current for more than 2,000 years and have not yet exhausted their usefulness. This suggests that mankind has not changed very much since they were coined; but such verbal and psychological uniformity must not be allowed to hide the enormous changes in society and politics that have occurred. The earliest analytical use of the term monarchy occurred in ancient Athens, chiefly in Plato's dialogues, but even in Plato's time the word was not self-explanatory. There was a king in Macedon and a king in Persia, but the two societies, and therefore their institutions, were radically different. To give real meaning to the word monarchy in these two instances, it would be necessary to investigate their actual political and historical contexts. Any general account of monarchy required then, and requires today, an inquiry as to what circumstances have predisposed societies to adopt monarchy, and what have led them to reject it. So it is with all political terms,

This article is divided into the following sections:

PRIMITIVE GOVERNMENT

Primitive government 141

Agricultural society. So long as humankind were few, there was hardly any government. The division of function between ruler and ruled occurred only, if at all, within the family. The largest social groups, whether tribes or villages, were little more than loose associations of families, in which every elder or family head had an equal voice. Chieftains, if any, had strictly limited powers; some tribes, no doubt, did without chieftains altogether. This prepolitical form of social organization may still be found in undeveloped regions of the world, such as the Amazonian jungle in South America or the Upper Nile Valley in Africa.

The rise of agriculture began to change this state of affairs. In the land of Sumer (modern Iraq) the invention of irrigation necessitated grander arrangements. Control of the flow of water down the Tigris and Euphrates rivers had to be coordinated by a central authority, so that downstream fields could be watered as well as those further up. It became necessary also to devise a calendar, so as to know when the spring floods might be expected. As these skills evolved, society evolved with them. In early Sumer, it is reasonable to assume, the heads of the first cities. which were little more than enlarged villages, only gradually assumed the special attributes of monarchy, the rule of one; and the village council only gradually undertook a division of labour, so that some specialized as priests and others as warriors, farmers, or tax gatherers (key figures in every civilized society). As organization grew more complex, so did religion: an elaborate system of worship was necessary to propitiate the quite elaborate family of gods who, it was hoped, would protect the city from attack. from natural disaster, and from any questioning of the political arrangements deemed necessary by the ruler group.

Unfortunately, but inevitably, the young cities of Sumer quarrelled over the distribution of the rivers' water, and their wealth excited the greed of nomads outside the still comparatively small area of civilization. War, perhaps the most potent of all forces of historical change, announced its arrival, and military leadership became at least as important an element of kingship as divine sanction. It was to remain so throughout the long history of monarchy: whenever kings have neglected their military duties they have endangered their thrones. The wars of Sumer also laid bare another imperative of monarchy-the drive for empire, arising from the need to defend and define frontiers by extending them, and the need to find the means to pay for troops and weapons, whether by the plunder of

an enemy or by the conquest of new lands.

The spread of civilization. The history of Old World monarchy, and indeed of civilization, was to consist largely of variations on these patterns for four or five millennia. Trade contacts carried the principles of civilization to Egypt and to India (China seems to have evolved independently); and everywhere, once the social order was established, the problem of defending it became paramount. For although the broad zone of civilization spread steadily, so that by the reign of the Roman emperor Trajan (AD 98-117) there was a continuous band of civilized societies from Britain to the China Sea, it was always at risk from the barbarian nomads who roamed the great steppelands of central Eurasia. These nomads had retained the loose and simple institutions of humanity's infancy, but they had in other ways evolved as rapidly and successfully as the cities themselves (and partly under the cities' influence). The steppe was horse country, and, armed with bows and arrows, the barbarians of all epochs were marvelously swift and deadly light cavalry. They fought constantly among themselves for pasturage, and the losers were forever being driven west, south, and east, where they all too often overcame such defenses as the farms and cities of civilization could muster against them.

The nomads' military challenge was never sufficient to overturn civilization entirely. Either the invaders would overrun the settled lands and then adopt civilized customs, or the frontier defenses would prove strong enough to hold them off. There were even long periods of peace, when the barbarian threat was negligible. It was at such times that the spontaneous ingenuity of mankind had greatest play, in politics as in everything else. But it is noteworthy that, in the end, what may be described as the ancient norm always reasserted itself, whether in Europe, the Middle East, India, or China. Military crises-civil war or barbarian invasion or both-recurred and necessitated the strengthening of government. The effort to secure a measure of peace and prosperity required the assertion of authority over vast distances, the raising of large armies, and the gathering of taxes to pay for them. These requirements in turn fostered literacy and numeracy and the emergence of what later came to be called bureaucracy, government

imperial imperatives

Prepolitical societies

by official. Bureaucratic imperialism emerged again and again and spread with civilization. Barbarian challenge occasionally brought it low but never for very long. When one city or people rose to hegemony over its neighbours, it simply incorporated their bureaucracy with its own. Sumer and Babylon were conquered by Assyria; Assyria was overthrown by the Medes, in alliance with Babylon and nomad Scythians; the empire of the Medes and Persians was overthrown by Alexander of Macedon; the Macedonian successor states were conquered by Rome, which was in due course supplanted in the Middle East and North Africa by the Islamic Caliphate of Baghdad. Conquerors came and went; life for their subjects, whether peasants or townsmen, was not much altered by anything they did, so long as the battles occurred at safely remote sites.

Bureaucratic monarchy

Nevertheless, from time to time experiments were made, for no monarchy commanded the resources to rule all its subjects directly. So long as they paid tribute punctually, local rulers and local communities were perforce left very much to govern themselves. Even if they did not pay, the effort required to mount a military operation at a distance from the imperial centre was so great that only in exceptional circumstances would it be undertaken, and even then it might not succeed, as the kings of Persia found when they launched punitive expeditions against mainland Greece at the beginning of the 5th century BC. So, in normal times, the inhabitants of the borderlands had extensive freedom of action.

Although civilization, as its advantages became clear, spread west and northwest out of Asia, bureaucratic monarchy could not easily follow it, for the sea was becoming a historical factor as important as the steppe and the great irrigable rivers. Tyre and Sidon, maritime cities of Phoenicia, had long exploited their coastal situation, not only to remain independent of the landward empires but also to push across the sea, even beyond the Strait of Gibraltar, in quest of trade. Their daughter-cities, Carthage, Utica, and Cádiz, were the first colonies, but primitive communications made it impossible for Phoenicia to rule them from afar.

The city-state. The Phoenician example was followed by the Greeks. The Greeks were originally Indo-European nomads, who gradually made their way down to the Aegean and there took to the sea. They built on the achievements of earlier peoples, even taking over the first bureaucratic monarchy to appear on European soil: the Minoan civilization of the island of Crete, which succumbed to the invaders about 1450 BC. Continuing invasions from the north overthrew the mainland kingdoms of Mycenae, Tiryns, and Pylos in about 1200 BC. The so-called dark ages of Greece that then began lasted until the 8th century BC, by which time the Greeks had not only recovered literacy, by adapting the Phoenician alphabet, and begun to found overseas colonies, but had also brought the city-state to something near maturity. This form of government was the great political invention of classical antiquity.

Mediterranean geography is such that every little fishing village had to be able to defend itself against attack from land or sea, for outside help could not reach it easily. A man's dependence on his community, for physical as well as economic survival, was therefore obvious and complete. The city (polis) had first claim on his labour and loyalty, a claim that was usually freely recognized. It was this reality that led Aristotle (who himself came from just such a small commonwealth, Stageira, or Stagirus) to define man as a political animal.

Coastal mountain ranges made it difficult for any community to dominate more than a few square miles of land. They also for a long time deterred the rise of an empire to federate and control all the cities. If a few of these centres nevertheless rose to imperial greatness, like Tyre and Sidon before them, it was in the main because, like their Phoenician predecessors, they traded across the sea successfully. Athens, for example, exported olive oil, silver, and pottery. The profits of this trade enabled it to build a great navy and formidable city walls. Athenian

ships defeated Persia (480 BC) and won a small empire in the Aegean Sea; the combination of ships and walls enabled Athens long to defy, and nearly to defeat, its chief rival among the Greek cities, Sparta. Even after Sparta's triumph at the end of the Peloponnesian War (404 BC), Athens remained an independent sovereign state until its defeat by Philip of Macedon at the battle of Chaeronea (338 BC). In short, during the period of its prime Athens was free to make what experiments it liked in the realm of government, and to that period are owed not just the first example of successful democracy in world history but also the first investigations in political thought

Monarchy, oligarchy, democracy. No Athenian believed that he had anything to learn from the bureaucratic monarchies of the East, which were incompatible with Greek notions of citizenship. All monarchies, indeed, seemed bound to deteriorate into such tyrannies. Self-defense necessitated that every adult male be required, and indeed be willing, to fight when called on; in return he had to be given some measure of respect and of personal autonomy-in a word, freedom. To protect that freedom, government was necessary; anarchy had no attractions for any Greek. The central question of politics, then, was the distribution of power among the citizens. Was Greek freedom best preserved and defined by the rule of the few or by that of the many? On the whole the great names favoured aristocracy, the rule of the best. Plato believed that the object of politics was virtue, and that only a few would ever thoroughly understand the science by which virtue could be attained. These trained few, then, should rule. Aristotle, his pupil, seems to have put the cultivation of the intellect highest among human goods; and he believed-quite reasonably, given the limited resources then available-that this fruit of civilization could be reaped only among a leisure class supported by the labours of the many. In return for their leisure the gentry would agree to sacrifice some of their time to the tedious business of governing, which only they would be sufficiently disinterested and well informed to do successfully. Neither of these apologies for oligarchy had any success in practice. The democrats carried the day, at any rate in Athens and its allied cities. In return for playing their parts as soldiers or sailors, ordinary Athenians insisted on controlling the government.

The result was impressive. The people were misled by demagogues; they were intolerant enough to put Plato's master, Socrates, to death; they were envious of all personal distinction; and of their three great wars (against Persia, Sparta, and Macedon), they lost two. Furthermore, passionate devotion to the idea that Athens was the greatest of all cities, the school of Greece, and the wonder of civilization, misled them into basing their society in large part on slave labour, into wanton imperial adventure abroad, and into denying Athenian citizenship to all who were not born to it (even Aristotle), however much they contributed to the city's greatness and however much more they might have done. The foundations of Athenian democracy were narrow and shallow and fragile. But to say all this is only to say that the city could not entirely shake off the traditions of its past. Its achievement was the more remarkable for that. Seldom since has civilized humanity equalled democratic Athens, and until the last the city was satisfactorily governed by law and by popular decision. It owed its fall less to any flaw than to the overwhelming force that was mounted against it.

For to the north of Hellas proper a new power arose. Greek civilization had slowly trained and tamed the wild men of Macedon. Their king Philip forged them into a formidable army; he and his son Alexander then seized the opportunity open to them. History and geography made it impossible for the Greek cities to unite, and so they hanged separately. It seemed as if the city-state had been but a transient expedient. Henceforward Athens and Sparta would take their orders from the Great King.

The republic. As it turned out, the city-state had barely begun to display its full political potential. To the west, two non-Greek cities, Carthage and Rome, began to strugViews of Plato and Aristotle

The polis

gle for mastery, and after the defeat of Hannibal at Zama (202 BC) Rome emerged as the strongest state in the Mediterranean.

The Greeks did not know how to classify Rome. The Greek historian Polybius, who chronicled Rome's rise, suggested that its constitution was such a success because it was a judicious blend of monarchy, aristocracy, and democracy. The Romans, a conservative, practical people, showed what they thought of such abstractions by speaking only of an unanalyzed "public thing"-res publicaand thus gave a new word to politics. With this focus the patriotism of the city-state reached its greatest intensity.

The Romans were deeply attached to their traditions, and these traditions all taught the same lesson. For example, the legendary hero Mucius Scaevola gave his right hand to the flames to prove that there was nothing a Roman would not endure for his city. This passionate devotion to Rome's survival was tested again and again in war. All the tales of early Rome turn on battle. With dour persistence the peasants who had gathered for self-protection on the seven hills resisted every invader, fought back after every defeat, learned from all their mistakes, and even, however reluctantly and belatedly, modified their political institutions to meet the new needs of the times as they arose. Polybius was right: power in Rome was indeed shared among the people, the aristocracy, and the consuls, the executive officers of the republic who had replaced the kings. The claims of the many and of the few were fought out at election time, when the world's first clearly identifiable political parties appeared. Until Rome's late decadence, the results of elections were universally respected, and the triumphant alliance of the few and the many against the world was proclaimed in the letters blazoned on the city's buildings and battle standards: spor, for Senatus Populusque Romanus, the Senate and the people of Rome.

Like Athenian democracy, this system worked well for a surprisingly long time, and if the chief Athenian legacy was the proof that politics could be understood and debated logically and that under the right conditions democracy could work, Rome proved that the political process of competition for office and public discussion of policy was

a valuable thing in itself.

Nevertheless, the Roman republic had been forged in a grim world. Its power had gradually extended over Italy in wars, always supposedly of self-defense. It is not surprising that what impressed the world most about the city was its military strength rather than its political institutions, even though the two were intimately related. As the weakness of Rome's neighbours became apparent, the Romans began to believe in their mission to rule, "to spare the conquered and war down the proud," as the poet Virgil put it. Military strength, in short, led to military adventurism. By the 1st century BC, Rome, having become a naval power as well as a military one, had conquered the whole Mediterranean basin and much of its hinterland. The strains of empire building made themselves felt. The Roman armies, no longer composed of citizens temporarily absent from the plow or the workshop but of lifetime professionals. were now loyal to their generals rather than to the state; and these generals brought on civil war as they competed to turn their foreign conquests into power at home. The population of Rome swelled, but economic growth could not keep pace, so that many citizens became paupers de-pendent on the public dole. The aristocrats appointed to govern the provinces saw their postings merely as opportunities to get rich quickly by pillaging their unfortunate subjects. The republic could not solve these and other problems and was in the end superseded by the monarchy of Caesar Augustus.

The empire. The bedrock of Augustus' power was his command of the legions, but he himself was a much better politician than he was a general, and he knew quite well that naked political power is as unstable as it is expensive. He reduced the military establishment as much as was prudent, laboured to turn the revolutionary faction that had supported his bid for power into a respectable new ruling class, and proclaimed the restoration of the republic. But not even Augustus could make the restoration real. With the safety of the state, questions of war and

peace, and most of the business of governing the empire in the hands of a monarch, there was not enough for the Senate to do, and Augustus never went so far as to restore genuinely free elections or the organs of popular government. He kept the crowd happy with chariot races gladiatorial contests, and the dole of bread. Nevertheless, he could not give up the attempt to legitimize his regime Like earlier monarchs elsewhere, he called in the aid of religion, even though the religion of Rome was as republican as its constitution. Later emperors made their own divinity a tenet of the public faith

For four centuries the resemblance between Rome and the bureaucratic eastern monarchies steadily increased. Roman nationalism, Roman traditionalism, and Roman law survived as legacies that posterity would one day claim; and if nobody much believed in the constitutional shams of Augustus' day, the example of his constitutional monarchy was to prove potent at a much later period.

The age of the city-state was at last drawing to a close. The emperor Caracalla extended Roman citizenship to all subjects of the empire, but that was merely so that he could tax them more heavily. The demands of the imperial administration began to bankrupt the cities, which had previously prospered as the local organs of government under Rome. New barbarian attacks threw the empire onto the defensive, and in AD 410 Rome fell to the Visigoths.

THE MIDDLE AGES

Dissolution and instability. Seen against the background of the millennia, the fall of Rome was so commonplace an event that it is almost surprising that so much ink has been spilt in the attempt to explain it. The Visigoths were merely one among the peoples who had been dislodged from the steppe in the usual fashion. They and others, unable to crack the defenses of Sasanian Persia or of the Roman Empire in the east (though it was a near thing), probed farther west and at length found the point of weakness they were seeking on the Alps and the Rhine.

What really needs explaining is the fact that the western empire was never restored. Elsewhere the universal throne was never vacant for long. In China, after every time of troubles, a new dynasty received "the mandate of Heaven," and a new Son of Heaven rebuilt order. For instance, in AD 304 the Huns had invaded China, and a long period of disruption followed; but at the beginning of the 7th century the T'ang dynasty took charge and began 300 years of rule. The Europeans failed to emulate this story. Justinian, the greatest of the eastern Roman emperors, reconquered large portions of the West in the 6th century, though the destruction wreaked by his soldiers made things worse rather than better. In 800, Charlemagne, king of the Franks, was actually crowned emperor of the West by the Pope. In later centuries the dynasties of Hohenstaufen and Habsburg tried to restore the empire; so, as late as the 19th century, did Napoleon Bonaparte. None of these attempts succeeded. Probably the chance was only real in the earliest period, before Europe had got used to doing without an overlord. But at that time there was never a long enough breathing space for society to regain its stability and strength. Most of the barbarian kingdoms, successor states to Rome, succumbed to later assailants. Britain fell away from the empire in the 5th century; the little kingdoms of the Angles and Saxons were just coming together as one kingdom of England when the Viking invasions began. In the 7th century the Arabs conquered North Africa, and in the 8th they took Spain and invaded Gaul. Lombards, Avars, Slavs, Bulgars, and Magyars poured into Europe from the East. Not until Otto I's victory over the Magyars at Lechfeld in 955 did these incursions cease, and not until the late 11th century was Latin Christendom more or less secure within its borders; and by then it had been without an effective emperor for more than 600 years.

Feudalism. Various institutions had emerged to fill the gap. The church, against enormous odds, had kept the light of religion and learning alive and spread what was left of Roman civilization into Ireland, England, Central Europe, and Scandinavia. It also provided a reservoir of literacy against the day when professional government

should be possible again. The kings of the barbarians, of whom Charlemagne was the greatest, had provided military leadership and tried to acquire some of the prestige and governmental machinery of the Roman emperors. But the troublous times ensured that effective power fell to a military aristocracy. Its members called themselves nobiles in the Roman fashion and appropriated various late imperial titles such as comes (count) and dux (duke). But this was mere decoration. The new kings, lacking the machinery for imperial taxation, could not pay for standing armies. Besides, this was the age in which the heavily armoured cavalryman (chevalier in French; knight in English) dominated war. He was an independent force and thus a much less dependable instrument than a Roman legionary had been. Legally, the new masters of the soil were liegemen of the various kings (it was a maxim that every man had a lord), but in practice they could usually ignore royal claims. Europe thus fell under the rule of armoured lords; and the course of the next few hundred years gave everyone reason to wonder whether the democrats of Greece had not been right to distrust the very idea of oligarchy, for the tonic note of noble rule seemed to be almost incessant warfare.

Even at their height the military aristocrats never had it all their own way. Strong monarchies gradually developed in England, France, and, a little later, in the Iberian Peninsula. During the heyday of the papacy (c. 1050-1300) the Roman Catholic Church was able to modify, if not control, baronial behaviour. Trade gradually revived and brought with it a revival of the city-state in Italy, the Rhineland, and the Low Countries, for the newly prosperous burghers could now afford to build stout walls around their towns, and it became difficult for the nobility to muster the force to besiege them successfully. Even the peasants from time to time made themselves felt in bloody uprisings. The nobility itself was far from a homogeneous

or united class.

The rise of law and the nation-state. Medieval Europe, in short, was a constantly shifting kaleidoscope of political arrangements; to the extent that it ever settled down, it did so on the principle that since everybody's claim to power and property was fragile and inconsistent with everybody else's, a certain degree of mutual forbearance was necessary. This explains the great importance attached to custom or (as it was called in England) common law. Disputes were still often settled by force, especially when kings were the disputants, but the medieval European became almost as fond of litigation as he was of battle Every great estate was hung about with quasi-permanent lawsuits, and the centralization of the church on the papal courts at Rome ensured yet more work for lawyers, the greatest of whom began to merge with the military nobility into an aristocracy of a new kind. Rights, titles, and privileges were forever being granted, revoked, and reaffirmed. Parchment deeds came to regulate men's political, social, and economic relationships at least as much as the sword did. In these ways the idea of the rule of law was reborn. By the beginning of the early modern period, legally demonstrable privileges had become the universal cement of European society. The weak were thus enabled to survive alongside the strong, and Europe, where everyone knew to which order of society he belonged, thus took on a faint resemblance to India, where the caste system was so strong as to make many of the usual functions of government quite unnecessary.

But there was a dynamism in European society that prevented it from setting permanently into this or any other pattern. This evolving Europe of privileged orders was also the Europe of rising monarchies. With many setbacks the kings clawed power to themselves; by 1500 most of them presided over bureaucracies (initially staffed by clerics) that would have impressed any Roman emperor. But monarchy could no longer claim universality. The foundations of the new monarchies were purely territorial. The kings of England, France, and Spain had enough to do to enforce their authority within the lands they had inherited or seized and to hammer their realms into some sort of uniformity. This impulse explains the wars of the English against the Welsh, Scots, and Irish; the drive of the French

kings toward the Alps, the Pyrenees, and the Rhine; and the rigour of the Spanish kings in forcing Catholicism on their Jewish and Moorish subjects. Uniformity paved the way for the most characteristic governmental form of the modern world, the nation-state.

EMERGENCE OF THE MODERN WORLD

The failure of absolutism. That evolution was not easy. for kings or anybody else. The invention of gunpowder enabled kings to overbear their turbulent nobles, for cannon were exceedingly effective at demolishing the castles in which rebellious barons had formerly been quite safe. But artillery was cruelly expensive. This fact underlies the rise and persistence of the greatest political discovery of the later Middle Ages: the principle of representation. A sufficient revenue had always been one of the chief necessities of monarchy; none of the great European kingdoms had ever succeeded in securing one for long. The intractable complexities of medieval society permitted very little coercion of taxpavers; for the rest, money could be secured only by chicanery, or by selling offices or crown lands (at the price of a long-term weakening of the monarch). or by robbing the church, or by a lucky chance, such as the acquisition of the gold and silver of Mexico and Peru by the king of Spain, or by dealing, on a semi-equal footing, with parliaments (or estates, as they were more generally known).

Yet the principle of parliamentary representation was of slow and uncertain growth, except perhaps in England, where the folly of the Stuart kings ensured its survival. Before then, three great occurrences, the Renaissance, the Reformation, and the discovery of America, had trans-

formed Europe.

The impact of the Renaissance defies summary, even if its political consequences are all that need be considered. The truest symbol of its importance is the printing press. For one thing, this invention enormously increased the resources of government. Laws, for example, could be circulated far more widely and more accurately than ever before. But more important still was the fact that the printing press increased the size of the educated and literate classes. Renaissance civilization thus took a quantum jump, acquiring deeper foundations than any of its predecessors or contemporaries by calling into play the intelligence of more individuals than ever before. But the catch (from a ruler's point of view) was that this development also brought public opinion into being for the first time. Not for much longer would it be enough for kings to win the acquiescence of the nobility and the upper clergy; a new force was at work, as was acknowledged by the frantic attempts of all the monarchies to control and censor the press.

The Reformation was the eldest child of the press; it. too, had diffuse and innumerable consequences, the most important of which was the destruction of the Roman Church's claim to universality. It had always been a somewhat fraudulent claim: the pope had never actually been accepted by all the Christian bodies, even all the orthodox ones; but after Martin Luther and John Calvin, the scope of his commands was radically reduced. In the long run the consequence was the secularization of politics and administration and the introduction of some measure of religious toleration. Gradually the way became clear for rational, utilitarian considerations to shape government.

The discovery of the Americas opened a new epoch in world history. The Spanish overthrew the monarchies of the Aztecs and the Incas, thanks partly to the superior weapons that they brought with them and partly to the diseases. It was a spectacular episode, the first to proclaim that the old struggle between the steppe and the sown had been bypassed: from now on the drama of history would lie in the tension between the oceans and the land. The globe was circumnavigated for the first time; European ships, bearing explorers, traders, pirates, or men who were something of all three, penetrated every sea and harbour; and although the ancient civilizations of Islam, India, China, and Japan saw no need to alter their customs to take account of European innovations, the signal had been given for their fall.

principle of representation

Weaknesses of monarchy

Portuguese and Spanish explorations gave far-flung overseas empires to both countries, and perhaps as many difficulties as benefits. Other countries-France, England, the Netherlands, Sweden, Denmark-thought it both undesirable and unsafe not to seek empire themselves; the Iberian monarchies were thus involved in a perpetual struggle to defend their acquisitions. This entailed incessant expenditure, more, in the end, than the kingdoms' revenues could match. Financial weakness was one of the chief causes of the ultimate decline of Spain. But by then the inadequacies of the monarchical system had been cruelly exposed in such episodes as the revolt of the Netherlands, the defeat of the Spanish Armada by England, and, worst of all, the snail's-pace development of the colonies in the New World. Charles V and Philip II were as able as all but a few monarchs in history; but they could not overcome the structural weaknesses of hereditary monarchy. There was no mechanism by which they could devolve their most crushing duties on their ministers, so government moved slowly, if at all. As lawful sovereigns they were bound by the customs of their numerous realms, which frequently blocked necessary measures. They were unable to guarantee that their heirs would be their equals. The same difficulties eventually ruined the French monarchy. The only remedy discoverable within the system was for the king in effect to abdicate in favour of a chief minister. Unfortunately a man equal to the task was seldom found, and anyway no minister, however great, was ever safe from the constant intrigues and conspiracies of disgruntled courtiers. Problems tended to accumulate until they became unmanageable.

Representation and constitutional monarchy. Meanwhile, in England, the rise of Parliament introduced a republican, if not a democratic, element into the workings of one of Europe's oldest kingdoms.

The republican tradition had never quite died out. The Dutch had emerged from their long struggle against Catholic Spain clinging triumphantly to their new religion and their ancient constitution, a somewhat ramshackle federation known as the United Provinces, Switzerland was another medieval confederation; Venice and Genoa were rigidly oligarchical republics. What set England apart was that everywhere else in monarchical Europe the medieval representative institutions-the États-Généraux in France, the Cortes in Spain, the various diets of the Germanic countries-fell into oblivion. In England alone the expense of naval war, the incompetence of the kings, the exhaustion of all other sources of finance, and the absence of a standing army brought about the continuance and strengthening of Parliament. The climax came under William III, a Dutchman who was quite content to let Parliament take an unprecedentedly large share in government so long as it voted money for his war against Louis XIV of France. He conceded, in short, full power of the purse to the House of Commons, and before long it became a maxim of the dominant Whig Party that no man could be legally taxed without his own consent or that of his representatives. A radically new age had dawned.

The Whig system was called constitutional monarchy. Disputes about the right and legal way of governing England had raged throughout the 17th century. Civil wars and revolutions had been accompanied, perhaps in part caused, by endless rummaging through old manuscripts and a nearly ceaseless war of printed pamphlets. The increasingly rationalist temper of the times, exemplified in the works of John Locke, finally buried some of the more blatantly mythological theories of government, such as that of the divine right of kings; and after the flight of King James II in 1688, Parliament finally settled the issues that had so vexed the country by passing a series of measures that gave England a written fundamental law for the first time. Henceforth the country was to be ruled by a partnership between King and Parliament (in practice, between the king and an oligarchy of country gentlemen who controlled most parliamentary elections); and if many Englishmen looked with distaste on the squabbles of party politics, which were the sordid result of this arrangement, few could propose a plausible alternative. Tories drank toasts to the King over the water; republicans published more pamphlets; and Sir Robert Walpole ruled for 21 years as the first British prime minister.

The secret of Walpole's strength lay in his ability simultaneously to please the King, to give the country sound government finances, and to command a majority in the houses of Parliament. He performed this last trick partly by giving out sinecures, salaries, and titles to his supporters, partly by his superiority in debate, and partly by exploiting Whig fears of Tories and Roman Catholics. These three elements—party interest, practical decision making, and party ideology—have in one form or another come to dominate most modern political systems where brute force is at a discount.

Even after Walpole's fall his arrangements continued. They were vindicated by the Seven Years' War (1756-63), when Britain defeated both the French and Spanish empires and emerged predominant in every ocean and (especially) in North America. Immediately afterward republican ideology found its classical expression.

The American and French republics. The limited British monarchy found it little easier to govern a sea-borne empire than did the kings of France and Spain. If Britain's American colonies were to grow in population and riches, so as to become sources of strength to the empire, not military and financial liabilities, they had to be given a substantial measure of religious, economic, and political independence, and the gift could not be revoked. Once British policy had created a chain of more or less self-governing communities along the Atlantic seaboard of North America-communities much like the city-states of old-it could not undo its own work, even when it found its clients unreasonable, small-minded, and recalcitrant. Thus, when the British government attempted to impose tighter rule from London, the old empire broke down in bickering about taxation and, in riot, rebellion, and civil war-in short, in the American Revolution. From 1775 to 1783 the Anglo-Americans fought with determination and good luck against their former overlord, King George III; and in 1776 their leaders determined to be free of him and the British Parliament forever. The principles on which they meant to found a new commonwealth were expounded in the Declaration of Independence:

... We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain inalienable Rights, that among these are Life, Liberty and the pursuit of Happiness. —That, to secure these rights, Governments are instituted among Men, deriving their just powers from the consent of the governed. ...

The Declaration of Independence

The application of these principles was more difficult than their enunciation, and it took the Americans 12 years to get themselves a suitable form of government. When they did adopt a new constitution it served them so well that it is still operative. This durability is not unconnected with the fact that the Constitution opened the door to modern liberal democracy. "The consent of the governed" was agreed to be the key to governmental legitimacy, and in practice the phrase rapidly came to mean "the consent of the majority." The principle of representation was embodied in the Constitution (the first article of which was entirely devoted to the establishment of Congress, the American parliament); this implied that there was no limit to the potential size of a successful republic. From Plato to Rousseau, theorists had agreed that democracies had to be small, because by definition all their citizens had to be able to give their consent in person. This restriction was alone almost sufficient to explain the recurrent failures of republican government down the ages. Now it had been evaded.

Yet its example might have had little effect on Europe but for the French Revolution of 1789. The French had helped the Americans to beat the British, but the effort had been too much in the end for the monarchy's finances. To avert state bankruptey the États-Généraux were summoned for the first time in 175 years, and soon in the whole government had been turned upside down. The French repudiated the divine right of kings, the ascendancy of the nobility, the privileges of the Roman Catholic Church, and the regional structure of old France, and, in the end, they set up a republic and cut off the former king's head.

Rise of the British Parliament Political

parties

Unfortunately for peace, in destroying the monarchy, the Revolution also crowned its centuries-old labours. The kings had created the French state; the Revolution made it stronger than ever. The kings had united their subjects in the quest for glory; now the nation made the quest its own. In the name of rationality, liberty, and equality (fraternity was not a foremost concern), France again went to war. The Revolution had brought the new invention, the nation-state, to maturity, and soon it proved capable of conquering the Continent, for everywhere French armies went, the revolutionary cred went, too.

In all this the French Revolution was giving expression to a general longing for government devoted to the greatest happiness of the greatest number. But there was also considerable resistance, which increased as time went on, to receiving the benefits of modern government at the hands of the French. Besides, the facts of demography began to till against the Revolution, as population growth in Britain and Germany accelerated and that of France slowed down. The century that began with the victories of Marengo, Austerlitz, and Jena ended with the Third Republic nervously on the defensive and French society

still bitterly at odds with itself.

Yet, on the whole, the work of the French Revolution survived. However many changes of regime France endured (seven between 1814 and 1870), its institutions had been thoroughly democratized, and the underlying drift of events steadily reinforced this achievement. By midcentury universal manhood suffrage had been introduced. putting France in this respect on the same footing as the United States. Britain, pursuing its own historical logic, evolved in much the same way; its oligarchs slowly and ungraciously consented to share political power with other classes rather than lose it altogether. By the end of the century manhood suffrage was clearly at hand in Britain, too, and women would not much longer be denied the vote. Smaller European countries took the same course. And everywhere (in America as well as western Europe) the representative principle combined with the necessity of government to produce the modern political party. Elections could be won only by organized factions; politicians could attain or retain power only by winning elections. Permanent parties resulted. The Industrial Revolution and continuing population growth made an elaborate state apparatus increasingly more necessary. The spread of education and prosperity made more citizens feel fully equal to taking part in politics, whether as voters or statesmen. Modern government in the West thus defined itself as a blend of bureaucracy, party politics, and passionate individualism, the whole held together by the cement of an equally passionate nationalism.

Nationalism and imperialism. The kingdom of Prussia and the empires of Austria and Russia readily learned from the French Revolution that it was necessary to rationalize government. They had been struggling along that path even before 1789. Carrying out the necessary changes proved exceedingly difficult. (Russia, which in some ways was more like ancient Egypt than a modern country, made far too few changes until far too late.) Meanwhile the libertarian and egalitarian components of the revolutionary legacy were rigidly resisted. The great dynasts, and the military aristocracies that supported them, had no intention of admitting their obsolescence. Though they were forced to make limited concessions between 1789 and World War I, the autocratic citadel of their power was never surrendered. Instead, the myth of the nation was adopted to reinforce the authority of the state.

Nationalism intensified the competitiveness that had always been a part of the European state system. Peoples, it emerged, could be as touchy about their prestige as monarchs. But for a hundred years an uneasy peace prevailed in Europe, leaving the powers free to pursue interests in other parts of the world. Asia and Africa thus came to feel the full impact of European expansion, as the Americas had felt it before. Only the Japanese proved to have the resources to adapt successfully to the new ways, taking what suited them and rejecting the rest. They kept their millennial sacred monarchy but modernized the armed forces. In 1895 they fought and won a war against China.

which was sliding into chaos, and in 1905 they defeated a great power, Russia. However, Japan was wholly exceptional. Elsewhere European power was irresistible. Britain gave up the attempt to govern overseas settlements of its own people directly—the experiment had proved fatal in America and nearly so in Canada—but it had no scruple about assuming direct rule over more non-British peoples. France, Germany, and the United States eagerly followed the example; The Netherlands, Spain, and Portugal clung to what they had, though the last two suffered great imperial losses as Mexico, Brazil, and others shook off colonial rule. It seemed that before long the whole world would be ruled by half a dozen powers.

It did not turn out so, or not for long. The problem of governmental legitimacy in central, eastern, and southern Europe was too explosive. The obstinate conservatism of the dynasts proved fatal to more than monarchy. There were too many who regarded the empires as unacceptable. either because they were the instruments of class oppression, or because they embodied foreign rule, or both, And the romantic tradition of the French Revolution-the fall of the Bastille, the Reign of Terror, the Jacobin dictatorship-helped to drive many of these critics into violent rebellion, permanent conspiracy, and corrosive cynicism about the claims of authority. Authority itself, corrupted by power and at the same time gnawingly aware of its own fragility, embarked on more risky militarist adventures. The upshot was the war of 1914, the revolutions that followed it, and the new model government that emerged in the Russian empire at the end of the period.

20TH-CENTURY MODELS

The Soviet state. In theory the Soviet Union was a democracy, but in practice it was an oligarchical tyranny. Lenin and his followers had won power in the turmoil of revolutionary Russia because they were abler and more unscrupulous than any other group. They retained and increased their power by force, but they argued that the social theories of Karl Marx, as developed by Lenin, were of universal, permanent, and all-sufficient validity, that the leadership of the Communist Party had a unique understanding of these theories and of the proper tactics for realizing them, and that therefore its will could never legitimately be resisted. All institutions of the Soviet state were devised primarily to assure the untrammelled power of the party, and no methods were spurned, from mass starvation to the suppression of works of art, in furtherance of this aim. Even the economic and military achievements of the regime were secondary to this overall purpose: its most characteristic institution, next to the party, was the secret police.

The Soviet model found many imitators. Lenin's strictly disciplined revolutionary party, the only morality of which was unswerving obedience to the leader, was a particularly attractive example to those intent on seizing power in a world made chaotic by the world wars. Benito Mussolini of Italy modelled his Fascist Party on the Leninists; Adolf Hitler of Germany copied Mussolini; Mao Zedong led a Communist movement in China. All three men won power, which they criminally abused, in conditions of social and political collapse like those that Lenin had exploited. In the Soviet Union itself, Lenin's successor and disciple, Joseph Stalin, outdid his master in building up his power by mass terror and party discipline. After World War II, Stalin was able to extend the Soviet model directly to eastern Europe. However, after his death in 1953 his empire began to lurch from crisis to crisis, never resolving its basic dilemma: party dictatorship condemned the Soviet Union and its vassal states to permanent inefficiency and unrest, but reform would probably blow away the Communist ascendancy. In 1985 a new generation came to power with Mikhail Gorbachev, who was willing to take enormous risks in order to revitalize the Soviet empire. Before long the Communist regimes disintegrated in most of central and eastern Europe, and in 1991 the Soviet Union itself dissolved. In China a similar attempt at reform ran into similar difficulties. It thus became clear suddenly to most of the world that the Leninist experiment had definitively failed.

Legitimacy and upheaval

Stalinist totalitarianism Liberal democracy. Government in the West after World War II evolved more successfully. The democratic system was everywhere in the ascendant and brought with it greater influence for the working classes, for women, for non-European races, and for small states. The turbulent processes of open debate and decision produced an economic order that proved vastly more productive than the command economics of the East and brought greatly improved living standards for the great majority. Free elections meant that bad, or at any rate unpopular, governments were regularly dismissed by the voters with historically unparalleled ease and peacefulness. No Western democracy made war against any other.

But Western democracy, however perfect its forms (and nowhere were they entirely consistent with its principles), always had problems on its hands that might in the end prove too much for it. The Soviet threat might be replaced by others, as was dramatically demonstrated in 1990 when Iraq seized the emirate of Kuwait. Class conflicts were muted rather than resolved. Nationalism still distorted voters' judgments in matters of foreign policy; greed mistored when over economic policy. Demagogues abounded as much as they ever did in ancient Athens, and many

politicians were corrupt.

The great experiment of European imperialism had collapsed. The two world wars robbed the powers of the will and the means to maintain overseas rule. Unfortunately, the empires were not immediately succeeded by new governmental forms fully capable of dealing with the problems of technologically backward, overpopulated, culturally premodern societies. In the Muslim world the idea of the Islāmic republic arose in the 1980s. In Iran it amounted to an attempt to wed religion and government indissolubly, the religion being Shī'ite Islām. This Islāmic Leninism has not yet been tried anywhere else, and in any case it cannot spread outside regions of Islamic dominance. In India a regime of more or less democratic nationalists endeavours to overcome a pervasive regionalism and social stratification that have been part of the subcontinent for most of its history. Japan has adapted to Western notions of capitalism and parliamentarism without contributing any fresh ideas. In the Third World the commonest expedient adopted was dictatorship, usually military, in which the ancient tradition of autocracy reasserted itself; but it was autocracy without its ancient stability, and of all current political forms it seems by far the least likely to deal effectively with the universal enemies: hunger, war, poverty, disease, waste, and violence. Some thinkers believe that only a form of world government can make decisive headway against these evils, but no one has yet suggested either how world government can be set up without a world war or how, if such a government did somehow come peacefully into existence, it could be organized so as to be worthy of its name. Even effective global cooperation among national governments is extremely difficult, as the story of such international bodies as already exist demonstrates all too sadly. In the circumstances it is wonderful that the one really important post-1945 innovation, the confederation of Europe, has made as much progress as it has.

Another hopeful development was the ending of the ruthless competition between the two superpowers, the former Soviet Union and the United States; but the cessation of the Cold War provoked a revival of nationalism, especially in eastern Europe. Self-determination has become the universal aspiration, and the nation-state is the universal norm; these developments, however, have not yet made for general peace. The incompatible claims of the city-states ruined ancient Greece; the modern world may yet be ruined by the claims of the nations. If man, the political animal, is to save himself and his civilizations, he cannot yet rest from seeking new forms of government to meet the ever-new needs of his times.

BIBLIOGRAPHY. Classical texts on governmental forms are widely available in numerous editions. They include PLATO, The Republic; ARISTOTLE, Politics: NICCOLÒ MACHIAVELLI, The

Prince and The Discourses: THOMAE HOBBS, Leviathan, JOHN LOCKE, Second Treatise of Government, MONTESQUIEU, The Sprint of Law; BENNIAGQUES ROUSEAU, The Social Contract, Sprint of Law; BENNIAGQUES ROUSEAU, The Social Contract, Benniagous Rouseau, The Federalist: Each WIND BURKE, Reflections on the Revolution in France: THOMAS PANIE, Rights of Mar. KLINS BE TOCQUESTUEL, Democracy in America, WALTER BAGEHOT, The English Constitution; JAMES BRYCE, The American Commonwealth; REIBDRICH BEOILS, The STRUCK, The American Commonwealth; REIBDRICH BEOILS, The State and Revolution.

For a subject of this nature, a solid background in world history is absolutely necessary, and WILLIAM H. MCNEILL, A World History, 3rd ed. (1979), is an excellent introduction. GORDON CHILDE, What Happened in History, rev. ed. (1954, reprinted 1982), is a classic survey of the contribution of archaeology to our understanding of prehistory and the ancient world. For the development of governmental forms in Greece, see The Cambridge Ancient History, 3rd ed. (1970-); and N.G.L. HAMMOND, A History of Greece to 332 B.C., 2nd ed. (1967, reprinted 1981). A.H.M. JONES, Athenian Democracy (1957, reprinted 1975), is indispensable, particularly as a corrective to Plato, Aristotle, and Thucydides. The most exciting work about the Romans written since Gibbon is RONALD SYME, The Roman Revolution (1939, reprinted 1974); those wanting more general accounts of the Romans may turn to J.P.V.D. BALSDON (ed.). The Romans (1966); and H.H. SCULLARD. From the Gracchi to Nero. 5th ed. (1982). A.H.M. JONES, The Later Roman Empire, 2 vol. (1964), is the most authoritative account of the fall of the empire.

The best introduction to the medieval papacy is walter ULL-MANN, A Short History of the Papacy in the Middle Ages (1972). The same authors Growth of Papal Government in the Middle Ages, 3rd ed. (1970), links ideas and institutions but makes few concessions to beginners. MARC BLOCH, Feddle Society (1964), reissued 1974; originally published in French, 1939), is an indispensable study of its subject.

The development of political thought from the Renaissance to the 19th century is well presented in 20th P. PLAMENATZ, Man and Society, 2 vol. (1963, reprinted 1972-74). An attempt to trace modern government back to its origins is demonstrated in Barrinton Moore, 19th, Social Origins of Dicatorship and Democracy (1966). See also PERRY ANDERSON, Lineages of the Absolutist State (1974); and FRANCO VENTUR, Utopia and Reform in the Enlightenment (1970; originally published in Italian, 1970).

Works on governmental forms of a general, comparative nature include A. GOODWIN (ed.). The European Mobility in the Eighteenth Century, 2nd ed. (1967); a. Government Finance

vernment finance refers to the wide range of activities undertaken by governments in financial and economic matters. In earlier times, a government's financial activities were limited to raising funds, whether from taxes or other levies, to support its wars and its other activities. For centuries sovereigns were allowed to spend such funds as they chose; the control of expenditures came much later, not becoming a matter of concern for legislatures until the late 17th and 18th centuries. The tradition grew up that expenditures must flow from appropriations, and appropriations were to be made for specific purposes. Out of this evolved the more formal governmental budgets of today.

As the proportion of national income that is controlled by the various levels of government has increased, so has the importance of the budget for the general working of the economy. If a government raises more money than it spends (creating a surplus), the overall level of spending in the economy-along with personal income and employment-may be reduced. Conversely, if the government spends more than it raises, which creates a deficit. fiscal and monetary expansion is implied, which may influence inflation and growth. Thus budgets have come to serve as instruments of economic management, used to stabilize or stimulate the economy. The composition of the budget also has other economic effects. The most important of these effects are brought about by its allocative function (deciding what is supplied by the public sector and to whom) and its distributive function (deciding who gets what and how income is distributed and redistributed). The national budget, then, has become the most important instrument of a nation's economic management, and in many countries the presentation of the new budget has become synonymous with the primary annual assessment and statement of economic policy. For coverage of related topics in the Macropædia and Micropædia, see the Propædia. sections 531-536.

A governmental budget is the forecast by a government of its expenditures and revenues for a specific period of time. In national finance, the period covered by a budget is usually a year, known as a financial or fiscal year, which may or may not correspond with the calendar year. The word budget is derived from the Old French bougette ("little

Taxation

Traditional functions. Government budgetary institutions in the West grew up largely as a result of the struggle for power between the legislative and executive branches of government. With the decline of the feudal system, it became necessary for kings and princes to obtain resources for their ventures from taxation rather than dues. With the disappearance of the old feudal bonds, taxpayers demanded to be consulted before they were taxed. In England this was written into Magna Carta (1216), which stated:

No scutage or aid shall be imposed in our kingdom unless by common counsel of our kingdom, except for ransoming our person, for making our eldest son a knight, and for once marrying our eldest daughter, and for these only a reasonable aid shall be levied.

This related to taxes only, not expenditures. For centuries Parliament seemed content to restrict the amounts that the sovereign levied while letting him spend the money as he pleased. Only after the controversies of the 17th century culminated in the Revolution of 1688 and the Bill of Rights did Parliament extend its concern from taxation to the question of expenditure control.

The histories of many countries have turned on financial crises. In France, for instance, the struggle between the monarchy and the nobility over control of tax revenues was one of the causes of the Revolution of 1789 that led to the overthrow of both the monarchy and the nobility.

The U.S. budget system also evolved out of controversy. In the early days of the republic there was a dispute between Alexander Hamilton and Thomas Jefferson as to the amount of discretion that the executive branch should exercise in the spending of public funds. Jefferson's victory enabled Congress to assert its authority by making appropriations so highly specific as to hinder executive action. Had Hamilton won, the treasury would have attained extraordinary power in relation both to Congress and to the

Modern functions. A high proportion of economic activity is controlled, directly or indirectly, by various levels of government (federal, or central, state, local, etc.). Thus the budget has taken on a number of other functions as well as the simple monitoring of the overall revenue and expenditure of government. Expenditure programs are now planned in considerable detail, but the sheer scale of public spending raises major control problems, and varying systems of control have been tried in different countries. Taxation is used not only to raise revenue but also to redistribute income and to encourage or discourage certain activities. Government borrowing, in order to finance recurring deficits or wars, is so substantial that budgetary policy has important effects on capital markets and on interest and credit generally.

The budget has also come to be used to achieve specific goals of economic policy. It was long recognized that government borrowing and the levels of expenditure and taxation could affect the total demand for goods and services in the economy. This raised the possibility that by changing these levels the government could use its fiscal policy to achieve full employment and reduce economic fluctuations. This stabilization function has been used by many countries, with varying degrees of success, to expand the econo-

my out of recession and to control inflationary pressures. As well as affecting the overall economy, the budget may have significant (intended and unintended) effects in specific areas. Taxes affect incentives to work or to consume, while taxes, benefits, and expenditures all affect the distribution of income. In this manner, budgets, particularly those that cause major changes, have considerable political as well as economic impact.

THE ACCOUNTING FUNCTIONS OF THE BUDGET

Traditionally the budget is presented to allow scrutiny (by taxpayers, voters, and the legislature) of the resources raised by government and the uses to which these will be put. The publication of a budget thus performs the role of generating accountability for the actions of government at various levels. Historically, the focus of budgets has been to ensure that expenditures and revenues are properly authorized; more recently, the budget has been developed as a framework within which complex decisions on the allocation of resources can be made more effectively.

ALTERNATIVE APPROACHES TO THE BUDGET

In order to deal with the increasing complexity of government's role, most countries have experimented with a variety of forms for the budget and its presentation. Among the more important of these are the administrative budget, the current and capital budget, program and zero-base budgeting, and the full-employment budget. The variety of budgeting methods is extended to the types of efficiency measures used to increase value for money and to the alternative methods of projecting expenditures in cash, voltime, and cost terms.

Administrative budget. The traditional administrative budget contains the executive's recommendations concerning the raising of what Magna Carta referred to as "scutage or aid" and the disposal of it for purposes of government. This kind of budget is designed to control expenditure; accordingly, it emphasizes the salaries and tasks of civil servants rather than the results that they are supposed to achieve. The control objective of the administrative budget naturally gives rise to the doctrine that the budget should be balanced. Deficits imply irresponsibility. Surpluses imply the imposition of unwarranted tax burdens on the public.

The limitation of the administrative budget is that some important items receive less than adequate attention or are excluded from it entirely. Military procurement is one example. Neither budget offices nor appropriations committees are well equipped to scrutinize the actual procurement of ships or aircraft. Consequently, in most countries large expenditures on military items are often treated perfunctorily while the activities of civil servants receive inordinate amounts of attention. The basic weakness of the adminis-· trative budget is that it is principally concerned with whether expenditure has been properly authorized, rather than whether money has been well spent.

Moreover, the administrative budget often excludes trust funds used to finance contributory old-age and unemployment insurance; taxes are paid directly into the funds and disbursements made out of them. The theory is that the government acts as trustee for the public and that the publie is protected by having its social security taxes put in a separate fund. Many countries have adopted this idea of "social insurance"; it formed the heart of Bismarck's social policy for Germany in the 1870s and of the British welfare state, founded in 1948. In most cases, however, the attempt to generate a distinct fund has failed, and "contributions" have become just another tax with expenditures on, for example, retirement pensions paid irrespective of the resources available to the fund.

Other items may be included in the budget on a net rather than a gross basis. For instance, the total receipts and expenditures of the post office or other commercial activities of the public sector usually do not appear; only the deficit or surplus does. This is justified by the theory that, first, business management is not well performed by legislative committees and, second, that so long as a business undertaking pays its way, its conduct is not a matter of public concern. The problem is that the distinction between commercial and noncommercial activities is often arbitrarily made.

Current and capital budget. The administrative budget traditionally deals only with current expenditures; in many countries, some items are regarded as inappropriate for inclusion because they finance capital expenditures or are loans to other public bodies. Such items are then included below the line," and the traditional concept of budget balance is not applied to them; instead, it is regarded as permissible to finance them by borrowing.

"Below the line" items

Direct public works or investment in nationalized industries are regarded by most countries as suitable for loan financing on the ground that they are productive assets that will yield a revenue sufficient to cover their cost. They may do so either directly, as in the case of a toll highway, or indirectly by increasing the general economic welfare, as in the case of a free highway. If, however, there is no market in which the output of a public activity is sold, there can be no objective test of its value. Hence, governments are often tempted to classify expenditure on such assets as capital items that yield a social but no economic return (e.g., free playgrounds) or a lower economic return than any private sector institution would accept (as in government support for declining industries). For this reason, distinctions between current and capital expenditures in public accounts are often viewed with suspicion.

This suspicion may be increased where, as is often the case, the rules for what is regarded as current or capital are rather indistinct. Moreover, governments have been reluctant to adopt the systematic distinction between current and capital items, or between cash flows and profit and loss accounts, or to construct a balance sheet, even though these mechanisms of monitoring receipts and expenditures are universal in private sector accounting. The federal government of the United States, for example, has resisted the idea of a capital budget, even though there was strong pressure for one in the 1930s when economists and politicians wanted to legitimize the government deficit. Among U.S. state and municipal governments, however, loan financing of public works is the regular practice for two reasons. First, those bodies are usually unable to finance their projects by current taxation; second, they do not want to finance them because the projects are generally of a

long-term nature. Most national governments have become accustomed to thinking in terms of national economic policies in which the amount of borrowing to be undertaken depends on current requirements for stability and growth. This makes capital budgeting less attractive, particularly if the government wishes to use the budget to supplement the national flow of savings. The more need there is to increase saving, the smaller should be the amount of government borrowing. On the other hand, government borrowing is justified when private savings tend to exceed private capital requirements.

This lack of explicit monitoring for the capital position of governments can have serious consequences when the government unwittingly takes on large liabilities or uses capital assets to finance current expenditures. Examples are provided by the growing problems in some countries in financing generous state pension schemes and the wasting of assets such as oil reserves.

Time lags

in cash

budgets

Cash and unified budgets. Faced with the increasing complexity of government activities, many countries have fallen back on the idea of the cash budget, which resembles the cash flow account of a modern business. Trust fund expenditures and receipts are included, as well as cash payments and receipts involved in loan transactions. Government business undertakings such as the post office, however, are still included on a net basis.

The cash budget suffers from the defect that it is not directly tied to government decision making. Liabilities incurred do not synchronize completely with payments. This is because government expenditures result from appropriations and other forms of commitments; cash expenditures may follow appropriations and other commitments of money only after a considerable lag, notably in the case of construction and procurement. Appropriations relate to actions in the future. Expenditures result from past decisions. Both kinds of information are needed for a complete appraisal

In 1968 the U.S. government, in an effort to reduce public confusion over the large variety of budgetary concepts, adopted a so-called unified budget concept that is more logical than the cash budget but differs from it only in some details that do not materially affect the budget aggregates. The unified budget differs from the traditional administrative budget in two main ways: it includes the receipts and outlays of most funds, and it eliminates inter-

agency transfers. Program budgeting. Traditionally, government expenditures have been considered as inputs rather than outputs. This is because, in the classical 19th-century conception. the well-run government does not produce a marketable output. The program budget derives from this concept: it attempts, however, to classify expenditures in terms of the outputs to which they are devoted. For example, a traditional school budget would categorize expenditures in terms of teachers, books, and buildings; what came out of the process would be left to the reader's intuition or experience. The program budget, in contrast, attempts to assign expenditures to specific outputs, categorizing them according to numbers of children completing various pro-

In government, budgets have traditionally been constructed according to departments and agencies of government. This may be justified on historical or administrative grounds, but it does not necessarily correspond to the structure of activity. Every country organizes the civilian and military components of its foreign policy in separate departments, but this is frequently a serious obstacle to effective policy-making. Again, the requirements of good administration suggest that there should be a single department of agriculture. But that department's activities impinge on those of others, in both domestic and foreign policy. A budget constructed according to actual programs would cut across departmental boundaries.

Program budgeting is an attempt to apply the economics of choice to public decision making. Its basic assumption is that explicit choice among alternative courses of action leads to better results than do other methods of decision making. At the highest governmental levels difficult choices must be made that involve the use of a portion of the nation's resources. But the same principles apply to decision making at lower levels. The problem of allocating resources within a specific field, such as health or education, is conceptually similar to that faced in drawing up the na-

Program budgeting also takes account of the time dimension in many government programs. New undertakings often take time to come into operation. A typical new program may have to pass through a research and development phase and an investment or construction phase before it reaches the operating phase. Alternative programs may differ considerably in this respect. The process of choosing among alternatives frequently involves trading the present against the future. One alternative may require 10 years before it yields results; another may yield smaller results but more quickly. The kinds of choices made in government often involve alternatives that cannot be measured in terms of market value. For this reason governmental decisions involve much more uncertainty than do most business decisions.

A governmental program must therefore be frequently revised in the light of unfolding circumstances. Indeed, every year should be thought of as the first year of a new program. Pervasive uncertainty also requires a high degree of flexibility and a capacity for program revision. A number of options should be held open, particularly in the development phase. Even though this may appear costly, it is less costly than commitment to a design that proves to be inappropriate because of circumstances that could not be foreseen in the early stages.

In most countries the usual procedure for deciding on government expenditure in a forthcoming year has been to assume that existing expenditure was appropriate and then to decide on incremental expenditure for each program. Such an approach means, however, that the change is likely to increase, rather than decrease, expenditure and that little attention is paid to what the full existing program actually accomplishes.

Full-employment budget. Although the idea of budget balance in the administrative budget has been the dominant consideration in the budgetary policy of most countries, it has gradually been realized that such a concept may be inappropriate when external shocks such as exchange rate movements or a world recession occur. Because varying levels of unemployment are a major reason why expenditures may change without comparable change in the public sector output, the concept of a full-employment budget has emerged. This type of budgeting is based on receipts and expenditures that would prevail under conditions of full employment. The approach views the actual expenditures and receipts for the coming year as of secondary importance; it assigns primary importance to the influence of the budget on the national economy. In time of recession a budget deficit may thus be presented as a necessary step toward achieving a balanced budget at full employment. Ideally, the budget should include estimates of expenditures and revenues at full employment, and also estimates of the same items at the anticipated level of employment. These ideas have been extensively used in the United States. An analogous procedure could be used with respect to inflation, but this idea is still far from acceptance, because governments are no less reluctant to anticipate inflation than they are to budget for unemployment.

Value for money measurements. As the emphasis in budgetary policy has shifted away from mere authorization of government spending and toward more public scrutiny of what government accomplishes, the idea of appraising value received for money spent in government finance has grown in importance. This has led to an increasing variety of measurements of public sector efficiency. In general terms, taxpayers need to be satisfied that their money is being used wisely. Because of the wide variety of items within even a single program, however, it is often difficult to identify precisely what is spent on the provision of each service, and the services that are provided rarely have welldeveloped private sector counterparts to act as a basis for comparison.

In some programs, governments have developed efficiency measures that relate observable facts, such as the quality of national health or the number of operations performed, to the cost of providing the service. The use of such measures is by no means widespread, however, and their basis is often open to question. The principal difficulty is that there is either no meaningful measure of the output of a public service-defense, for example-or output is complicated and multidimensional-as with education or health. The result is that any method used to measure efficiency is open to debate and challenge.

Attempts to control public expenditure, particularly since the mid-1970s, led to some examination of which programs should remain in the public sector.

Budgetary planning: cash, volume, and cost terms. There are three principal bases for public expenditure planning: cash, volume, and cost. The cash basis is concerned simply with the projected money expenditure on the services involved. Making such projections is difficult because what the cash expenditure will buy depends on what hap-

Obstacles allocating efficiency

Rasic assumption of program budgeting

pens to prices over the planning period. Moreover, many public expenditures cannot be planned in cash terms, because legislation prescribes the output. Most social benefits, for example, must be paid to anyone who is entitled to receive them, and this means that the government cannot control directly the amount of the expenditure.

The volume basis is concerned with the planned output of public services. The difficulties of measuring output, however, have already been noted. More often the planning process, assuming that changes in inputs are associated with changes in outputs, operates with reference to the

The rela-

tive price

effect

cost basis of programs. All countries have an annual program of public expenditure allocation, in which those responsible for individual programs argue for greater allocations for their activities and those responsible for raising the money attempt to control the amount allocated. In practice, the results of this process depend as much on the political weight of individuals in charge of a spending program as on an objective assessment of its desirability. The normal practice is to take as a base what each program spent the previous year and then argue about incremental changes, rather than to consider each program in its totality, as is the case in an approach known as zero-based budgeting. This creates perverse incentives, however, in that departmental heads who have saved money in one area in a particular year have an incentive to spend more in other areas in order to protect next year's total budget.

The basis for most expenditure planning is therefore the number of public employees already in place and the volume of goods and services purchased in the base year. This, multiplied by base year prices, gives the input volume in the base year. In the late 20th century many countries (particularly the United Kingdom) began abandoning this approach, largely because it gave inadequate control of total expenditure. One reason for a given volume's costing too much to supply is the so-called relative price effect. This arises because goods and services bought by the public sector (labour, medical care, or defense equipment) may rise in price more quickly than commodities generally. Once this has been determined, volume can be expressed in cost terms. The relative price effect is somewhat subjective, however, because of the difficulty of measuring the quality of goods and services. Particularly in the case of health care and defense, the relative price effect will often contain the increased price of services and improved equipment, which are actually a volume increase.

Cost measures, however, merely reflect the cost of a given input; controlling public expenditure in cost terms without taking full account of the relative price effect's change may lead to inappropriate volume responses or, more commonly, spiraling costs as existing input volume is maintained. Hence many countries have moved one stage further, attempting to monitor and control public expenditure in purely cash terms. The United Kingdom's public expenditure programs, for instance, are now "cash limited."

Although planning in cash has a superficial simplicity, in times of significant inflation it is not a very appropriate tool, and differential price rises may lead to a balance of expenditure provision somewhat different from the intended plan. In practice, although cash planning is presented as the base on which decisions are taken, those countries that have adopted this approach in fact allow informal flexibility in cash budgets, with volume measures being implicitly, if not explicitly, adopted.

Components of the budget

In the United States the budget for each fiscal year contains detailed information on the outlays intended by the federal government and the receipts expected, including those from trust funds. The budget also divides authorized expenditure into that which can be carried out without action by Congress and that which requires further authorization. In any year, about half of federal expenditure requires authorization from Congress; by witholding this authorization, Congress is able to force changes in the government's budgetary policy. The budget also summarizes the outstanding debt of the federal government and estimates the size of the surplus or deficit expected on the basis of the revenue and expenditure projected in the budget.

The U.S. budget is presented as a coherent whole for lengthy consideration by Congress, during which time it is often substantially revised. This joint consideration of revenue and expenditure is also common in most European countries. Practice in the United Kingdom, and in other countries with a British parliamentary tradition, continues to reflect the historical separation of revenue and expenditure. The U.K. budget consists of a number of different documents, with only limited attempts being made to relate one to another. A pre-budget report of the government's intentions is given in an Autumn Statement usually published in November, and detailed expenditure plans are provided in February or March in a White Paper. The U.K. budget, usually presented in March, is mainly concerned with taxation and is represented in a separate volume entitled Financial Statement and Budget Report This gives a general outline of budgetary strategy, details of proposed tax changes, and estimates of likely revenues, as well as details of such items as capital receipts from asset sales and the size of the contingency reserve of unallocated money to cover unforeseen events.

Partly because of this fragmentation of the U.K. budget. and the difficulty of relating the public expenditure White Paper to the Financial Statement and Budget Report, debate is limited, and it is rare for any detail to be changed after the documents are published. The fragmentation of the budget is exacerbated further by the presentation of details of social security expenditure in yet another docu-

ment.

Composition of public expenditure. Expenditures authorized under a national budget are divided into two main categories. The first is the government purchase of goods and services in order to provide services such as education, health care, or defense. The second is the payment of social security and other transfers to individuals and the payment of subsidies to industrial and commercial companies. Both types are usually labeled "public expenditure," and in many countries attention usually focuses on the aggregate of the two. This obscures important differences in the economic significance of the two items, however. The first represents the public sector's claim on total national resources; the second the scale of its redistribution within the private sector.

In most Western countries, the share of the public sector in total economic activity averages between 20 and 30 percent. This reflects the proportion of workers who are employed in the public sector or in publicly financed activities, the proportion of national output generated there, and the proportion of incomes derived for productive services that is earned by public sector employees.

Some of these activities yield commercial revenues-the postal service, for example, Most have to be financed by taxation. In addition, the government raises taxation in order to redistribute income within the private sector of the economy. It taxes some activities and subsidizes othersthrough investment credits, for example. On a larger scale, it uses the benefit and social security system to make payments to needy individuals and raises taxes in order to subsidize those who warrant it. With this redistributive activity, plus the direct government productive activity financed from legislation, the total share of incomes taken in taxation is higher than the share of government in total production. It averages around 40 percent in Western

In addition to direct expenditures, attention has been drawn to "tax expenditures." If the government favours a particular activity-such as investment-grants or tax concessions may be awarded to that activity. The two procedures have much the same effect on investment and on government revenues, but one appears to raise public expenditure and the other to reduce taxation. It has been suggested that these tax expenditures-tax reductions motivated by an economic or social objective-should be the subject of a tax expenditure budget similar to the pub-

Variations in U.S. and U.K. budgets

The two categories of public expendilic expenditure budget, and several countries have now moved in that direction.

For all private and public purposes within the economy, the scale of public activity is best measured as a proportion of national income: the total of incomes generated or (equivalently) of expenditures on goods and services.

of national income: the total of incomes generated or (equivalently) of expenditures on goods and services.

The overall proportion of national income that is collected in taxes raised from profits on government activities on

The overall proportion of national income that is conected in taxes, raised from profits on government activities, or borrowed varies widely in the developed nations. This variation reflects different national decisions concerning the proportion of a nation's activity deemed most appropriate to have carried out by the various levels of government or by government agencies. Much of the variation occurs because of choices over the provision of health care and over the level and importance of transfer payments.

Expenditures on transfers also vary widely, depending partly on how redistributive the government wishes to be, partly on how much of this redistribution is carried out through the tax system, and partly on factors such as the number of old people and the level of unemployment. The dominant payment in every country is for old-age pensions, and the amount depends on how well-developed private sector pensions are. Another factor is the extent to which the government chooses to use direct subsidies rather than tax concessions to stimulate the economy.

(J.A.Ka./Ed.) Growth of public expenditure. The proportion of national income devoted to public spending rose considerably during the 19th and 20th centuries. Much of this historical rise, however, cannot be taken as a direct measure of either the relative importance of government as a whole in economic decision making or of the comparative roles of central and lower levels of government. Inflation aside, in most countries the major reasons for the persistent rise in public spending since the middle of the 19th century have been war and the preparation for war, the rise in the cost of pensions for veterans, the great increase of the administrative role of government in response to expanded and urbanized populations, and the marked rise in the demand for a varied list of public services as the vote was gradually extended to the lower income classes.

Writing in 1890, the Irish economist Charles Bastable observed that "in nearly all modern States outlay is steadily increasing," and "the older doctrines of economy and frugality have disappeared." He was referring to doctrines that had developed in the latter part of the 18th century, particularly in connection with the Industrial Revolution. He did not mean that there had been a "golden age" in which governments entirely refrained from interfering in the private sector. As Bastable himself pointed out, even the strictures of Anne-Robert-Jacques Turgot and Adam Smith on "excessive" government intervention did not preclude the encouragement of new industries.

In western Europe there was a long tradition of government influence on private economic decisions. The interventionist policies in the England of Henry VIII, Elizabeth I, and Oliver Cromwell, the France of Louis XIV and Colbert, and the Russia of Peter the Great are examples of such influence. But the sense of confidence conferred on the industrial class through the industrial and transportation revolutions of the 19th century, especially in Britain and the United States, produced an atmosphere that was unfavourable to government intervention. This did not, however, prevent rising pressure for government spending on economic resources, together with a secular rise in the magnitude and variety of the output of public goods that is still in evidence.

Is still in evidence.

G.A.K.A./K.E.P.)

Problems of public expenditure control. The problems of controlling public expenditure vary across programs. Some are "demand led." Transfer payments, and particularly social security payments, are largely dependent on the number of old or unemployed people. Apart from reducing benefits (which may in turn be prevented by past commitments), or through macroeconomic policies designed to reduce unemployment, for example, there is little that can be done to limit these payments. Most countries have seen a steady rise in transfer payments as the longevity of the population and the benefits of pension schemes increase.

Public expenditure also depends on the price of the goods and services that the public sector buys and on the efficiency with which they are used. Public sector workers are often highly organized and may be well placed to demand pay increases from an employer who is able to recoupt the costs from taxation. Public sector purchasing may be ineficient—civil servants may find it easier to enjoy a comfortable relationship with their suppliers, and, in fields such as health and military expenditures, administrators may demand the latest technologies with little regard for their cost-effectiveness.

At the same time, much of the public sector lacks the incentives to increase efficiency that apply to private firms in competitive markets. It is easier to resist innovation, and bureaucracies often have a conservative culture in which it is more important to avoid mistakes than to experiment with new techniques and procedures. With few external indicators of performance, managers in the public sector may feel inclined simply to promote the growth of their organization and the staff numbers and budgets that they control.

control.

As the level and complexity of governmental involvement in the economy has risen, so public expenditure has become increasingly difficult to control. The only people with enough information to monitor their program. Coupled with technological change, the general tendency has been for expenditures to rise without any clear evidence of increased levels of service being provided. Indeed, in many key areas, such as health and education, expenditures have risen steadily at the same time that the public perceived a deterioration of service.

Governments in most countries have responded to this problem by occasional severe contraction of particular programs or of public expenditure in general. Numerous ocountries have adopted cost-cutting exercises with some limited success. But attempts at cost reduction can provoke inappropriate reactions. If politicians discover expenditure can be reduced without reducing the value of the services provided, they may insist on further cuts. If, on the other hand, popular or politically sensitive activities are restricted, there will be pressure to restore expenditures. Managers of public sector programs therefore often have incentives to respond to cuts in ways that maximize, rather than minimize, the effects on the services provided.

REVENUE

Governments acquire the resources to finance their expenditures through a number of different methods. In many cases, the most important of these by far is taxation. Governments, however, also have recourse to raising funds through the sale of their goods and services, and, because government budgets seldom balance, through borrowing. The subject of borrowing, because of the intriaccies of deficit spending, is covered in a separate section of this article.

Taxation. Most countries raise resources through a variety of taxes, including direct taxes on wage and property income, contributions to trust funds, and a variety of indirect taxes on goods, either at the final point of sale or on the inputs used to make them. A smaller amount of revenue is raised from taxes on property, on capital gains, and on capital transfers, particularly at death. Most countries have a separate corporate income tax.

The composition of fax revenues. The balance between these different taxes has varied considerably over time and between countries. In the United States, sales taxes are relatively unimportant, accruing mainly to state and local governments. Federal government revenue is principally derived from taxes on personal and corporate income. This dominant reliance on income taxes in the United States is a post-World War II phenomenon; at the beginning of the 20th century about half of all tax revenue came from taxes on property and half from sales taxes. Income tax was introduced on a regular basis only in 1913.

The tradition in Europe is somewhat different, with indirect taxes being relatively more important. All the countries in the European Communities impose a tax (at varying rates) on value added, charging tax on output from Resistance to rising expendi-

Charles Bastable's observations

Transfer

expendi-

fures

Valueadded tax industry and rebating it on inputs. In the United Kingdom, for example, value-added tax (VAT) raises about half as much as the personal income tax, and together excise duties and VAT raise about one-third of total tax revenue.

Australia, New Zealand, and the Scandinavian countries all rely heavily on income and profits taxes, which account

Payroll tax

for about half of all revenue raised from taxation. Payroll taxes are relatively unimportant, raising significant amounts only in Australia, Austria, France, Ireland, and Sweden but rarely exceeding 5 percent of total revenue. Property taxes rarely account for more than another 5 percent, with the United Kingdom being the exception in this case. Sales taxes, excise duties, and VAT account for nearly one-half of all revenue in Greece, Ireland, and Portugal, compared with less than one-fifth in Japan.

The relationship between tax rates and revenues. In deciding how to raise enough money to finance its expenditure program, a government faces a large number of different considerations. First, the tax system is complex, containing many different taxes, each often having a complex structure. Perhaps the major consideration is the effects on behaviour that particular tax rates will cause.

Income tax has a graduated structure whereby no tax is paid on the first segment of income and then each subsequent segment is taxed at a higher rate than the previous one. In the United Kingdom most taxpayers pay tax at a uniform marginal rate, while other countries have more steeply rising rate schedules. Higher marginal tax rates make work less rewarding, which tends to reduce work effort. High marginal rates, however, may have less impact in some areas than others, a factor that needs to be considered when deciding who should bear the tax burden. Such considerations presumably have influenced the trend in many countries to tax the wealthiest groups,

Whatever the structure of the tax, the general proposition that increasing tax rates will reduce work effort usually holds; and this, in turn, tends to reduce tax revenue again. A debate arose over the "Laffer curve," which postulates that at some level of tax the disincentive effects will be so great as to mean that an increase in tax rates actually re-

Effect of

tax rates

on con-

sumption

Tax rates affect the pattern and level of consumption. Excise duties, value-added tax, and sales taxes all change the relative prices of goods and the attractiveness of consumption relative to saving. Once again, an increase in tax rates will generate responses that tend to cause a reduction in revenue, and, again, governments must balance the strength of these effects when deciding on which rates to increase. Other considerations, such as the protection of domestic industries, also affect such decisions.

Tax rates also affect commercial decisions, and the balance between individual and corporate taxes must reflect this. Accordingly, many countries have sought to attract new manufacturing industry with tax concessions. Finally, as rates rise, taxpayers seek more ways to avoid taxes. They employ tax advisers to find more tax-efficient routes, which, in particular, can involve a search for capital rather than income-yielding assets and the movement of activities

overseas to less heavily taxed countries.

The balance between taxes. As the share of public expenditure in overall national income has risen, so has the strain on traditional sources of tax revenue. The original stalwarts, property and capital taxes, have shrunk in importance and been replaced by increasing reliance on income taxes, on social security contributions, and on sales taxes of various kinds. The balance between these taxes varies considerably among countries, which make differing decisions about the appropriate balance between taxes.

Each of the main types of tax is perceived by taxpayers in different ways. Social security taxes have everywhere risen in importance, partly as a result of the growth of social security expenditures but also because their association with the benefits received, however loose, reduces the unpopu-

larity of increases. Sales taxes are less obvious, as they change the price of goods rather than one's income. But sales taxes too have their limits; when the proportion of tax on a good is sufficiently high, consumption declines, and there is political pressure from consumers and industry to reduce the tax increases. Governments have been reluctant to increase indirect taxes significantly as the control of inflation has become a major policy goal

Sale of goods and services. Taxation is not the only means by which a government can raise revenue. It can charge for the services it provides, or it can undertake profitable commercial activities. This is done to some degree by all Western governments, although the revenue raised is revenue

sources of

much less than that raised by taxation. Charging for public services faces a number of difficulties. Perhaps the most important is collection costs. Public services such as roads and parks are difficult to charge for, because they are closely integrated with the community. Some countries have tolls on major highways, and a few parks have admission charges, but in the main these are supplied free of charge. Other goods, such as museums and art galleries, are easier to charge for, but attempts at charging often generate more political opposition than can be justified by the limited revenue that could be raised.

A second consideration in deciding on charges is that it is rarely economically efficient to charge for public goods. Parks and roads, for example, have high initial costs but relatively low costs per user. Imposing a charge will mean that fewer people use them, and unless congestion is sufficiently severe to reduce others' enjoyment, less overall wel-

fare will be generated.

In many countries many industries are publicly owned, and these include highly profitable industries such as those supplying gas or electricity. The profits from these industries provide revenue. It is an open question, however, whether they provide as much revenue as would the assets employed if these were invested in private sector companies. Other publicly owned undertakings make substantial losses, and this reduces the net value of any surplus.

(J.A.Ka.)

GOVERNMENT BORROWING

Although most of the resources required for public spending are raised each year through taxation, it is rare for any modern budget to balance in any one year. For a variety of reasons, ranging from a desire to accelerate capital spending to a policy of economic stabilization, governments may choose to raise some of their resources by borrowing rather than taxation. Many countries run an annual budget deficit, and the deficits have tended to increase in size. For some countries this means that the burden of the debt has been steadily increasing. In times of inflation, however, it may be possible for a government to run a deficit without actually increasing the real burden of debt, as inflation erodes the real value of its existing debt.

Forms of public debt. The necessity for governments to borrow in order to finance a deficit budget has led to the development of various forms of public debt, which are now a central feature of all capital markets. Governments may owe public debt in the form of bonds, notes, bills, and the like, which require specified payments to the holders at designated times. For the most part, public debt differs from private debt only in that it is an obligation of government rather than of private individuals or corporations.

Public debt may be classified according to various crite-

External and internal debt. If the debt is held outside of the issuing jurisdiction, it is called external; if it is held within the jurisdiction, it is called internal.

Maturity period. Public debt ranges in maturity downward from infinity to periods of a month or even a few days. Debt instruments without a maturity date, requiring merely the payment of interest, are often called consols. The name originated in Great Britain, where the first important indeterminate-period debt issue happened to be one that consolidated a number of separate issues.

A large portion of government debt consists of bonds with specific maturities of five years to 99 years or more. Twenty- and 30-year periods are common. These are often known as long-term or funded debt.

Debt of maturity less than five years is often called shortterm or floating debt and may take several forms: notes, with maturities from one to five years; treasury bills, with maturities from one month to a year and often sold at aucPublic versus private Debt

liquidity

tion; and certificates of indebtedness, with similar maturity periods but available at a fixed interest rate.

The length of the maturity period affects what is known as the liquidity of the debt-i.e., how quickly it can be converted into money. Securities with very short maturity periods are constantly repayable in money and thus have maximum liquidity. As the period of maturity increases, the liquidity falls, unless a capital loss is to be incurred, and the pure debt characteristic increases.

Type of issuer. Government debt may be directly issued by a government or by semiautonomous governmental organizations. Examples of the latter would include the railways and provincial power authorities in Canada and various federal lending agencies in the United States. Their issues may be guaranteed by the government (general obligation bonds) or may rest solely upon the enterprises themselves, to be paid out of their revenues. In the United States the latter type of obligation is known as a revenue

Marketability. The great bulk of all government debt consists of marketable securities. These securities are negotiable and are sold freely on the market. They are usually issued in relatively large denominations, \$1,000 or higher, and interest is paid by check or coupon on a periodic basis. Since they are salable, their price fluctuates from time to time, going above maturity value when the current market interest rate falls below the interest rate that they bear and falling below the maturity value when the current rate rises or when fear about the ability of the government to pay interest develops.

Other bonds (such as savings bonds) are not marketable but can be redeemed, at least after a specified period, for

their principal plus accrued interest. Other characteristics. Bondholders may receive current interest either by redemption of coupons attached to the bonds or by check from the government. Alternatively, interest may be receivable only upon maturity or redemption of the bond, as in the case of savings bonds. Interest and principal are usually payable in fixed monetary units, but they may be payable in amounts with fixed purchasing power based on changes in price levels.

Economics of government borrowing. Government borrowing is likely to have effects upon the economy substantially different from those of other methods of financing, and the existence of a sizable debt may likewise have important consequences. The effects of retiring (or repaying) the debt may also be significant. National government borrowing has the greatest impact, but that of subordinate units may have some influence as well.

Effects of borrowing. Government borrowing in the strict sense includes only borrowing from the private sector of the economy-from individuals, corporations, and various financial institutions, including banks. When the government obtains its funds from the central bank (the Bank of England, the Bank of Italy, the Bank of Japan, or the Federal Reserve System in the United States), it is really creating money rather than borrowing it, since the purchasing power is made by the central bank and no obligations to the public are created.

When a government borrows, funds are transferred from the lender to the government, the lender exchanging his money for government securities. The effect is to reduce the liquidity of the lender-his command over cash-to an extent dependent upon the nature of the securities. The reduction in liquidity is small with short-term securities and greatest with nonsalable, nonredeemable securities-a type seldom issued except in time of war or other crises that create financial emergencies.

Funds loaned to the government almost certainly come from savings, unlike, for example, funds paid in higher taxes, which are more likely to come out of consumption. In many countries the major holders of public debt are, in fact, pension funds, which invest in government debt on behalf of the individual members of their pension schemes. To pay higher taxes, many individuals are forced to reduce their consumption since they have no margin of savings and are unable or unwilling to go into debt; others do so as a matter of choice, in an effort to keep their savings intact. Lending, on the other hand, is entirely voluntary. The

person who buys government securities is not likely to increase his rate of saving or to decrease his consumption. If government borrowing raises the market rate of interest. this may in turn encourage the diversion of additional money to saving, as may government securities that offer additional attractions-such as small denominations or redeemability-not possessed by other securities. But both effects in total are not likely to be of any particular significance.

The net effect of government borrowing on total spending and thus on employment and national income depends upon its influence on real investment-the purchase of new capital goods. In a period of unemployment, when savings are available in greater quantity than is required for investment, government borrowing does not compete with private investment nor make it more costly. In effect, the government absorbs funds that would otherwise be idle. In periods of full employment the situation is substan-

tially different. With banks loaned up to the limit of their

reserves and real investment absorbing all of savings, government borrowing will restrict private spending as much as an increase in taxation will under the same conditions. Government borrowing is of economic significance in several other respects. First, the buying and selling of government securities provides the central bank with a means of influencing the money supply, essential for effective monetary policy. Second, borrowing avoids the adverse effects that taxes may have on incentives, particularly if the taxes are raised sharply above levels to which persons have become accustomed. Third, borrowing permits government expenditures to be higher than would otherwise be feasible. Finally, the foreign borrowing of some governments gives them access to a greater quantity of foreign ex-

change, which enables them to finance the import of

capital goods essential for economic growth. This consid-

eration is not of concern to highly developed countries. Effects of debt. The existence of a government debt is of economic significance in itself, as distinct from the effects of the borrowing. In the first place, individuals who hold government securities regard them as a portion of their personal wealth. This is true even though the only way the government will ever pay the interest on the debt or repay the principal is by levying taxes on the community, which holds the debt. In this sense "we owe it to ourselves." But since these links are not immediately apparent, the existence of a debt may make individuals spend more on consumption and save less than they otherwise would. The additional consumption may reduce the rate of capital formation and economic growth; it may also increase the level of employment over what it would otherwise be,

Second, because government securities are more liquid than most other investments, their holders are able to increase consumption out of accumulated savings more easily than they could otherwise. This may contribute to inflationary pressures.

Third, if investors, and particularly the business community, regard the national debt as a source of potential economic instability, their willingness to undertake real investment will be lessened. At times, particularly in the 1930s, there has been widespread fear of government debt even though there was, in reality, little basis for the fear. A similar phenomenon sometimes arises in the case of subordinate units of government. A large debt may discourage expansion of economic activity because of the fear of high taxes in the future and the realization that the large debt may prevent borrowing for urgently needed local improvements.

When governments borrow they must meet interest obligations, and these are usually paid out of taxes. The payment of interest on government debt thus involves a transfer of wealth from taxpayers to bondholders. The taxes may have adverse effects upon incentives, while receipt of the interest will provide no offset to these adverse effects. The tax-and-interest-payment program is also likely to redistribute wealth in favour of higher income groups, since government bonds are likely to be held to a greater extent by those groups. The effect may be to increase saving and reduce consumption.

Finally, large interest obligations lessen the ability of the

Borrowing during full employment

Resistance

to national

How governments borrow

government to finance other governmental activities. This effect is particularly obvious at the local level, where there are limited tax potentials.

Retiring the debt. The retirement of government debt arising from a budget surplus has effects opposite from those of borrowing. Bondholders receive money in exchange for their bonds; though they could increase their consumption, they are more likely to put the funds into other securities and, as a consequence, security prices rise and money capital becomes more readily available for business investment. Whether it is used for that purpose depends, of course, on factors within the existing general economic situation.

Money for retirement must be obtained from some source. If it is simply created, there is no repressive effect on consumption or investment, and total spending in the economy rises-although by an amount relatively small compared to the total retirement. If, as is more common, the debt is retired from tax revenues, consumption is reduced in substantial measure; the remainder of the tax is absorbed from savings, and real investment may be reduced. The net curtailment in spending from the program of debt retirement is likely to reduce total spending in the economy. Elimination of the debt has one other effect; while current taxes will be increased, future taxes required

to meet interest and principal obligations will be reduced. It is commonly thought that borrowing shifts the burden of governmental activities to future generations, since those generations will be assessed higher taxes to pay the interest and principal. Some economists have disputed the idea, noting that future generations will inherit both the bonds and the obligations to pay them and collectively will be neither richer nor poorer than if the debt had not been incurred, except as a result of the difficulties incident to the debt and its retirement noted in preceding sections. Regardless of the methods of financing, the real cost of any governmental activity, war or otherwise, is borne in the form of reduced private consumption and investment and harder work or the like during the period in which it is carried on. The only burden on the future is that arising from the depletion of natural resources, and this is not affected by methods of financing. Nevertheless, the method of financing may affect the way in which the burden of public expenditure is shared among different groups, including

Limitations on public sector debt. Although borrowing can often seem an attractive alternative to raising money from taxation or indeed to spending less, there are limits to how far a government can allow itself to become in debt either to its own citizens or to overseas investors (including intergovernmental agencies, such as the International Monetary Fund). Exceeding these limits can have serious results for the stability of the country concerned. When debt rises to unacceptable levels, so that investors cease to believe in the ability of the country's tax base to support it, then drastic measures are forced upon the country, including severe contraction of the economy.

Problems of borrowing. The desirability of government borrowing has been debated for centuries. The traditional argument against borrowing is, of course, the interest burden to which it gives rise, an argument applicable equally to private and governmental borrowing. These interest obligations require either higher levels of taxes, with possibly adverse effects on the economy, or reduced expenditures for other purposes. The payment of interest may easily result in a transfer of purchasing power to higher income groups, contrary to accepted standards of equity.

As well as causing more and more of the government's resources to be used to pay interest on its debt, a large public debt can push interest rates up for other borrowers. If * the government is persuading a high proportion of available funds to be spent on public debt, the amount remaining for investment in other places, for example, investment in industry, is correspondingly small, with the result that a higher price (or higher interest rate) needs to be paid to attract such investment. This has been seen as a serious constraint in recent years, and most Western governments have tried to reduce their borrowing in order to keep interest rates down. There is some debate over just how important public borrowing is for interest rates, with monetarists believing it to be extremely important. Other types of economists are more skeptical, contending that factors such as inflation and the availability of private sector in-

vestment opportunities are more significant. The financing of expenditures by borrowing instead of taxation and the debt itself, once incurred, increase total spending and so tend to produce higher prices and other inflationary effects in periods of full employment, During periods of full employment, any increase in government expenditures not offset by an equivalent decline in private spending for consumption or business expansion will be inflationary. This is the usual argument made against the use of borrowing instead of taxation from the standpoint of the goal of economic stability. It is primarily relevant to national government borrowing because the national government must assume the primary responsibility for lessening economic instability. But state and local borrowing is, of course, equally inflationary.

Borrowing, if freely employed, can easily lead to increases in government expenditures beyond levels regarded by society as the optimum and may reduce the nessures for efficiency and elimination of waste. As governments consider expenditure levels, the adverse reaction to taxation serves as an offset against the favourable response to increased services that will have to be paid for by taxation and thus facilitates the attainment of a balance between government-produced services and privately produced services. But if borrowing replaces taxation and is generally accepted as a suitable routine method of financing, the pendulum will swing in the direction of increased governmental activity, and appropriate balancing will be lost. The best evidence of this danger is to be found in the history of state and local government finance in the early 19th century in the United States, when large sums of money were borrowed for purposes of limited usefulness to society. Borrowing appears to be a less painful method of financing government, but, as has been noted, the costs of public expenditure still have to be met from current consumption or investment.

Restrictions on borrowing. Efforts have been made in some countries to set restrictions on government borrowing through legislative acts. In the United States, fear of excessive borrowing has resulted in restrictions on the amounts the executive, and even the legislative branches of government, can borrow. When many states found themselves in financial difficulties after borrowing heavily to provide funds for canals and railroads in the middle of the 19th century, public debt provisions were written into the constitutions of all but seven states. The provisions limiting borrowing differ widely. In most jurisdictions a maximum, usually expressed as an absolute dollar sum and one relatively low in terms of present-day expenditure levels, is set. Either this figure cannot be exceeded at all (except by amending the constitution) or it can be exceeded only with the approval of the voters at an election. In some places all bond issues require approval by popular vote and in some instances by more than a bare majority. The purposes for which funds may be borrowed and the duration of the issue are also frequently restricted. These constitutional restrictions have unquestionably lessened state borrowing; in so doing they have, perhaps, reduced waste, but they have also sometimes prevented urgently sought improvements. The limits have likewise greatly increased the use of revenue bonds, which are normally not subject to the restrictions. Unfortunately, the interest rate on these bonds is

higher than the rate on other bonds. Restrictions on municipal borrowing in the United States are almost universal. The restrictions, established either in the state constitutions or by state legislation, limit the total sum to be borrowed by any particular unit to a certain percentage (from 2 percent to more than 20 percent) of the total assessed value of its property. The limits vary for different types of local units (city, county, school district, etc.). They usually do not apply to debts incurred for selfliquidating enterprises. In many states every bond issue must be approved by popular vote, in some instances by a two-thirds majority. In other states the limits established may be exceeded by popular vote, often with a require-

gressional

restrictions

borrowing

ment beyond a mere majority. Legislative controls also include maximum interest rates that may be paid, the duration of the issues, the purposes of the borrowing, and the establishment of means of retiring the bonds. Several states exercise review over local bond issues. Like the states, the local governments have found means of escaping the restrictions. Special taxing districts with their own debt limits are often formed when a city has reached its limit. Revenue bonds are also employed. In some states, such as Pennsylvania, there has been widespread creation of special authorities, school building authorities, for example, that have been established with the power to finance the building of schools by issuing revenue bonds. In turn, the authority pays interest and principal on the bonds from rentals obtained from the school districts using the build-

While there are no constitutional limits on federal borrowing powers in the United States, Congress for many years has restricted borrowing by the Treasury Department. Before 1917 borrowing was permitted only upon specific authorization by Congress. After 1917 maximum figures were set at first for each type of loan and then, after 1938, as an overall total. The 1938 figure of \$45,000,000,-000 was gradually increased to a high of \$300,000,000,000 in 1945 and reduced to \$275,000,000,000 in 1946. Buttressed by a strong belief prevailing in Congress that refusal to raise the limit would check growth in government spending, the limit remained at the 1946 level until 1954. Eventually, pressure on the limit became so great that various government bodies such as lending agencies were forced to borrow on their own at higher interest rates. A series of increases was made in the 1960s and 1970s, and by the early 1980s the limit exceeded \$1,000,000,000,000. Experts differ in their estimates of the usefulness of the federal limit. Some believe that it curtails government waste and unjustified increases in expenditures, while others argue that it reduces flexibility in meeting emergencies, checks needed increases in various activities, could prevent quick action to stave off a depression, and leads to uneconomical forms of borrowing,

By the mid-1980s, the U.S. deficit approached an annual figure of \$200,000,000,000 and was seen as a central economic problem. A movement grew for a constitutional amendment to prescribe a balanced federal budget. Such a constitutional provision would not, however, specify how such an outcome was to be achieved. Nor, given the many budgetary concepts described, would balance easily be defined. Congress instead passed the Gramm-Rudman-Hollings Act in 1985, which required arbitrary reductions in spending in all programs if the overall deficit failed to fall within certain limits that were set for the purpose of eliminating the deficit by the end of the decade.

In Canada, neither the dominion nor provincial governments are subject to debt limitations. Local government limits are comparable to those in the United States, and in several provinces bond issues must receive the approval of a provincial agency. In the United Kingdom borrowing by local governments is subject to control, and limits are usually established in terms of a ratio of debt to total ratable value (assessed value of property). After World War II much local borrowing was channeled through the Public Works Loan Board, and thus was subject to additional control. There are no arbitrary limitations on the amount the U.K. central government may borrow; effective limits are set by the reaction of capital markets and of interest rates to borrowing.

Wartime finance. The use of borrowing is regarded as inevitable in periods of major war. If taxes were increased sufficiently to finance all war costs, they could seriously impede the war effort by impairing incentives to work and by reducing the overall morale of the people. The limits of economically and politically tolerable taxation may well be below the maximum feasible allocation of resources to the war effort. Adequate tax increases would also aggravate the inequities of the tax structure; an overall level that would reduce total consumer spending to a level equal to the rate of output of consumer goods might well push some persons below subsistence levels and make it impossible for others to meet fixed commitments. While the use of borrowing as a method of war finance makes the control of inflation more difficult, there appears to be no escape from the necessity

Evolution of government borrowing. The evolution of government borrowing was very slow. The extensive use of loans by governments became possible only after the ruler had become differentiated from the state and after the fact of the continuity of the state had been separated from the persons of the rulers. Other factors were also required: the development of a regular revenue source to provide funds for repayment of loans, a monetary system, and an organized money market. The earliest loans of medieval times were either forced loans or personal borrowing by the sovereign. Government borrowing in its modern form first occurred in medieval Genoa and Venice when the city governments borrowed on a commercial basis from the newly developed banks.

Early forms of government borrowing

In contemporary economies, the absolute figures of growth in government debt exaggerate the actual growth in the debt relative to the economy as a whole. In the first place, the general price level has increased significantly over recent decades; since debt obligations are stated in fixed monetary terms, the relative magnitude goes down as the price level goes up. The general rise in prices over a neriod thus reduces the problems created by the debt for the government and the magnitude of the adverse effects of the interest payments on the economy. The gain occurs at the expense of the bondholders, whose real economic position is worsened by the change.

Second, the rise in national income reflecting an increase in output reduces the real significance of a fixed sum of

debt for the economy.

Sovereign debt. The oil crisis of 1973-74 and its aftermath created a new instability in world capital markets. Some countries, particularly Middle East producers with few economic activities not based on oil, gained revenues much in excess of their capacity to spend. Others, particularly in the less developed world, faced balance-of-payments problems that they found difficult to cover. Some other oil producers, such as Mexico, borrowed heavily in anticipation of rapidly increasing revenues. Those countries with surpluses of revenues over expenditures wanted to retain the liquidity of the financial assets that they acquired, and Western banks increasingly took on the role of intermediaries between the surplus and deficit countries. This led to the growth of sovereign lending-bank lending either to governments or to agencies of governments with government guarantees. While a bank lending to a private individual or company normally requires examination of the relationship of the loan to the borrower's assets, and of the interest to income or cash flow, banks felt able to apply more relaxed criteria to sovereign loans.

By the early 1980s, however, it was apparent that for many countries sovereign debt had grown to levels at which even the interest on these loans would be met only by further borrowings. Moreover, these countries' limited capacity to repay might be undermined by political or economic instability. The problem was particularly acute in Latin America, where U.S. banks had lent aggressively. Argentina, Brazil, and Mexico had very large external debts; smaller countries such as Bolivia, Ecuador, and Peru had debt burdens that were even larger in relation to their capacity to service them. Similar difficulties were encountered in Africa and in parts of eastern Europe, particularly Poland.

The debtor countries were reluctant to repudiate their debts, which would have deprived them of access to the world capital markets and even perhaps to the world trading and payments system for a considerable time. At the same time, the lending banks were reluctant to demand repayment of their loans, which would have led to default and losses that would have wiped out a substantial portion of their reserves. Thus, there was a mutual interest in using the financial system to continue to support the indebted governments, and, paradoxically, the negotiating position of the borrowers was stronger than that of the lenders.

These were highly unstable arrangements, arousing fears that major defaults would occur. Such defaults might well set off a cumulative process of demands for repayment and Complications of sovereign borrowing

Borrowing restrictions in Canada

defaults that would undermine not only the economies of the debtor countries but also the banking and financial systems of the countries in which the lending institutions were located. Avoiding such a crisis has demanded continued sensitive responses on the part of international financial agencies, such as the International Monetary Fund and national regulatory institutions. (J.F.D./J.A.Ka.)

The economic functions of government

Over time, there have been considerable changes in emphasis on these different economic functions of the budget. In the 19th century, government finance was primarily concerned with the allocative function. The job of government was to raise revenue as cheaply and efficiently as possible to perform the limited tasks that it could do better than the private sector. A significant development in the intellectual history of the 20th century was the explicit recognition by economists, politicians, and the public at large of the importance of government in the operation of the economy. The national budget generally reflects the policy of the government toward the economy. Three main roles of the government in controlling the economy may be considered: the allocative function, the stabilization function, and the distributive function.

THE ALLOCATIVE FUNCTION

Govern-

main roles

in control-

ling the

Debate

paying for public

works

over

economy

ment's

The allocative function in budgeting determines on what government revenue will be spent. Because a high proportion of national income is now devoted to public expenditure, allocation decisions become more significant in political and economic terms. In practice, most democracies contain a number of different factions that disagree on the proper allocation of resources and indeed the proper level of public sector involvement in the economy.

Public goods. Economists have sought to provide objective criteria for public expenditures through the so-called theory of public goods. It is generally recognized that some goods needed by the public cannot be provided through the private market. Lighthouses are a classic example. The costs of a lighthouse are such that no one shipowner will want to finance it; on the other hand, if a lighthouse is provided for one shipowner, it can be made available to all for no additional cost. Indeed it must be available to all, since there is no practical means of excluding ships from using the facility provided by the lighthouse, even if their owners have refused to pay for it. The only practical method of providing such services is by collective action.

If goods are to be provided in this way, rather than through the private market, it is immediately necessary to confront the twin problems of deciding how much to provide and who should pay for that provision. Even if all individuals wanted the service equally-as, perhaps, with lighthouses-their views on the extent of the service would be influenced by the allocation of the costs. Where different households may have different preferences and some may not want the service at all-as, for example, with defense by nuclear weapons-these difficulties are compounded. Economists have tried to devise abstract voting schemes that would reconcile these difficulties, but these appear to have little practical application.

Genuine public goods pose severe problems for the national budget; it is very difficult to decide how far particular goods-the arts, national parks, even defense-should be supplied, and therefore no formal procedure of determination is likely to evolve. What should be given to each will continue to be the subject of intense political debate, with allocation changing as the government changes. In the context of public policy, the efficient allocation of resources consists not merely of distributing funds in the pursuit of given objectives but also involves determining the objectives themselves.

Merit goods. The concept of merit goods assists governments in deciding which public or other goods should be supplied. Merit goods are commodities that the public sector provides free or cheaply because the government wishes to encourage their consumption. Goods such as subsidized housing or social services, which predominantly help the poor, or health care services, which help the poor and elderly, are generally regarded as having considerable merit and therefore have a strong claim on government resources. Other examples include the provision of retraining schemes or urban regeneration programs.

Cost-benefit analysis. Once decisions have been made on how the limited national budget should be divided between different groups of activities, or even before this, public authorities need to decide which specific projects should be undertaken. One method that has been used is cost-benefit analysis. This attempts to do for government programs what the forces of the marketplace do for business programs: to measure, and compare in terms of money, the discounted streams of future benefits and future costs associated with a proposed project. If the ratio of benefits to costs is considered satisfactory, the project should be undertaken, "Satisfactory" means, among other things, that the project is superior to any available public or private alternative. Or, if funds are limited, public investment projects may be assigned priorities according to their cost-benefit ratios

One difficulty with cost-benefit analysis is that every government agency has an incentive to estimate favourable ratios for its own projects. It must, after all, compete with other agencies for funds. No one can be certain as to the returns to be expected from an irrigation canal or a highway. Private investors have also been known to exaggerate their claims in appealing to stockholders, but they are generally subject to market sanctions that encourage them to err on the side of caution.

In addition to the possibility that cost-benefit analysis may be biased by the preformed views of those commissioning the study, there are other, more fundamental difficulties. Almost all proposals have effects that are difficult to value in monetary terms. The siting of a new airport brings problems of noise and property blight to local people and increases the risk that civilians may die in an accident. Putting a sensible value on human life has been a continuing difficulty for those carrying out cost-benefit analyses, even though every project does in fact affect probabilities of life and death. These problems are, of course, not confined to cost-benefit analysis. Additional expenditure on health service or on road safety or better housing or heating old people's homes in winter all affect the number of people who die prematurely. The failure of cost-benefit analysis to provide answers to the problems of valuing life, or the quality of life, is a reflection of the wider problem confronting all decisions on public expenditure: the influence of subjective judgment.

Public ownership and privatization. Until the mid-1970s the proportion of economic activity controlled by the government and the share of taxes in national income tended to increase in most countries. Since then, however, challenges to this growth in the role of government have become increasingly influential, and moves to privatization have been common.

There are several types of privatization. One involves the sale to private owners of state-owned assets, and this is most correctly called privatization. Another is the sale of publicly owned industries, thus reversing the move to nationalization that occurred, particularly in western Europe, around and after World War II.

Privatization can also mean the dismantling of existing statutory restrictions on competition. State activities are often protected by legal prohibitions on competing private enterprise. The dismantling of such restrictions is seen as one method of improving the efficiency of state concerns.

Another aspect of privatization is the contracting out of publicly provided services. For example, U.S. municipalities entrust activities such as refuse collection, and in some cases even fire service, to private contractors.

While the objective of privatization is often to increase the efficiency of government activities, its implementation may also have important effects on government revenue. If an industry is sold for the present value of its expected earnings and if these earnings are the same in public and private ownership, privatization should have no net impact on public finances. If it is expected to be more efficient in the private sector, government finance, on balance, gains. If it is sold for less than the maximum revenue that would

The trend to privati-

zation

Privatiza-

tion and

govern-

revenue

ment

be obtained-and this is often the case, either because of the difficulty of selling assets as large as nationalized industries or because the government wishes to secure a wide dispersion of share ownership-the impact is likely to be negative.

Other forms of government intervention. Government spending is not the only way in which government allocates resources. Its regional policies will determine whether domestic and overseas investors build factories in particular places, while its taxation policies will determine whether they build them at all. Government competition and merger policies affect the structure of industry and commerce, while regulatory activities-setting the number of hours shops may be open or who may buy cigaretteshave profound effects on commercial activities.

Government also affects allocations by setting the legal and administrative framework within which the economy functions. It may specify minimum wage levels or control the siting of new ventures and the activities of existing ones. Such activities of government profoundly affect the allocation of resources, but they are rarely monitored or subject to serious control.

THE STABILIZATION FUNCTION

Stabilization of the economy (e.g., full employment, control of inflation, and an equitable balance of payments) is one of the goals that governments attempt to achieve through manipulation of fiscal and monetary policies. Fiscal policy relates to taxes and expenditures, monetary policy to financial markets and the supply of credit, money, and other financial assets.

History of stabilization policy. The use of fiscal and monetary policy as a means of stabilizing the economy is relatively recent, for the most part a development of the period after World War II. During the 19th century the only stabilization policy was that associated with the international gold standard. Under the gold standard, if a deficit occurred in a country's balance of payments, gold tended as a tool of to flow out of the country. To counteract this process, the monetary authorities would raise interest rates and stiffen credit requirements, causing a fall in prices, income, and employment; this in turn led to a reduction in imports and an expansion of exports, thus improving the balance of payments. If a country had a surplus in its balance of payments, gold tended to flow in; this meant that interest rates fell and the supply of money and credit was increased. As a consequence, imports were stimulated and exports discouraged so that the surplus in the balance of payments tended to disappear. The adjustment mechanism also included another important element: capital movements between countries. When interest rates fell in surplus countries and rose in deficit countries, mobile international financial capital tended to flow from the former to the latter, contributing to the elimination of deficits and surpluses in the balance of payments. The working of this mechanism was partly automatic and partly the result of deliberate actions by the monetary authorities in each

In this form of stabilization policy, external stability was achieved at the cost of stability in the domestic economy: fluctuations in domestic prices, incomes, and employment functioned as the levers for bringing about equilibrium in the balance of payments. Occasionally governments attempted to reduce the impact of this mechanism on the domestic economy, particularly on the price level. In particular, governments in some surplus countries took "sterilization actions" to prevent the gold inflow from increasing the supply of money and credit to the maximum extent. This could be done if the central bank offset its purchases of foreign exchange and gold with sales of government securities on the domestic credit market.

A somewhat more ambitious type of stabilization policy emerged in the period after World War I. During the 1920s unemployment in Great Britain rose to very high levels (between 20 and 30 percent of the labour force). Consequently, there was much discussion of whether employment could be increased by actions of the public authorities. Some maintained that budget deficits could raise the level of economic activity. An active part in this

discussion was taken by British economist J.M. Keynes. and also by the Liberal Party, which in 1928 published proposals for government intervention entitled Britain's Industrial Future.

Stabilization theory. The new stabilization policy needed a theoretical rationale if it was ever to win general acceptance from the leaders of public opinion. The main credit for providing this belongs to Keynes. In his General Theory of Employment, Interest and Money (1935-36) he argued that high levels of unemployment might persist indefinitely unless governments took monetary and fiscal action. At that time he believed that fiscal action was likely to be more effective than monetary measures. Keynes's pessimistic view of monetary policy had a strong influence on economists and governments during and immediately after World War II.

Fiscal policy. Fiscal policy attempts to control the actions of individuals and companies by means of spending and taxation decisions. On the expenditure side, it can achieve this by spending money in ways-for example, on construction projects-that stimulate other activity, while on the taxation side it can affect work, investment, or production decisions by changing tax rates and levels. Fiscal policy thus has two major components: an overall effect generated by the balance between the resources the government puts into the economy through expenditures and the resources it takes out through taxation, charges, or borrowing; and a microeconomic effect generated by the specific policies it adopts. Both are important in stabilizing the economy-that is, they are countercyclical.

Overall fiscal policy involves the government in deciding whether it should spend more than it receives or less. Experience with countercyclical fiscal policy has been disappointing; in many cases, the lag between identifying the problem and fiscal response has been too long, with the result that a fiscal boost coincided with the next boom, while a contraction might coincide with the next recession. Fiscal policies that were intended to be countercyclical could end up exacerbating the original problems.

Another facet to fiscal policy is a government's attempt to guide the development of the economy by more specifically targeted policies. Thus most countries have from time to time attempted to cushion particular areas from the effects of a decline in their dominant industry by regional policies. to affect labour supply and demand by taxation, and to change the pattern of consumer purchases by changes to indirect taxes. These policies sometimes backfire as un-

foreseen consequences and interactions occur. The heyday of fiscal stabilization policies occurred in the 1950s and '60s. In the 1970s governments became increasingly concerned about inflationary pressures, and important disturbances, particularly the oil crisis, disrupted world economies. Stabilization became a less important policy goal and one that governments were increasingly unable to achieve. Monetarist economic theories acquired increased influence until the turn of the 21st century, when some economists challenged the effectiveness of monetary policy and called for greater use of fiscal stabilization poli-

Monetary policy. Although the governmental budget is primarily concerned with fiscal policy (defining what resources it will raise and what it will spend), the government also has a number of tools that it can use to affect the economy through monetary control. By managing its portfolio of debt, it can affect interest rates, and by deciding on the amount of new money injected into the economy, it can affect the amount of cash in circulation and, therefore, indirectly affect prices and other economic variables.

At its simplest, monetarist theory postulates that in the economy there is a fixed amount of money, which circulates at a given velocity. This money is then available to finance the various transactions carried out in the economy at the prevailing prices. Under these circumstances, according to the theory, control of the price level can be maintained by controlling the amount of available money. Although a desire to control inflation prompted many countries to adopt monetary policies, a number of different facets of economic behaviour can be affected by the use of monetary policy. In time of unemployment the central

tion

bank may stimulate private investment expenditure, and possibly also household spending on consumer goods, by reducing interest rates and taking measures to increase the supply of credit, liquid assets, and money. The customary tools for doing this are open market operations, the discount rate of the central bank, and cash reserve requirements for commercial banks.

In open market operations the central bank buys government securities-bonds and treasury bills-from the private sector. The effect is to reduce interest rates by bidding up bond prices. In response, firms are likely to increase their investment expenditures, and households are likely to

spend more on consumer goods.

The second tool of monetary policy, the discount rate of the central banks, is often used together with open market operations. If the discount rate is reduced, banks become more willing to extend credit to private borrowers because they can obtain funds themselves on easier terms. In many countries, changes in the discount rate tend to be followed by similar changes in the interest rates charged by banks to their borrowers.

The third tool of monetary policy, that of the cash reserve requirements (and, in some countries, certain types of government securities) for commercial banks, provides that banks must maintain money balances (in the form of deposits in the central bank) at a certain proportion of their liabilities. If the government reduces the reserve requirements, the banks can expand their loans further, thus increasing the total volume of credit outstanding.

Monetary policy, like fiscal policy, may also be used to combat inflationary tendencies by reversing the above measures; the central bank will then sell government securities (thereby increasing interest rates and reducing the supply of private credit and money), raise the discount

rate, or increase reserve requirements.

Stabilization policy problems. Governments have displayed serious deficiencies in their ability to handle stabilization policy. Political leaders often lack economic information and understanding, and their economic advisers find it difficult to explain the economic situation to them and to apprise them of the relevant tools. There are also a variety of political inhibitions against taking action. One consequence is that what is designed to be a countercyclical policy becomes a procyclical one; instead of stabilizing the economy, it tends to destabilize it. The postwar experience in Britain is held by some to demonstrate the deficiencies of government in handling monetary and fiscal policy. In time of boom the government often followed an expansionary course; when a balance-of-payments crisis developed, it then took restrictive action-too lateand pushed the economy into deeper recession than would otherwise have occurred. On the basis of this experience, some economists have argued that a policy that did not attempt to counter the short-run swings in the economy would have been more successful in achieving stabilization. They maintain that the authorities should concentrate on letting the volume of money and credit increase steadily at a rate dictated by the long-term growth trend of the economy. Those who hold this view believe that capitalist economies are inherently stable, that crises are usually the result of bad policies on the part of the public authorities. Most economists do not share their optimism as to the stability of the economy if left alone; they continue to believe that governments must seek better tools for the purpose of short-run stabilization.

THE DISTRIBUTIVE FUNCTION

Virtually everything that a government does has some effect on the distribution of income or wealth at the various levels of society. Improvements in health care facilities benefit the sick, the old, and those about to have children. An increase in taxes on tobacco and beer affects the poor disproportionately, while an increase in capital taxes similarly affects the rich. Even regulatory and legislative activity benefits one group out of proportion to another. The redistributive consequences of the governmental budget can be reflected in a variety of ways; sometimes they are explicit and sometimes they are cited in the debate that follows the presentation of a budget. In the end, however, these consequences are hidden, unintended, and imperfectly understood. (A.Li./J.A.Ka.)

Graphic Design

raphic design is the art and profession of selecting and arranging visual elements-such as typography, images, symbols, and colours-to convey a message to an audience. Sometimes it is called "visual communications," a term that emphasizes its function of giving form-e.g., the design of a book, advertisement, logo, or Web site-to information. An important part of the designer's task is to combine visual and verbal elements into an ordered and effective whole. Graphic design is therefore a collaborative discipline: writers produce words and photographers and illustrators create images that the designer incorporates into a complete visual communication.

The evolution of graphic design as a practice and profession has been closely bound to technological innovations, societal needs, and the visual imagination of practitioners. Graphic design has been practiced in various forms throughout history; indeed, strong examples of graphic design date back to manuscripts in ancient China, Egypt, and Greece. As printing and book production developed in the 15th century, advances in graphic design developed alongside it over subsequent centuries, with compositors or typesetters often designing pages as they set the type.

In the late 19th century, graphic design emerged as a distinct profession in the West, in part because of the job specialization process that occurred there, and in part because of the new technologies and commercial possibilities brought about by the Industrial Revolution. New production methods led to the separation of the design of a communication medium (e.g., a poster) from its actual production. Increasingly, over the course of the late 19th and the early 20th centuries, advertising agencies, book publishers, and magazines hired art directors who organized all visual elements of the communication and brought them into a harmonious whole, creating an expression appropriate to the content. In 1922 typographer William A. Dwiggins coined the term "graphic design" to identify the emerging field.

Throughout the 20th century, the technology available to designers continued to advance rapidly, as did the artistic and commercial possibilities for design. The profession expanded enormously, and graphic designers created, among other things, magazine pages, book jackets, posters, compact-disc covers, postage stamps, packaging, trademarks. signs, advertisements, kinetic titles for television programs and motion pictures, and Web sites. By the turn of the 21st century, graphic design had become a global profession, as advanced technology and industry spread throughout the

Typography is discussed in this essay as an element of the overall design of a visual communication. Similarly, the evolution of the printing process is discussed in this essay as it relates to developments in graphic design. For a complete history of these areas, see PRINTING, TYPOGRAPHY, and PHOTOENGRAVING.

MANUSCRIPT DESIGN IN ANTIQUITY AND THE MIDDLE AGES

Although its advent as a profession is fairly recent, graphic design has roots that reach deep into antiquity. Illustrated manuscripts were made in ancient China, Egypt, Greece, and Rome. While early manuscript designers were not consciously creating "graphic designs," scribes and illustrators worked to create a blend of text and image that was at once harmonious and effective at conveying the idea of the manuscript. The ancient Egyptian Book of the Dead, which contained texts intended to aid the deceased in the afterlife, is a superb example of early graphic design. Hieroglyphic narratives penned by scribes are illustrated with colourful illustrations on rolls of papyrus. Words and pictures are unified into a cohesive whole: both elements are compressed into a horizontal band, the repetitive vertical structure of the writing is echoed in both the columns and the figures, and a consistent style of brushwork is used for the writing and drawing. Flat areas of colour are bound by firm brush contours that contrast vibrantly with the rich texture of the hieroglyphic writing.

During the Middle Ages, manuscript books preserved and propagated sacred writings. These early books were written and illustrated on sheets of treated animal skin called parchment, or vellum, and sewn together into a codex format with pages that turned like the pages of contemporary books. In Europe, monastic writing rooms had a clear division of labour that led to the design of books. A scholar versed in Greek and Latin headed the writing room and was responsible for the editorial content, design, and production of books. Scribes trained in lettering styles spent their days bent over writing tables, penning page after page of text. They indicated the place on page layouts where illustrations were to be added after the text was written, using a light sketch or a descriptive note jotted in the margin. Illuminators, or illustrators, rendered pictures and decorations in support of the text. In designing these works, monks were mindful of the educational value of pictures and the capacity of colour and ornament to create spiritual overtones

Manuscript production in Europe during the Middle Ages generated a vast variety of page designs, illustration and lettering styles, and production techniques. Isolation and poor travel conditions allowed identifiable regional design styles to emerge. Some of the more distinctive medieval art and design approaches, including the Hiberno-Saxon style of Ireland and England and the International Gothic style prevalent in Europe in the late 14th and early 15th centuries, were used in manuscript books that achieved major graphic-design innovations. The Book of Kells, an illuminated gospel book believed to have been completed in the early 9th century at the Irish monastery of Kells, is renowned as one of the most beautiful Hiberno-Saxon manuscripts. Its page depicting the appearance of Christ's

Book of the Dead

> Book of Kells

clearly conveys the sacred nature of the religious content, From the 10th through the 15th centuries, handmade manuscript books in Islāmic lands also achieved a masterful level of artistic and technical achievement, especially within the tradition of Persian miniature painting. The pinnacle of the Shīrāz school of Persian manuscript design and illustration is evident in a page by an unknown designer illustrating the great poet Nēzāmī's Khamseh ("The Quintuplet"). This page from 1491 depicts the Persian king Khosrow II in front of the palace of his beloved, Shīrīn. Human figures, animals, buildings, and the landscape are presented as refined shapes defined by concise outlines. These two-dimensional planes are filled with vibrant colour and decorative patterns in a tightly interlocking composition. The calligraphic text, contained in a series of rectangles across the top and bottom of the page, balances the crisp illustrations.

EARLY PRINTING AND GRAPHIC DESIGN

While the creation of manuscripts led to such high points in graphic design, the art and practice of graphic design truly blossomed with the development of printmaking technologies such as movable type. Antecedents of these developments occurred in China, where the use of woodblock, or relief, printing, was developed perhaps as early as the 6th century AD. This process, which was accomplished by applying ink to a raised carved surface, allowed multiple copies of texts and images to be made quickly and economically. The Chinese also developed paper made from organic fibres by 105 AD. This paper provided an economical surface for writing or printing; other substrates, such as parchment and papyrus, were less plentiful and more costly to prepare than paper.

Surviving artifacts show that the Chinese developed a wide range of uses for printing and that they achieved a high level of artistry in graphic design and printing from an early date. Artisans cut calligraphic symbols into woodblocks and printed them beautifully; printed sheets of paper bearing illustrations and religious texts were then pasted together to make printed scrolls. By the 9th or 10th century, paged woodblock books replaced scrolls, and literary, historical, and herbal works were published. Paper money and playing cards were also designed, the designs cut into woodblocks and printed. Chinese alchemist Pi Sheng invented a technique for printing with movable type about 1041-48 AD; however, this technology did not replace the hand-cut woodblock in Asia, in part because the hundreds of characters used in calligraphic languages made setting and filing the movable characters difficult.

Chinese inventions slowly spread across the Middle East and into Europe. By the 15th century, woodblock broadsides and books printed on paper were being made in Europe. By 1450 Johannes Gutenberg of Mainz, Germany, invented a method for printing text from raised alphabet characters cast on movable metal types. After this, printed books began to replace costly handmade manuscript books. Designers of early typographic books in Europe attempted to replicate manuscripts, often designing type styles based on current manuscript lettering styles. When the type was printed, spaces were left for illuminators to add pictures, ornate initials, and other decorative material. In this way, the compositor or typesetter was in effect the designer as he set the type. Some surviving copies of Gutenberg's landmark 42-line Bible have headers, initials, and sentence markers applied by hand in red and blue

Over time, typographic books developed their own design vocabulary. By the mid-15th century, printers combined woodblock illustrations with typeset text to create easily produced, illustrated printed books. They printed woodblock decorative borders and ornamental initials along with the type, subsequently having colour applied by hand

to these printed elements. The first complete printed title page-identifying the book title, author, printer, and date-was designed in 1476.

The prevalence of movable type and increasingly advanced printing technology in Europe meant that, while other cultures continued to create manuscript designs and printed communications, major advances in graphic design over the next several centuries would often be centred in Europe.

Graphic design in the 16th-18th centuries

RENAISSANCE BOOK DESIGN

The Renaissance saw a revival, or "rebirth," of Classical learning from ancient Greece and Rome throughout Europe. Beginning in the late 15th century, printing played a major role in this process by making knowledge from the ancient world available to all readers. Typeface designs evolved toward what are now called Old Style types, which were inspired by capital letters found in ancient Roman inscriptions and by lowercase letters found in manuscript writing from the Carolingian period.

The Italian scholar and printer Aldus Manutius the Elder founded his Aldine Press in 1495 to produce printed editions of many Greek and Latin classics. His innovations included inexpensive, pocket-sized editions of books with cloth covers. About 1500 Manutius introduced the first italic typeface, cast from punches cut by type designer Francesco Griffo. Because more of these narrow letters that slanted to the right could be fit on a page, the new pocketsized books could be set in fewer pages.

The prototype for Renaissance book design was the Aldine Press's Hypnerotomachia Poliphili (1499; Figure 1), believed to be written by Francesco Colonna. The design of the work achieves an understated simplicity and tonal harmony, and its elegant synthesis of type and image has seldom been equaled. The layout combined exquisitely light woodcuts by an anonymous illustrator with roman types by Griffo utilizing new, smaller capitals; Griffo cut these types after careful study of Roman inscriptions. Importantly, double-page spreads were conceived in the book as unified designs, rather than as two separate pages.

During the 16th century, France became a centre for fine typography and book design. Geoffroy Tory-whose talents included design, engraving, and illustration, in addition to his work as a scholar and author-created books with types, ornaments, and illustrations that achieved the seemingly contradictory qualities of delicacy and complexity. In his 1531 Book of Hours he framed columns of roman type with modular borders; these exuberant forms were a perfect complement to his illustrations.

Typeface designer and punch-cutter Claude Garamond, one of Tory's pupils, achieved refinement and consistency in his Old Style fonts. Printers commissioned types from him rather than casting their own, making Garamond the first independent typefounder not directly associated with a printing firm. Works by Tory, Garamond, and many other graphic artists and printers created a standard of excellence in graphic design that spread beyond France.

The 17th century was a quiet time for graphic design. Apparently the stock of typeface designs, woodblock illustrations, and ornaments produced during the 16th century satisfied the needs of most printers, and additional innovation seemed unnecessary.

ROCOCO GRAPHIC DESIGN

The 18th-century Rococo movement, characterized by complex curvilinear decoration, found its graphic-design expression in the work of the French typefounder Pierre-Simon Fournier. After studying art and apprenticing at the Le Bé type foundry, Fournier opened his own type design and foundry operation. He pioneered standardized measurement through his table of proportions based on the French pouce, a now-obsolete unit of measure slightly longer than an inch. The resulting standard sizes of type enabled him to pioneer the "type family," a series of typefaces with differing stroke weights and letter widths whose similar sizes and design characteristics allowed them to be used together in an overall design. Fournier designed a

wide range of decorative ornaments and florid fonts, enabling French printers to create books with a decorative complexity that paralleled the architecture and interiors of the period. Because French law forbade typefounders from printing, Fournier often delivered made-up pages to the printer, thereby assuming the role of graphic designer.

Copperplate engraving became an important medium for book illustrations during this period. Lines were incised into a smooth metal plate, ink was pressed into these recessed lines, excess ink was wiped clean from the surface.

and a sheet of paper was pressed onto the plate with sufficient pressure to transfer the ink from the printing plate to the paper. This allowed book illustrations to be produced with finer lines and greater detail than woodblock printing. In order to make text more compatible with these fine-line engravings, designers increasingly made casting types and ornaments with finer details. English engraver Robert Clee's engraved trading card (Figure 2) demonstrates the curvilinear decoration and fine detail achieved in both text and image by designers during the Rococoo.

Graphic design often involves a collaboration of specialists. Eighteenth-eentury artists often specialized in book illustration. One such artist was Frenchman Charles Eisen, who illustrated French poet Jean de La Fontaine's Contes et nouvelles en vers (1762; Tales and Novels in Verse), In this work, Joseph Gerard Barbou, the printer, used types and ornaments by Fournier, full-page engravings by Eisen, and complex spot illustrations and tailpieces by Pierre-Phillippe Choffard. This superb example of Rococo book design combined the ornamented types, decorative initials, elaborate frames and rules, and intricate illustrations typical of the genry.

NEOCLASSICAL GRAPHIC DESIGN

In the second half of the 18th century, some designers tired of the Rocco style and instead sought inspiration from Classical art. This interest was inspired by recent archaeological finds, the popularity of travel in Greece, Italy, and Egypt, and the publication of information about Classical works. Neoclassical typographic designs used straight lines, rectilinear forms, and a restrained geometric ornamentation. John Baskerville, an English printer of the time, created book designs and typefaces that offered a transition between the Roccoco and Neoclassical periods. His use of superbly designed types, printed on smooth paper without ornament or illustration, resulted in books of stately and restrained elegance. Baskerville's fonts had sharper serifs, more contrast between thick and thin strokes, and a more vertical, geometric axis, than Roccoco typefaces.

In the late decades of the 18th and early decades of the 19th century, Giambattista Bodoni, the Italian printer at the Royal Press (Stamperia Reale) of the Duke of Parma, achieved Necolassical ideals in his books and typefaces. Bodoni laid forth his design statement in Manuale tipografico (1788; "Inventory of Types"); another edition of this book was published in 1818, after his death, by his widow and foreman. Bodoni advocated extraordinary pages for exceptional readers. He achieved a purity of form

Figure 2: Black-and-white print of engraved trading card by Robert Clee, 18th century.

John Baskerville with sparse pages, generous margins and line-spacing, and severe geometric types; this functional purity avoided any distractions from the act of reading. He drew inspiration from Baskerville as he evolved his preferences from Rococo-derived designs toward modern typefaces.

The Didot family

Posters

The Didot family of French printers, publishers, and typefounders also achieved Neoclassical ideals in their work. Books designed by the Didots have minimal decoration, generous margins, and simple linear borders. Pierre l'aîné Didot achieved technical perfection in his printing of the lavish éditions du Louvre. In these books, Pierre utilized types, designed at his brother Firmin's foundry, that provided a crisp counterpoint to the engraved illustrations by various artists working in the school of the French Neoclassical painter Jacques-Louis David. The illustrations of idealized figures in ancient Roman environments were engraved with flawless technique, obsessive detail, and sharp contrasts of light and shadow.

Graphic design in the 19th century

THE INDUSTRIAL REVOLUTION AND DESIGN TECHNOLOGY The Industrial Revolution was a dynamic process that began in the late 18th century and lasted well into the 19th century. The agricultural and handicraft economies of the West had used human, animal, and water power, but they evolved into industrial manufacturing economies powered by steam engines, electricity, and internal-combustion motors. Many aspects of human activity were irrevocably changed. Society found new ways (often commercial) to use graphic designs and developed new technologies to produce them. Industrial technology lowered the cost of printing and paper, while making much larger pressruns possible, thus allowing a designer's work to reach a wider audience than ever before.

One popular medium for the graphic designer became the poster. Posters printed with large wood types were used extensively to advertise new modes of transportation, entertainment, and manufactured goods throughout the 19th century. This was possible in part because typefounders developed larger sizes of types for use on posted announcements and innovated new typefaces including sans serif, slab serif, and decorative designs. An American printer, Darius Wells, invented a lateral router that enabled the economical manufacture of abundant quantities of large wooden types, which cost less than half as much as large metal types. Wood-type posters usually had vertical formats: types of a mixture of sizes and styles were set in horizontal lines with a left-and-right alignment that created a visual unity.

The poster became even more popular as a result of advances in lithography, which had been invented about 1798 by Alois Senefelder of Bavaria. Building upon this discovery, colour lithographs, called chromolithographs, were widely used in the second half of the 19th century, and designers created increasingly colourful posters that filled the walls of cities. Designers of chromolithographic prints drew all the elements-text and image-as one piece of artwork; freed from the technical restraints of letterpress printing, they could invent fanciful ornaments and lettering styles at will. Many chromolithographs reflected an interest in the 1856 publication of English designer Owen Jones's The Grammar of Ornament, a methodical collection of design patterns and motifs that contained examples from Asian, African, and Western cultures. (Such explorations were consistent with the fascination with historicism and elaborate decoration found in architecture and product design during the Victorian era.)

Momentum for this poster-design approach began in France, where poster designer Jules Chéret was a pioneer of the movement. Beginning his career in 1867, he created large-scale lithographic posters that featured vibrant colours, textured areas juxtaposed against flat shapes, and happy, animated figures that captured la belle epoch of turn-of-the-century Paris (Plate 1). Chéret designed over one thousand posters during his career.

Chromolithography also made colourful pictures available to the homes of ordinary people for the first time in history. Designers developed ideas for packaged goods that were offered in tins printed with iconic images, bright colours, and embellished lettering. They also created trade cards, and "scrap," which were packets of printed images of birds, flowers, and other subjects collected by children.

As the century progressed, graphic design reached many people through magazines, newspapers, and books. The automation of typesetting, primarily through the Linotype machine, patented in the United States in 1884 by Ottmar Mergenthaler, made these media more readily available. One Linotype operator could do the work of seven or eight hand compositors, dramatically reducing the cost of typesetting and making printed matter less expensive.

WILLIAM MORRIS AND THE PRIVATE-PRESS MOVEMENT

During the 19th century, one by-product of industrialism was a decline in the quality of book design and production. Cheap, thin paper, shoddy presswork, drab, gray inks, and anemic text typefaces were often the order of the day. Near the end of the century, a book-design renaissance began as a direct result of the English Arts and Crafts Movement. William Morris, the leader of the movement, was a major figure in the evolution of design. Morris was actively involved in designing furniture, stained glass, textiles, wallpapers, and tapestries from the 1860s through the 1890s. Deeply concerned with the problems of industrialization and the factory system, Morris believed that a return to the craftsmanship and spiritual values of the Gothic period could restore balance to modern life. He rejected tasteless mass-produced goods and poor craftsmanship in favour of the beautiful, well-crafted objects he designed.

In 1888 Morris decided to establish a printing press to recapture the quality of books from the early decades of printing. His Kelmscott Press began to print books in 1891, using an old handpress, rich dense inks, and handmade paper. Decorative borders and initials designed by Morris and woodblocks of commissioned illustrations were cut by hand. Morris designed three typefaces based on

types from the 1400s.

The Kelmscott Press recaptured the beauty and high standards of incunabulum (texts produced when books were still copied by hand), and the book again became an art form. The press's masterwork is the ambitious 556-page The Works of Geoffrey Chaucer. Four years in the making, the Kelmscott Chaucer has 87 woodcut illustrations from drawings by renowned artist Edward Burne-Jones. For the single work, Morris designed 14 large borders, 18 smaller frames for the illustrations, and over 200 initial letters and words. An exhaustive effort was required by everyone in-

volved in the project.

The influence of William Morris and the Kelmscott Press upon graphic design, particularly book design, was remarkable. Morris's concept of the well-designed page, his beautiful typefaces, and his sense of design unity-with the smallest detail relating to the total concept-inspired a new generation of graphic designers. His typographic pages, which formed the overwhelming majority of the pages in his books, were conceived and executed with readability in mind, another lesson heeded by younger designers. Morris's searching reexamination of earlier type styles and graphic-design history also touched off an energetic redesign process that resulted in a major improvement in the quality and variety of fonts available for design and printing; many designers directly imitated the style of the Kelmscott borders, initials, and type styles. More commercial areas of graphic design, such as job printing and advertising, were similarly revitalized by the success of Morris.

The Kelmscott Press's influence became immediately apparent in the rise of the private-press movement: printers and designers established small printing firms to design and print carefully crafted, limited-edition books of great beauty, Architect and designer Charles Robert Ashbee founded the Essex House Press in London, and bookbinder Thomas James Cobden-Sanderson joined printer Sir Emery Walker in establishing the Doves Press at Hammersmith. Books from the Doves Press, including its monumental masterpiece, the 1903 Doves Press Bible, are remarkably beautiful typographic books. They have no illustrations or ornaments; the press instead relied upon fine paper, perfect presswork, and exquisite type and spacing to

Kelmscott

Press Bible

produce inspired page designs. The Ashendene Press, directed by Englishman C.H. St. John Hornby, was another exceptional English private press. Following the example of Morris, these presses believed in the social value of making attractive and functional visual communications available to citizens of all walks of life.

In the United States, typeface designers, in particular Frederic W. Goudy and Morris F. Benton, revived traditional typefaces. Also inspired by the Arts and Crafts Movement, American book designer Bruce Rogers played a significant role in upgrading book design. By applying the ideals of the beautifully designed book to commercial production, Rogers set the standard for well-designed books in the early 20th century. An intuitive Classicist, Rogers possessed a fine sense of visual proportion. He also saw design as a decision-making process, feeling that subtle choices about margins, paper, type styles and sizes, and spatial position combine to create a unity and harmony, Type historian Beatrice Warde wrote that Rogers "managed to steal the Divine Fire which glowed in the Kelmscott Press books, and somehow be the first to bring it down to earth.'

ART NOUVEAU

Art Nouveau was an international design movement that emerged and touched all of the design arts-architecture, fashion, furniture, graphic, and product design-during the 1890s and the early 20th century. Its defining characteristic was a sinuous curvilinear line. Art Nouveau graphic designs often utilized stylized abstract shapes, contoured lines, and flat space inspired by Japanese ukiyo-e woodblock prints. Artists in the West became aware of ukiyo-e prints as trade and communication between Eastern and Western nations increased during the last half of the 19th century. Building upon the example of the Japanese, Art Nouveau designers made colour, rather than tonal modeling, the primary visual attribute of their graphics.

One of the most innovative posters of the Art Nouveau movement was artist Henri de Toulouse-Lautrec's 1891 poster of the dancer La Goulue, who was performing at the Moulin Rouge. Toulouse-Lautrec captured the atmosphere and activity of the dance by reducing imagery to simple, flat shapes that convey an expression of the performance and environment. Although Toulouse-Lautrec produced only about three dozen posters, his early application of the ukiyo-e influence propelled graphic design toward more reductive imagery that signified, rather than depicted, the subject. He often integrated lettering with his imagery by drawing it in the same casual technique as the pictorial elements.

Alphonse Mucha, a young Czech artist who worked in Paris, is widely regarded as the graphic designer who took Art Nouveau to its ultimate visual expression. Beginning in the 1890s, he created designs-usually featuring beautiful young women whose hair and clothing swirl in rhythmic patterns-that achieved an idealized perfection. He organized into tight compositions lavish decorative elements inspired by Byzantine and Islāmic design, stylized lettering, and sinuous female forms. Like many other designers at the time, Mucha first captured public notice for poster designs, but he also received commissions for magazine covers, packages, book designs, publicity materials, and even postage stamps. In this way, the role and scope of graphic-design activity expanded throughout the period.

Will Bradley, a self-taught American designer, emerged as another early practitioner of Art Nouveau. His magazine covers, lettering styles, and posters displayed a wide range of techniques and design approaches. Bradley synthesized inspiration from the European Art Nouveau and Arts and Crafts movements into a personal approach to visual imagery. By the 1890s, photoengraving processes (making printing plates from original artwork) had been perfected, which allowed reproductions to replicate the original artwork more accurately; hand engraving was often only an engraver's interpretation of an original. Bradley's work, in which he integrated words and picture into a dynamic whole, was printed from plates using this new technology, Art Nouveau rejected historicism and emphasized formal invention, and so it became a transitional movement from

Victorian design to the modern art movements of the early 20th century. This sense of transition is quite evident in the work of the Belgian artist and designer Henri van de Velde, After turning from Postimpressionist painting to furniture and graphic design in the 1890s, he used lines and shapes inspired by the natural world and abstracted them to the point that they appeared as "pure form"; that is, they appeared as abstract forms invented by the designer rather than as forms from nature. In works such as his poster for Tropon food concentrate (1899; Plate 1), undulating linear movements, organic shapes, and warm-hued colours combine into a nonobjective graphic expression. Although this poster has been interpreted as signifying the process of separating egg yolks and whites, the typical viewer perceives it as pure form.

Similarly exploring issues of form, and inspired in part by the theories and work of the American architect Frank Lloyd Wright, architects Charles Rennie Mackintosh and J. Herbert McNair joined artists (and sisters) Margaret and Frances Macdonald in a revolutionary period of creativity beginning in the 1890s. This group in Glasgow, Scotland, combined rectangular structure with romantic and religious imagery in their unorthodox furniture, crafts, and graphic designs. In a poster it made for the Glasgow Institute of Fine Arts (1895), for example, the group's emphasis upon rising vertical composition is evident.

Charles Rennie Mackin-

Graphic design in the 20th century

EARLY DEVELOPMENTS

In the first decade of the 20th century, the experiments with pure form begun in the 1890s continued and evolved. Although the Glasgow group received a cool reception in the British Isles, designers in Austria and Germany were inspired by their move toward geometric structure and simplicity of form. In Austria, a group of young artists led by Gustav Klimt broke with the Künstlerhaus in 1897 and formed the Vienna Secession. These artists and architects rejected academic traditions and sought new modes of expression. In their exhibition posters and layouts for the Secession magazine, Ver Sacrum, members pushed graphic design in uncharted aesthetic directions. Koloman Moser's poster for the 13th Secession exhibition (1902) blends three figures, lettering, and geometric ornament into a modular whole. The work is composed of horizontal, vertical, and circular lines that define flat shapes of red, blue, and white. Moser and architect Josef Hoffmann were instrumental in establishing the Wiener Werkstätte ("Vienna Workshops"), which produced furniture and design objects.

The German school of poster design called Plakatstil Plakatstil ("Poster Style") similarly continued the exploration of pure form. Initiated by Lucian Bernhard with his first poster in 1905, Plakatstil was characterized by a simple visual language of sign and shape. Designers reduced images of products to elemental, symbolic shapes placed over a flat background colour, and they lettered the product name in bold shapes. Plakatstil gained numerous adherents, includ-

ing Hans Rudi Erdt, Julius Gipkens, and Julius Klinger. Concurrent with these developments, in Germany Peter Behrens played an important role in graphic design. Behrens helped to develop a philosophy of Neue Sachlichkeit ("New Objectivity") in design, which emphasized technology, manufacturing processes, and function, with style subordinated to purpose. In 1907 Emil Rathenau, head of the AEG (Allgemeine Elektrizitäts Gesellschaft, a vast electrical manufacturing firm), appointed Behrens as artistic adviser for all of AEG's activities. Rathenau, a farsighted industrialist, believed industry needed the visual order and consistency that could only be provided by design. For AEG, Behrens developed what may be considered the first cohesive "visual identity system" (Plate 1); he consistently used the same logo, roman typeface styles, and geometric grids to create product catalogs, magazines, posters, other printed matter, and architectural graphics. Behrens's work for AEG was a harbinger of a major area of graphic design in the second half of the 20th century: the creation of a corporate identity through a program using trademarks, typefaces, formats, and colour in a consistent, controlled manner.

MODERNIST EXPERIMENTS BETWEEN THE WORLD WARS

Building upon the formal design experiments from the beginning of the century, between the world wars. European graphic designers utilized the new forms, organization of visual space, and expressive approaches to colour of such avant-garde movements as Cubism, Constructivism, De Stijl, Futurism, Suprematism, and Surrealism, Inspired by these movements, graphic designers pursued the most elemental forms of design. Such a concern with the essential formal elements of a medium characterize the Modernist experiments prevalent in all the arts of the period.

One pioneer of this approach was an American working in England, E. McKnight Kauffer, who was one of the first designers to understand how the elemental symbolic forms of Cubist and Futurist painting could be applied to the communicative medium of graphic design. Throughout the first half of the 20th century, his posters, book jackets, and other graphics achieved an immediacy and vitality well-suited to the fast-paced urban environment in which his visual communications were experienced.

Cassandre (the pseudonym of Adolphe Jean-Marie Mouron) used figurative geometry and modulated planes of colour, derived from Cubism, to revitalize postwar French poster design. From 1923 until 1936, Cassandre designed posters in which he reduced his subject matter to bold shapes and flat, modulated icons. He emphasized two-dimensional pattern, and he integrated lettering with his imagery to make a unified overall composition. Cassandre also utilized airbrushed blends and grading to soft-

en rigid geometry. His clients included steamship lines and railway transportation, clothing, food, and beverage com-

The austere visual language developed by artistic move-

ments such as De Stijl in The Netherlands and by Suprematism and Constructivism in Russia influenced a Modernist approach to page layout. Suprematism, founded by Kasimir Malevich, inspired a young generation of designers to move toward a design based on the construction of simple geometric forms and elemental colour. Attributes of this approach in design included an underlying structure of geometric alignments, asymmetrical composition, elemental sans-serif typefaces, and simple geometric elements. Ornament was rejected, and open areas of white space were used as compositional elements. Works by the Russian Constructivist El Lissitzky exemplify this design approach. He developed design programs that utilized consistent type elements and placements. For example, his book design for Vladimir Vladimirovich Mayakovsky's Dlva golosa (For the Voice) (1923; Plate 1) is a seminal work of graphic design. The title spread for each poem is constructed into a dynamic visual composition, with geometric elements having symbolic meaning. In the title page to one poem, Lissitzky used a large red circle to signify the

sun, the subject of the poem. The Bauhaus, a German design school founded in 1919 with architect Walter Gropius as its director, became a crucible where the myriad ideas of modern art movements were examined and synthesized into a cohesive design movement. In its initial years, the Bauhaus held an Expressionist and utopian view of design, but it later moved toward a functionalist approach. Bauhaus artists and designers sought to achieve a unity between art and technology and to create functional designs-often utilizing the pure forms of Modernism-that expressed the mechanization of the machine age. In 1923 the Hungarian Constructivist László Moholy-Nagy joined the faculty. Among his numerous contributions, Moholy-Nagy introduced a theoretical approach to visual communications. Important in his theory was the use of photomontage (a composite photographic image made by pasting together or superimposing different elements) as an illustrative medium. He promoted the integration of words and images into one

unified composition and the use of functional typography. Herbert Bayer was appointed first master of the newly founded Druck and Reklame ("Printing and Advertising") workshop at the Bauhaus in 1925. Bayer's poster for Wassily Kandinsky's 60th-birthday exhibition (1926) incorporates Constructivist and De Still influences. It clearly embodies the Bauhaus design philosophy: elemental forms are shorn of ornament, and forms are selected and arranged in order to serve a functional purpose ("clarity of information"), with a visual hierarchy of size and placement in descending prominence from the most important to secondary facts. The elements are masterfully balanced and aligned to create a cohesive composition, and the tilting at a diagonal angle energizes the space.

The unprecedented graphic designs produced during this period were explained and demonstrated to printers and designers through writings and designs by Jan Tschichold, a voung German designer. As a result, many designers in Europe and throughout the world embraced this new approach to graphic design. An announcement for Tschichold's book Die Neue Typographie (1928; "The New Typography") typifies his own philosophy. Tschichold advocated functional design that uses the most direct means possible. His systematic methodology emphasized contrast of type sizes, widths, and weights, and he used white space and spatial intervals as design elements to separate and organize material. He included only elements that were essential to the content and page structure.

Many designers sought other ways to use geometry to evoke a modern spirit for the machine age, Art Deco. streamline, and moderne are terms used to denote the loosely defined trend in art, architecture, and design from the 1920s to the 1940s that utilized decorative, geometric designs. Everything from skyscrapers to furniture to-in the case of graphic design-cosmetics packaging, posters, and typefaces used zigzag forms, sunbursts, and sleek geometric lines to project a feeling of a new technological era. At the same time, a number of Dutch designers, includ-

ing Piet Zwart, drew upon the Modernist vocabulary of form and colour to develop unique personal approaches to graphic design, applying their vision to the needs of clients. While working at an architectural firm in the early 1920s, Zwart received commissions for graphic-design projects by happenstance. In his work from the 1920s and '30s, he rejected the conventional norms of typography and instead approached the layout of an ad or brochure as a spatial field upon which he created dynamic movements and arresting forms. This is seen, for example, in a dynamic advertisement for Nederlandsche Kabelfabriek Delft (NKF) cable factory (1924), which proclaims, "Normaal cable [is the best cable for the price." Zwart believed the fast pace of 20th-century life meant viewers had little time for lengthy advertising copy. He used brief telegraphic text, bold typefaces placed at an angle, and bright colours to attract attention and to convey his client's message quickly and effectively.

Swiss designers also brought tremendous vitality to graphic design during this period. After studying in Paris with Fernand Léger and assisting Cassandre on poster projects, Herbert Matter returned to his native Switzerland, where from 1932 to 1936 he designed posters for the Swiss Tourist Board, using his own photographs as source material. He employed the techniques of photomontage and collage in his posters, as well as dynamic scale changes, large close-up images, extreme high and low viewpoints, and very tight cropping of images. Matter carefully inte-

grated type and photographs into a total design. When the Nazis rose to power in Europe during the 1930s, Modernist experiments were denounced, and many artists, architects, and designers immigrated to the United

GRAPHIC DESIGN, 1945-75

The International Typographic Style. After World War II, designers in Switzerland and Germany codified Modernist graphic design into a cohesive movement called Swiss Design, or the International Typographic Style. These designers sought a neutral and objective approach that emphasized rational planning and de-emphasized the subjective, or individual, expression. They constructed modular grids of horizontal and vertical lines and used them as a structure to regularize and align the elements in their designs. These designers preferred photography (another technical advance that drove the development of graphic design) as a source for imagery because of its machine-made precision and its ability to make an unbiased record of the subject. They created asymmetrical layouts. and they embraced the prewar designers' preference for sans-serif typefaces. The elemental forms of the style possessed harmony and clarity, and adherents considered these forms to be an appropriate expression of the postwar scientific and technological age.

Josef Müller-Brockmann was a leading designer, educator, and writer who helped define this style. His poster, publication, and advertising designs are paradigms of the movement. In a long series of Zürich concert posters, Müller-Brockmann used coiour, an arrangement of elemental geometric forms, and type to express the structural and rhythmic qualities of music. A 1955 poster for music by Igor Stravinsky, Wolfgang Fortner, and Alban Berg demonstrates these properties, along with Müller-Brockmann's belief that using one typeface in two sizes (display and text) makes the message clear to the audience.

The programmatic uniformity of this movement would be widely adopted by designers working in the area of visual identity systems during the second half of the 20th century. Multinational corporations soon adopted the tenets of the International Typographic Style: namely, the standardized use of trademarks, colours, and typefaces; the use of consistent grid formats for signs and publications; the preference for the contemporary ambiance of sans-serif types; and the banishment of ornament.

Postwar graphic design in the United States. While designers in Europe were forging the International Typographic Style into a cohesive movement, American designers were synthesizing concepts from modern art into highly individualistic and expressive visual statements. From the 1940s through the 1960s, New York City was a maintenance for international control of the property of the 1960s, New York City was a maintenance for international control of the 1960s.

major centre for innovation in design and the fine arts. During the 1940s, Paul Rand emerged as an American designer with a personal and innovative approach to modern design. Rand understood the vitality and symbolic power of colour and shape in the work of artists such as Paul Klee, Wassily Kandinsky, and Pablo Picasso. In a 1947 poster promoting New York subway advertising (Plate 1), for example, Rand created a design from elemental geometric forms and colours that can be read as both an abstracted figure as well as a target, conveying the concept that one can "hit the bull's-eye," or reach potential audiences for plays, stores, and other goods and services by advertising in the subway. An ordinary message is rendered extraordinary through the power of visual forms and symbols. Rand's work spanned a range of graphic media including advertising, book jackets, children's books, corporate literature (such as annual reports), packaging, posters, trademarks, and typefaces.

In the 1950s Rand began to spend more of his time on corporate image projects, and he designed what would become ubiquitous trademarks and visual identities for major corporations including IBM, Westinghouse, ABC television, and UPS. Many other prominent designers—including Saul Bass (whose many visual identity programs included logos for AT&T), Lester Beall, and the partnership of Tom Geismar and Iyan Chermayeff.—focused their

practices upon corporate design, as multinational corporations understood the need for consistent graphic standards in their facilities and communications.

Bradbury Thompson, a prominent magazine art director, designed a publication called Westvaco Inspirations for a major paper manufacturer from 1938 until the early 1960s. His playful and innovative approach to type and imagery is shown in the design of a spread from Westvaco Inspirations 210 (1958; Plate 2). Here, Thompson responded to the geometric forms of African masks in the Ben Somoroff photograph in the spread by "drawing" a masklike face out of letters spelling "Westvaco," Thompson's complex layouts combined art with coloured shapes and unusual typographic arrangements. He explored printing techniques by separating the four plates used to print full-colour images-cyan (a warm blue), magenta, yellow, and black-and having them printed in different positions on the page. He also had engravings from old books enlarged and overprinted in unexpected colours. These experiments were very influential, as they showed a generation of designers new possibilities.

Magazines placed more emphasis upon graphic design during the postwar period. Alexey Brodovitch, the art director of Hurper's Bazuar from 1934 until 1958, pioneered a new approach to magazine design. He created a flowing perceptual experience for the reader who paged through his magazines by varying sizes of type and imagery, alternating complex pages with simple layouts containing large areas of white space, and creating an overall sense of rhythmic movement. The beauty of Brodovitch's designs was enhanced by the impressive team of collaborators at Bazuar, which included photographer Richard Ayedon.

The postwar period has been called a "golden age" of magazine design, when art directors including Henry Wolf (at Esquire and Harper's Bazam') and Otto Storch (at McCall's) extended Brodovitch's imaginative approach to page layout in large-format magazines. Storch believed concept, text, type, and image should be inseparable in editorial design, and he applied this belief to the editorial pages of McCall's.

pages of McCata S.

The emergence of television began to alter the roles of print media and graphic design, while also creating new opportunities for designers to work on television commercials and on-air graphics. "Motion graphics" are kinetic graphic designs for film titles and television that occur in the fourth dimension—time. A variety of animated film techniques were applied to motion-picture tilling in the 1950s by Saul Bass and, in Canada, by Norman McLaren of the Canadian National Film Board. For example, Bass's titles for Otto Preminger's 1959 film Anatomy of a Murder reduce a prone figure to disjointed parts, which move onto the screen in carefully orchestrated sequences that conclude with their positioning to form the figure; the lettering of the film's title appress are not of the screen in a contraction.

ing of the film's title appears as part of the sequence. Vernacular imagery and popular culture inspired a generation of American designer/fillustrators who began their careers after World War II, including the 1954 founders of the Push Pin Studio in New York. Their work combined a fascination with the graphic simplicity and directness of comic books with a sophisticated understanding of modern art, especially of Surrealism and Cubism. The Push Pin artists' unabashedly eelectic interest in art and design history led them to incorporate influences ranging from Persian rugs to children's art and decorative Victorian typefaces. In their work, a graphic vibrancy supported a

strong conceptual approach to the visual message. Several major directions emerged in American graphic design in the 1960s. Political and social upheavals of the decade were accompanied by a resurgence of poster art addressing the Civil Rights Movement, the women's movement, environmentalism, and the Vietnam War. Placing ads on radio and television was beyond the economic means of most private citizens, independent art groups, and social-activist organizations; however, they could afford to print and distribute flyers and posters, and they could even sell their posters to public sympathizers to raise

money for their causes.

As popular music became increasingly culturally significant, graphics for the recording industry emerged as a locus

Miller-

Brock-

mann

Political design of design creativity. One Push Pin Studio founder, Milton Glaser, captured the imagination of a generation with his stylized curvilinear drawing, bold flat colour, and original concepts. Glaser's poster (1967; Plate 2) for folk-rock musician Bob Dylan is one of many music graphics from the 1960s that achieved an iconic presence not unlike that of Flagg's "I Want You" poster from World War I. Over the course of the second half of the century, Glaser steadily expanded his interests to include magazine design, restaurant and retail store interiors, and visual identity systems.

The 1960s also saw the rapid decline of hand- and machine-set metal type, as they were replaced by display-andkeyboard phototype systems. Since it is very inexpensive to produce new typefaces for photographic typesetting the widespread use of phototype systems set off a spate of new designs and reissues of long-unavailable typefaces, such as decorative Victorian wood types. American Herb Lubalin is notable among the designers who embraced the new flexibility phototype made possible for designers. Type could be set in any size, the spaces between letters and lines could be compressed, and letters could be expanded, condensed, touched, overlapped, or slanted. Lubalin's ability to make powerful visual communications solely with type is seen in a 1968 announcement (Plate 2) for an antiwar poster contest sponsored by Avant Garde magazine. The magazine's logo, placed in the dot of the exclamation point, uses ligatures (two or more letters combined into one form) and alternate characters to form a tightly compressed image. This logo was developed into a typeface named Avant Garde. one of the most successful and widely used fonts of the phototype period.

A creative revolution in advertising writing and design Advertising also occurred during this period. Advertising agencies approached marketing objectives through the use of witty headlines, simple layouts, and clever visual images. Copywriters and art directors, working as collaborative creative teams, sought a synergy between word and image. The Doyle Dane Bernbach advertising agency played an influential role in the history of graphic design by creating advertisements that spoke intelligently to consumers and avoided the hyperbole of the typical "hard sell."

> One of the many advertising designers who launched his career at Doyle Dane Bernbach was George Lois, whose works were engagingly simple and direct. Lois went on to design over 90 covers for Esquire magazine in the 1960s. He used powerful photographs and photomontages, usually by Carl Fischer, to make succinct editorial statements about the United States. These designs acted as independent visual/verbal statements about such topics as assassi-

nations and civil rights.

Postwar graphic design in Japan. During the 1960s and '70s, American graphics from the New York area, as well as European graphics from the International Typographic Style, influenced designers around the world.

In postwar Japan, for example, when the country emerged as a major industrial power, graphic design evolved into a major profession serving the needs of industry and cultural institutions. European Constructivism and Western design exerted an important influence on Japanese design, but these lessons were assimilated with traditional Japanese art theory. For example, the Japanese tradition of family crests inspired many Japanese designers' approach to trademark design. Similarly, symmetrical composition, central placement of iconic forms, harmonious colour palettes, and meticulous craftsmanship-all characteristics of much of Japanese art-were often elements of Japanese graphics.

The first generation of graphic designers to emerge after the war was led by Kamekura Yüsaku, whose importance to the emerging graphic-design community led to the af-'fectionate nickname "Boss." Kamekura's poster proposal (1967) for the Japanese World Expo '70 in Osaka, for example, displays his ability to combine 20th-century Modernist formal experiments with a traditional Japanese sense

Kamekura

Yūsaku

In counterpoint to the formalist tendencies found in much Japanese graphic design, some Japanese designers drew upon other sources of inspiration to arrive at individual approaches to visual-communications problems. Iconography from diverse mass media-including comic books, popular science-fiction movies, and newspaper photographs-provided a rich vocabulary for Yokoo Tadanori, whose work beginning in the 1960s inspired a new generation of Japanese designers. In his early posters and magazine covers he utilized a variety of contemporary techniques; for example, he used crisp line drawings to contain photomechanical screens of colour. He worked in a Pop-art idiom, but he used revered Japanese imagery as source material, rather than the contemporary imagery usually found in Pop art. In his poster publicizing four no theatre productions (1969), for example, he placed iconic images on a luminous gold-and-blue field, combining traditional imagery with a contemporary sense of whimsy. Over time, montage effects became increasingly important to Yokoo, as he built his designs from photographic and graphic elements filled with dramatic luminosity.

A very different vision emerged in the work of Sato Kōichi, who from the 1970s created an otherworldly, metaphysical design statement. He used softly glowing blends of colour, richly coloured and modulated calligraphy, and stylized illustrations to create poetic visual statements that ranged from contemplative quietude to celebratory exuberance. For example, in his poster for a musical play-which was itself adapted from a nursery rhyme about soap bubbles-Satō combined an astronomical sky chart and a handprint glowing with a lavenderand-blue aura to evoke a feeling of ephemeral atmospheric space. Such designs achieve a rare level of visual poetry.

GRAPHIC DESIGN, 1975-2000

Postmodern graphic design. By the late 1970s, many international architectural, product, and graphic designers working in the Modernist tradition thought that the movement had become academic and lost its capacity for innovation. Younger designers challenged and rejected the tenets of Modernism and questioned the "form-followsfunction" philosophy that came to be associated with the diluted, corporate version of Modernism that derived from the International Typographic Style, Designers began to establish and then violate grid patterns; to invert expected forms; to explore historical and decorative elements; and to inject subjective-even eccentric-concepts into design. This reaction to Modernist developments is called postmodernism, and it took design in many new directions.

During the late 1970s, April Greiman was acclaimed for her postmodernist experimentation. (In the 1970s and '80s, increasing numbers of women entered the graphic-design field and achieved prominence.) Her dynamic typographic innovations and colourful montages were often made in collaboration with photographer Jayme Odgers. A cover for Wet magazine, for example, evokes the vibrant cultural scene in southern California. In this work from 1979, a colour photocopy of singer Ricky Nelson, collaged images from magazines, Japanese papers, and airbrushed blends of colour are combined into a cohesive design. Greiman also explored the application of video imagery to print graphics.

The dynamic spatial arrangement and decorative geometric patterns that enliven many postmodern designs are seen in a 1983 poster designed by William Longhauser. The letters forming the last name of postmodern architect Michael Graves become fanciful edifices, which echo the patterns and textures found in Graves's buildings. As with much postmodern design, the result is strikingly original. Such a disruption of expected forms and grids was also apparent in the work of Japanese designer Igarashi Takenobu. After studying design fundamentals in Los Angeles, Igarashi began his independent design practice in Tokyo and used basic design elements-point, line, plane, grids, and isometric perspectives-as the building blocks of his work. This design vocabulary enabled him to invent imaginative solutions. His poster proposal (1982; Plate 2) for Expo '85, an international exposition of the dwelling and construction industry, turns the letters into structural forms pulled apart to reveal their inner structures. His ex-

perimentation with form fulfilled both an aesthetic and a

commercial purpose: the deconstructed forms clearly

make reference to his client, the construction industry.

Women and design Graphic design in developing nations. Late in the 20th century, increasingly accomplished graphic-design activity began to appear in developing nations. These advancements occurred because of a number of factors, including expanded access to professional education at local schools and abroad, the increased availability of computer and printing technology, and a growing base of industrial, cultural, and communications-industry clients. Designers from these nations often drew upon established design approaches from industrialized nations, but they commingled these lessons with local and national traditions in their quest for effective visual communications.

Design in the Middle Fast In the Middle East, graphic designers often applied new technology to depictions of traditional subject material conography. Throughout the late 20th century, Iranian graphic designer Ghobad Shiva evoked the colour palette, traditional Arabic calligraphy, and page layouts of ancient Persian manuscripts in his graphic work, which ranged from packaging to advertising and editorial design to stage sets. His poster (1984; Plate 2) celebrating the 800th anniversary of the birth of the Iranian poet Sadi, for example, displays his exquisite control of colour and his ability to create a vibrant image. These stylized illustrations continued the traditions of ancient Persian manuscripts, but within the context of a conte

Design in Africa Graphic design developed slowly in Africa after World War II, but by the end of the 20th century, a number of designers there received international acclaim for their individual creations. In Zimbabwe, filmmaker and designer Chaz Maviyane-Davies created films and graphic designs in the late 1980s and the 1990s. His posters, advertising designs, and magazine covers captured the spirit and life of his nation and often promoted social change. His interest in photographic and cinematic symbolism is apparent in a powerful library poster in which a young man has wings that are covered with printed matter from the library. Here, the image and social message—"Knowledge will set you free"—untie in a powerful visual statement.

Design in Latin America

Computer

graphics

In Latin America, professional graphic design similarly developed slowly after World War II. Eventually, in Argentina, and then in other nations, a graphic-design profession began to evolve. Latin American designers often built upon European and North American influences to develop distinctive communication designs. For example, a film festival poster (1992) by Venezuelan designer Santiago Pol utilizes clear symbolic forms within a highly sophisticated spatial configuration, both elements of Modernist graphic design. In this work, dynamic shapes signify three peppers, symbols that are redolent with regional symbolism; the central pepper is formed by the white, or negative, space between the red and green ones. These peppers are punctuated by film sprocket holes, which connect the image to the poster's theme of film. In this way, Pol's creative combination of symbols provides a distinct regional image for the film festival.

The digital revolution. Until the late 20th century, the graphic-design discipline had been based on handicraft processes layouts were drawn by hand in order to visualize a design; type was specified and ordered from a type-setter; and type proofs and photostats of images were assembled in position on heavy paper or board for photographic reproduction and platemaking. Over the course of the 1980s and early '90s, however, rapid advances in digital computer hardware and software radically altered

graphic design.

Software for Apple Computer's 1984 Macintosh computer, such as the MacPaint's program by programmer Bill Adkinson and graphic designer Susan Kare, had a revolutionary human interface. Tool icons controlled by a mouse or graphics tablet enabled designers and artists to use computer graphics in an intuitive manner. The Postsript's page-description language from Adobe Systems, Inc., enabled pages of type and images to be assembled into graphic ic designs on screen. By the mid-1990s, the transition of graphic design from a drafting-table activity to an on-screen computer activity was virtually complete.

Digital computers placed typesetting tools into the hands of individual designers, and so a period of experimentation occurred in the design of new and unusual typefaces and page layouts. Type and images were layered, fragmented, and dismembered; type columns were overlapped and run at very long or short line lengths; and the sizes, weights, and typefaces were often changed within single headlines, columns, and words. Much of this research took place in design education at art schools and universities. American designer David Carson—art director of Beach Culture magazine in 1989–91 (Plate 2), Surfer in 1991–92, and Ray Gum magazine in 1992–6—captured the imagination of a youthful audience by taking such an experimental approach into publication design.

Rapid advances in on-screen software also enabled designers to make elements transparent; to stretch, scale, and bend elements; to layer type and images in space, and to combine imagery into complex montages. For example, in a United States postage stamp from 1998, designers Ethel Kessler and Greg Berger digitally montaged John Singer Sargent's portrait of Frederick Law Olmsted with a photograph of New York's Central Park, a site plan, and botanical art to commemorate the landscape architect. Together these images evoke a rich expression of Olmsted's life and work.

The digital revolution in graphic design was followed quickly by public access to the Internet. A whole new area of graphic-design activity mushroomed in the mid-1990s when Internet commerce became a growing sector of the global economy, causing organizations and businesses to scramble to establish Web sites. Designing a Web site involves the layout of screens of information rather than of pages, but approaches to the use of type, images, and colour are similar to those used for print. Web design, however, requires a host of new considerations, including designing for navigation through the site and for using hypertext links to jump to additional information. An example of strong Web design is the Herman Miller for the Home Web site, designed by BBK Studio in 1998. These designers created a strong visual identity, effective navigation, and informational clarity. Attributes that added to the effectiveness of this Web site included a consistent colour palette, an informative use of pictures of products, and a scrolling montage of products.

Because of the international appeal and reach of the Internet, the graphic-design profession is becoming increasingly global in scope. Moreover, the integration of motion graphics, animation, video feeds, and music into Web-site design has brought about the merging of traditional print and broadcast media. As kinetic media expand from motion pictures and basic television to scores of cable-television channels, video games, and animated Web sites, motion graphics are becoming an increasingly important

area of graphic design.

In the 21st century, graphic design is ubiquitous; it is a major component of complex print and electronic information systems. It permeates contemporary society, delivering information, product identification, entertainment, and persuasive messages. The relentless advance of technology has changed dramatically the way graphic designs are created and distributed to a mass audience. However, the fundamental role of the graphic designer—giving expressive form and clarity of content to communicative messages—remains the same. (P.B.M.)

ravitation is a universal force of attraction acting between all matter. It is by far the weakest known force in nature and thus plays no role in determining the internal properties of everyday matter. Due to its long reach and universality, however, gravity shapes the structure and evolution of stars, galaxies, and the entire universe. The trajectories of bodies in the solar system are determined by the laws of gravity, while on Earth all bodies have a weight, or downward force of gravity, proportional to their mass, which the Earth's mass exerts on them. Gravity is measured by the acceleration that it gives to freely falling objects. At the Earth's surface, the acceleration of gravity is about 98. metres (32 feet) per second per second. Thus, for every second an object is in free fall, its speed increases by about 98. metres (32 feet) per second its speed increases by about 98. metres (32 feet) per second.

The works of Isaac Newton and Albert Einstein dominate the development of gravitational theory. Newton's classical theory of gravitational force held sway from his Principia, published in 1687, until Einstein's work in the early 20th century. Even today, Newton's theory is of sufficient accuracy for all but the most precise applications. Einstein's modern field theory of general relativity predicts only minute quantitative differences from the Newtonian theory except in a few special cases. The major significance of Einstein's theory is its radical conceptual departure from classical theory and its implications for further growth in physical thought.

DEVELOPMENT OF GRAVITATIONAL THEORY

Early concepts. Until Newton's findings, it was not realized that both the movement of celestial bodies and the free fall of objects on Earth are determined by the same force. The classical Greek philosophers, for example, did not consider the celestial bodies to be affected by gravity because the bodies were observed to follow perpetually repeating, non-descending trajectories in the sky. Thus, Aristotle considered that each heavenly body followed a particular "natural" motion, unaffected by external causes or agents. Aristotle also believed that massive earthly objects possess a natural tendency to move toward the Earth's centre. These ideas and two other Aristotelian viewpoints prevailed for centuries: that a body moving at constant speed requires a continuous force acting on it and that force must be applied by contact rather than interaction at a distance. These views impeded the understanding of the principles of motion and precluded the development of ideas about universal gravitation. During the 16th and early 17th centuries, however, several scientific contributions to the problem of earthly and celestial motion set the stage for Newton's later gravitational theory.

The 17th-century German astronomer Johannes Kepler accepted the Copernican perspective in which the planets orbit the Sun rather than the Earth. Using the improved measurements of planetary movements made by the Danish astronomer Tycho Brahe during the 16th century, Kepler described the planetary orbits with simple geometric and arithmetic relations. Kepler's three quantitative laws of planetary motion are: (1) the planets describe elliptic orbits, of which the Sun occupies one focus (a focus is one of two points inside an ellipse; rays coming from one of the points bounce off any side of the ellipse and go through the other focus); (2) the line joining a planet to the Sun sweeps out equal areas in equal time; and (3) the square of the period of revolution of a planet is proportional to the cube of its average distance from the Sun. During this same period the Italian astronomer and physicist Galileo made progress in understanding "natural" motion and simple accelerated motion for earthly objects. He realized

that bodies that are uninfluenced by forces continue indefinitely to move and that force is necessary to change motion, not to maintain constant motion. In studying how objects fall toward the Earth, Galileo discovered that the motion is one of constant acceleration. He was able to show that the distance a falling body travels from rest in this way varies as the square of the time. As noted above, the acceleration due to gravity at the surface of the Earth is about 9.8 metres per second per second.

Newton's law of gravity. Newton discovered the relationship between the motion of the Moon and the motion of any falling body on Earth. His gravitational theory explained Kepler's laws and established the modern quantitative science of gravitation. Newton assumed the presence of an attractive force between all massive bodies, one which does not require bodily contact and acts at a distance. By invoking his law of inertia (bodies not acted upon by a force move at constant speed in a straight line). Newton concluded that a force exerted by the Earth on the Moon is needed to keep it in a circular motion about the Earth rather than moving in a straight line. He realized that this force could be, at long range, the same as the force with which the Earth pulls objects on its surface downward. When Newton discovered that the acceleration of the Moon is 1/3,600 smaller than the acceleration at the surface of the Earth, he related the number 3,600 to the radius of the Earth squared. He calculated that the circular orbital motion of radius R and period T requires a constant inward acceleration A equal to the product of $4\pi^2$ and the ratio of the radius to the square of the time:

$$A = \frac{4\pi^2 R}{T^2}.$$
 (1)

Newton applied his results to the Moon's orbit, which has a period of 27.3 days and a radius of about 384,000 kilometres (approximately 60 Earth radii). He found the Moon's inward acceleration in its orbit to be 0.0027 metre per second per second, the same as ("\o'o)" of the acceleration of a falling object at the surface of the Earth. Because Newton could thus relate the two accelerations to

Aristotle's views

Kepler's laws of planetary motion Newton saw that the gravitational force between bodies must depend on the masses of the bodies. Since a body of mass M experiencing a force F accelerates at a rate F/M, a force of gravity proportional to M would be consistent with Galileo's observation that all bodies accelerate under gravity toward the Earth at the same rate. In Newton's equation, F_{12} is the magnitude of the gravitational force acting between masses M, and M_2 separated by distance T_{12} . The force equals the product of these masses and of G, a universal constant, divided by the square of the distance.

The universal constant G

$$F_{12} = \frac{GM_1M_2}{r_{12}^2}$$
 (2)

The constant G is a quantity with the physical dimensions (length) $\frac{1}{mass}$ (time) $\frac{1}{s}$; its numerical value depends on the physical units of length, mass, and time used. (G is discussed more fully in subsequent sections.)

The force acts in the direction of the line joining the two bodies and so is represented naturally as a vector, F. If r is the vector separation of the bodies, then

$$F = \frac{GM_1M_2r}{r^3}. (3)$$

In this expression, the factor r/r^3 acts in the direction of r and is numerically equal to $1/r^2$.

The attractive force of a number of bodies of masses M_1 on a body of mass M is

$$F = \frac{GM \sum_{i} M_{i} r_{i}}{r^{3}},$$

where L, means that the vector forces due to all the attracting bodies must be added together. This is Newton's gravitational law essentially in its original form. A simpler expression, equation (5), gives the surface acceleration on Earth. Setting a mass equal to the Earth's mass M_E and the distance equal to the Earth's radius r_E, the downward acceleration of a body at the surface g is equal to the product of the universal gravitational constant and the mass of the Earth divided by the square of the radius:

$$g = \frac{GM_{\rm E}}{r_{\rm E}^2}.$$
 (5)

Weight and mass The weight W of the body can be measured by the equal and opposite force necessary to prevent the downward acceleration; this is M_{γ} . The same body placed on the surface of the Moon has the same mass, but, as the Moon has a mass of about $^{1/8}$ times that of the Earth and a radius of just 0.27 that of the Earth, the body on the lunar surface has a weight of only $^{1/6}$ its Earth weight, as the U.S. Apollo astronauts demonstrated. Passengers and instruments in orbiting satellites, where no force prevents the free fall of the satellites in the gravitational field, experience weightless conditions even though their masses remain the same as on Earth

Equations (1) and (2) above can be used to derive Kepler's third law for the case of circular planetary orbits. By using the expression for the acceleration A in equation (1) for the force of gravity for the planet GM_pM_d/R^2 divided by the planet's mass M_p , the following equation, in which M_s is the mass of the Sun, is obtained:

$$\frac{GM_{\rm S}}{R^2} = \frac{4\pi^2 R}{T^2}$$

Ot

$$R^3 = \left(\frac{GM_S}{4\pi^2}\right)T^2. \tag{6}$$

Newton was able to show that all three of Kepler's observationally derived laws follow mathematically from the assumption of his own laws of motion and gravity. In all observations of the motion of a celestial body, only the product of G and the mass can be found. Newton first estimated the magnitude of G by assuming the Earth's average mass density to be about 5.5 times that of water (somewhat greater than the Earth's surface rock density) and by calculating the Earth's mass from this. Then, taking M_F and Γ_F as the Earth's mass and radius, respectively, the value of G was

$$G = \frac{gr_{\varepsilon}^2}{M_{\tau}},$$
 (7)

which numerically comes close to the accepted value of $6.6726 \times 10^{-11} \text{ m}^3\text{s}^{-2}/\text{kg}^{-1}$, first directly measured by a Cavendish balance experiment (see below).

Comparing equation (5) above for the Earth's surface acceleration g with the R^3/T^2 ratio for the planets, a formula for the ratio of the Sun's mass, $M_{\rm E}$, to Earth's mass, $M_{\rm E}$ was obtained in terms of known quantities, $R_{\rm E}$ being the radius of the Earth's orbit.

$$\frac{M_{\rm S}}{M_{\rm E}} = \frac{4\pi^2 R_{\rm E}^3}{g T_{\rm E}^2 r_{\rm E}^2} \cong 325,000. \tag{8}$$

Using observations of the motion of the moons of Jupiter discovered by Galileo, Newton determined that Jupiter was 318 times more massive than the Earth but only 1/4 as dense, having a radius 11 times larger than the Earth.

When two celestial bodies of comparable mass interact gravitationally, both orbit about a fixed point (the centre of mass of the two bodies). This point lies between the bodies on the line joining them at a position such that the distances to each body multiplied by each body's mass are equal. Thus, the Earth and the Moon move in an orbit about their common centre of mass. This motion of the Earth has two observable consequences. First, the direction of the Sun as seen from the Earth relative to the very distant stars varies each month by about 12 arc seconds in addition to the Sun's annual motion. Second, the line-ofsight velocity from the Earth to a freely moving spacecraft varies each month by 2.04 metres per second according to very accurate data obtained from radio tracking. From these results the Moon is found to have a mass 1/81 times that of the Earth. With slight modifications Kepler's laws remain valid for systems of two comparable masses; the foci of the elliptical orbits are the two-body centre-ofmass positions, and, putting $M_1 + M_2$ instead of M_5 in the expression of Kepler's third law, equation (6) above, the third law reads:

$$R^{3} = \frac{G(M_{1} + M_{2})}{4 - 2} T^{2}.$$
 (9)

This agrees with equation (6) when one body is so small that its mass can be neglected. The rescaled formula can be used to determine the separate masses of binary stars (pairs of stars orbiting around each other) that are a known distance from the solar system. Equation (9) determines the sum of the masses; and, if R_1 and R_2 are the distances of the individual stars from the centre of mass, the ratio of the distances must balance the inverse ratio of the masses, and the sum of the distances is the total distance R. In symbols.

$$\frac{R_1}{R_2} = \frac{M_2}{M_1}; R_1 + R_2 = R. \tag{10}$$

These relations are sufficient to determine the individual masses. Observations of the orbital motion of double stars, of the dynamic motion of stars collectively moving within their galaxies, and of the motion of the galaxies themselves verify that Newton's law of gravity is valid to a high degree of accuracy throughout the visible universe.

Ocean tides, phenomena that mystified thinkers for centuries, were also shown by Newton to be a consequence of the universal law of gravitation, although the details of the complicated phenomena were not understood until comparatively recently. They are caused specifically by the gravitational pull of the Moon and, to a lesser extent, of the Sun (See Oceans): Tide-generating forces).

It was already known in Newton's day that the Moon does not move in a simple Keplerian orbit. Later, more accurate observations of the planets also showed discrepInteraction among celestial bodies

Poisson's

equation

ancies from Kepler's laws. The motion of the Moon is particularly complex; however, apart from a long-term acceleration due to tides on the Earth, it can be accounted for by the gravitational attraction of the Sun, the Earth, and the other planets. In addition, the gravitational attraction of the planets for each other explains almost all the features of their motions. The exceptions are nonetheless important. Uranus, the seventh planet from the Sun, was observed to undergo variations in its motion that could not be explained by perturbations from Saturn, Jupiter, and the other planets. Two 19th-century astronomers, John Couch Adams of Britain and Urbain-Jean-Joseph Le Verrier of France, independently assumed the presence of an unseen eighth planet that could produce the observed discrepancies. They calculated its position within a degree of which the planet Neptune was discovered in 1846. Measurements of the motion of the innermost planet, Mercury, over an extended period led astronomers to conclude that the major axis of this planet's elliptical orbit precesses in space at a rate 43 arc seconds per century faster than could be accounted for from perturbations of the other planets. In this case, however, no other bodies could be found that could produce this discrepancy, and very slight modification of Newton's law of gravitation seemed to be needed. Einstein's theory of relativity precisely predicts this observed behaviour of Mercury's orbit (see RELATIVITY).

Potential theory. For irregular, nonspherical mass distributions in three dimensions, Newton's original vector equation (4, above) is inefficient, though theoretically it could be used for finding the resulting gravitational field. The main progress in classical gravitational theory after Newton was the introduction of potential theory, which is the mathematical representation of gravitational fields. It allows practical as well as theoretical investigation of the gravitational variations in space and of the anomalies due to the irregularities and shape deformations of the Earth.

Potential theory led to the following elegant formulation: the gravitational acceleration, g a function of position R, g(R), at any point in space is given from a function, Φ . called the gravitational potential, by means of a generalization of the operation of differentiation.

$$g(R) = \frac{\partial \Phi}{\partial x} i + \frac{\partial \Phi}{\partial y} j + \frac{\partial \Phi}{\partial z} k,$$
 (11)

in which *i*, *j*, and *k* stand for unit basis vectors in a threedimensional Cartesian coordinate system. The potential and therefore *g* are determined by an equation discovered by the French mathematician Siméon-Denis Poisson:

$$\left(\frac{\partial^{2}}{\partial x^{2}} + \frac{\partial^{2}}{\partial y^{2}} + \frac{\partial^{2}}{\partial z^{2}}\right) \Phi(R) = -4\pi G \rho(R). \quad (12)$$

The significance of this approach is that Poisson's equation can be solved under rather general conditions, which is not the case with Newton's equation. When mass density ρ is nonzero, the solution is expressed as a definite integral:

$$\Phi(R) = G \int \frac{\rho(R')dR'}{|R - R'|}.$$
 (13)

When $\rho = 0$ (in particular, outside the Earth), Poisson's equation reduces to the simpler equation of Laplace.

The appropriate coordinates for the region outside the nearly spherical Earth are spherical polar coordinates: R, the distance from the centre of the Earth; \(\theta\), the colatitude measured from the North Pole; and the longitude measured from Greenwich. The solutions are series of powers of trigonometric functions of colatitude and longitude, known as spherical harmonics; the first terms are:

$$\Phi(R) = \frac{GM_E}{R} \left[1 - J_2 \left(\frac{R_E}{R} \right)^2 \frac{3 \cos^2 \theta - 1}{2} - J_3 \left(\frac{R_E}{R} \right)^3 \frac{5 \cos^3 \theta - 3 \cos \theta}{2} + \dots \right],$$
(14)

The constants J_2 , J_3 , and so forth are determined by the detailed mass distribution of the Earth; and, since Newton showed that for a spherical body all the J_a are zero, they must measure the deformation of the Earth from a spher-

ical shape. J_2 measures the magnitude of the Earth's rotational equatorial bulge, J_1 measures a slight pear-shaped deformation of the Earth, and so on. From observations of perturbations on satellite orbits, the parameters J_2 and J_3 have been found to be $1.082.7 \times 10^{-6}$ and -2.4×10^{-6} , respectively.

Much the largest variation in the potential around the Earth is due to the equatorial bulge, and there is a corresponding increase in the value of gravity on the surface of the Earth from the Equator to the poles. Newton was the first to give a theory of the equatorial bulge; among the data he used to estimate its size were some pendulum measurements made at Saint Helena by the English astronomer Edmond Halley (see below). Many more harmonic components have been estimated from observations of the orbits of artificial satellites close to Earth; the sum of the most important of them can be shown by contours on a map of Earth's surface at sea level, where the potential is a constant (see Figure 1).

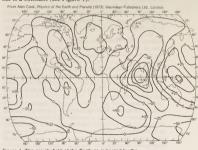

Figure 1: The gravity field of the Earth as indicated by the shape of the sea-level surface; contours (in metres) of deviations from a spheroid of flattening 1/298.25.

Effects of local mass differences: Spherical harmonics are the natural way of expressing the large-scale variations of potential that arise from the deep structure of the Earth. However, spherical harmonics are not suitable for local variations due to more superficial structures. Not long after Newton's time, it was found that the gravity on top of large mountains is less than expected on the basis of their visible mass. The idea of isostasy was developed, according to which the unexpectedly low acceleration of gravity on a mountain is caused by low-density rock 30 to 100 kilometres underground, which buoys up the mountain. Correspondingly, the unexpectedly high force of gravity on ocean surfaces is explained by dense rock 30 to 100 kilometres beneath the ocean bottom.

kilometres beneath the ocean bottom.

Portable gravimeters, which can detect variations of one part in 10° in the gravitational force, are in wide use today for mineral and oil prospecting. Unusual underground deposits reveal their presence by producing local gravitational variations (see below).

Weighing the Earth. Because the mass of the Earth can be calculated from g and the planet's radius if G is known, the English physicist-chemist Henry Cavendish and other early experimenters termed their work "weighing the Earth." The mass of the Earth is about 5.98 × 10³⁴ kilograms, while the mean densities of the Earth, Sun, and Moon are, respectively, 5.52, 1.43, and 3.3 times that of water.

ACCELERATION AROUND THE EARTH, MOON, AND PLANETS
The value of the attraction of gravity or of the potential is
determined by the distribution of matter within the Earth
or other celestial body. In turn, the distribution of matter
determines the shape of the surface on which the potential
is constant (Figure 1). Measurements of gravity and the
potential are thus essential both to geodesy, which is the
study of the shape of the Earth, and to geophysics, the

Concept of isostasy

Variations in g. Changes due to location. The acceleration g varies by about 1/2 of 1 percent with position on the Earth's surface, from about 9.78 metres per second per second at the Equator to approximately 9.83 metres per second per second at the poles. This variation stems chiefly from the rotation of the Earth, as part of the Earth's pull is balanced by keeping objects rotating with the Earth instead of flying tangentially off into space (as mud does off a spinning wheel). This effect is also responsible for the bulge of the Earth at the Equator and the slight flattening at the poles. The distance to the centre of the Earth, therefore, increases with the bulge from the poles to the Equator, and consequently the value of g, which for a spherical Earth of radius r_E and mass M_E is given simply by $GM_{\rm F}/r_{\rm F}^2$, is less toward the Equator.

In addition to this broad-scale variation, local variations of a few parts in 106 or smaller are caused by variations in the density of the Earth's crust as well as height above

Changes with time. At any one place, g varies with time as the result of the changing positions of the Sun and the Moon-namely, the tidal variation. For most purposes it is necessary to know only the variation of gravity with time at a fixed place or the changes of gravity from place to place; then, the tidal variation can be removed. Accordingly, almost all gravity measurements are relative measurements of the differences from place to place or from time to time.

Measurements of g. Unit of gravity. Because gravity changes are far less than one metre per second per second, it is convenient to have a smaller unit for relative measurements. The gal (after Galileo) has been adopted for this purpose; one gal equals 1/100 of one metre per second per second. The unit most commonly used is the milligal (mgal), which equals 10-5 metre per second per secondi.e., 1/1,000,000 of the average value of g.

Absolute measurements. Two basic ways of making absolute measurements of gravity have been devised: timing the free-fall of an object and timing the motion under gravity of a body constrained in some way, almost always by a pendulum. In 1817 the English physicist Henry Kater, building on the work of the German astronomer Friedrich Wilhelm Bessel, was the first to use a reversible pendulum to make absolute measurements of g. If the periods of swing of a rigid pendulum about two alternative points of support are the same, then the separation of those two points is equal to the length of the equivalent simple pendulum of the same period. By careful construction, Kater was able to measure the separation very accurately. The so-called reversible pendulum was used for absolute measurements of gravity from Kater's day until the 1950s. Since that time, electronic instruments have enabled investigators to measure with high precision the half-second time of free-fall of a body (from rest) through one metre. It is also possible to make extremely accurate measurements using light interference. Consequently, direct measurements of free-fall have replaced the pendulum for absolute measurements of gravity. Nowadays lasers serve as light sources for interferometers; the falling object, in effect, becomes a retroreflector that returns a beam of light back upon itself. Transportable versions of such apparatus have been used in different locations to establish a basis for measuring differences of gravity over the entire Earth. The accuracy attainable in these measurements is about one part in 108

Relative measurements. From the time of Newton, measurements of differences of gravity (strictly, the ratios of values of gravity) were made by timing the same pendulum at different places. During the 1930s, however, static gravimeters replaced pendulums for local measurements over small ranges of gravity. Today, free-fall measurements have rendered the pendulum obsolete for all purposes,

Spring gravimeters balance the force of gravity mg on a mass m in the gravity field to be measured, against the elastic force of the spring, using either electronic or me- Spring chanical means to achieve high sensitivity. Vibrating string gravity gravimeters in which the string's vibration frequency is determined by g also have been developed. A device of this type was employed by the Apollo 17 astronauts on the Moon to conduct a gravity survey of their landing site. Another relatively recent development is the superconducting gravimeter, an instrument in which the position of a magnetically levitated superconducting sphere is sensed to provide a measure of g.

Modern gravimeters may have sensitivities better than 0.005 milligal, the standard deviation of observations in exploration surveys being on the order of 0.01-0.02 milligal. Differences in gravity measured with gravimeters are obtained in quite arbitrary units-divisions on a graduated dial, for example. The relation between these units and milligals can only be determined by reading the instrument at a number of points where g is known as a result of absolute or relative pendulum measurements. Further, because an instrument will not have a completely linear response, known points must cover the entire range of gravity over which the gravimeter is to be used.

Gravimetric surveys. Recently, by combining all available absolute and relative measurements, it has been possible to obtain the most probable gravity values at a large number of sites to a high degree of accuracy. The culmination of gravimetric work begun in the 1960s has been a worldwide gravity reference system having an accuracy of at least one part in 107 (0.1 milligal or better).

Since g is an acceleration, the problem of its measurement from a vehicle that is moving and therefore unavoidably accelerating relative to the Earth raises a number of fundamental problems. Pendulum, vibrating-string, and springgravimeter observations have been made from submarines; using gyrostabilized platforms, relative gravity measurements with accuracies approaching a few milligals have been and are being made from surface ships. Experimental measurements with various gravity sensors on fixed-wing aircraft as well as on helicopters have been carried out.

Geophysics. The value of gravity measured at the terrestrial surface is the result of (1) the gravitational attraction of the Earth as a whole, (2) centrifugal force caused by the Earth's rotation, (3) elevation, (4) unbalanced attractions caused by surface topography, (5) tidal variations, and (6) unbalanced attractions caused by irregularities in underground density distributions. Most geophysical surveys are aimed at separating out the last of these in order to interpret the geologic structure. It is therefore necessary to make proper allowance for the other factors.

The first two factors imply a variation of gravity with latitude that can be calculated for an assumed shape for the Earth. The third factor, which is the decrease in gravity with elevation, due to increased distance from the centre of the Earth, amounts to -0.3086 milligal per metre. This value, however, assumes that material of zero density occupies the whole space between the point of observation and sea level, and it is therefore termed the free-air correction factor. In practice, the mass of rock material that occupies part or all of this space must be considered. In an area where the topography is reasonably flat, this is usually calculated by assuming the presence of an infinite slab of thickness equal to the height of the station, h, and having an appropriate density σ ; its value is +0.04185 σh milligal per metre. This is commonly called the Bouguer correction factor.

Terrain or topographic corrections also can be applied to allow for the attractions due to surface relief if the densities of surface rocks are known. Tidal effects (the amplitudes are less than 0.3 milligal) can be calculated and allowed for. (Ja.F./A.H.C.)

The Moon and the planets. It was noted above that the large-scale features of the Earth's potential are obtained from observations of Earth-orbiting satellites and may be shown as a map of the sea-level surface (Figure 1). Although the Apollo astronauts used a gravimeter at their lunar landing site, most scientific knowledge about the Moon's gravitational attraction has been derived from observations of its effects on the accelerations of spacecraft. Information about the gravitational force of various plan-

The work

of Henry

Kater

The freeair and Bouguer corrections

force law

ets has been obtained in this way as well. Radio tracking makes it possible to estimate the accelerations of spacecraft very accurately, and the results can be expressed either as terms in a series of spherical harmonics or as the variation of gravity over the surface. As in the case of the Earth, spherical harmonics are more effective for studying gross structure, while the variation of gravity is more useful for local features. Because spacecraft must descend close to the surface to detect local gravity variations, only data for the Moon and Mars have been obtained so far.

The Moon's polar flattening is much less than that of the Earth, while its equator is far more elliptical. There are also large, more local irregularities from visible and concealed structures. Mars also exhibits some large local variations, while the equatorial bulges of Mercury and Venus are very slight. By contrast, the major planets, all of which rotate quite fast, have large equatorial bulges, and their gravity is dominated by a large increase from equator to pole. These results are crucial to understanding the internal properties of the planets.

GRAVITATIONAL THEORY AND OTHER ASPECTS OF PHYSICAL THEORY

Special

electro-

magnetic

field theory

and

relativity

The Newtonian theory of gravity is based on an assumed force acting between all pairs of bodies— ℓe , an action at a distance. When a mass moves, the force acting on other masses has been considered to adjust instantaneously to the new location of the displaced mass. Special relativity theory states that no physical signal travels faster than

masses has been considered to adjust instantaneously to the new location of the displaced mass. Special relativity theory states that no physical signal travels faster than the speed of light and that all signals travel at this speed through empty space. This theory, with the field theory of electrical and magnetic phenomena, has met such empirical success that most modern gravitational theories are constructed as field theories consistent with the principles of special relativity. In a field theory the gravitational force between bodies is formed by a two-step process: (1) One body produces a gravitational field that permeates all surrounding space but has weaker strength farther from its source. A second body in that space is then acted upon by this field and experiences a force. (2) The Newtonian force of reaction is then viewed as the response of the first body to the gravitational field produced by the second body, there being at all points in space a superposition of gravitational fields due to all the bodies in it.

Field theories of gravitation. The possibility that gravitation might be linked with the other forces of nature in a unified theory of forces greatly increased interest in gravitational field theories during the 1970s and '80s. The first such unified field theory, and so far the only successful one, is that of physicists Abdus Salam of Pakistan and Steven Weinberg and Sheldon L. Glashow of the United States, who proposed that the electromagnetic forces and the weak force responsible for beta decay are different manifestations of one and the same basic interaction. Physicists now are actively seeking other possible unified combinations. Because the gravitational force is exceedingly weak compared with all others and because it seems to be independent of all physical properties except mass, the unification of gravitation with the other forces will be the most difficult to achieve. This challenge has provided a tremendous impetus to experimental investigations to determine whether there may be some failure of the apparent independence.

The prime example of a field theory is Einstein's general relativity, according to which the acceleration due to gravity is a purely geometric consequence of the properties of space-time in the neighbourhood of attracting masses (Aswill be seen below, general relativity makes certain specific predictions that are borne out well by observation.) In a whole class of more general theories, these and other effects not predicted by simple Newtonian theory are characterized by free parameters; such formulations are called parameterized post-Newtonian (PPN) theories. There is now considerable experimental and observational evidence for limits to the parameters, So far, no deviation from general relativity has been demonstrated convincingly.

Field theories of gravity predict specific corrections to the Newtonian force law, the corrections taking two basic forms: (1) When matter is in motion, additional gravitational fields (analogous to the magnetic fields produced by moving electric charges) are produced; also, moving hodies interact with gravitational fields in a motion-dependent way. (2) Unlike electromagnetic field theory, in which two or more electric or magnetic fields superimpose by simple addition to give the total fields, in gravitational field theory nonlinear fields proportional to the second and higher power of the source masses are generated, and gravitational fields proportional to the product of different masses are created. Gravitational fields themselves become sources for additional gravitational fields. Examples of some of these effects are shown below. The acceleration, A, of a moving particle of negligible mass that interacts with a mass, M, which is at rest, is given in the following formula, derived from Einstein's gravitational theory. The expression for A now has, as well as the Newtonian expression from equation (1), further terms in higher powers of GM/R^2 —that is, in G^2M^2/R^4 . As elsewhere, V is the particle's velocity vector. A is its acceleration vector. R is the vector from the mass M, and c is the speed of light. When written out, the sum is

$$A = -\frac{GMR}{R^3} + 2\frac{G^2M^2R}{c^2R^2} - \frac{3}{2}\frac{GMR}{R^3} {V^2 \choose c^2}$$

$$-\frac{V \cdot AV}{c^2} - \frac{1}{2}\frac{V^2}{c^2}A + \dots$$
(15)

This expression gives only the first post-Newtonian corrections; terms of higher power in 1/c are neglected. For planetary motion in the solar system the 1/e terms are smaller than Newton's acceleration term by at least a factor of 10⁻⁴, but some of the consequences of these correction terms are measurable and important tests of Einstein's theory. It should be pointed out that prediction of new observable gravitational effects requires particular care; Einstein's pioneer work in gravity has shown that gravitational fields affect the basic measuring instruments of experimental physics—clocks, rulers, light rays—with which any experimental result in physics is established. Some of these effects are listed below:

1. The rate at which clocks run is reduced by proximity of massive bodies; *i.e.*, clocks near the Sun will run slowly compared with identical clocks farther away from it.

2. In the presence of gravitational fields the spatial structure of physical objects is no longer describable precisely by Euclidean geometry; for example, in the arrangement of three rigid rulers to form a triangle, the sum of the subtended angles will not equal 180°. A more general type of geometry, Riemannian geometry, seems required to describe the spatial structure of matter in the presence of gravitational fields.

3. Light rays do not travel in straight lines, the rays being deflected by gravitational fields. To distant observers the light-propagation speed is observed to be reduced near massive bodies.

Gravitational fields and general theory of relativity. In Einstein's general theory of relativity the physical consequences of gravitational fields are stated in the following way, Space-time is a four-dimensional non-Fuclidean continuum, the curvature of space-time's Riemannian geometry being produced by or related to the world's matter distribution. Particles and light rays travel along the geodesics (shortest paths) of this four-dimensional geometric world.

There are two principal consequences of the geometric view of gravitation: (1) the accelerations of bodies depend only on their masses and not on their chemical or nuclear constitution, and (2) the path of a body or of light in the neighbourhood of a massive body (the Sun, for example) is slightly different from that predicted by Newton's theory. The first is the weak principle of equivalence. Newton himself performed experiments with pendulums that demonstrated the principle to better than one part in 1,000 for a variety of materials, and, at the beginning of the 20th century, the Hungarian physicist Roland, Baron von Eotwos, showed that different materials accelerate in the Earth's field at the same rate to within one part in 10°, More recent experiments have shown the equality of

Weak principle of equiva-

lence

accelerations in the field of the Sun to within one part in 10¹¹. Newtonian theory is in accord with these results because of the postulate that gravitational force is proportional to a body's mass.

Inertial mass is a mass parameter giving the inertial resistance to acceleration of the body when responding to all types of force. Gravitational mass is determined by the strength of the gravitational force experienced by the body when in the gravitational field g. The Eötvös experiments, therefore, show that the ratio of gravitational and inertial mass is the same for different substances.

Einstein's special theory of relativity views inertial mass as a manifestation of all the forms of energy in a body according to his fundamental relationship $E=mc^2$, E being the total energy content of a body, m the inertial mass of the body, and c the speed of light. Dealing with gravitation, then, as a field phenomenon, the weak principle of equivalence indicates that all forms of nongravitational energy must identically couple to or interact with the gravitational field, because the various materials in nature possess different fractional amounts of nuclear, electrical, magnetic, and kinetic energies, yet they accelerate at identical rates

In the general theory of relativity the gravitational field also interacts with gravitational energy in the same manner as with other forms of energy, an example of that theory's universality not possessed by most other theories of gravitation.

The Sun has an appreciable fraction of internal gravitational energy, and the repetitions of the Edivõe seperiments during the 1970s with the Sun instead of the Earth as the attracting mass revealed that bodies accelerate at identical rates in the Sun's field as well as in that of the Earth. Extremely accurate laser measurements of the distance of the Moon from the Earth have made possible a further test of the weak principle of equivalence. The chemical constitutions of the Earth and the Moon are not the same, and so, if the principle did not hold, they might accelerate at different rates under the Sun's attraction. No such effect has been detected.

Newton's third dynamic law states that every force implies an equal and opposite reaction force. Modern field theories of force contain this principle by requiring every entity that is acted upon by a field to be also a source of the field. An experiment by the American physicist Lloyd Kreuzer established to a one-part-in-20,000 accuracy that different materials produce gravitational fields with a strength the same as that of gravitational fields acting upon them. In this experiment a sphere of solid material was moved through a liquid of identical weight density. The absence of a gravitational effect on a nearby Cavendish balance instrument during the sphere's motion is interpreted as showing that the two materials had equal

potency in producing a local gravitational-field anomaly. Other experiments have brought confirmation of Einstein's predictions to an accuracy of a few percent. Using the Mössbauer effect to monitor the nuclear reabsorption of resonant gamma radiation, a shift of wavelength of the radiation that traveled vertically tens of metres in the Earth's gravitational field was measured, and the slowing of clocks (in this case the nuclear vibrations are clocks as predicted by Einstein was confirmed to 1 percent precision. If ν and $\Delta\nu$ are clock frequency and change of frequency, respectively, h is the height difference between clocks in the gravitational field g. Then

$$\frac{\Delta v}{v} = -\frac{gh}{c^2}.$$
 (16)

For a height of 10 metres, there is only a one-part-in-10¹⁵ change in clock rates.

The paths of particles and light. The idea that light should be deflected by passing close to a massive body had been suggested by the British astronomer and geologist John Michel to the 18th century. However, Einstein's general relativity theory predicted twice as much deflection as Newtonian physics. Quick confirmation of Einstein's result came from measuring the direction of a star close to the Sun during an expedition led by the British astronomer Sir Arthur Stanley Eddington to observe the

solar eclipse of 1919. Optical determinations of the change of direction of a star are subject to many systematic errors. and far better confirmation of Einstein's general relativity theory has been obtained from measurements of a closely related effect-namely, the increase of the time taken by electromagnetic radiation along a path close to a massive body. In fact, both effects may be understood as due to a decrease in the speed of light near a massive object. Timing the round-trip travel time for radar pulses between the Earth and other inner planets or artificial satellites passing behind the Sun, experiments have confirmed to about 4 percent the prediction of an additional time delay. Δt . This additional time delay is given by the following formula, in which Me is the Sun's mass, R, and R, are the distances from the Sun to Earth and to the other reflecting body, and D is the distance of closest approach of the radar pulses to the Sun (In stands for natural logarithm);

$$\Delta t = \frac{4GM_S}{c^3} \ln \frac{4R_1R_2}{D^2}.$$
 (17)

The additional precession of the orbit of Mercury of 43 arc seconds per century (see above) was known before the development of the theory of general relativity. With radar measurements of the distances to the planets, similar anomalous precessions have been estimated for Venus and the Earth and have been found to agree with general relativity.

Gravitational radiation. An important consequence of field theories of gravitation is that the gravitational field itself can oscillate in the same way that an electromagnetic field can. Thus, if the masses that are the source of a field change with time, they may be expected to radiate energy through waves in the field. The radiation would be very weak, and, though some extremely sensitive instruments have been built in an effort to detect gravitational radiation, none has been observed with certainty so far. The principal sources are expected to be double stars in their regular motions and massive stars collapsing as supernovas. Even though no gravitational radiation has yet been detected on Earth, there are strong grounds for believing that it exists. One particular double star system has a pulsar as one of its components, and, from measurements of the Doppler shifts of the pulsar frequency, precise estimates of the period of the orbit show that the period is changing, corresponding to a decrease in the energy of the orbital motion. Gravitational radiation is the only known means by which this could happen

(K.L.N./A.H.C.)

SOME ASTRONOMICAL ASPECTS OF GRAVITATION

As stated above, studies of gravity enable researchers to determine the masses and densities of celestial bodies and thereby make it possible to investigate the physical constitutions of stars and planets. Because gravitation is a very weak force, however, its distinctive effects appear only when masses are extremely large. The idea that light might be attracted gravitationally had been suggested by the aforementioned John Michell and examined by the French mathematician and astronomer Pierre-Simon Laplace. Predictions by classical physics and general relativity that light passing close to the Sun might be deflected are described above. There are two further consequences for astronomy. Light from a distant object may pass close to objects other than the Sun and be deflected by them. In particular, they may be deflected by a massive galaxy. If some object is behind a massive galaxy, as seen from Earth, deflected light may reach the Earth by more than one path. Operating like a lens that focuses light along different paths, the gravity of the galaxy may make the object appear multiple; examples of such apparently double objects have been found.

Both Michell and Laplace pointed out that the attraction of a very dense object upon light might be so great that the light could never escape from the object, rendering it invisible. Such a phenomenon is a black hole. The relativistic theory of black holes has been thoroughly developed in recent years, and astronomers have conducted an intense search for them. One possible class of black holes comprises stars that have used up all their nuclear

Possible sources of gravitational radiation

The gravitational redshift

Black holes

Black holes from which no radiation is able to escape cannot be seen by their own light, but there may be observable secondary effects. If a black hole were one component of a double star, the orbital motion of the pair and the mass of the invisible member might be derived from the oscillatory motion of a visible companion. Because black holes attract matter, any gas in the vicinity of an object of this kind would fall into it and acquire, before vanishing into the hole, a high velocity and consequently a high temperature. The gas may become hot enough to produce X rays and gamma rays from around the hole. While there is still no definite proof, such a mechanism may be the origin of at least some powerful X-ray and radio astronomical sources, including those at the centres of galaxies and quasars (see cosmos: Black-hole model for active galactic nuclei). Only astronomical objects can be expected to be sources of detectable gravitational radiation. As already mentioned, gravitational radiation is probably responsible for secular changes in the orbits of some double stars, and so in the very long term it may have an effect on the stability of celestial objects. If and when gravitational radiation is detected, new astronomical phenomena will no doubt be discovered.

EXPERIMENTAL STUDY OF GRAVITATION

The essence of Newton's theory of gravitation is that the force between two bodies is proportional to the product of their masses and the inverse square of their separation and that the force depends on nothing else. With a small geometric modification, the same is true in general relativity. Newton himself tested his assumptions by experiment and observation. He made pendulum experiments to confirm the principle of equivalence and checked the inverse square law as applied to the periods and diameters of the orbits of the satellites of Jupiter and Saturn. During the latter part of the 19th century many experiments showed the force of gravity to be independent of temperature, electromagnetic fields, shielding by other matter, orientation of crystal axes, and other factors. The revival of such experiments during the 1970s was the result of theoretical attempts to relate gravitation to other forces of nature by showing that general relativity incompletely describes gravity. New experiments on the equivalence principle were performed, and experimental tests of the inverse square law were made in the laboratory. There also has been a continuing interest in the determination of the constant of gravitation. G. although it must be pointed out that G occupies a rather anomalous position among the other constants of physics. In the first place, the mass, M, of any celestial object cannot be determined independently of the gravitational attraction that it exerts. Thus, the combination GM, not the separate value of M, is the only meaningful property of a star, planet, or galaxy. Second, according to general relativity and the principle of equivalence. G does not depend on material properties but is in a sense a geometric factor. Hence, the determination of the constant of gravitation does not seem as essential as the measurement of quantities like the electronic charge or Planck's constant. It is also much less well determined experimentally than any of the other constants of physics. Experiments on gravitation are in fact very difficult, as

Experiments on gravitation are in fact very difficult, as a comparison of experiments on the inverse square law of electrostatics with those on gravitation will show. The electrostatic law has been established to within one part in 10% by using the fact that the field inside a closed conductor is zero when the inverse square law is in effect and then detecting any residual fields with very sensitive electronic devices. Gravitational forces have to be detected by mechanical means, most often the torsion balance, and, though the sensitivities of mechanical devices have been greatly improved, they are still far less sensitive than electronic equipment. Mechanical arrangements also preclude the use of a complete gravitational enclosure. Last, extraneous disturbances are relatively large because gravi-

tational forces are very small (something that Newton first pointed out). Thus, the inverse square law is established over laboratory distances to no better than one part in 104.

The inverse square law. The current interest in the inverse square law arises from two suggestions. First, the gravitational field itself might have a mass, in which case the constant of gravitation would change in an exponential manner from one value for small distances to a different one for large distances over a characteristic distance related to the mass of the field. Second, the observed field might be the superposition of two or more fields of different origin and different strengths, one of which might depend on chemical or nuclear constitution. Deviations from the inverse square law have been sought in three ways: (1) the law has been checked in the laboratory over distances up to about one metre, (2) the effective value of G for distances between 100 metres and one kilometre has been estimated from geophysical studies, and (3) there have been careful comparisons of the value of the attraction of the Earth as measured on the surface and as experienced by artificial satellites.

Search for deviations from the inverse square law

Early in the 1970s an experiment by the American physicist Daniel R. Long seemed to show deviation from the inverse square law at a range of about 0.1 metre. Long compared the maximum attractions of two rings upon a test mass hung from the arm of a torsion balance. The maximum attraction of a ring occurs at a particular point on the axis and is determined by the mass and dimensions of the ring. If the ring is moved until the force on the test mass is greatest, the distance between the test mass and the ring is not needed. Two later experiments over the same range showed no deviation from the inverse square law. In one, conducted by the American physicist Riley Newman and his colleagues, a test mass hung on a torsion balance was moved around in a long hollow cylinder. The cylinder approximates a complete gravitational enclosure and, allowing for a small correction because it is open at the ends, the force on the test mass should not depend on its location within the cylinder. No deviation from the inverse square law was found. In the other experiment, performed in Cambridge, Eng., by Y.T. Chen and associates, the attractions of two solid cylinders of different mass were balanced against a cylinder with a third mass so that only the separations of the cylinders had to be known; it was not necessary to know the distances of any from a test mass. Again no deviation of more than one part in 104 from the inverse square law was found. Other somewhat less sensitive experiments at ranges up to one metre or so also have failed to establish any greater deviation.

The geophysical tests go back to a method for the determination of the constant of gravitation that had been used in the 19th century, especially by the British astronomer Sir George Airy. Suppose the value of gravity, g, is measured at the top and bottom of a horizontal slab of rock of thickness t and density d. The values for the top and bottom will be different for two reasons. First, the top of the slab is t farther from the centre of the Earth, and so the measured value of gravity will be less by 2(t/R)g, where R is the radius of the Earth. Second, the slab itself attracts objects above and below it toward its centre: the difference between the downward and upward attractions of the slab is $4\pi Gtd$. Thus, a value of G may be estimated. Frank D. Stacey and his colleagues in Australia have made such measurements at the top and bottom of deep mine shafts and have claimed that there may be a real difference between their value of G and the best value from laboratory experiments. The difficulties lie in obtaining reliable samples of the density and in taking account of varying

densities at greater depths.

The absolute measurements of gravity described earlier, together with the comprehensive gravity surveys made over the surface of Earth, allow the mean value of gravity over the Earth to be estimated to about one part in 10°. The techniques of space research also have given the mean value of the radius of the Earth and the distances of artificial satellites to the same precision; thus, it has been possible to compare the value of gravity on the Earth with that acting on an artificial satellite. Agreement to about one part in 10° shows that, over distances from the surface

Geophysical tests of the inverse square law

The constant of gravitation as a geometric factor of the Earth to close satellite orbits, the inverse square law is followed.

It seems at present that all the most reliable experiments and observations reveal no deviation from the inverse square law, although there should possibly be further investigations on the geophysical scale.

The principle of equivalence. Experiments with ordinary pendulums test the principle of equivalence to no better than about one part in 105. Eötvös obtained much better discrimination with a torsion balance. His tests depended on comparing gravitational forces with inertial forces for masses of different composition. Eötvös set up a torsion balance to compare, for each of two masses the gravitational attraction of the Earth with the inertial forces due to the rotation of the Earth about its polar axis. His arrangement of the masses was not optimal, and he did not have the sensitive electronic means of control and reading that are now available. Nonetheless, Eötvös found that the weak equivalence principle (see above) was satisfied to within one part in 109 for a number of very different chemicals, some of which were quite exotic. His results were later confirmed by the Hungarian physicist J. Renner. Renner's work has been analyzed recently in great detail because of the suggestion that it could provide evidence for a new force. It seems that the uncertainties of the experiments hardly allow such analyses, however.

Eötvös suggested that the attraction of the Sun upon test masses could be compared with the inertial forces of the Earth's orbital motion about the Sun. He performed some experiments, verifying equivalence with an accuracy similar to that which he had obtained with his terrestrial experiments. The solar scheme has substantial experimental advantages, and the American physicist Robert H. Dicke and his colleagues, in a careful series of observations in the 1960s (employing up-to-date methods of servo control and observation), found that the weak equivalence principle held to about one part in 1011 for the attraction of the Sun on gold and aluminum (Figure 2). A later experiment, with very different experimental arrangements, by the Russian researcher Vladimir Braginski, gave a limit of about one part in 1012 for platinum and aluminum.

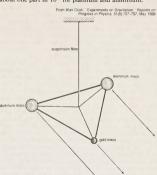

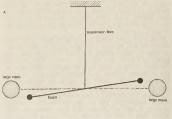

Figure 2: Experiment comparing the inertial and gravitational accelerations of gold and aluminum attracted by the Sun.

The constant of gravitation. The constant of gravitation has been measured in three ways: (1) the comparison of the pull of a large natural mass with that of the Earth, (2) the measurement with a laboratory balance of the attraction of the Earth upon a test mass, and (3) the direct measurement of the force between two masses in the laboratory. The first approach was suggested by Newton; the earliest observations were made in 1774 by the British astronomer Nevil Maskelyne on the mountain of Schiehallion in Scotland. The subsequent work of Airy

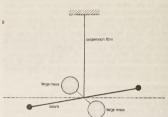

Figure 3: Principle of the determination of G from the change in period of a torsion balance with attracting masses in different positions

From Alan Cook, "Exper 51(5):707-757, May 1988 ts on Gravitation." Reports on Progress in Physics

and more recent developments are noted above. The laboratory balance method was developed in large part by the British physicist John Henry Poynting during the late 1800s, but all the most recent work has involved the use of the torsion balance in some form or other for the direct laboratory measurement of the force between two bodies. The torsion balance was devised by Michell, who died before he could use it to measure G. Cavendish adapted Michell's design to make the first reliable measurement of G in 1798; his results were so good in fact that it is only in comparatively recent times that clearly better results have been obtained. Cavendish himself measured the change in deflection of the balance when attracting masses were moved from one side to the other of the torsion beam. The method of deflection was analyzed most thoroughly in the late 1800s by Sir Charles Vernon Boys, an English physicist, who carried it to its highest development using a delicate suspension fibre of fused silica for the pendulum.

The second scheme involves observing the changes in the period of oscillation of a torsion balance when attracting masses are placed close to it such that the period is shortened in one position and lengthened in another (see Figure 3). Period measurements can be made much more precisely than those of deflection, and this scheme, introduced by Carl Braun of Austria in 1897, seems to have given the best results so far. Indeed it is only recently that the value obtained by the American physicist Paul R. Heyl and his colleagues has been improved upon by Gabriel G. Luther and William R. Towler (see table).

In the third scheme, a balance with heavy attracting masses is set up near a free test balance and adjusted so that it oscillates with the same period as the test balance. The latter is then driven into resonant oscillations with an amplitude that is a measure of the constant of gravitation. The technique was first employed by J. Zahradnicek of Czechoslovakia during the 1930s and was effectively used again by C. Pontikis of France some 40 years later.

The variation of the constant of gravitation with time. The 20th-century English physicist P.A.M. Dirac, among others, suggested that the value of the constant of gravi-

Possible rates of change

tation might be proportional to the age of the universe; other rates of change over time also have been proposed. The rates of change would be extremely small, one part in 1011 per year if the age of the universe is taken to be 1011 years; such a rate is entirely beyond experimental capabilities at present. There is, however, the possibility of looking for the effects of any variation upon the orbit of a celestial body, in particular, the Moon. It has been claimed from time to time that such effects may have been detected. As yet, there is no certainty.

Fundamental character of G. The constant of gravita-tion is plainly a fundamental quantity, since it appears to determine the large-scale structure of the entire universe. Gravity is a fundamental quantity whether it is an essentially geometric parameter as in general relativity or whether it is the strength of a field that is one aspect of a more general field of unified forces. The fact that, so far as is known, gravitation depends on no other physical factors makes it likely that the value of G reflects a basic restriction on the possibilities of physical measurement, just as special relativity is a consequence of the fact that, beyond the shortest distances, it is impossible to make separate measurements of length and time.

General: ISAAC NEWTON, The Mathematical Principles of Natural Philosophy, 2 vol. (1729, reissued in 1 vol., 1975; originally published in Latin, 1 vol., 1687), often referred to as the Principia, is the origin of all fundamental work on gravity. STEPHEN W. HAWKING and W. ISRAEL (eds.), Three Hundred Years of Gravitation (1987), provides many authoritative review articles in commemoration of the tercentenary of the publication of Newton's Principia. CHARLES W. MISNER, KIP S. THORNE, and JOHN ARCHIBALD WHEELER, Gravitation (1973), is a leading work on gravitational theory. ALAN COOK, The

Motion of the Moon (1988), discusses theories of the lunar orbit, with a chapter on applications that includes an account of gravitational studies

Gravity around the Earth, Moon, and planets: ALAN COOK, Physics of the Earth and Planets (1973), includes a chapter on methods and results of gravity measurements, wor FGANG TORGE, Geodesy: An Introduction (1980), contains a full and upto-date chapter on gravity measurements. JAMES A. HAMMOND and JAMES E. FALLER, "Results of Absolute Gravity Determinations at a Number of Sites," Journal of Geophysical Research, 76(32):7850–7854 (Nov. 10, 1971), gives an account of absolute measurements by free fall. c. Morelli et al., The International Gravity Standardization Net 1971 (I.G.S.N. 71) (1974), is the result of adjusting a large number of gravity measurements over the Earth. ALAN COOK, Interiors of the Planets (1980), summarizes knowledge of the gravity fields of the planets and their interpretation

Theories of gravitation and astronomical aspects: Stephen W. HAWKING, A Brief History of Time: From the Big Bang to Black Holes (1988), is a nonmathematical book by an outstanding author; see especially the chapter on black holes. CLIFFORD M. WILL, Theory and Experiment in Gravitational Physics (1981. reprinted 1985), is a thorough treatment. See also J.H. TAYLOR and P.M. MCCULLOCH, "Evidence for the Existence of Gravitational Radiation from Measurements of the Binary Pulsar PSR 1913+16," Annals of the New York Academy of Sciences, 336:442-446 (1980); and B.W. PETLEY, The Fundamental Physical Constants and the Frontier of Measurement (1985, reprinted 1988).

Experiments on gravitation: Experiments on aspects of gravitation are treated in the following journal articles: ALAN COOK, "Experiments on Gravitation," Reports on Progress in Physics. 51(5):707-757 (May 1988), a comprehensive review, with many references to early work, to the measurements of G in the table, and to recent studies of the inverse square law; P.G. ROLL, R KROTKOV, and R.H. DICKE, "The Equivalence of Inertial and Passive Gravitational Mass," Annals of Physics, 26(3):442-517 (Feb. 20, 1964), a thorough account of a classical experiment; HENRY CAVENDISH, "Experiments to Determine the Density of the Earth," Philosophical Transactions of the Royal Society of London, 88:469-526 (June 21, 1798), the first measurement of G; GABRIEL G. LUTHER and WILLIAM R. TOWLER, "Redetermination of the Newtonian Gravitational Constant G," Physical Review Letters, 48(3):121-123 (Jan. 8, 1982), probably the best measurement of G up to that time; F.D. STACEY et al., physics and the Law of Gravity." Reviews of Modern Physics. 59(1):157-174 ((Jan. 1987), a review of work on a possible difference between G as measured in the laboratory and estimated geophysically; and T.C. VAN FLANDERN, "Is the Gravitational Constant Changing?" The Astrophysical Journal, 248(2):813-816 (Sept. 1, 1981), a discussion of relevant observations of the

Treece

reece (Ellás), or the Hellenic Republic (Ellinikí Dhimokratía), is the southernmost of the countries of the Balkan Peninsula. It is a land of mountains and of sea. It is difficult to be far out of range of either, a fact that has had an important influence on the country's economic and historical development. Mountains have historically restricted internal communications, but the sea has opened up wider horizons. Greece has an area of 50,949 square miles (131,957 square kilometres), of which one-fifth constitutes the Greek islands. The area of Greece is approximately the same as that of England or the U.S. state of Alabama.

The country is bordered to the west by the Ionian Sea, to the south by the Mediterranean Sea, and to the east by the Aegean Sea; only to the north and northeast does it have land borders. These run from west to east with Albania (153 miles [247 kilometres]), Macedonia (the former Yugoslav Republic of Macedonia; 159 miles [256 kilometres]), Bulgaria (295 miles [475 kilometres]), and Turkey (126 miles [203 kilometres]), totaling altogether 734 miles

(1,181 kilometres).

Greece has more than 2,000 islands, of which 170 are inhabited; some of the easternmost Aegean islands lie just a few miles off the Turkish coast. Given this situation, it is no accident that Greece has always had a strong nautical tradition.

The country's capital is Athens, which has expanded rapidly in the period since World War II. The area around the capital (Attica) is now home to about one-third of the

country's entire population.

A Greek legend has it that God distributed all of the available soil through a sieve and used the stones that remained to build Greece. The country's barren landscape has been a powerful factor impelling Greeks to migrate, a process that has continued for centuries until very recent times. The Greeks, like the Jews and Armenians, are a people of the diaspora; there are several million people of Greek descent in various parts of the world. Xeniteia, or sojourning in foreign parts, with its strong overtones of nostalgia for the faraway homeland, has been a central element in the historical experience of the Greek people.

Greece lies at the juncture of Europe, Asia, and Africa. It is heir to the heritages of classical Greece, the Byzantine Empire, and nearly four centuries of Ottoman Turkish rule. From ancient Greece the modern country inherited a sophisticated culture and a language that has been documented for almost three millennia. The language of Periclean Athens in the 5th century BC and the presentday language of the Greeks are recognizably one and the same; few languages can demonstrate such continuity. From the Byzantine Empire it has inherited Eastern Orthodox Christianity and from Ottoman rule attitudes and values that continue to be of significance, not least in shaping the country's political culture.

Greece is a country that is at once European, Balkan, and Mediterranean. It is also a country that is peculiarly burdened by its past: Greece is the only country in the world, Greek the only language, and Greeks the only people regularly prefaced by the epithet "modern." References to Greece and Greek usually denote ancient Greece and ancient Greek. Greeks, however, take great pride in their cultural heritage, and the notion of an unbroken continuity between ancient and modern Greece is an essential

element in the Greek self-image.

Economy and society

Results of the Fourth Crusade

In 1981 Greece joined the European Community (renamed the European Union in 1994). It was the first eastern European country to do so, and its heritage of Ottoman rule and Orthodox Christianity set it apart from the existing member states. The centuries of Ottoman rule have insulated the Greek lands from many of the important historical movements, such as the Renaissance, the Reformation, the Enlightenment, the French Revolution, and the Industrial Revolution, that shaped the destinies of the countries of western Europe. Membership in the European Union has been a factor in buttressing Greece's somewhat uncertain identity as a European country.

Physical and human geography

THE LAND

dominant features of the landscape

The Greek landscape is conspicuous not only for its beauty but also for its complexity and variety. Three elements dominate. The first is the sea. A glance at the map shows that the Greek mainland is indented. Arms and inlets of the sea penetrate deeply so that only a small, wedgeshaped portion of the interior mainland is more than 50 miles (80 kilometres) from the coast. The rocky headlands and peninsulas extend out to sea as island arcs and archipelagoes; indeed, islands make up roughly 18 percent of the territory of modern Greece. The southernmost part of mainland Greece, the Peleponnese Peninsula, is joined to the mainland only by the narrow isthmus at the head of the Gulf of Corinth (Korinthiakós). The country's second landscape element is its mountainousness. Roughly 80 percent of Greece is mountain terrain, much of it deeply dissected. A series of mountain chains on the Greek mainland, aligned northwest-southeast, enclose narrow parallel valleys and numerous small basins that once held lakes. With the riverine plains (most extensive toward the coast) and thin, discontinuous strips of coastal plain, these interior valleys and basins account for the third dominant feature of the Greek landscape, the lowland. Although not extensive in Greece (accounting for 20 percent of the land area), it has played an important role in the life of the country

Relief. Three characteristics of geology and structure underlie these landscape elements. First, northeastern Greece is occupied by a stable block of old (Hercynian) hard rock. Second, younger and weaker rocks (predominantly of limestone origin) make up western and southern Greece. These were heavily folded in the Alp-building phase of the Tertiary Period (66.4 to 1.6 million years ago) when earth movements thrust the softer sediments east-northeast against the unvielding Hercynian block, producing a series of roughly parallel tectonic zones that gave rise to the mountain-and-valley relief sequence noted above. Third, both the Hercynian block and the Hellenidic (Alpine) ranges were subsequently raised and fractured by movements of the earth. These dislocations created the sunken basins of the Ionian and Aegean seas as well as the jagged edges so typical of Greece's landscape. Even today, earthquakes are all-too-frequent reminders that

similar earth movements continue, particularly along the major fracture lines. Another consequence of the region's geologic instability is the widespread occurrence of marble (limestone altered by pressure and heat). Seismic disturbances are sometimes associated with volcanic explosions, notably involving the island of Thera (Santorin), which was virtually destroyed by a major eruption in the 2nd millennium BC. The vents of the Kaïméni Isles in the seafilled explosion crater of Thera remain active. The island of Melos (Mílos), which rises to 2,464 feet (751 metres), is composed of young volcanic rocks. Thus, relief and geology provide the basis for describing the Greek landscape in terms of six major regions.

Central Greece: the Pindus Mountains. The central mountain range, the rugged Pindus (Pindhos) Mountains. forms the core of mainland Greece. Following the general northwest-southeast trend of the mountains of the Balkan Peninsula, the Pindus sweep down from the Albanian and Macedonian frontiers, creating a powerful communications barrier. Two passes (Métsovon and Mount Timfristós) divide the range into three units: a fairly open one in the north where impervious shales and sandstones have weathered into extensive upland valleys and gently inclining hills; the Pindus proper, some 20 miles in width and predominantly limestone, in the centre; and an almost uncrossable southern zone, some 50 miles wide, deeply dissected by winding rivers and composed of a mixture of limestone, slates, and sandstones. The highest point, Mount Smólikas, 8,652 feet (2,637 metres) high, is found in the northern Pindus.

Northeastern Greece: Macedonia and Thrace. A number of topographic regions surround the main mountainous core and are often penetrated by extensions of it. The northernmost part, roughly the regions of Greek Macedonia (Makedhonía) and Thrace (Thráki), extends in a long, narrow, east-west band between the Aegean coast and the frontier with the Republic of Macedonia and Bulgaria. It consists of a series of forest-clad, crystalline mountain massifs and plateaus created by the fracturing of the old Hercynian block and separated from each other by the alluvial deposits of the five great rivers of northern Greece, the Maritsa, Néstos, Struma, Vardar, and Aliákmon rivers. The complexities of that fracturing account for the odd three-pronged shape of the Chalcidice (Khalkidhikí) Peninsula, on whose easternmost prong, Áyion

(Holy) Mountain, is located Mount Athos (Athos), the famous site of Greek Orthodox monastic communities. Along and beyond the Bulgarian border rise the Rhodope (Rodhópis) Mountains, composed mainly of sharp-edged and frequently sloping plateaus, often rising more than 7,000 feet (1,800 metres) and reaching 7,287 feet (2,212 metres) at Mount Orvilos, The Maritsa (Evros) River in its low-lying, marshy valley marks the Turkish border. From here to the lower Struma (Strimon) River extends a succession of plains, often swampy (like the deltaic plain of the lower Néstos), some of which have been turned into fertile agricultural land (like the former Lake Akhinós). Inland there are basins of structural origin (such as the Dhrámas Plain). The lakes of Korónia and Vólvi, which separate the Chalcidice Peninsula from the rest of the coastal region, also occupy structural depressions. Farther west the large plain drained by the Vardar (Axiós) and lower Aliákmon rivers is being continually extended as the river deltas push out into the Gulf of Thérmai (Thermaikós). The forested Vérmion (Vírmion) Mountains and, beyond them, the barren inland basins around Lakes Vegorritis and Kastorias mark the boundary with the Pindus Mountains.

Eastern Greece: Thessaly and Attikí. This region epitomizes the physical geography of Greece. To the west are the massive limestones so characteristic of northern and western Greece, while to the east the peninsula of Attiki (Attica) represents the western margin of the old (Hercynian) crystalline rocks of the Aegean shores. Essentially an upland area, its relief is articulated by four northwestsoutheast-trending spurs thrusting out from the main Pindus mass. A number of distinctive basins and plains lie amid these upland ribs. The northernmost, a rather broken spur called the Kamvounia Mountains, runs along the coast of the Gulf of Thérmai and continues south to form the peninsula bounding one side of the Vólou Bay. Among its peaks are Mount Olympus (Ólimbos)—the mythical seat of the gods, whose often cloud-topped summit rises to 9,570 feet (2,917 metres), the highest point in Greeceand the equally fine peaks of Mount Ossa and Mount Pelion (Pilion). The next spur on the west is the Othris mountain range, which continues across the narrow Oreón (Oreón) Channel in the northern sector of the long, narrow island of Euboea (Évvoia). Between the two spurs lie the ancient basins (formetly the site of lakes) of Thessaly (Thessalia), Trikala (Trikkala), and Lárisa, drained by the Piniós. Just to their south the basin of Almirós, of similar oriein. lies around Vólou Bay.

To the southwest, the third spur leaving the Pindus is that of the Oiti, continued in the Okhi Mountains of southern Euboea. Just before the Oiti reaches the sea, near the head of the Gulf of Maliakós, is the pass of Thermopylae (Thermopilai), scene of the famous battle of antiquity. The last (and perhaps the most important) of the four spurs thrusting down into eastern Greece is the one that curves away to the southeast through the twin-peaked mass of Mount Parnassus (Parnassós). This mountain rises to 8.061 feet (2,457 metres) and was held to be the home of the Muses. The view from its summit at sunrise, with a broad expanse of the heart of Greece gradually unfolding, is regarded as one of the finest in the world. The range continues as the backbone of the peninsula lying between the Gulf of Euboea and the Gulf of Corinth, and it reaches as far as Mount Párnis, just to the north of Athens. To its north lie the plains of Phocis (Fokis) and Boeotia (Voiotia), and around its southern tip lie the depressions of Attiki, hotter and more arid but with a strategic importance that helps to explain the rise of Athens.

Mount Parnassus and its regional context

Southern Greece: the Peloponnese. The entire southern portion of mainland Greece forms a peninsula lying to the south of the Gulf of Corinth. Technically, this region, the Peloponnese, or Pelopónnisos, also known as the Morea, is now an island, for the 3.9-mile Corinth Canal cuts across the narrow neck of land formerly separating the Gulf of Corinth from that of Aegina (Aívina). The Peloponnese consists of an oval-shaped mountain mass with peaks rising to 7,800 feet and four peninsular prongs that point southward toward the island of Crete. At its heart are the arid limestone plateaus of Arcadia (Arkadhía), where streams disappear underground into the soluble rock and from which the barren upland of the Taïyetos Mountains (7,800 feet) extends southward to form the backbone of one of the southern peninsulas. A thin fringe of fertile coastal plain in the north and west, together with the larger alluvial depressions forming the Gulfs of Laconia (Lakonikós), Messenia (Messiniakós), and Árgolis, surrounds this mountainous core. The coast is indented and offers some fine harbours.

Western Greece: Epirus and Arkananía. The distinctiveness of the western side of the Greek mainland (consisting of Epirus [[piros] and Arkananía) north of the Gulf of Corinth to the Albanian frontier and the offshore Ionian (Iónioi) Islands is enhanced by the fact that the barrier effect of the Pindus and the ameliorating climatic influences from the west that result in a quite different landscape from that of the rest of Greece have exaggerated the historic isolation from the other areas of mainland Greece. Fertile basins are not well developed, constricted as they are by the parallel ranges of the coastal mountains. The mountain regions themselves, however, are adequately supplied with rainfall. The flat, alluvial plain of Arta, built up from detritus brought down by the Arachthos (Árakhthos) River, has become, with irrigation, a fertile agricultural region.

The islands of Greece. The Ionian Islands off the western coast of Greece structurally resemble the folded mountains of Epirus. Of the seven main islands, Corfu (Kerkira), opposite the Albanian frontier, is the northernmost. It is fertile and amply endowed with well-watered lowland. The other islands, Paxos (Paxof), Leukas (Levkás), Skorpiós, Itheaa (Itháki), Cephalonia (Kefallinia), and Zacynthus (Zákinthos), lie farther south. Lack of rainfall accentuates their gaunt, broken limestone relief, although Leukas and Zacynthus have sheltered eastern plains. The Aegean Islands, also exhibiting the characteristic landforms of the mainland, are situated in distinct clusters in the Aegean Sea, east of the Greek mainland.

In the north, off Thrace, lie Thásos (an oval block of ancient mineral rocks similar in composition to neighbouring blocks on the mainland) and harbourless Samothrace (Samothráki), an island of volcanic origin. Lemnos (Lim

Regional clusters of islands

Sunlight on the whitewashed walls of Thira, chief town of Thera, the southernmost island of the Cyclades group of the Aegean Islands.

nos), situated midway between Asia Minor and Áyion Mountain peninsula, is almost cut in two by the northern Pourniás Bay and the deep southern harbour afforded by the Bay of Moüdhrou.

To the southeast the rocky but sheltered islands of Lesbos (Lésvos), Chios (Khios), and Sámos lie close to the Turkish coast and are extensions of peninsulas on the coast of Asia Minor. Across the central Aegaan, near northern Euboca, lie the Northern Sporades (Vorioi Sporádhes), or "Scattered Islands"; their crystallier rocks are similar to those of the Greek mainland. Farther south, in the heart of the Aegaan, lie the Cyclades (Kikládhes), "Islands in a Circle." These roughly centre on Delos (Dhios) and represent the tips of drowned mountain ridges continuing the structural trends of Euboca and the region around Athens.

Between the Cyclades and the region around Attens. Between the Cyclades and the Turkish coast, the Dodecanese (Dhodhekánisos) group, with Rhodes (Ródhos) the largest of a dozen major islands, has a varied geologic structure ranging from the gray limestones of Kálimnos, Simi, and Khálki to the complete ancient volcanic cone that forms Nisirios,

Finally, the long narrow shape of Crete (Kriti) stands to the south at the entrance of the Aegean. By far the largest of the Aegean Islands and the fifth largest island in the Mediterranean (3,190 square miles), Crete is geologically linked to the south and west of mainland Greece. Its rugged, deeply ravined, asymmetrical limestone massif, falling steeply to the south, is so divided as to resemble four separate islands when seen from a distance: the westernmost Lévka ("White") Mountains; the central Ídhi (or Psiloritis) Mountains, with Crete's highest point, the summit of Mount Idhi, Stavros, 8,058 feet (2,456 metres) high; the east-central Dhíkti Mountains; and the far eastern Thriptis (Thrifti) Mountains. Another range, the Asterousia (or Kófinos) Mountains, runs along the southcentral coast between the Mesará Plain and the Libyan Sea. Of Crete's 650 miles (1,046 kilometres) of rocky coastline, it is the more gradual slope on the northern side of the island that provides several natural harbours and coastal plains. (J.S.Bo./C.D.S.)

Climate. The basically Mediterranean climate of Greece is subject to a number of regional and local variations occasioned by the country's physical diversity. In winter the belt of low-pressure disturbances moving in from the North Atlantie shifts southward, bringing with it warm, moist, westerly winds. Squalls and spells of rain ruffle the Aegean, but sunshine often breaks through the clouds. As the low-pressure areas enter the Aegean region, they may draw in cold air from those eastern regions of the Balkans that, sheltered by the Dinarie mountain system from west-

ern influences, are open to climatic extremes emanating from the heart of Eurasia. This icy wind is known as the boreas. Partly as a result, Thessaloniki (Salonika) has an average January temperature of 43° F (6° C), while Athens has 50° F (10° C) and Irkálion (Hérakleion) 54° F (12° C). Shílok, or warm winds, are similarly drawn in from the south. The western influences bring plentiful rain to the Ionian coast and the mountains behind it; winter rain also starts early, and snow lingers into spring. At Corfu, January temperatures average 50° F (10° C), and the island's average annual rainfall is 52 inches (1,320 millimetres), compared with the total on Crete of 25 inches and the total at Athens of 16 inches. On Crete, snow is almost permanent on the highest peaks.

In summer, when the low-pressure belt swings away again, the climate is not and dry almost everywhere, with the average July sea-level temperature approaching 80° F (27° C), although heat waves can push the temperature up over the 100° F (38° C) mark for a day or so. Topography is again a modifying factor: the interior northern mountains continue to experience some rainfall, while all along the winding coast the afternoon heat is eased slightly by sea breezes. In other regions, such as Crete, the hot, dry summers are accentuated by the parching neltemi, or Etesian winds, which become drier and drier as they are drawn southward.

In all seasons—perhaps especially in summer—the quality of light is one of Greece's most appealing attractions. However, atmospheric pollution has become a serious problem in the cities, notably Athens, and a hazard to the ancient monuments.

Drainage. The main rivers of Greece share several characteristics: in their upper courses most flow in broad, gently sloping valleys; in their middle courses they plunge from intermontane basin to basin through narrow, often spectacular gorges; in their lower courses they meander across the coastal plain to reach the sea in marshy, ever-growing deltas. Most rivers are very short. In limestone districts a generally permeable surface with sinkholes (katavóthra) leading to underground channels complicates the drainage network. In all regions river regimes are erratic, unsuitable for navigation, and of limited usefulness for irrigation. The Vardar, Struma, and Néstos, which cross Greek Macedonia and Thrace to enter the northern Aegean, are the major rivers, but only because they drain large regions beyond the Greek frontier. Also in the northeast are the eastward-flowing Aliákmon and Piniós (Peneus). In the Peloponnese, only the Evrótas is noteworthy.

Plant and animal life. As in other Balkan countries, the vegetation of Greece is open to influences from several

The boreas

Crete

major biogeographic zones, with the major Mediterranean and western Asian elements supplemented by plants and animals from the central European interior. Add to this the climatic effects of altitude, the contrast between north and south, and the role of local relief, together with the ubiquitous human factor, the result of some eight or nine millennia of settlement and land use, and it is not difficult to appreciate either the subtlety or the complexity of the vegetation mosaic. Degraded plant associations (reduced in variety and height of species and density of plant cover) and soil erosion are commonplace.

On the mountain flanks, and in the north generally, the central European types of vegetation prevail. In central and southern regions and in narrow belts along the valleys of the mountains, about half the land is under scrub of various kinds; and maquis, the classic Mediterranean scrub complex-with oleander, bay, evergreen oak, olive, and juniper-is particularly well developed in the Peloponnese. Evergreen trees and shrubs and herbaceous plants are found in the lowlands, with the flowers offering brilliant patterns in springtime. Pines, planes, and poplars line the rivers, the higher slopes, and the coastal plains. Oak, chestnut, and other deciduous trees are found in the north, giving way at higher altitudes to coniferous forests dominated by the Grecian fir, in which clearings are carpeted in spring and summer with irises, crocuses, and tulips. Forests and scrub are found at the highest levels; the black-pine forests covering Mount Olympus are especially noteworthy.

The forested zones, especially in the north, harbour such European animals as the wildcat, martin, brown bear, roe deer, and, more rarely, wolf, wild boar, and lynx. Animals of the Mediterranean regions include jackals, wild goats, and porcupines, all adapted to the lack of moisture and to the heat. Birds include pelicans, storks, and herons, while many varieties from farther north winter in Greece. Reptile and fish life is rich and varied.

Settlement patterns. In terms of human geography, Greece can be described as "classical Mediterranean" only in part, the other part being distinctly "Balkan," History rather than the physical environment accounts for fundamental paradoxes and contrasts in settlement pattern, social composition, and demographic trends that cannot be explained simply by reference to the difference between "Old Greece" and territories annexed in the early 20th century. For instance, although Greece is an "old country," relatively densely occupied in prehistoric times and well settled and much exploited in, and since, ancient times (as the large number of ancient monuments and important archaeological sites testifies), instability is as characteristic of Greece's settlement pattern as of its history. New villages, associated not only with Ottoman colonization but more recently (the first third of the 20th century) with agrarian reform, are juxtaposed with some of the most ancient towns of Mediterranean Europe (including Mycenea, Pilos, Thira, Argos, Athens, Sparta, and Thebes). Traditionally, towns as well as villages have depended on the food potential of the surrounding land. This self-sufficiency, the autarkeia of the ancient citystates, survives in the remote villages, perforce traditional in their isolation, of mountainous Greece. Only Corinth and, above all, Athens were major trading centres in ancient times. The other major nuclei of trade were found where routeways (sea and land) coincided with cultivatable land. From the Byzantine period onward, fortification became an essential factor for monastic and secular settlement alike, emphasizing the importance of the mountain regions and of sites "perched" above lowland. As late as the 1960s, more than 40 percent of Greece's population lived in mountain regions. Intermittent periods of relative stability saw a return to the plains where the settlement pattern, dispersed or nucleated, often geometrically laid out, thus always seems to be "new."

Greeks have preserved a strong sense of community. Village life remains a powerful influence, and village-square discussions reflect the cosmopolitan nature of the communities. This holds true despite the decline of the rural population in the late 20th century (still, more than onethird of Greece's total population is classified as rural). The same may be said about the small villages and towns

Juxtaposition of new and old settlements

Greek Orthodox priests from the monastery of St. John the Theologian celebrating an outdoor Easter service on Pátmos, island of the Dodecanese group, Aegean Sea.

at the bottom of the urban hierarchy. At the other end of the urban scale, however, Greece's larger towns and cities have gained considerably in size and commercial importance since the 1970s. Athens, with a population of 750,000 increasing to about 3,000,000 for the entire metropolitan area (including the port of Piraeus), stands alone, but towns such as Thessaloníki, Patras, Vólos, Lárisa (Lárissa), and, on Crete, Iráklion are all fast-growing centres. Almost two-thirds of the population is now classified as urban, and another 10 percent as semiurban. Urbanization also is reaching out into the countryside, especially where excessive fragmentation of landholding (a consequence of agrarian reform) attracts urban-based financial and marketing entrepreneurs. Curiously, early Greek city planning, unlike Roman, has bequeathed little to the layout of modern urban centres.

Linguistic, ethnic, and religious background. The inherent instability of the Balkan Peninsula-located as it is at the crossroads of invading Turks, migrating Slavs, and colonizing powers from western or central Europe (Venetians, Austro-Hungarians)-has bequeathed a bewildering amount of cultural confusion to Greece. Even in the south or on the islands, centuries of population migration and forced population exchanges continued well into the 20th century. Despite the long Ottoman administration (perhaps because of its failure to create a nation-state), all but a very small part of the population belong to the Church of Greece (Greek Orthodox church). This body appoints its own ecclesiastical hierarchy and is headed by a synod of 12 metropolitans under the presidency of the archbishop of Athens. The Greek church has links in dogma with the other Orthodox churches. Virtually all Cretans belong to a special branch of the Church of Greece, headed by the archbishop of Crete and directly responsible to the patriarchate of Constantinople.

The Muslim minority, which constitutes most of the non-Orthodox group, is mainly Turkish and is concentrated in western Thrace and the Dodecanese, Roman and Greek Catholics, concentrated in Athens and the western islands formerly under Italian sway, account for the rest, except for a few thousand adherents of Protestant churches and of Judaism, the last group having been much reduced in numbers by the Nazi genocide of World War II.

In terms of ethnic composition, Greeks again make up all but a small part of the total, the remainder being composed of Macedonians, Turks, Albanians, Bulgarians, Armenians, and Gypsies. Except in Cyprus, southern Albania, and Turkey, there are no major enclaves of Greeks in nearby countries, although Greek expatriate communities play a distinctive role in western Europe, North and South America, and Australia.

Demography. The Greek population has never displayed high rates of growth, although-despite losses in a succession of wars and constant emigration as a result of poor economic conditions—it has usually shown a regular increase since the first census, in 1828. Most of its growth in the years since Greece gained its independence from the Turks in 1832 resulted from two factors-annexations of surrounding areas (the Ionian Islands; Thessaly and Arta; Epirus, Greek Macedonia, and Crete; Thrace; and the Dodecanese) and the influx of some 1,300,000 Greek refugees from Asia Minor in the 1920s. Emigration has continued to be a limiting factor: the years 1911-15 were an active period, and emigration became particularly heavy after World War II. The most common destinations of the emigrants have been the United States, Canada, Australia, and, somewhat later, Germany, Belgium, and Italy.

With a total population, according to the 1991 census, of 10,264,156, the two decades since the demographically stagnant 1950s and '60s have seen a remarkable revitalization in Greece. This is, however, almost wholly due to international population movements, not to an increase in natural growth rates, which remain low. Within the country, the contrast between regions losing population (twothirds of the southern Peloponnese, all the Ionian isles except Corfu, the mountains of central, southwestern, and northeastern mainland Greece, and most of the islands of the eastern Aegean) and those rapidly gaining people (Attiki and other districts outside the major cities) holds a range of important social and political implications at all

THE ECONOMY

Despite a rapid rate of growth in the post-World War II period. Greece's economy is one of the least developed in the European Union (EU). Natural resources are limited. industrialization has been achieved only partially, and there are chronic problems with the balance of payments. Shipping, tourism, and, decreasingly, migrant remittances are the mainstays of the economy. By the 1990s receipts from tourism amounted to one-quarter of the trade deficit. Although the Greek economy has been traditionally based on free enterprise, many sectors of the economy have come under direct or, through the banks, indirect government control. This process of expanding state ownership of the economy has, historically, been associated as much with right-wing as with centre to left governments. Trade unions, which are fragmented and highly politicized, wield significant power only in the public sector. Measures were taken in the late 1980s and the early 1990s to diminish the degree of state control of economic activity. Following entry into the European Union, Greece has been a major beneficiary of subsidies for its generally inefficient agricultural sector and for infrastructural projects. Rates of productivity, however, remain low in both the agricultural and industrial sectors, and the development of the country's economy has lagged behind that of its EU partners. Unemployment, hitherto low, has grown as temporary migrants to other European countries have returned to Greece because of those countries' declining demand for immigrant labour. However, some sectors of the economy. notably shipping, have shown considerable dynamism.

Resources. Greece has few natural resources. Only in the case of nonferrous metals are there substantial deposits. Of these the most important is bauxite, reserves of which amount to more than 650 million metric tons.

Fossil fuels, with the exception of lignite of low calorific value, are in short supply. There are no deposits of bituminous coal, and oil production, based on the Prinos field near the island of Thasos, is very limited. The complex dispute between Greece and Turkey that developed in the 1970s over the delineation of the two countries' respective continental shelves-and hence the right to such minerals, in particular oil, as may exist under the Aegean seabedshows no sign of being resolved.

Much of Greece's electrical power needs are supplied by lignite-fueled power stations and by hydroelectric power. Recently, attention has been given to the possibilities of solar and wind power.

Agriculture, forestry, and fishing. Greece's agricultural potential is hampered by poor soil, low rainfall, a system of landholding that has resulted in the proliferation of uneconomic smallholdings, and a general flight from the countryside to either the towns or overseas. About 30 percent of the land area is cultivable, the remainder consisting of scrub or forest. Only in the plains of Thessaly, Macedonia, and Thrace is cultivation possible on a reasonably large scale. Here corn (maize), wheat, barley, sugar beets, cotton, and tobacco are grown, Greece being a major EU producer of the last two items.

Other crops grown in considerable quantities are olives (much of the annual crop being turned into olive oil), grapes, melons, peaches, tomatoes, and oranges, which are exported to other EU countries. Historically, Greek wine production, including the resin-flavoured retsina, has been primarily for domestic consumption, but efforts have been inititated to produce wines of higher quality for the world market.

Although inefficient, Greek agriculture has benefited substantially from EU subsidies, and there are many signs of growing rural prosperity. The importance of the agricultural sector to the economy, however, is diminishing.

Forests, mostly state-owned, cover approximately onefifth of the land area, but they are subject to major forest fires. Forest products make no significant contribution to the economy.

The Greek Orthodox church

Crops

Parliament

bution of fishing to the economy.

Industry. The industrial sector in Greece is weak. An established tradition exists only in the production of textiles, processed foods, and cement. (What is said to be the world's largest cement factory is located in Vólos.) In the past, private investment has been oriented much more toward real estate than toward industry, and concrete apartment blocks proliferate throughout the country. In the 1960s and '70s, taking advantage of an investment regime that privileged foreign capital. Greek shipowners invested significantly in sectors such as oil refining and shipbuilding. Shipping continues to be a key industrial sector, with the merchant fleet being one of the largest in the world, even if many of its ships are older than the world average. In the 1970s many ships that had hitherto registered under flags of convenience returned to the Greek flag. The fact that Greek ships, predominantly bulk carriers, are principally engaged in carrying cargoes between third countries renders the shipping industry vulnerable to downturns in international economic activity.

Tourism

Since the 1960s tourism has developed markedly although Greece has not had much success in attracting high-spending tourists and is facing growing competition from Turkey. The number of tourists tripled between the early 1970s and the late 1980s. Most tourists come from other European countries. The emergence of a consumer society has created a seemingly insatiable demand for imported consumer goods, with negative consequences for the balance of trade. Road transport has improved immeasurably over the past 50 years, and there is a welldeveloped network of truck- and car-carrying ferries linking mainland Greece to the numerous islands and to Italy.

Finance. The central bank is the Bank of Greece. A significant number of the country's commercial banks are state-controlled. In the early 1990s banks controlled by the state held some 70 percent of total deposits. There is also a considerable degree of state control of the insur-

ance sector.

In the early 1990s 118 public companies were quoted on the Athens stock exchange. For many Greeks, however, real estate, foreign currency, gold, and jewelry have proved a more attractive investment than stocks and shares. A pension and social insurance system of byzantine complexity is a major obstacle to economic modernization. The main social security fund, the Social Insurance Institute (IKA), is prone to recurrent crises in funding.

Trade. By the early 1990s some two-thirds of Greece's trade was with the other member countries of the European Union, the two main trading partners being Germany and Italy. Basic manufactures (e.g., steel, aluminum, cement, and textiles), miscellaneous manufactured items (e.g., clothing), and food (including livestock) each accounted for under one-quarter of exports; refined petroleum and petroleum-based products constituted a further 10 percent. Exports grew rapidly in the 1970s but slowed markedly in the '80s. Shipping and tourism contributed just over 10 percent to the gross domestic product (GDP) in the early 1990s, but there was a serious deficit in the balance of payments. This was offset by borrowing, limited foreign investment, and, to a decreasing extent, by emigrant remittances

Transportation. Internal communications in Greece have, historically, been poor. Only during the post-World War II period have all the country's villages become accessible to wheeled traffic (and linked to the national electricity grid). There are no navigable rivers and only one canal, the Corinth Canal (completed in 1893), which divides the Peloponnese from mainland Greece. Although the canal significantly shortens the sea route from the Italian ports to Piraeus, the port of Athens, it has never fulfilled the economic expectations of its builders, because of its shallow draft and narrow width.

Railway construction got under way in the 1880s, and, given the rugged terrain of the country, it involved some difficult feats of engineering. The total track is slightly under 1,600 miles in length, including the narrow-gauge railway network in the Peloponnese. The railway system is being modernized with the aid of EU funding. Trunk roads are inadequate by European standards, and Greece has one of the worst automobile accident records in Europe. Public transport in the Athens metropolitan area is heavily dependent on an overcrowded and unreliable bus network. After many postponements, work on the muchneeded Athens metro commenced in earnest in 1993 This will supplement the small suburban railroad network linking Athens' northern suburb of Kifisia with the port

The extensive internal bus-and-ferry network has been augmented since the 1960s by the development of a domestic flight network linking Athens with 25 domestic airports. The country's main airports are Ellinikon in suburban Athens (to be replaced in the late 1990s by an entirely new airport at Spata in Attiki) and Macedonia, near Thessaloniki. Other international airports, which service the country's important tourist industry, are to be found on the islands of Crete (Iraklion), Corfu, Rhodes, Cos, and Lesbos and at Alexandroúpolis in Thrace and Andravida in the northwestern Peloponnese. The national carrier is Olympic Airways, which is 51-percent state-owned.

ADMINISTRATION AND SOCIAL CONDITIONS

of Pirague

Government. Constitutional framework. The current constitution was introduced in 1975 following the collapse of the 1967-74 military dictatorship. The considerable powers it vouchsafed to the president were never invoked before they were reduced in the constitutional revision of 1986. Presidential powers are now largely ceremonial. The president is elected by the parliament (Vouli) and may hold office for two five-year terms.

The prime minister, who has extensive powers, must be able to command the confidence of the parliament. The latter consists of 300 deputies and is elected for a four-year term by direct, universal, and secret ballot. It has the power to revise the constitution, as happened in 1986. A distinctive feature of the electoral system is the practice of incumbent governments, of whatever political hue, amending the electoral law to suit their own political

advantage. Voting is compulsory.

The party system. Although the political system is in the process of modernization, many elements of traditional politics remain, notably the personalistic nature of the party system, with parties being heavily dependent on the charisma of their (frequently elderly) leaders and the

importance of patronage at all levels.

There are three main political concentrations: the right, the centre, and the left. In the 1990s these were represented respectively by New Democracy (ND), the Panhellenic Socialist Movement (PASOK), and the Communist Party of Greece (KKE). New Democracy, founded by the veteran conservative politician Constantine Karamanlis, has progressively espoused "neoliberal," antistatist policies meant to limit the power of the state and to encourage private initiatives. PASOK, although it has substantially moderated the Third World liberationist rhetoric of its earlier years, retains a strong commitment to a radical foreign policy and an idiosyncratic form of socialism, which reflects the fact that only some 40 percent of the working population are wage or salary earners (the remaining 60 percent being self-employed). On the far left the KKE advocates a Soviet-style communism even after the demise of the Soviet Union. The broadly "Eurocommunist" Coalition of the Left and Progress has limited electoral appeal.

Local government. The country is divided into 13 geographic regions (9 mainland and 4 insular). These, in turn, are further subdivided into 51 departments (nomoi), each administered by a government-appointed prefect (nomarkhis). There is a government minister with special

responsibility for Macedonia and Thrace.

The governmental system is highly centralized. The powers of local government are severely circumscribed by its inability to raise revenue.

Armed forces. The military has been a major arbiter of political life during the 20th century, but there has been no sign of political activity since 1974. Greece's expenditure on defense, at some 6 percent of GDP, is the highest in

The Corinth

Canal

Judicial system. The judicial system is essentially the Roman law system prevalent in continental Europe. The two highest courts are the Supreme Court (Areios Pagos), which deals with civil and criminal cases, and the Council of State (Symvoulion Epikrateias), which is responsible for disputes arising out of administration. A Court of State Auditors has jurisdiction in a number of financial matters. A Special Supreme Tribunal, whose members include the heads of the three courts mentioned above, deals with disputes arising out of the interpretation of the constitution and checks the validity of parliamentary elections and referenda.

Education. Education has long been prized in Greece both as an end in itself and as a means of upward social mobility. Wealthy Greeks of the diaspora have been major benefactors of schools and universities in their homeland. The educational system is somewhat rigid and heavily centralized, but the rate of literacy is high, Because of the inadequacies of state education, many children attend private phrontistiria, or institutions providing supplementary

coaching outside normal school hours. Competition for university places, which hold out the prospect of job security, is exceptionally severe. The oldest university-level institutions are the National Capodistrian University of Athens (1837), the National Technical University of Athens (1836), and the Aristotelian University of Thessaloniki (1925). This last institution has a tradition of innovation as compared with the more conservative University of Athens. From the 1960s to the '80s, a number of new universities were founded in Ioánnina, Patras, Thrace, Crete, Corfu, and the Aegean. However, they are often inadequately equipped and still do not offer a sufficient number of places to satisfy the demand for university-level education, forcing many Greek students to study abroad. Although there is a constitutional ban on private universities, a number of university-type institutions, some of dubious quality, have come into existence.

Health and welfare. Major strides have been made in the post-World War II period in eradicating diseases such as malaria, tuberculosis, typhoid, and dysentery. There are more doctors per person in Greece than in most of the other member countries of the European Union, and in the 1980s the PASOK government of Andreas Papandreou instituted a national health system. Many Greeks, however, where they can afford it, choose to travel abroad for medical care. Pension provision in Greece is a subject of extraordinary complexity. Some 80 percent of the working population are insured under the Social Insurance Institute and the Agricultural Insurance Organization

(OGA; for farmers) programs.

During the 1980s important changes were introduced in Family law Greek family law. Civil marriage was instituted in parallel with religious marriage, the dowry system was abolished (in theory), divorce was made easier, and the hitherto dominant position of the father in the family was restricted.

CULTURAL LIFE

The important sites of Greek antiquity that attracted European noblemen to the Greek lands in the 18th century, and which were such a potent influence on architectural styles in the West, continue to attract tourists from all over the world. Newly excavated sites such as the supposed tomb of Philip II of Macedon at Verghina and the Pompei-like remains at Thera are further indications of an astonishingly rich heritage from antiquity that has still not been fully explored. Over the past century there has been a greater awareness of the richness of the architectural and artistic heritage of the medieval empire of Byzantium.

The arts. Against the background of this extraordinary artistic heritage, Greece enjoys a thriving cultural life. It is in the field of literature that Greece has made its greatest contributions. Constantine Cavafy (1863-1933), who lived most of his life in Alexandria, Egypt, is frequently ranked among the great poets of the early 20th century. His poetry is suffused with an ironic nostalgia for Greece's

past glories. Two Greek poets have won the Nobel Prize for Literature, George Seferis in 1963 and Odysseus Elytis in 1979. The novelist best known outside Greece is the Cretan Nikos Kazantzákis, whose Zorba the Greek was made into a popular film. A number of Greek composers have acquired an international reputation, including Nikos Skalkottas, Manos Hadiidakis, Mikis Theodorakis, and Iannis Xenakis, a French composer of Greek descent. Well-known painters in the post-World War II period include Ghika, Yannis Tsarouchis, and Photis Kontoglou, who drew his inspiration from the ascetic traditions of

There is a lively theatrical tradition, in which political satire plays an important part. The traditional shadow puppet theatre, Karaghiozis, is now largely extinct, having been displaced by the ubiquitous television,

Cultural institutions. A thriving theatrical tradition is reflected in a myriad of theatres in the capital, whose repertoire ranges from Western classics to political satire. During the summer months huge audiences are attracted to performances of ancient Greek drama held in the theatre of Epidaurus, which dates from the 4th century ac and whose acoustics are extraordinary; the 2nd-century-AD Roman theatre of Herodes Atticus at the foot of the Acropolis in Athens also draws many visitors and is the location for concerts given in the framework of the annual Athens Festival held during the summer months. Live performance of orchestral music, limited in comparison with that of other European capitals, was given a major boost with the opening in 1991 of a newly built concert hall, the Megaro Mousikis (palace of music).

Given the richness of the country's archaeological heritage and the emphasis in the country's official self-perception on continuity with the classical past, the Archaeological Service has assumed particular importance. Frequently working in cooperation with the various foreign archaeological institutes, it is responsible for excavating relics of the past and for running the country's museums. Public library provision is relatively limited, and there is no adequate national library. The country's most prestigious learned society is the Academy of Athens. A distinctive feature of intellectual life is the numerous societies devoted to the study of local and regional archaeology, history, and folklore, a development that reflects the strong regional loyalties of many Greeks.

Daily life. In the hot summers social life in Greece tends to be conducted outdoors. In small towns and villages the tradition of the volta continues, when much of the population strolls up and down the main street or, on the islands, the quayside at sundown. In summer and winter much leisure time is passed in the numerous cafes and coffee shops. These latter have traditionally been a male preserve, and it is not uncommon to find in a single village one coffee shop where the adherents of one political party congregate and another for supporters of the rival party. Television and other forms of video entertainment, how-

ever, threaten to undermine traditional leisure patterns. The country's cuisine, particularly sweets such as baklava Cuisine and kataifi, reflect the influence of the centuries of Turkish rule. The food in Thessaloníki, the capital of northern Greece, which was annexed to the Greek state only in 1912, reflects the Ottoman influence and is testimony to the massive influx of refugees from Asia Minor in the 1920s. These immigrants were often facetiously referred to by the native inhabitants as yiaourtovaptismenoi ("baptized in yogurt") on account of their fondness for yogurt in their appreciably superior cuisine. The traditional diet of the peasants was a healthy one based on vegetables, olives, olive oil, cheese, and bread, with meat being a luxury to be eaten only on special occasions. With growing affluence meat has come to assume a more important place in the country's diet, and the incidence of heart disease has risen accordingly

Greek society is noted for its tight family structures and the low rate of crime. The extended family, and the obligation placed on family members to provide mutual support, is all-important. The centrality of the family has been little affected by the process of embourgeoisement that has been a characteristic feature of the development The Archaeological Service

of Greek society in the period since the end of World War II. Although the dowry system has officially been abolished, marriages still continue to be seen to a degree as economic alliances. The great majority of the country's businesses remain small, family-run enterprises. This is also true of ship-owning, the most dynamic sector of the economy. Tightly knit clans of ship-owning families dominate this industry. The family structure of industry acts as an impediment to modernization. The wheels of society continue to be lubricated by mesa (connections) and rouspheti (the reciprocal dispensation of favours).

The main holiday periods revolve around Easter and the Feast of Dormition (Assumption) of the Virgin in mid-August. Easter is the most important religious and family festival, with many people returning to their native villages for the traditional festivities, which include the vigil in church on Saturday evening, the lighting of the Holy Fire at midnight, and the roasting of whole lambs on the spit. August is the traditional holiday month. The national sport is football (soccer), and the fortunes of the principal teams are the focus of passionate loyalties. Hunting is another popular pastime.

Press and broadcasting. During the 1980s traditional newspaper proprietors were to an extent displaced by new entrepreneurs. Most newspapers became tabloids. The circulation of morning papers declined while that of evening papers increased. Leading newspapers include Kathimerini ("Daily"), Eleftherotypia ("Free Press"), and Ethnos ("Nation"). For the most part, newspapers tend to be unashamedly partisan in their political comments, with the laws of libel inspiring little fear in publishers. The government monopoly of television and radio broadcasting was broken in the 1980s. Private television and radio stations now exist in profusion. Like the press, broadcasting is unrestrained, particularly in its handling of political issues, although often at the expense of quality.

(R.R.M.C.)

History

Geographically, Greece forms, as previously noted, the southernmost extension of the Balkan Peninsula. It is a region dominated by mountain systems, and, although not particularly high, these cover some 80 percent of the surface area. The main formations are those of the Dinaric Alps, which push down from the western Balkan region in a southeasterly direction and which, in the Pindus Mountains, dominate western and central Greece. Extensions and spurs of these mountains form the salient features of southern Greece and the Peloponnese. The Balkan range lies north of Greece, extending eastward from the Morava River for about 340 miles (550 kilometres) as far as the Black Sea coast, but the Rhodope Mountains form an arc stretching from this range through Macedonia toward the plain of Thrace. The coastal and riverine plains are in consequence relatively limited in extent; moreover, they are differentiated by marked variations in climate, ranging from the Mediterranean type along the coast to the continental type inland, in the highlands. These plains reveal an accentuated settlement pattern consisting of a series of fragmented geopolitical entities, separated by ridges of highlands, that fan out along river valleys toward the coastal areas. This structure played a significant role in shaping the history of preclassical and classical Greece and continued to do so in the medieval period; for, in spite of the administrative unity and relative effectiveness of the fiscal and military administration of the later Roman and Byzantine states, these still had to function in a geophysical context in which communications were particularly difficult. The southern Balkan Peninsula has no obvious geographic focal point. The main cities in the medieval period were Thessaloniki and Constantinople, yet these were peripheral to the peninsula and its fragmented landscape. The degree of Byzantine political control during the Middle Ages is clearly reflected in this. In the Rhodope Mountains, perhaps the most inaccessible of those mentioned, as well as in the Pindus Mountains, state authority, whether Byzantine or Ottoman, always remained a rather distant factor in the lives of the inhabitants. These were regions in which paganism and heresy could survive with little interference or control from a central government or church establishment.

This geophysical structure also has affected land use. The highland regions are dominated by forest and woodland and the lower foothills by woodland, scrub, and rough pasture. Only the plains of Thessaly and Macedonia offer the possibility of extensive arable exploitation. The riverine plains and the coastal strips associated with them (such as the region around the Gulf of Argolis and, much more limited in extent, the Gulf of Corinth) present a similar but more restricted potential; they have been used for orchards, viticulture, and oleoculture. Inevitably, the pattern of settlement of larger urban centres as well as of rural communities is largely determined by these features Finally, the relationship between this landscape of mountains, gulfs, and valleys, on the one hand, and the sea on the other, is fundamental to the cultural as well as to the political and military history of Greece. The sea surrounds Greece except along its northern bounds; and the extended coastline, including gulfs such as those of Corinth and Thessaloníki, which penetrate deep into the interior, has served as a means of communication with surrounding areas to the extent that even interior districts of the Balkans often share in the Mediterranean cultural world. The sea was also a source of danger: seaborne access from the west, from the south, or from the northeast via the Black Sea made Greece and the Peloponnese particularly vulnerable to invasion and dislocation.

GREECE DURING THE BYZANTINE PERIOD (c. AD 300-c. 1453)

Late Roman administration. At the beginning of the 4th century the regions comprising very approximately the modern state of Greece were divided among eight provinces: Rhodope, Macedonia, Epirus Nova, Epirus Vetus, Thessaly, Achaea, Crete, and the Islands (Insulae). (For the earlier history of Greece, see the article GREEK AND ROMAN CIVILIZATIONS, ANCIENT.) Of the eight provinces, all except Rhodope and the Islands were a part of the larger diocese of Moesia, which stretched up to the Danube River in the north: Rhodope belonged to the diocese of Thrace, while the Islands were classed as part of the diocese of Asiana, consisting, for the most part, of the westernmost provinces of Asia Minor. By the early years of the 5th century, administrative readjustments had divided the older diocese of Moesia into two sections, creating in the north the diocese of Dacia and in the south that of Macedonia, made up of the provinces of Macedonia I and II, with Epirus Novus and Epirus Vetus, Thessaly, Achaea, and Crete. Further changes during the middle of the 6th century resulted in the establishment of a military command known as the quaestura exercitus, a zone made up of the Islands and Caria, from the diocese of Asiana, together with the province of Moesia II on the Danube; it was designed as a means of providing for the armies based along the northern frontier in regions that were too impoverished or devastated to support them adequately. In turn, these diocesan groups were parts of larger administrative units, the praetorian prefectures. Most of the Greek provinces were in the praetorian prefecture of Illyricum, except Rhodope, which, as a province of the diocese of Thrace, was in the prefecture of Oriens, as were the Islands. This pattern was radically altered by the developments of the 7th century.

Some of the ancient names for the regions of Greece disappeared from everyday use. However, many continued to be used in literary and administrative contexts, at least, especially in the administration of the church, or were revived by classicizing writers during the late Byzantine period. Thus, Aitolia, Akarnania, Achaia, Arkadia, and Lakedaimon were used in the 13th century and after. Similarly, in central Greece Boeotia, Euboea, and Thessaly all survived, in different contexts. Typical of their history is Euboea, which was so called until the 8th century, after which it was referred to variously as Chalkis or Euripus. After 1204 Western writers identified it as Negroponte, although the Byzantines also called it Euboea. The names Epirus and Macedonia seem never to have dropped out of

Geophysical structure land use

Quaestura exercitus

Greece in the early Byzantine period (7th and 8th centuries)

regular use. However, many new names also were coined during the Byzantine period; these tended to be geographic descriptions (such as Strymon or Boleron) used for both provincial and administrative divisions as well as to describe regions with a particular ethnic composition, for

example, Vlachia in southern Thessalv.

The evolution of Byzantine institutions. As in other parts of the Roman world, the function of cities in the administrative structure of the state underwent a gradual evolution from the 3rd century on as the central government found it increasingly necessary to intervene in municipal affairs in order to assure itself of its revenues. This need for intervention developed when the vitality of cities became eroded as a result of a range of factors, most particularly the economic damage to urban infrastructures that accompanied the civil wars and barbarian inroads of the 3rd century. Further, the so-called "decline" of the curial order, that is to say, the weakening of the fiscal and economic independence of many towns by the tendency of members of urban elites to avoid municipal obligations, played a role. Finally, in the eastern parts of the empire, the transformation of Byzantium into Constantinople as a new imperial capital in 330 had important results for patterns of internal trade and commerce as well as for social relations between provincial elites and the state establishment. Nevertheless, the cities of the southern Balkans were able to survive the raids and devastation of both Goths and Huns in the 4th and 5th centuries, and there is no evidence that cities ceased to carry on their function, where it existed, as centres of market activity, local administration, and social life. Those cities that were artificiali.e., purely administrative creations of the Roman statewere the first to suffer, and, under difficult conditions, they generally disappeared. On the other hand, the statethrough its regional and central military administrationappears also to have been involved in promoting different types of smaller defended urban centres, better adapted to these conditions.

In the 7th century a series of developments combined to further promote what was already in the process of becoming a radically different pattern of settlement and administration. In the first place, the results of the long-term developments already referred to, in terms of both social and economic stability, must be borne in mind. (Of particular significance is the fact that the municipal landowning elites transferred their attention—especially in respect of investment in the imperial system—away from

their local cities to the imperial capital.) In the second place, the economic disruption brought about by the infiltration of large numbers of Slav settlers and immigrants was exacerbated by the devastation and insecurity caused by the wars between the empire and the Avars, a Turco-Mongol confederacy that was able, from the 560s to the 630s, to harness the resources of those peoples in the plain of Hungary and in the Balkans under its thrall to launch a series of extremely damaging and disruptive attacks on the empire. Although the disruptions of the earlier invasions of the Huns and Goths may have been as damaging in the short term, the Balkans were by this time suffering from the cumulative effects both of two centuries of constant insecurity and warfare and of endemic plague, which had struck the eastern empire in the 540s. It is clear from the imperial legislation of the late 5th to the 6th centuries dealing with the Danubian provinces and with Thrace, as well as from the archaeological record, that the final results of this economic disruption were to bring about the abandonment of the traditional pattern of urban economies. Even the construction of churches, which had experienced a certain efflorescence during the 6th century, virtually ceased in the 7th century; secular construction stopped; an extended process of ruralization of settlement and of economic life took place; and new populations penetrated far into the Peloponnese. The extent to which these new settlers replaced, or were able to live alongside, the indigenous population remains unclear.

As a consequence of these changes, the traditional administration collapsed, chiefly because the government at Constantinople could control only the coastal plains and some river valleys. The cities that remained in imperial hands, such as Corinth or Thessaloníki, for example, were well-defended fortresses or had access to the sea, from where they could be supplied. Inland, tribal groupings and chieftaincies (sklaviniai) dominated many districts; and, while it appears that the empire claimed a political sovereignty over such regions, it was rarely able to make this effective or to extract regular revenues (although "tribute" was obtained at times). The sklaviniai, however, did not control the entire inland region; there were many areas in which the indigenous population and the traditional patterns of local social structure and political organization may have survived and where imperial authority may have been recognized. The evidence is too sparse to draw definite conclusions.

Evidence for the degree of Byzantine control over the

traditional administration

The changing role of cities area is reflected dimly in the lists of signatories to ecclesiastical councils (especially those of 680 at Constantinople and of 787 at Nicaea) and in the various lists of bishoprics (Notitiae episcopatuum). From these, it is clear that ecclesiastical administration in the south, especially the Peloponnese, had suffered considerably. Many bishoprics were abandoned and had ceased to exist; at the council of 680 only 4 bishops from this region (Athens, Corinth, Lakedaimon, and Argos) and 12 from Macedonia attended; a (probably) 7th-century episcopal list (the Pseudo-Epiphanios) records the names of only 5 metropolitan bishops from Greece, mostly from the north.

Administratively, those districts that remained under Byzantine control were organized from the later 7th century onward into the military province, or theme (Greek: thema), of Hellas, under its general (strategos). The theme initially encompassed in all likelihood only the easternmost parts of central Greece but gradually came to include also parts of Thessaly and, possibly, of the Peloponnese, although in the latter case only the coastal regions were involved.

The islands of the Aegean remained largely in imperial hands. In late antiquity they had been relatively heavily populated, the larger ones among them-especially Lemnos and Thasos in the north-being well-known sources of agricultural produce. Arab piracy and raiding from the later 7th century on altered this, causing many of the smaller islands to become deserted; however, the islands

recovered during the 10th century.

Byzantine fortress-towns testify to the presence of sizable rural populations needing shelter from attack; the towns also served as refuges for people from the mainland fleeing Avar, Slav, or Bulgar raids. Administratively, they formed in the second half of the 7th century an element of the districts allotted to the naval theme (in the original sense of the term-i.e., "army") of the Karabisianoi (Greek karabos, a light ship), which represented the rump of the quaestura exercitus. During the first half of the 8th century this command appears to have been subdivided to form the naval themes of the Kibyrrhaiotai (including parts of western Asia Minor and named after the district and town of Kibyrrha in southwestern Asia Minor), Samos or the Kolpos (Gulf) in the southern zone, and Aigaion Pelagos covering the northern districts. Further subdivisions took place in the 10th-12th centuries, so that commands of the Dodecanese or the Cyclades also appear in the sources.

It must be stressed that, even though the archaeological record clearly supports the conclusion that a dramatic collapse of traditional urban society and economic relations occurred, it also gives evidence of significant regional variations. The process of change was neither uniform across Greece, nor was it always as extreme in one area as in another. The degree of access to imperial resources and the ability to maintain regular contact with the imperial government were factors that gave some areas a very different appearance from others. It is important that this be borne in mind when considering the history of the various

regions of Greece in the following period.

Byzantine recovery. The Byzantine recovery of effectively lost provinces began toward the end of the 8th century. The emperor Nikephoros I (802-811) is traditionally credited with a major role in this, although the process was certainly under way before his accession. The degree of Slavicization appears to have varied considerably. For example, it is clear that by the 10th century many districts of the Peloponnese were well Hellenized and thoroughly Christian once more. Yet outposts of Slavic language and culture-sometimes partly Hellenized, often relatively independent, in practice, of central imperial control-survived in the less-accessible regions until the 13th and 14th centuries and perhaps beyond. Traces of the preconquest social and political structures of the northern Peloponnese may be reflected in the story of the widow Danelis, a rich landowner whose wealth was almost proverbial in the later 9th century. She was a sponsor of the young Basil, later Basil I (867-886), and may have represented the last in a line of Christianized but semiautonomous Slavic princelings or chieftains who had dominated the region around Patras in Achaia.

Different parts of Greece were reconquered at different Pattern of times. Epirus in the northwest was gradually placed under Byzantine military administration, which was advancing inland from the coast during the first part of the 9th century. The themes of Cephalonia (Kefallinia) and Dyrrachion (Durazzo; modern Durrës) had been established by the 830s; that of Nikopolis appeared at the end of the 9th century. The theme of the Peloponnese emerged as a separate region in 812, although it was almost certainly created before this date; that of Thessaloníki had probably been established by about 812 (although this remains debated); those of Strymon and Boleron appeared likewise during the course of the 9th century.

Ecclesiastical organization once again reflects this process. A 9th-century list of bishoprics contains 10 Greek metropolitan sees, including those of Patras and Athens. compared with the 5 that appear in earlier records. And during the first half of the 8th century (in the context of the Iconoclastic Controversy, a religious controversy concerning the veneration of icons, or sacred images) the ecclesiastical provinces of the old prefecture of Illyricum. which had been subject to Rome were withdrawn by the emperor Leo III (717-741) from papal authority and placed under Constantinople, thus permitting a unified program of re-Christianization of much of this region. As Byzantine control became firmer, and as Byzantine

military and political expansion northward accelerated during the 10th and early 11th centuries, older themes were subdivided, forming a mosaic of small administrative divisions. Thus the themes of Berroia, Drougoubiteia (clearly reflecting a Slavic tribal territory), Jericho (on the Adriatic coast between Dyrrachion and Nikopolis), and Edessa or Vodena (northwest of Thessaloniki) all appeared during the period from the later 9th to the 11th century. Economy and society. Like other regions of the Byzantine Empire, Greece had suffered economically from the warfare of the 7th and 8th centuries. The rise of the khanate of the Bulgars, established south of the Danube after 681, whose rulers were able to exercise a hegemony over their politically fragmented Slavic neighbours, meant that warfare remained endemic and economic insecurity a factor of daily existence. Yet the restoration of Byzantine military and political power from the later 8th century onward and the growth of Byzantine cultural and religious influence throughout the Balkans during the 9th and 10th centuries created a context favourable to economic and demographic recovery throughout the empire, especially in the southern Balkan region. During the 11th and 12th centuries Greece experienced a powerful economic upswing, certainly more so than Anatolia. Cities such as Thessaloníki, Thebes, and Corinth became centres of flourishing local industries and of market exchange, rivaling the imperial capital in many respects. The silk industry that developed around Thebes was especially important. The evidence for greater wealth, and more especially greater disposable wealth in the hands of local elites, is found not only in documentary sources but also in a number of splendidly endowed churches, some still extant today. Many other towns, particularly those with a harbour or shelter for ships, became flourishing centres of trade and commerce and were sought-after locations for the trading posts of the Italian merchant republics after

the 11th century. Results of the Fourth Crusade. The Fourth Crusade, called by Pope Innocent III to reconquer the Holy Land, was diverted to Constantinople. Following the crusaders' seizure and sack of the city in 1204, the European territories of the Byzantine Empire were divided up among the Western magnates. Whereas in Asia Minor Byzantine resistance was successful, so that two independent successor empires were established (those of Nicaea and Trebizond), most of Greece was quickly and effectively placed under Frankish (Western Christian) rule. The principality of Achaia (the Morea) and the duchy of the Archipelago were subject to the Latin emperor, the ruler of the Latin Empire (also referred to as Romania) set up in Constantinople in 1204 by the Latin (Western) Christians of the Fourth Crusade and claiming jurisdiction over the territories of the Byzantine state. A kingdom of Thessaloníki was es-

tablished, to whose ruler the lords of Athens and Thebes owed fealty; while the county of Cephalonia (which, along with the islands of Ithaca and Zákinthos had in fact already been under Italian rule since 1194, in the person of Matteo Orsini) was nominally subject to Venice, although it was in fact autonomous and after 1214 recognized the prince of Achaia as overlord. Finally, the lord of Euboia (Negroponte) was subject to the authority of both Thessaloníki and Venice. Byzantine control remained in the form of the despotate of Epirus in the northwest, in the area around Monemvasia in the eastern Peloponnese, and in the mountain fastness of the Taïyetos in Achaia and Arcadia, In 1261, however, the Nicaean forces were able to recover Constantinople and put an end to the Latin Empire. The recovery of some of the territory held by Frankish rulers followed, although Monemvasia actually fell, for a while, to a Frankish force in 1248; by the end of the 13th century parts of central Greece were once again in Byzantine hands, and the Byzantine despotate of Morea controlled much of the central and southeastern Peloponnese; but the principality of Achaia remained an important Frankish power to its north.

The history of Greece, as stated above, reflects very closely its geopolitical structure. This fact is particularly clear in the period following the Fourth Crusade, when the former Byzantine administrative divisions were organized into various petty states, each having its own local history and political evolution.

Despotate of Epirus. The so-called despotate of Epirus (ruled by a despotes, or lord), which usually included Cephalonia, was established by Michael I Komnenos Doukas, who established effective control after 1204 over northwestern Greece and a considerable part of Thessaly. His brother and successor Theodore was able to retake Thessaloníki from the Latins in 1224, where he was crowned as emperor, thus challenging the emperors of Nicaea who claimed legitimate imperial rule. But in 1242 the Nicaean ruler John III Vatatzes compelled Theodore's son and successor John to abandon the title of emperor, and by 1246 Thessaloníki was under Nicaean rule. In 1259 much of Epirus came under Nicaean control, but this was lost by 1264; thereafter Epirus continued to be ruled by independent despots (despotai) until 1318. Its sheltered geographic position, between the spine of the Pindus range and the Adriatic, facilitated a degree of political separatism and independence from Constantinople until the Ottoman conquest. The Byzantine emperors, however, always insisted on their rights to confer the title of despotes, and for much of the 14th and 15th centuries they regarded the rulers of Epirus as rebels.

From 1318 until 1337 Epirus was ruled by the Italian Orsini family, and, after a short Greek recovery, it was taken by the Serbs in 1348. Ioánnina and Arta were its main political centers. From 1366 to 1384 Ioánnina was ruled by Thomas Kommenos Palaeologus, also known as Preljubovič, the son of the caesar Gregory Preljub, who had been Serbian governor of Thessaly under Stefan Uroš.

IV Dušan He was able to assert Serbian control over northern Epirus and fought with the Albanian lords of Arta (Ghin Bua Spata and Peter Ljoša) in the south, eventually defeating them with Ottoman help. In 1382 his title of despotes was confirmed by the Byzantine emperor at Constantinople. He was assassinated late in 1384, probably by members of the local nobility who objected to his rule. His widow, the Byzantine Maria Angelina Doukaina Palaiologina, married the Italian nobleman Esau Buondelmonti, who ruled as despotes until about 1411. Thereafter the despotate came under the Italian house of Tocco. whose rulers were able to recover Arta from the Albanians. But in 1430 the Ottomans took Ioannina, and Arta fell to them in 1449. Thenceforth Epirus was to be part of the Ottoman Empire. Cephalonia was taken in 1479, but Venice seized it in 1500.

Thessaly and surrounding regions. The political history of the other regions of Greece during this period is no less complex. Thessaly was ruled in its eastern parts by the Franks after 1204, while the western regions were disputed by the rulers of Epirus and Nicaea. About 1267 John I Doukas established himself as independent ruler, with the Byzantine title sebastokrator, at Neopatras, but in expanding his control eastward he came into conflict with Michael VIII, whose attacks he repelled with the assistance of the dukes of Athens and Charles I of Anjou. Venetian support, the result of a favourable trading relationship (Thessaly exported agricultural produce), helped maintain Thessalian independence until the arrival in 1309 of the Catalan Grand Company. This band of Spanish mercenaries, who originally had been hired by Andronicus II (1282-1328) to fight the Seljuks in Anatolia, had turned against imperial authority and established themselves in the Gallipoli peninsula. From there they moved into Greece through Thrace and Macedonia, which they plundered, and from 1318 onward they occupied the southern districts of Thessaly. The northern regions remained independent until 1332 (under the ruler Stephen Gabrielopoulos), after which they were taken by John II Orsini of Epirus. In 1335 Thessalv was retaken by the Byzantine Empire, and from 1348 it acknowledged the overlordship of the Serbian ruler Stefan IV. After his death (1355) the self-styled emperor Symeon Uroš, despotēs of Epirus and Akarnania, was able to seize control of both Epirus and Thessaly and rule independently following the death of Nikephoros II of Epirus in 1358/59. He was succeeded by his son John, who adopted the monastic life in 1373 The caesar Alexios Angelos Philanthropenos took control, governing as a vassal of the Byzantine emperor John V; but in 1393 the conquest of Thessaly by Ottoman forces put an end to its independence.

Athens, Thebes, and Corinth. In the south, Greece was divided among a number of competing political units. After 1204 the dukes of Athens controlled much of central Greece, with their main base at Thebes. They had political interests to the north and in the Peloponnese. However, in 1311 the Catalan Grand Company established its power over the duchies of Athens and Thebes, turning out their Latin lords. Under the protection of the Aragonese king Frederick II of Sicily (three sons of whom became dukes of Athens), they dominated the region until the Navarrese Company (an army of mercenaries originally hired by Luis of Evreux, brother of Charles II of Navarre [1349-87], to help assert his claim over Albania and then temporarily in the service of the Knights Hospitalers, a military-monastic order) took Thebes in 1378 or 1379. This weakened Catalan power and opened the way for the Florentine Acciajuoli, lords of Corinth, to take Athens in 1388. The latter then ruled all three regions until their defeat at the

hands of the Ottomans in the 1450s. The Peloponnese. In the Peloponnese, the political rivalry between the Byzantines and the Frankish principality of Achaia dominated. The principality was at its most successful under its prince William II Villehardouin (1246–78), but in 1259 he had to cede a number of fortresses, including Mistra, Monemvasia, and Maina, to the Byzantines Internecine squabbles weakened resistance to Byzantine pressure, especially from the 1370s onward, when Jacques de Baux hired the Navarrese Company to The Catalan Grand Company

The Acciajuoli family fight for his claim to the principality. Upon his death in 1383 the Navarrese exercised effective political control over the Frankish territories under the commanders of the company. The last Navarrese prince, Pierre de St. Superan. joined the Ottomans in 1401 to raid Byzantine possessions in the southern Peloponnese; he died in 1402. He was succeeded by his widow, Maria Zaccaria, representative of an important Genoese merchant and naval family. She passed the title to her nephew Centurione II Zaccaria, who, however, lost much territory to the Byzantine despotate of the Morea. In 1430 he married his daughter to the Byzantine despotes Thomas Palaeologus, handing over his remaining lands as her dowry. From this time on, the Byzantine despotate of the Morea effectively controlled most of the Peloponnese. However, the Ottoman presence and the fall of Constantinople to Sultan Mehmed II in 1453 effectively ended this final period of Byzantine rule. The Morea resisted Ottoman conquest until 1460, when it was finally incorporated into the Ottoman Empire (a year earlier than the empire of Trebizond, which fell in 1461). All of Greece was by this time under Ottoman authority, with the exception of some of the islands, which retained a tenuous independence under Venetian or Genoese protection

Serbian and Ottoman advances. Byzantine power in the northern Greek regions was effectively destroyed by the expansion of the Serbian empire under Stefan Uroš IV Dušan (1331-55), the results of which included the loss of Epirus, Thessaly, and eastern Macedonia, as noted above. From the 1350s the Ottomans established themselves in Europe, taking the chief towns of Thrace in the 1360s and Thessaloniki in 1387. Apart from the despotate of the Morea, therefore, and certain of the Aegean isles, there remained in Greece no Byzantine imperial possessions by

the beginning of the 15th century.

The islands. A particularly complex picture is represented by the islands, which were a focus for the activities of the Seljuks and later the Ottomans, of the Venetians and Genoese, and of the Byzantines. Following the Fourth Crusade, much of the southern part of the Aegean came under Venetian authority; and, although Byzantine power was restored for a while in the late 13th century, Naxos remained the centre of the Latin duchy of the Archipelago, established in 1207 among the Cyclades by Marco Sanudo, a relative of the Venetian doge, with a body of freeboot-Archipelago ing merchants and nobles. Initially under the overlordship of the Latin emperor at Constantinople, the duchy later transferred its allegiance to Achaia (in 1261) and to Naples (in 1267), although Venice also claimed suzerainty. The Sanudo family was replaced in 1383 by the Lombard Crispi family, which retained its independence until 1566, when the duchy was conquered by the Ottomans (although ruled by an appointee of the sultan until 1579, when it was properly incorporated into the state).

The remaining islands were held at different times by the Venetians, the Genoese, the Knights Hospitalers, and, eventually, the Turks, Rhodes played a particular role in the history of the Hospitalers' opposition to the Ottomans. Until the early 13th century, the island had been in the hands of a succession of Italian adventurers, most of whom acknowledged the overlordship of the emperor at Nicaea. In 1308 the Hospitalers took control, having been based on Cyprus since 1291, the time of their expulsion from the Holy Land. Rhodes, however, fell finally in 1523, when the knights were permitted to remove to Malta. Of the northern Aegean islands, Lemnos remained Byzantine until 1453, before coming for a while under the rule of the Gattilusi of Lesbos (whose independence of the Ottomans finally ended in 1462). In 1460 it was awarded to Demetrios Palaeologus, formerly despotés of the Morea, along with the island of Thasos (the latter having come under Ottoman domination in 1455). In 1479 it was occupied by Ottoman forces and formally incorporated into the Ottoman state. Other islands had equally checkered histories. Naxos and Chios fell only in 1566; complete Ottoman control was not achieved, indeed, until 1715, when Tenedos, which remained until that year under Venetian control, was taken.

The real exception to the Ottoman success in the Aegean,

however, was Crete. Separately administered until the Crete 820s, when it was seized by Spanish Arabs, it was conquered in 961 by the general and later Byzantine emperor Nicephoros II Phocas. After 1204 it was handed over to Boniface of Monferrat, who proceeded to sell it to Venice Although oppressive and unpopular, Venetian rule witnessed the evolution of a flourishing Italo-Hellenic literary and political culture. It lasted until 1669, when, after a long siege of Candia and the creation and collapse of a range of temporary alliances between Venice and various western powers on the one hand and the Ottomans and their supporters on the other, the island passed into Ottoman hands.

Economic and social developments. In spite of the political instability after 1204, Greece seems to have experienced relative prosperity in the later Byzantine period. Population expansion accompanied an increase in production as marginal lands were brought under cultivation. and trade with major and minor Italian mercantile centres flourished. Although hostility at the level of state politics was endemic, social relations between the ruling elites of Byzantine- and Latin-dominated areas were not mutually exclusive. Intermarriage was not uncommon, and a certain modus vivendi appears to have evolved. This contrasted with the attitude of the peasantry and ordinary population, whose perceptions were shaped by the Orthodox church. an identity as either Greek or Byzantine ("Roman"), and by hostility to the Western church and its ways. The Ottoman conquest was not seen as necessarily worse than Latin domination; in many cases, it was certainly welcomed as less oppressive.

Population and languages. One of the most vexing questions concerning the history of medieval Greece has been that of the extent to which the indigenous "Hellenic" population survived and brings with it the question whether this term can properly be used of anything other than a cultural (as opposed to ethnic or racial) identity. The archaeological data, certainly, can offer answers only in terms of cultural similarities and differences, so that the question, as it has been traditionally expressed, of a Hellenic ethnic survival, cannot be answered. The issue must be explored in the context of the influx of large numbers of Slavs during the later 6th-8th centuries as well as the migration across Greece of nomadic or seminomadic pastoral groups such as the Vlachs from the 10th or 11th century and the Albanians from the 13th century. Although the evidence of place-names suggests some lasting Slavic influence in parts of Greece, the evidence is qualified by the fact that the process of re-Hellenization that occurred from the later 8th century seems to have eradicated many traces of Slavic presence. Evidence of tribal names found in both the Peloponnese and northern Greece suggests that there were probably extensive Slavicspeaking populations in many districts; and from the 10th century to the 15th century Slavic occupants of various parts of the Peloponnese appear in the sources as brigands or as fiercely independent warriors. Whereas the Slavs of the south appear to have adopted Greek, those of Macedonia and Thessaly retained their original dialects, becoming only partially Hellenophone in certain districts.

The Albanians. The origins of the Albanians (Albanoi/ Arvanitai in Greek) remain uncertain. They appear to be the descendants of the Illyrian populations who withdrew into the highlands of the central Dinaric chain. Their name may originate from the valley of the Arbanon (along the Shkumbi River) in the theme of Dyrrachion (Durrës/ Durazzo), in which they were first noted by outside commentators. Their language probably evolved from ancient Illyrian (formerly classed with the Hellenic group of Indo-European languages but now generally recognized as an independent member of the latter family), but it is heavily influenced by Greek, Slavic, and Turkish, as well as medieval Italian. For reasons not yet fully understood, the Albanians began in the 14th century to advance into the western coastal plain, where they served both Byzantine and Serbian overlords as well as ruling independently under various warlords and chiefly families; they were also present in considerable numbers in Thessaly, Boeotia, Attica, and the Peloponnese, serving as soldiers and as

The Latin duchy of the

The

Vlachs

language

farmers, colonizing deserted lands. Albanians arrived in large numbers in the Peloponnese during the reign of the despotēs Manuel Kantakouzenos, who brought them there to serve as soldiers and to resettle depopulated regions. The impact of their presence on the region's existing eth-

nic and linguistic structure remains debated.

The Vlachs. In central and southern Thessaly, the Vlachs played an important role. They have generally been identified with the indigenous, pre-Slav populations of Dacian and Thracian origin, many of whom migrated into the less-accessible mountainous areas of Greece and the northern Balkan region because of the Germanic and Avar-Slav invasions and immigration of the 5th-7th centuries. The Vlachs maintained a transhumant, pastoral economy in those areas. Their language belongs to the so-called Macedo-Romanian group and is closely related to that known from the 13th century on as Romanian (Daco-Romanian); it is essentially rooted in the late Latin, heavily influenced by the Slavic dialects with which the Daco-Thracian populations were in regular contact. By the 11th century the Vlachs are described as communities of shepherds who moved with their flocks between their winter pastures in Thessaly and summer pastures of the Gramoz Mountain and Pindus range; they are found in Byzantine armies and are mentioned in many documents dealing with landholdings in northern Greece, where-as is often the case in relations between settled and nomadic populations-they were regarded as troublemakers and thieves. Byzantines were often imprecise in their use of ethnic names; the Vlachs seem frequently to have been confused with the Bulgarians, through whose territory they also wandered on their seasonal routes and pasturage. A major modern debate about the role of the Vlachs in the establishment of the Second Bulgarian empire after 1185 continues, strongly marked by nationalist sentiment,

Emerging Greek identity. As the Byzantine Empire declined, the predominant role of Greek culture, literature, and language became ever more apparent. For Christians of the early and middle Byzantine worlds, the terms Hellene and Hellenic generally (although not exclusively, since in certain literary contexts a classicizing style permitted a somewhat different usage) had a pejorative connotation, signifying pagan and non-Christian rather than "Greek." From the 12th century, however, in the context of increasing conflict with Western European culture on the one hand and the encroaching Turkish powers on the other, this situation changed. With the territorial reduction of the empire to strictly Greek-speaking areas, the multiethnic tradition gave way to a more self-consciously "national" Greek consciousness, and a greater interest in "Hellenic" culture in a positive sense evolved. Byzantines began to refer to themselves not just as Rhomaioi, the traditional term, but as Hellenes. Notions of nationhood developed, and among learned circles a deep interest in the classical past was cultivated. While there was a powerful secularist tradition in this, culminating in the ideas of the neoplatonic Byzantine philosopher George Gemistus Plethon (who argued for the implementation of the political-philosophical system outlined in Plato's Republic), it was the combination of popular Orthodoxy (and strongly anti-Western ecclesiastical sentiment) with a specifically Greek identity that shaped the Byzantines' notions of themselves in the twilight years of the empire. With the political extinction of the empire, it was the Greek Orthodox church and the Greek-language community, in both "Greece" and Asia Minor that continued to cultivate this identity as well as the ideology of a Byzantine imperial heritage rooted in both the Roman and the classical Greek past.

GREECE UNDER OTTOMAN RULE

Constantinople fell to the Ottoman Turks on May 29, 1453. The Byzantine emperor, Constantine XI Palaeologus, was last seen fighting alongside his troops on the battlements; his death gave rise to the widely disseminated legend that the emperor had turned to marble but that one day he would return to liberate his people. By 1453 the Byzantine Empire was but a pathetic shadow of its former glories. The fall of this symbolic bastion of Christendom in the struggle against Islam may have sent shock waves through Western Christendom, but the conquest was accepted with resignation by many of the inhabitants of the city; as they saw it, their plight was a consequence of the sinfulness of the Byzantine Empire. Moreover, for many people Ottoman rule, and the maintenance of the integrity of the Orthodox faith, was preferable to accepting the pretensions of the papacy, the price Western Christendom had sought to exact in return for military assistance to ward off the Turkish threat. What was more, it was widely believed that the end of the world would come in 1492.

The millet system. With the conquest of the territories that had constituted the Byzantine Empire, the Ottoman sultans were faced with the problem of governing large non-Muslim populations. Christians and Jews, as "People of the Book," were afforded a considerable degree of toleration. Indeed, it was to the Ottoman Empire rather than Christian Europe that many Spanish Jews migrated following their expulsion from Spain in 1492. The Ottomans confronted the problem of the governance of these large heterodox and polyglot populations by establishing millets. These were organized on the basis of religious confession rather than ethnic origin, of which, in any case, in the early centuries of Ottoman rule there was little consciousness. The ruling millet within the empire was made up of the Muslims. Next in importance was the Orthodox Christian millet-i Rūm, or "Greek" millet, as it was known. There was also an Armenian, a Jewish, a Roman Catholic, and even, in the 19th century, a Protestant millet. Although its head, the ecumenical patriarch, was invariably of Greek origin, the term "Greek" millet was something of a misnomer, for it included, besides the Greeks, Romanians, Bulgarians, Serbs, Albanians, Vlachs, and substantial Arab populations. With the rise of nationalism in the 18th and 19th centuries the non-Greek members of the "Greek" millet came increasingly to chafe at the Greek stranglehold on the higher reaches of the hierarchy of the Orthodox church, through which the millet was administered.

The powers of the ecumenical patriarch were indeed extensive, although there is uncertainty as to the precise nature of the privileges granted by Sultan Mehmed II to the man whom he elevated to the highest office in the church. This was Gennadios II Scholarios, a known opponent of those who, in the last years of the Byzantine Empire, had advocated union with the Western church. Patriarchal authority was considerable and extended to civil as well as to strictly religious matters. In many respects, indeed, it was greater than that enjoyed by the patriarchs in Byzantine times. The privilege of a considerable degree of autonomy in directing the affairs of the millet carried with it the responsibility of ensuring that its members were unshaken in their loyalty to the Ottoman Porte, or government. If disloyalty manifested itself, then retribution was swift and harsh, as occurred at the time of the outbreak of the War of Greek Independence in 1821 when the patriarch Grigorios V was executed in reprisal, despite the fact that he had vigorously condemned the insurgents. In the West this was seen as an act of mindless barbarity. In the eyes of the Ottomans, however, Grigorios had signally failed to carry out his fundamental obligation, that of ensuring that

the Orthodox flock remained loyal subjects of the sultan. Disadvantages for non-Muslims. In keeping with Islamic tradition, members of the Greek millet enjoyed a considerable degree of autonomy in conducting their religious affairs. They were nonetheless at a disadvantage in a number of ways in comparison with members of the ruling Muslim millet. A Christian was not allowed to bear arms and was disbarred from military service (although this latter disability was in many ways a privilege), in lieu of which he had to pay a special tax, the haradj. In a court of law, a Muslim's word was always accepted over that of a Christian, although disputes between Christians were generally settled in courts under the control of the millet. A Christian could not marry a Muslim woman, and there was a strict prohibition against apostasy from Islām. Indeed, Christians who had embraced Islām and then reverted to Christianity, were, until well into the 19th century, invariably punished by death. These "neomartyrs," however, helped sustain the faith of the Orthodox populations during the centuries of Ottoman rule.

Compe-

tition for

high office

The janissary levy

The Leo

oracles

The most serious disability to which Christians were subject, until the practice died out toward the end of the 17th century, was the janissary levy (paidomazoma). Christian families in the Balkans were required, at irregular intervals, to deliver to the Ottoman authorities a given proportion of their most intelligent and handsome male children to serve, after being forcibly converted to Islām, as elite troops or civil servants. Inevitably the levy was much feared, but those conscripted frequently rose to high office and were sometimes able to help relatives or their native villages. Indeed, there is evidence of Muslim families seeking to pass their children off as Christian in the hope that they would be included in the levy and would thus be able to better their prospects. Under such pressures there were numerous instances of Christian conversion to Islam on both an individual and a mass basis. such conversions being particularly prevalent in the 17th century. Not infrequently, however, the conversions were only nominal, and these crypto-Christians secretly practiced the rituals of their former faith.

Resistance to Ottoman rule. During much of the four centuries of the "Tourkokratia," as the period of Ottoman rule in Greece is known, there was little hope that the Greeks would be able to free themselves by their own efforts, although there were sporadic revolts, such as occurred on the mainland and in the islands of the Aegean in the aftermath of the defeat inflicted on the Ottoman navy in 1571 by Don John of Austria; the short-lived revolt launched by Dionysius Skylosophos in Epirus in 1611; and the abortive uprising in the Peloponnese in 1770 at the time of the Russo-Turkish war of 1768-74. These uprisings had little chance of success, but throughout the centuries of the Tourkokratia there was a kind of armed resistance to the Turks in the form of the klephts (literally robbers). In their banditry the klephts did not distinguish between Greek and Turk, but their attacks on such manifest symbols of Ottoman authority as tax collectors led to their being seen as acting on behalf of the Greeks against Ottoman oppressors. Certainly they are viewed in this light in the corpus of klephtic ballads that emerged, extolling the bravery and military prowess of the klephts and their heroic resistance to the Ottomans.

In an effort to counter the depredations of the klephts and to control the mountain passes that were their favoured area of operation, the Ottomans established a militia of ammatoloi. Like the klephts, these were Christians, and the distinction between klepht and armatolos tended to be a narrow one. Moreover, the existence of such armed formations meant that, when the Greek revolt broke out in 1821, there was an invaluable reserve of military talent.

Belief in divine intervention. Greek aspirations for freedom were largely sustained by a corpus of prophetic and messianic beliefs that foretold the eventual overthrow of the Turkish voke as the result of divine rather than human intervention. Such were the oracles attributed to the Byzantine emperor Leo VI the Wise (886-912), which foretold the liberation of Constantinople 320 years after its fall-i.e., in 1773. Particular credence was placed in this prophecy, for its fulfillment coincided with the great Russo-Turkish war of 1768-74, one of the periodic confrontations between the two great regional powers. The Russians were the only Orthodox power not under foreign domination, and they were widely identified with the legendary "xanthon genos," a fair-haired race of future liberators from the north. The Russians were seen as forming part of a commonwealth linking the various parts of the Orthodox Christian world, with its common centres of pilgrimage such as the monastic republic of Mount Athos (forming one of the three fingers of the Chalcidice Peninsula) and Jerusalem.

The role of the Orthodox church. The Orthodox church was the only institution to which the Greeks could look as a focus. Through the use of Greek in the liturgy and through its modest educational efforts, the church helped to a degree to keep alive a sense of Greek identity, but it could not prevent Turkish (which was written with Greek characters) from becoming the verancular of a substantial proportion of the Greek population of Asia Minor and, indeed, of the Ottoman capital itself.

The Orthodox church, however, fell victim to the institutionalized corruption of the Ottoman system of government. The combining of civil with religious power in the hands of the ecumenical patriarchate and the upper reaches of the hierarchy prompted furious competition for high office. This was encouraged by the Ottomans, for it was soon the norm for a huge peshkesh, or bribe, to be paid to the grand vizier, the sultan's chief minister, on each occasion that a new patriarch was installed. Thus, despite the fact that, in theory, a patriarch was elected for life, there was a high turnover in office. Some even held the office more than once. Grigorios was executed by the Ottomans in 1821 during his third patriarchate, while during the second half of the 17th century Dionysius IV Mouselimis was elected patriarch no fewer than five times. It was this kind of behaviour that prompted an 18th-century Armenian chronicler to taunt the Greeks that they changed their patriarch more frequently than

they changed their shirt Bribes had to be paid to secure office at all levels, and these could be recouped only through the imposts placed on the Orthodox faithful as a whole. The clergy's reputation for rapacity led to the growth of anticlericalism at a popular level and, in particular, among the small nationalist intelligentsia that emerged in the course of the 18th century. The anonymous author of that fiery nationalist polemic the "Ellinikhi Nomarkhia" ("Hellenic Nomarchy"; 1806) was a bitter critic of the sloth and selfindulgence of the higher clergy, while Adamántios Koraïs (1748-1833), the intellectual mentor of the national revival, though careful to steer between what he termed the Scylla of superstition and the Charybdis of atheism, was highly censorious of the obscurantism of the clergy. What particularly incensed Koraïs and his ilk was the willingness with which the Orthodox hierarchy identified its interests with those of the Ottoman authorities. However, the views of men such as Anthimos, the patriarch of Jerusalem, who argued in 1798 that the Ottoman Empire was part of the divine dispensation granted by God to protect Orthodoxy from the taint of Roman Catholicism and of Western secularism and irreligion, were by no means unusual.

TRANSFORMATION TOWARD EMANCIPATION

Signs of Ottoman decline. During the 16th and 17th centuries the main preoccupation of the Greeks was with mere survival. In the course of the 18th century, however, a number of changes occurred both in the international situation and in Greek society itself that cumulatively gave rise to hopes that the Greeks might themselves launch a revolt against Ottoman authority with some promise of success. By the end of the 17th century the protracted process of Ottoman decline was clearly under way. The failure of the great siege of Vienna in 1683 signaled the beginning of a slow process of retreat in the European provinces of the empire. The military triumphs of earlier centuries gave way to pressure on the empire from the Austrians, the Russians, and the Persians. The Russian threat reached its apogee in the 1768-74 war with Turkey. The Russians were subsequently to claim the right to exercise a protectorate over all the Orthodox Christians of the Ottoman Empire on the basis of an optimistic reading of the terms of the peace settlement with the Ottoman Empire by the Treaty of Küçük Kaynarca.

As the empire lost territory as it was forced onto the defensive, so the control of the Ottoman Porte over its still enormous provinces weakened. In both European and Asaite Turkey, provincial warlords susurped the authority of the sultan, and the example of successful defiance of the Porte afforded by powerful satraps such as Ali Paşa wather of mainland Greece, gave encouragement to Greek nationalists, for it demonstrated that the empire was no longer the invincible monolith it once had been.

The Phanariotes. Of critical importance to the ultimate success of the national movement was the profound transformation that Greek society was to undergo during the course of the 18th century. Significant among these developments was the rise to power and influence of the Phanariotes, a small caste of Greek (and Hellenized Hospodar

Romanian and Albanian) families who took their collective name from the Phanar, or Lighthouse, quarter of Constantinople, the home of the ecumenical patriarchate. The roots of their ascendancy can be traced to the need of the Ottomans for skilled negotiators as the power of their empire declined. No longer in a position to dictate peace terms to their vanquished enemies, they now had to rely on diplomats skilled in negotiation who might mitigate the consequences of military defeat, and these were drawn from the Phanariotes, Between 1699, when the peace treaty with the Habsburg monarchy was signed at Carlowitz, and 1821, the year of the outbreak of the War of Greek Independence, Phanariote grandees monopolized the post of chief interpreter to the Porte. This was a more important post than it appeared, for its holder bore considerable responsibility for the conduct of foreign policy. Similarly, Phanariotes were invariably interpreters to the kapudan pasha, the admiral of the Ottoman fleet. Again their powers were wider than the title suggests, for these Phanariotes in effect acted as governors of the islands of the Aegean archipelago, whose Greek inhabitants were a principal source of the sailors manning the Ottoman fleet.

The most important posts held by Phanariotes were those of hospodar, or prince, of the Danubian principalities of Moldavia and Wallachia. Phanariotes ruled these potentially rich provinces as the viceroys of the sultans, and their sumptuous courts in Jassy (now Jasi, Rom.) and Bucharest aped on a lesser scale the splendour of the imperial court in Constantinople. Just as there was furious, and corrupt, jockeying for high office in the Orthodox church, so the appointment of the hospodars was accompanied by intrigue and corruption. Just as there was a high turnover in office of the ecumenical patriarch, so the average tenure in office of a Phanariote hospodar was less than three years. Because they needed to recoup their expenditures on bribes, hospodars acquired a not wholly justified reputation for greed and oppression. Some hospodars displayed an enlightened interest in legal and land reform. Most acted as patrons of Greek culture, education, and printing. The princely academies attracted teachers and pupils from throughout the Orthodox commonwealth, and there was some contact with intellectual trends in Habsburg central Europe. For the most part the Phanariotes were too closely wedded to the Ottoman system of government, of which they were major beneficiaries, to play a significant part in the emergence of the Greek national movement. Nonetheless, however much their interests coincided with the maintenance of the Ottoman status quo, they provided a pool of individuals with experience in diplomacy and politics when armed struggle erupted in 1821.

The mercantile middle class. The single most important development in the Greek world during the 18th century was the emergence of an entrepreneurial, prosperous, and far-flung mercantile middle class, which played a major role in the economic life of the Ottoman Empire but which was also active outside its bounds. Discouraged from investing their capital within the empire by the arbitrariness and rapacity of the state, these Greek merchants played an active role in developing commerce in Hungary and Transylvania, newly acquired by the Habsburg monarchy, and also in southern Russia, where they were encouraged to settle by the empress Catherine the Great after Russia's borders had reached the Black Sea. Greek became the basic language of Balkan commerce as these merchants challenged the existing hold of British. French, and Dutch merchants on the import-export trade of the empire, importing Western manufactured goods and colonial produce and exporting raw materials. Greek merchant communities, or paroikies, each with their own church, were established through much of central Europe. the Mediterranean littoral, and southern Russia, and even as far afield as India.

as lat aneut as mion.

Paralleling this development, a substantial merchant marine, based on the three "nauticail" islands of Hydra, Spetsai, and Psará, came into existence. This merchant marine prospered from running the continental blockade imposed by Great Britain during the period of the French revolutionary and Napoleonic wars. The existence of a reservoir of trained sailors was to prove of inestimable

advantage once the war of independence had broken out, when Greek fire ships became a formidable weapon against the cumbersome ships of the line of the Ottoman fleet.

The emergence of a mercantile middle class had a number of important consequences. Greeks were brought into contact with the ordered societies of western Europe, in which the state gave encouragement to commerce. They compared this state of affairs with that prevailing in the Ottoman Empire, where the absence of the rule of law and general arbitrariness militated against the generation of capital and still more its retention. Most of the merchants were, like the Phanariotes, too wedded to the status quo to give active encouragement to the national movement and thus potentially threaten their newfound prosperity. However, indirectly at least, they made a major contribution to the emerging national movement. For it was their wealth that provided the material basis for the intellectual revival that was such a significant feature of the last three decades of the 18th century and first two of the 19th. Impelled by the sense of local patriotism that had always been strong in the Greek world, they endowed schools and libraries. It was no accident that the three most important schools-cum-colleges in the Greek world on the eve of the war of independence were situated in Smyrna, Khios, and Ayvalik (on the coast of Asia Minor opposite the island of Lesbós), all three major centres of Greek commerce.

The intellectual revival. A significant number of schoolteachers studied, with the financial backing of their merchant benefactors, in the universities of western Europe, particularly those of Italy and the German states. There they came under the influence of the ideas of the European Enlightenment and encountered the intoxicating nationalist doctrines emanating from the French Revolution. Above all, they became aware of the reverence in which the language and culture of ancient Greece were held throughout Europe. This realization kindled in them a consciousness of their own past, a recognition of being the heirs to this same civilization and of speaking a language that had changed remarkably little in the two and a half millennia since the time of Pericles. During the 50 years or so before 1821 a veritable flood of books on the language, literature, and history of the ancient Greek world was published (albeit for the most part outside the Greek domains) for a Greek readership.

A leading role in the rediscovery of the past was played by Adamántios Koraïs. A native of Smyrna, where he was born in 1748, Koraïs sought, unsuccessfully, to establish himself as a merchant in Amsterdam. After studying medicine at the University of Montpellier, he moved to Paris in 1788, where he soon experienced the French Revolution firsthand. The main interest of his life, however, was classical philology, of which he became one of the foremost scholars in the Europe of his day. He devoted his years in Paris (until his death in 1833) to the study of this subject as well as to inspiring in his compatriots an appreciation of their classical ancestry. With the help of a family of rich merchants of Jannina (Ioánnina) he published a whole series of editions of classical authors, which he prefaced with exhortations to his compatriots to cast off their Byzantine ignorance by reviving the glories of the ancient world and by imitating the French, the people of modern Europe who, in his estimation, most resembled his classical forebears. His panacea for the degraded condition of the Greeks was education; it would enable them to free themselves from the double voke of the Ottoman Turks and the Orthodox church.

One consequence of what could be described as an obsession with antiquity on the part of the small nationalist
intelligentias was the practice of naming children (and
ships) after the worthies of ancient Greece, a custom dating
from the first decade of the 19th century. Another was the
vigorous debate that got under way, and which has lasted
until the present day, as to the form of the language that
was appropriate to a regenerated Greece. Some advocated
using the spoken language, the demotic, as the language
of educated discourse, Others favoured the Katharevousa,
or purified Greek, which would render it more akin to
the supposed purity of Attic Greek. Still others, such as
Korais, advocated a middle path.

Adamántios Koraïs

The merchant marine

FROM INSURGENCE TO INDEPENDENCE

Rigas Velestinlis. Toward the end of the 18th century Rigas Velestinlis (also known as Rigas Pheraios), a Hellenized Vlach from Thessaly, began not only to dream of, but actively to plan for, an armed revolt against the Turks. Rigas, who had served a number of Phanariote hospodars in the Danubian principalities, spent part of the 1790s in Vienna. There he had come under the influence of the French Revolution, as is manifest in a number of revolutionary tracts he had printed, intending to distribute them in an effort to stimulate a Pan-Balkan uprising against the Ottomans. These tracts included a "Declaration of the Rights of Man" and a "New Political Constitution of the Inhabitants of Rumeli, Asia Minor, the Islands of the Aegean, and the principalities of Moldavia and Wallachia." The latter proposed the establishment of what, in essence, would have been a revived Byzantine Empire, but an empire in which monarchical institutions would have been replaced by republican institutions on the French model. Rigas' insistence on the cultural predominance of the Greeks, however, and on the use of the Greek language, meant that his schemes had little potential interest for the other peoples of the Balkan Peninsula. In any case, Rigas' ambitious schemes came to naught. Before he had even set foot on Ottoman soil, he was betrayed by a fellow Greek to the Habsburg authorities, who promptly handed him and a small group of coconspirators over to the Ottoman authorities; he was strangled by them in Belgrade in the summer of 1798. At one level Rigas' conspiracy had thus been a miserable failure, but his almost single-handed crusade served as an inspiration to subsequent generations of Greek nationalists

Western encroachments. The arrest of Rigas thoroughly alarmed both the Ottoman authorities and the hierarchy of the Orthodox church, for it almost coincided with the occupation of the Ionian Islands in 1797 by the forces of revolutionary France and with Bonaparte's invasion of Egypt in 1798. These developments occasioned panic in Constantinople, for they seemed to indicate that the seditious and atheistic doctrines of the French Revolution had arrived at the very borders of the empire. The brief period of French rule in the Ionian Islands, attended as it was by the rhetoric of revolutionary liberation, soon gave way to a short-lived Russo-Turkish condominium, a further period of French rule, and finally, after 1815, the establishment of a British protectorate. Although governed like a colony, the Ionian Islands under British rule in theory constituted an independent state and thus afforded an example of free Greek soil, adjacent to but not under the control of the Ottoman Empire.

Phillik Etaireia. The example of Rigas Velestinilis was very much in the minds of the three young Greeks, lowly members of the Greek mercantile diaspora, who in 1814 in Odessa in southern Russia, the centre of a thriving Greek community, founded the Phillik Etaireia, or "Friendly Society," with the specific aim of laying the foundations for a coordinated, armed uprising against the Turks. The three founders, Emmanuil Xanthos, Nicholas Skouphas, and Athanasios Tsakalov, had little vision of the shape of the independent Greece for which they aimed beyond the liberation of the motherland.

The initiation rituals of the Philiki Etaireia were strongly influenced by those of the Freemasons. There were four categories of membership, ranging from the lowly vlamis (brother) to the pointin (shepherd). Those who betrayed

the conspiracy were ruthlessly dispatched. Initially the society's attempt to recruit members throughout the Greek world met with little success, but from 1818 noward it made some headway, finding the communities of the diaspora an important source of recruits. From the outset the leadership of the society, well aware that the overwhelming majority of the Greek people looked upon their fellow Orthodox, the Russians, as their most likely liberators, put it about, quite misleadingly, that the conspiracy enjoyed the support of the Russian authorities.

In this connection, two attempts were made to recruit as leader of the conspiracy Count Ioannis Kapodistrias, a Greek from Corfu, who, since 1816, had served as joint foreign minister to Tsar Alexander I of Russia and who was well versed in the ways of European diplomacy. The conservative Kapodistrias, however, was dismissive of the plot and urged the Greeks to bide their time until there was yet another of the regular wars between the Russian and Ottoman empires, when they might hope to achieve the kind of quasi-autonomy enjoyed by Serbia since 1813. Although he could see no future in the plans of the members of the Philikí Etaireía, Kapodístrias did net betray the secret of the conspiracy. It was to another Greek in the Russian service, Prince Alexander Ypsilantis, a Phanariote who held the position of aide-de-camp to Alexander but who lacked the political experience of Kapodistrias, that the leadership was offered

Like Rigas Velestinlis, the conspirators were hoping for the support of the Romanians and Bulgarians, but there was little enthusiasm for the project on the part of the other Balkan peoples, who were inclined to view the Greeks, with their privileged position in the Ottoman Empire and their enthusiasm for the ecclesiastical and cultural Hellenization of the other Balkan Christians, as scarcely less oppressive than the Turks.

Although unable to rely on the other Balkan peoples, the leadership of the conspiracy succeeded in exploiting the internal problems of the Ottoman Empire to its advantage. Sultan Mahmud II, who had ascended the throne in 1808. was bent on restoring the authority of the central government. To this end, in the winter of 1820, he launched an attack against Ali Paşa Tepelenë, a provincial warlord who, from his capital in Jannina, exercised control over large areas of mainland Greece. Although he nominally paid allegiance to the sultan, his virtual independence had for many years made him a thorn in the flesh of the Ottoman authorities. Taking advantage of the fact that large numbers of Ottoman troops were tied up in the campaign against Ali Paşa, Alexander Ypsilantis launched an attack from Russian territory across the Pruth River in March 1821, invoking the glories of ancient Greece in his call to arms from the Moldavian capital, Jassy. However, his campaign met with little success. He encountered no enthusiasm on the part of the supporters of Tudor Vladimirescu, who had risen against the oppression of the local Romanian boyars, or notables. Memories of Phanariote Greek oppression were altogether too vivid and recent. In June of 1821 Ypsilantis and his motley army were defeated at the battle of Dragatsani, and Ypsilantis was forced ignominiously to flee into Habsburg territory, where he died in captivity in 1828

Revolt in the Peloponnese. Shortly after Ypsilantis' incursion into Moldavia, scattered violent incidents coalesced into a major revolt in the Peloponnese. With atrocities being committed by both sides, the Turks, very much in a minority, were forced to retreat to their coastal fortresses. The diversion of Ottoman forces for the attack on Ali Paşa, the element of surprise, and the military and naval skills on which the Greeks could draw, gave the Greeks an advantage in the early years of what proved a length ystruggle.

The revolt caught the public imagination in western Europe, even if in the early years the reactionary governments of post-Napoleonic Europe were not prepared to countenance any disturbance of the existing order. Public sympathy in western Europe, however, was translated into more concrete expressions of support with the arrival in the Peloponnese of philhellene volunteers, the best-known of whom was the poet Lord Byron, who had traveled Civil war

extensively in the Greek lands before 1821. The military contribution of the philhellenes was limited, and some became disillusioned when they discovered that Greek reality differed from the idealized vision of Periclean Athens in which they had been nutrued in their home countries. But, the philhellenic committees that sprang up in Europe and the United States raised money for the prosecution of the war and the succour of its victims, such as the survivors of the great massacre on Chios in 1822, immortalized by the French painter Eugène Delacroix.

Factionalism in the emerging state. At a very early stage in the fighting the question of the governance of the liberated territories arose. Initially no fewer than three provisional governments concurrently came into existence, while in 1822 a constitution, which by the standards of the day was highly democratic, was adopted with more than half an eye to securing the support of enlightened public opinion in Europe. A revised constitution was adopted unifed in a central authority. However, unification and idnot bring unity. Feuding between rival groups culminated in outright civil war in 1824, prompting one chieftain, Makriyannis, to protest that he had not taken up arms against the Turks in order to end up fishting Greeks.

Such factionalism derived from a number of causes. There was a basic tension between the kodjabashis, or notables, of the Peloponnese, who were anxious to ensure that they retained the privileged status they had held under the Ottomans, and the military element, associated with such klephtic leaders as Theodoros Kolokotronis. who sought recognition in terms of political power for their contribution to the war effort. The island shipowners, whose contribution to the prosecution of the war at sea was vital, likewise laid claim to a share of power, while the small intelligentsia argued for the adoption of liberal parliamentary institutions. To some degree the clash can be seen as a confrontation between Westernizers and traditional elites, to some degree as a clash between the military and civilian parties. The Westernizers, who were consciously nationalist and whose attitudes were expressed by their adoption of a Western lifestyle and Western clothing, wanted independent Greece to develop along the lines of a European state, with a regular army and with a curb on the traditional powers of the church. The traditional elites, on the other hand, tended to see the struggle in terms of a religious crusade against the Muslims, and their national consciousness was less fully articulated. Anxious to maintain the power and privileges they had enjoyed before the struggle began, they were chiefly concerned with substituting the oligarchy of the Turks with their own.

The insurgents could ill afford internecine fighting. Mahmud II had by this time forged an alliance with his nominal subject, Muhammad 'Ali, the ruler of Egypt, and his son Ibrahim Pasha, who were promised lavish territorial rewards in return for their assistance in suppressing the revolt. From early 1825 Ibrahim Pasha engaged in a bitter war with the insurgents. As their initially favourable military position deteriorated, the insurgents looked increasingly for salvation to the Great Powers, which, from a combination of mutual suspicion as to each other's objectives and concern at the damage being done to their commercial interests, gradually moved toward a more incommercial interests, gradually moved toward a more in-

terventionist position. In 1826, by the Protocol of St. Petersburg, Britain and Russia committed themselves to a policy of mediation, to which France became a party through the Treaty of London of 1827. A policy of "peaceful interference," as the British prime minister Lord Canning described it, culminated in the not wholly planned destruction of the Turco-Egyptian fleet by a combined British, French, and Russian fleet at the Battle of Navarino in October 1827, the last great naval battle of the age of sail. This intervention by the Great Powers was instrumental in ensuring that some form of independent Greece came into existence, although its precise borders, which ran from Arta in the west to Volos in the east, took some years to negotiate. This process was overseen by Count Ioánnis Kapodístrias, who was elected the first president of Greece by the Assembly of Troezene, which in 1827 enacted the third constitution of the independence period. Besides overseeing the negotiation of the boundaries of the new state, in which his sevenise diplomatic experience in the Russian imperial service was employed to the full, Kapodistrias was also fully engaged in trying to create the infrastructure of a state in a country that had been ravaged by a vicious and destructive war. Schooled as he was in the traditions of Russian autocracy, Kapodistrias chafed under the provisions of the 1827 constitution, which, like its predecessors, was a remarkably liberal document, and he abrogated it. His paternalist and authoritarian style of government offended a number of key elements in the power structure of the embryonic Greek state. Growing unrest culminated in his assassination in Nauplia, the provisional capital, in October 1831.

BUILDING THE NATION, 1832-1913

Greece's existence as an independent state gained formal recognition in the treaty of 1832 between Bavaria and the Great, or "Frotecting," Powers. Significantly, the Greess themselves were not party to the treaty. Greece now, formally at least, became a sovereign state, and the Greeks were thus the first of the subject peoples of the Ottoman Empire to gain full independence. But the state contained within its borders scarcely one-third of the Greek populations of the Middle East, and the struggle to expand the nation's borders was to dominate the first century of independent statehood. Only in 1947, with the incorporation of the Dodecanese Islands (a group of islands off the southwestern coast of Turkey hitherto under Italian rule), were Greece's present borders established.

Moreover, the sovereignty of the small Greek state was not absolute. The Protecting Powers had determined that Greece should be a monarchy, and they retained certain ill-defined rights of intervention.

Greece under Otto of Wittelsbach. The Great Powers had chosen Otto of Wittelsbach, the 17-year-old son of King Louis I (Ludwig) of Bavaria, as king of Greece. Because Otto was still a minor, the Great Powers determined that until he came of age the country was to be ruled by three Bavarian regents, while the army was to be composed of Bavarians. The period of the "Bavarotratia," as the regents was termed, was not a happy one, for the regents showed little sensitivity to the mores of Orto's adopted countrymen and imported European models wholesale without regard to local conditions. Thus the legal and educational systems were heavily influenced by German and French models, as was the church settlement of 1833, which ended the traditional authority of the ecumenical patriarch and subjected ecclesiastical affairs to

civil control. Even after the formal ending of the regency in 1835, the Bavarian presence remained strong and was increasingly resented by those who had fought for independence and who now felt cheated of the fruits of victory. A further source of frustration for some was Otto's failure to grant a constitution, as had been provided for in the negotiations preceding independence. Despite the absence of a constitution, however, political parties of a kind came into existence; the "British," "Russian," and "French" parties were associated, as their names suggest, with the diplomatic representatives of the Great Powers, and their main appeal was strong personalities rather than well defined ideologies.

Toward the end of the decade of the 1830s there was ground discontent with Otto's rule. There was no sign of his conceding a constitution; Bavarians were still influential; his marriage to Queen Amalia had not produced an heir; the king remained a Roman Catholic in an Orthodox country with a strong anti-Catholic tradition; and much of the country's revenues were being expended in servicing the loan granted on independence by the Protecting Powers.

These various strands of discontent coalesced in the military coup of September 1843. Virtually bloodless, but on this occasion manifestly reflecting the popular will, the coup was the first of many military interventions in the political process. Otto was forced to grant a constitution (promulgated in 1844), which was a liberal document by

The
"Bavaro-

The Battle of Navarino

> The constitution of 1844

the standards of the day, providing for virtually universal manhood suffrage (although women were barred from voting until as late as 1952). However, Olto, in concert with his wilp prime minister, Ioannis Kolettis, was able to subvert the spirit of the new constitution by establishing a kind of parliamentary dictatorship. Moreover, the attempt to graft a liberal constitutional democracy onto an essentially premodern, traditional society that had evolved in quite a different fashion from those of western Europe gave rise to tensions both within the political system and in the relations between state and society which have continued until modern times. Rouspheti (the reciprocal dispensation of favours), patronage, manipulation, and, at times, outright force continued to characterize the politics of the postconstitutional period.

The Great Idea. It was during the debates that preceded the promulgation of the 1844 constitution that Kolettis first coined the expression the "Great Idea" (Greek: Megali Idea). This was a visionary nationalist aspiration that was to dominate foreign relations and, indeed, to a significant extent, to determine the domestic politics of the Greek state for much of the first century of its indeem-

dent existence.

If the expression was new in 1844, the concept was deeply rooted in the Greek popular psyche, nurtured as it was by the prophecies and oracles that had kept alive hopes of eventual emancipation from the Turkish yoke during the dark centuries of the Tourkokratia. In essence, the Great Idea envisaged the restoration of the Christian Orthodox Byzantine Empire, with its capital once again established in Constantinople, which would be achieved by incorporating within the bounds of a single state all the areas of Greek settlement in the Middle East. Besides the Greek populations settled over a wide area of the southern Balkan Peninsula, there were extensive Greek populations in the Ottoman capital, Constantinople (Istanbul) itself; around the shores of the Sea of Marmara; along the western littoral of Asia Minor, particularly in the region of Smyrna (Izmir): in central Anatolia (Cappadocia), where much of the Greek populace was Turkish-speaking but employed the Greek alphabet to write Turkish; and in the Pontus region of northeastern Asia Minor, whose geographic isolation had given rise to a form of Greek barely intelligible elsewhere in the Greek world.

The Great Idea, the liberation by the Greek state of the "unredeemed" Greeks of the Ottoman Empire, was to be achieved through a combination of military means—an ambitious objective indeed for a state with such limited resources—and a far-reaching program of educational and cultural propaganda aimed at instilling a sense of Hellenic identity in the very large Greek populations that remained under Ottoman rule. The University of Athens (founded 1837) attracted people from all parts of the Greek world to be trained as students and apostles of Hellenism.

Greece hoped to profit from the Crimean War (1854–56) fought between Russia (as stated above, the only sovereign Orthodox power and looked upon for so long as the most likely liberator of the Greeks) and the Ottoman Empire and its British and French allies. However, Greek neutrality in the conflict was enforced by a British and French occupation of Piraeus, the port of Athens; this was one of several interventions in Greece's internal affairs by the Protecting Powers that made light of Greece's sovereign status.

King Otto's enthusiasm for the Great Idea at the time of the Crimean War was popular with his subjects, but during the 1850s there was renewed discontent. The manipulation of the 1844 constitution had alienated a younger generation of politicians who had had no direct experience of the war of independence. Moreover, Otto had still not converted to the Orthodox church and still had no heir. The king was driven into exite following a coup in 1862; throughout his remaining days in exite in Bavaria he demonstrated an affection for his subjects that was largely unreciprocated.

Reform, expansion, and defeat. The downfall of King Otto obliged the Great Powers to search for a new sovereign who could not be drawn from their own dynasties. Their choice was a prince of the Danish Glücksburg family, who

reigned as King George I of the Hellenes from 1863 to 1913; thereafter the Glücksburg dynasty reigned intermittently until the 1974 referendum rejected the institution of monarchy. To mark the beginning of the new reign, Britain ceded to Greece the Ionian Islands, over which it had exercised a protectorate since 1815. This represented the first accession of territory to the Greek state since independence.

Political modernization. A new constitution in 1864 amplified the democratic freedoms of the 1844 constitution, although the sovereign retained substantial, if vaguely defined, powers in foreign policy. However, the realities of politics remained much as before, with numerous elections and even more frequent changes of administration, as politicians formed impermanent coalitions, jockeying for power in the disproportionately large parliament. It was not until 1875 that a decisive step was taken toward political modernization. In that year King George conceded that he would thenceforth entrust the government to the political leader enjoying the confidence of a majority of the deputies in parliament. During the last quarter of the 19th century the kaleidoscopic coalitions of earlier years gave way to a two-party system, in which power alternated between two men, Kharílaos Trikoúpis and Theodoros Deliyannis. Trikoúpis represented the modernizing, Westernizing trend in politics, while Delivannis was a political boss in the traditional mold, with no real program other than overturning the reforms of his archrival Trikoupis. Believing the modernization of the political system and economic development to be the essential preconditions of territorial expansion, Trikoúpis struggled to establish Greece's credit-worthiness in international markets and encouraged the country's hesitant steps in the direction of industrialization. He also promoted infrastructural projects such as road building, railway construction, the building of the Corinth Canal, and the draining of Lake Kopaïs in Thessaly. Such measures, however, and also Trikoúpis' concurrent efforts to modernize the country's armed forces, had to be paid for, and the increased taxation they entailed proved an easy target for a populist demagogue such as Delivannis, Delivannis was able to court further popularity by advocating an aggressive policy toward the Ottoman Empire, but his belligerence was to have disastrous economic consequences.

Extension of Greek borders. If Britain had hoped to dampen irredentist enthusiasm by ceding the Ionian Islands, it was sorely mistaken. The continuing agitation in the "Great Island" of Crete for union with the Greek kingdom, which erupted in periodic uprisings, caused inevitable friction in relations with the Ottoman Empire, as did Greece's rather maladroit effort to exploit the latter's discomfiture in the great Middle Eastern crisis of 1875-78, which gave rise to a war between Russia and the Ottoman Empire. The Great Powers, meeting in Berlin in 1878, besides cutting down to size the "Big Bulgaria" that had arisen from the conflict, pressed the Ottoman government to cede the rich agricultural province of Thessaly and a part of Epirus to Greece. Thus, in 1881 the second extension of the territory of the independent state came about, like the first-the cession of the Ionian Islandsas a result of mediation by the Great Powers rather than of armed conflict. In 1878, again as part of the Berlin settlement, the island of Cyprus, with its largely Greek population, came under British administration, while formally remaining under Ottoman sovereignty. The island was annexed by Britain in 1914 after the Ottoman Empire had entered the war on the side of the Central Powers, becoming a crown colony in 1925.

Rectification of frontiers The incorporation of Thessaly brought the northern frontier of Greece to the borders of Macedonia, which, with its mixed population of Greeks, Bulgarians, Serbs, Albanians, Turks, Vlachs, and Gypsies was a byword for ethnic complexity. It also brought Greece into contention with Serbia and Bulgaria, all of which cast covetous eyes over Macedonia, which remained under Ottoman rule. Initially, the contest was conducted by means of ecclesiastical, educational, and cultural propaganda, but at the turn of the century rival guerrilla bands, financed by their respective governments (and supported by public

Trikoúpis and Deliyannis opinion), sought to achieve by terror what they could not achieve by more peaceful means.

While Trikoupis argued for the strengthening of the state as the essential precondition of territorial expansion, Delivannis showed no such caution. But his mobilization in 1885 in an attempt to exploit a crisis over Bulgaria resulted in the imposition of a naval blockade by the Great Powers, while his support for the insurgents in Crete in 1897 led to humiliating defeat in the Thirty Days' War with Turkey. Greece was forced to pay compensation and to accept rectifications of its frontier. Moreover, the repayment of its substantial external debts was to be overseen by an international financial commission, another humiliating erosion of its sovereignty.

Emigration. Military endeavours compounded serious economic problems, which had culminated in national bankruptcy in 1893. Economic difficulties were primarily responsible for the great wave of emigration, principally from the Peloponnese to the United States, that characterized the last decade of the 19th and the first decade of the 20th century. About one-sixth of the entire population participated in this great exodus. Very largely male, the early emigrants had little intention of settling permanently overseas; few, however, returned to their homeland, although most retained strong nostalgic ties to their birthplace. Migrant remittances to relatives in the old country thenceforward made a significant contribution to the country's balance of payments.

The early Venizélos years. The clear lesson of the 1897 war was that, however weakened the Ottoman state might be, Greece, notwithstanding the impassioned rhetoric of nationalist politicians, was in no position to engage in single-handed military confrontation. Allies and the reinvigoration of the ramshackle state and economy were the necessary preconditions of a successful military challenge. The latter came about under the inspired leadership of Eleuthérios Venizélos, who had made his mark in the politics of his native Crete where an autonomous regime had been established in the aftermath of the 1897 war. A charismatic figure who was adored and execrated in equal measure, Venizélos dominated Greek politics during the first third of the 20th century.

The Goudi coup. Venizélos was projected from the provincial to the national stage as a consequence of a coup staged by the Military League, formed by disaffected army officers, from Goudi (at the outskirts of Athens) in 1909; this coup ushered in a persistent pattern of military involvement in politics during the 20th century. The conspirators demanded thoroughgoing reforms of both a nonmilitary and a military nature, the latter including the removal of the royal princes, who were held to favour the promotion of their own protégés, from the armed forces. Venizélos' reformist program. The short-lived but forceful intervention of the military compelled the discredited political establishment to make way for Venizélos, who had not been compromised by involvement in the petty politics of the kingdom. In elections held in December 1910 Venizélos and his newly founded Liberal Party won more than four-fifths of the seats in parliament. His power legitimized through elections, Venizélos plunged into a wide-ranging program of constitutional reform, political modernization, and economic development, which he combined with an energetic espousal of the Great Idea. Some 50 amendments to the 1864 constitution were enacted; provision was made for land reform; innovations were made in the educational system; and legislation benefiting the working population was introduced. These moderately reformist policies inhibited the development of the powerful agrarian and socialist movements that developed elsewhere in the Balkans. British naval and French military missions were brought in to overhaul the armed forces. Venizélos' continuing political ascendancy was confirmed with a sweeping victory in elections held in 1912

The Balkan Wars. The pessimism induced by the defeat of 1897 gave way to a period of optimism, in which Greece grandiosely saw itself as a power in the ascendant poised to displace a declining Ottoman Empire as the leading power in the Middle East. When, in 1911, Italy attacked the Ottoman Empire (in the process occupying the largely Greek-populated Dodecanese islands), Greece, no less than the other Balkan states, wanted its share of the spoils from the ever more likely collapse of Ottoman rule in the Balkans. However, Greece's situation differed from that of its Balkan neighbours, whose populations were relatively compactly settled within the Balkan peninsula. The Greeks alone were widely dispersed throughout the Middle Fast and hence were vulnerable to Turkish reprisals in the event of a war. Nonetheless, Greece could scarcely stand aside from the complex of alliances being formed among the Balkan states. These culminated in October 1912 in the First Balkan War, with Greece, Serbia. Bulgaria, and Montenegro declaring war on the Ottoman Empire. In contrast to earlier Balkan crises, the Great Powers did not intervene, and the heavily outnumbered Ottoman forces were forced into rapid retreat. Within less than a month. Thessaloniki (Salonica), the most important port in the northern Aegean, coveted by Bulgaria as well as by Greece, was captured by Greek forces. In February 1913 Greek forces took Ioánnina, the capital of Epirus. Meanwhile the Greek navy rapidly occupied the Aegean islands still under Ottoman rule.

The Balkan alliance was always a somewhat fragile affair in view of rivalries over Macedonia. Bulgaria, in particular, felt that its sacrifices had been in vain and turned against its erstwhile allies Greece and Serbia. This brief Second Balkan War (June to July 1913) led to the Treaty of Bucharest (August 1913), in which Bulgaria was forced to acknowledge the acquisition by Greece and Serbia of the lion's share of Macedonia. At the same time the formal union of Crete with the kingdom was recognized, although Greek hopes for the annexation of northern Epirus, with its large Greek population, were thwarted when the region was incorporated into the newly independent Albania.

The expansion of Greece's territories in the First and Second Balkan Wars had been truly breathtaking. Its land area had increased by some 70 percent, and so had its population (from 2.8 million to 4.8 million), but by no means were all of its newly acquired citizens ethnic Greeks. Indeed, in the city of Thessaloniki the largest single element in the city's population comprised Sephardic Jews, the descendants of the Jews expelled from Spain in 1492, who continued to speak Spanish. Elsewhere in "New Greece," as the recently acquired territories came to be known, there were substantial Slavic, Muslim (mainly Turkish), Vlach, and Gypsy populations. Like the Jews, many of these populations did not look upon the Greeks as liberators. The integration of "New" with "Old" Greece, the conservative core of the original kingdom, was not to be an easy process, but the problems it created did not emerge until much later.

At the conclusion of hostilities, Greece was gripped by euphoria. Under the charismatic leadership of Venizélos, the irredentist aspirations enshrined in the Great Idea appeared to be within reach. When King George I died at the hands of a deranged assassin in March 1913, there were demands that his successor, Crown Prince Constantine, be crowned not Constantine I (as he was) but Constantine XII to symbolize continuity with Constantine XI Palaeologus, the last emperor of Byzantium.

GREEK HISTORY SINCE WORLD WAR I

From National Schism to dictatorship. The dynamism and sense of national unity that had characterized the early Venizélos years gave way to rancour and vindictiveness that was to poison the country's political life throughout World War I and the interwar period. Greece was riven by the "National Schism," a division of the country into irreconcilable camps supporting either King Constantine I or his prime minister, Venizélos. The immediate grounds for tension were differences between the king and the prime minister as to Greece's alignment during World War I, although there were deeper causes underlying the split. The king advocated neutrality, while Venizelos was an enthusiastic supporter of the Triple Entente-Britain, France, and Russia-which he regarded as the alliance most likely to favour the implementation of Greece's remaining irredentist ambitions. The entente had, indeed, in an effort to lure Greece into the war, held out the attractive

The First Balkan War

question of alignment

The breach between the two became irrevocable when Venizélos in October of 1916 established a rival government in Thessaloníki, which, like most of "New Greece," was passionately loyal to Venizélos. In June 1917 the entente allies ousted King Constantine and installed Venizélos as prime minister of a formally united but bitterly divided Greece. Venizélos duly brought Greece, hitherto neutral, into the war on the side of the entente. Naturally, he expected to reap the reward for his loyalty at the Paris Peace Conference. In May of 1919 Greece was permitted to land troops in Smyrna (İzmir), the major port city in Asia Minor, with its large Greek population, and Greece was a major beneficiary of the Treaty of Sèvres of August 1920, the peace treaty with the defeated Ottoman Empire. However, for the Turkish nationalists, galvanized by the leadership of Mustafa Kemal (Atatürk), the treaty was from the outset a dead letter and the Greek landings a challenge they were prepared to meet.

In November 1920 Venizelos, to universal surprise, was defeated in elections, and the exiled King Constantine I was restored to his throne after a bogus plebiscite to the manifest displeasure of Britain and France. Meanwhile, the military situation in Asia Minor steadily deteriorated, a Turkish nationalist offensive in August/September 1922 resulted in a dramatic rout of the Greek armies in Asia Minor. Much of Smyrna was burned, and many Greeks and Armenians were killed. Tens of thousands of destitute Greek refugees fled to the kingdom. Thus ended a 2,500-year Greek presence in Asia Minor and with it the elusive

vision of the Great Idea.

Exchange

of popula-

tions

A military junta seized power in 1922 as King Constantine abdicated. Five royalist politicians and the deranged commander of the Asia Minor forces were tried and executed on a charge of high treason, although there was no evidence of deliberate treasher. The "Trial of the Six" was to poison the climate of interwar politics, exacerbating the already bitter feud between the supporters of Venizelos

and of the monarchy. At a peace conference in Lausanne an exchange of populations between Greece and the newly established Turkish Republic was agreed upon. The criterion employed was religion, one consequence of which was the exchange of many tens of thousands of Turkish-speaking Orthodox Christians for Greek-speaking Muslims. The ecumenical patriarchate was allowed to remain in Constantinople, as were the Greek inhabitants of that city and of the two islands. Imbros (now Gökce) and Tenedos (Turkish: Bozca), which straddled the entrance to the strategically sensitive Dardanelles. In return, the Muslims of Greek Thrace were allowed to remain in situ. An influx of some 1.3 million refugees (including significant numbers from Russia and Bulgaria) strongly tested the social fabric of a country prostrated by some 10 years of intermittent war. Nonetheless, leaving aside the prejudice they encountered on the part of the indigenous population, the process of their integration into Greek society was remarkably successful. The economy, benefiting from the entrepreneurial skills of the refugees, experienced a significant degree of industrialization during the interwar period. The remaining large estates were broken up to provide smallholdings for the newcomers, and rural Greece became a society of peasant smallholders, which made for social stability albeit not for economic efficiency. The majority of the refugees were settled in the territories of "New Greece," thereby consolidating the area's "Greekness." Although refugees were disproportionately represented in the leadership of the newly founded Greek Communist Party (KKE), they by and large rémained intensely loyal to Venizélos. Their vote was clearly instrumental in the formal establishment of a republic in 1923, shortly after the departure of King George II, who had briefly succeeded to the throne following his father's abdication in 1922. Indeed, the refugees and the army acted as the arbiters of political life during the interwar period.

In 1928 Venizélos made a political comeback, two years after the downfall of the short-lived military dictatorship headed by General Theodoros Pangalos in 1925-26. Although Venizélos initiated a good-neighbour policy with Italy and Greece's Balkan neighbours and brought about a remarkable rapprochement with Turkey, his government was knocked off course by the repercussions of the Stock Market Crash on Wall Street in 1929. Because Greece was dependent on the export of agricultural products such as olive oil, tobacco, and currents and on migrant remittances, it was severely affected by the slump in world trade. Moreover, after four years of relative stability, politics reverted to the confusion of the early 1920s. When the anti-Venizélists won the 1933 elections, Colonel Nikolaos Plastiras, a staunch supporter of Venizélos and the mastermind behind the 1922 coup, sought to restore Venizélos to power by force. His coup was unsuccessful and was shortly afterward followed by an attempt on Venizélos' life. The political arena was once again polarized between supporters of Venizélos and of the monarchy. Fear of a royalist restoration lay behind another attempted coup by Venizelist officers in March 1935, Because of his proven involvement on this occasion. Venizelos was forced into exile in France, where he died shortly afterward, but not before he had urged his supporters to effect a reconcilia-

tion with the king.

The royalists were the main beneficiaries of the abortive 1935 coup, in the aftermath of which King George II had been restored to his throne, following a distinctly dubious been restored to his throne, following a distinctly dubious of Greece was in a conciliatory mood. However, elections held under a system of proportional representation in January 1936 produced a deadlock between the two main parliamentary blocs, the Venizelists and the royalists. Both blocs engaged in secret negotiations with the communists, hitherto an insignificant force, who now, with 15 seats in the 300-seat trainment, held the balance of power.

The Metaxas regime and World War II. Public disillusionment with the endess intrigues of the political world, which had been growing apace in the preceding years, was exacerbated when the news leaked that the main political bloes were secretly negotiating with the communists. When the nonpolitical figure appointed by the king to head a caretaker government charged with overseeing the elections died, he was replaced as prime minister by General Ioannis Metaxas, a marginal figure on the far right of the political spectrum. Metaxas exploited labour unrest and a threatened general strike to persuade the king on Aug. 4, 1936, to suspend key articles of the constitution. Although the suspension purported to be temporary, parliament did not reconvene until 10 years later.

Backed by the army and tolerated by the king, the Metaxas dictatorship lasted four and a half years. The dictator, whose paternalistic style was signaled by the adoption of titles such as "National Father," "First Peasant," and "First Worker," shared the loathing of parliamentary democracy, liberalism, and communism characteristic of German Nazism and Italian Fascism, but the "Regime of the Fourth of August 1936" altogether lacked their dynamism. The Metaxas regime was neither aggressive nor racist, nor did it seek alliances with the European dictatorships. On the contrary, with the support of the king, Metaxas strove to maintain the country's traditional alignment toward Britain. The dictator, however, endeavoured to recast the Greek character in a more disciplined mode, invoking the values of ancient Greece and, in particular, of the Spartans. He furthermore sought to fuse them with the values of the medieval Christian Empire of Byzantium, thus fashioning what he pompously described as the Third Hellenic Civilization.

At the outhreak of World War II Metaxas tried to maintain neutrality, but Greece was increasingly subject to pressure from Italy, whose dictator Benito Mussolini sought an easy military triumph to match those of his ally Adolf Hitler. A series of provocations culminated in the delivery of a humiliating ultimatum on Oct. 28, 1940. Metaxas, reflecting the mood of the entire nation, rejected this without discussion. The Italians immediately invaded Greece from Albania, which they had occupied 18 months

The Metaxas dictatorship previously. But any hopes of a lightning military triumph were rapidly dashed. Within weeks not only had the Italians been driven from Greek territory, but Greek forces had pushed on to occupy much of what the Greeks term "Northern Epirus," the area of southern Albania with a substantial Greek minority.

While accepting token British military aid, Metaxas, until his death in January 1941, was anxious to avoid provoking German intervention in the conflict. However, his successor agreed to accept a British expeditionary force as it became apparent that Hitler's aggressive designs extended to the Balkans. The combined Greek and British forces, however, were able to offer only limited resistance when the German juggernaut rolled across the borders on April 6. 1941. By the beginning of June the country was overrun and subject to a harsh tripartite German, Italian, and Bulgarian occupation. King George II and his government-inexile fled to the Middle East. The requisitioning of food stocks resulted in a terrible famine during the winter of 1941-42, in which as many as 100,000 people died. In 1943 virtually the entire Jewish population was deported to death camps in Germany. A devastatingly high rate of inflation added to the miseries and humiliations of everyday life.

Almost from the outset of the occupation, acts of resistance were recorded. These took a more systematic form after the Communist Party in September 1941 founded the National Liberation Front (EAM), whose military arm was known under the initials ELAS. Although the communists had been a marginal force during the interwar period, EAM/ELAS became the largest resistance organization. Other groups came into being, the most important of which, the National Republican Greek League (EDES), opposed, as did EAM/ELAS, the return of the king upon liberation. With the support of a British military mission, the guerrillas engaged in some spectacular acts of resistance, the most notable of which was the destruction in November 1942 of the Gorgopotamos viaduct, which carried the railway line from Thessaloniki to Athens

Just as during the War of Independence and World War I, so during this time of grave national crisis internecine strife divided the resistance organizations. Besides fighting the Axis occupation, they jockeyed for postwar power. During the winter of 1943-44 civil war broke out in the mountains of Greece between EAM/ELAS and the much smaller EDES, which, however, enjoyed the support of the British authorities, who had become increasingly alarmed at the prospect of a postliberation seizure of power by the

Not for the first time in Greek history, the country's fate was to be determined by the Great Powers. The British prime minister, Winston Churchill, eager to see King George II restored to his throne, engaged in the summer and autumn of 1944 in some high-level negotiations with the Soviet leader, Joseph Stalin, trading Russian predominance in postwar Romania for British predominance in Greece. True to the spirit of this deal, it would seem. Stalin gave no encouragement to the Greek communists to make a bid for power in the autumn of 1944 as the Germans began their withdrawal, even though by this time they were by far the most powerful force in occupied Greece.

The confrontation was only postponed, however, for bloody fighting broke out in Athens in December 1944 between ELAS and the small British force that had accompanied the Greek government on its return from exile on October 18. It was a sign of Churchill's obsession with the crisis in Greece that he flew to Athens on Christmas Eve 1944 in an unsuccessful attempt to resolve it. The British prime minister, however, was able to persuade King George II not to return to Greece pending a plebiscite on the monarchy and to accept the regency of Archbishop Damaskinos of Athens. A temporary respite in the struggle between left and right was achieved at the Varkiza conference in February 1945, which aimed at a political settlement of the crisis.

Civil war and its legacy. The first elections since the fateful ones of 1936 were held in March 1946. These, however, were flawed, and, with the far left abstaining, resulted in a sweeping victory for the royalist right. In

September a plebiscite issued in a vote for the return of King George II: he died within six months and was succeeded by his brother Paul. Against this background the country slid toward civil war as the far left was undecided as to whether to work within the political system or to make an armed bid for power.

The turning point toward civil war came with the establishment in October 1946 of a communist-controlled. Democratic Army. In December 1947 the communists established a Provisional Democratic Government, Although heavily outnumbered, the communists were able. with the logistical support from the newly established communist regimes to the north, coupled with skillful use of guerrilla tactics, to control a wide area of northern Greece for a substantial period of time. Following the declaration of the Truman Doctrine in March 1947, which pledged support for "free peoples" in their fight against internal subversion, the tide gradually began to turn, as the United States, assuming Britain's former mantle as Greece's chief external patron, provided military equipment and advice. American intervention and the consequences of the break between Josip Broz Tito and Stalin, combined with factionalism and altered military tactics on the left, all contributed to the defeat of the communist guerrillas in the summer of 1949.

Greece emerged from the travails of the 1940s in a state of devastation. Nonetheless, if the post-civil-war political regime had a distinctly authoritarian hue, from the mid-1950s Greece underwent a rapid, if unevenly distributed. process of economic and social development, far surpassing its communist neighbours to the north in standard of living. The population of greater Athens more than doubled in size between 1951 and 1981, and by the early 1990s about one-third of the entire population was concentrated in the area of the capital. However, if urbanization progressed quickly and living standards rose rapidly, the country's political institutions failed to keep pace with rapid change. Following a brief centrist interlude, the right maintained a firm grip on power between 1952 and 1963 and was none too scrupulous about the means it employed to retain it.

By the early 1960s, however, the electorate (which now included women) had become increasingly disenchanted with the repressive legacy of the civil war and looked for change. This was offered by Georgios Papandreou, whose Centre Union Party secured a sweeping victory in 1964. Yet the promise of reform and modernization was thwarted as, against a background of renewed crisis in Cyprus, groups within the army conspired to subvert the country's democratic institutions. A guerrilla campaign in Cyprus, fought from the mid-1950s onward with tenacity and ruthlessness by the Greek-Cypriot general Georgios Grivas, had resulted in 1960 in the British conceding not the union with the Greek state sought by the overwhelming Greek-Cypriot majority on the island but independence. However, within three years the elaborate power-sharing arrangements between the Greek majority and the Turkish minority on the island had broken down.

During the civil war and after, Greece's armed forces had come to look upon themselves not only as the country's guardians against foreign aggression but also as its defenders against internal subversion, of which they were to be the final judge. They increasingly viewed Georgios Papandreou as a stalking horse for his much more radical American-educated son, Andreas Papandreou, who had returned to Greece and joined his father's government.

On April 21, 1967, middle-ranking officers, led by Colonel Georgios Papadopoulos, launched a coup designed to thwart an expected Centre Union victory in elections planned for May of that year. The conspirators took advantage of a prolonged political crisis, which had its origins in a dispute between the young King Constantine II, who had succeeded his father, King Paul, to the throne in 1964, and his septuagenarian prime minister, Georgios Papandreou. Alternating between policies that were heavyhanded and absurd, the "Colonels," as the military junta came to be known, misruled the country between 1967 and 1974. In December 1967, after a failed countercoup, King Constantine went into exile, with Papadopoulos as-

The National Liberation Front

Fighting in Athens

communists

suming the role of regent. In 1973, following student protests, which were violently suppressed, Papadopoulos was toppled from within the junta, to be replaced by the even more repressive brigadier general Demetrios Ioannidis, the head of the much-feared military police.

In July 1974, in the wake of an increasingly bitter dispute between Greece and Turkey over oil rights in the Aegean Sea, Ioannidis, seeking a nationalist triumph, launched a coup to depose Makarios III, the archbishop and president of Cyprus since 1960. Makarios survived, but the coup triggered the invasion of the northern part of the island by Turkey, which, together with Britain and Greece, was a guarantor of the 1960 constitutional settlement. The Turkish army occupied almost 40 percent of the land area of the island, despite the fact that the Turkish population numbered less than 20 percent. Ioannidis' response to the Turkish invasion was to mobilize for war with Turkey. The mobilization proved chaotic, however, and the regime, bit terly unpopular domestically and totally isolated diplomatically, collapsed in complete disarray.

Restoration of democracy. Konstantinos Karamanlis, a conservative politician, was summoned back from selfam-posed exile in France to restore democracy and rebuild a country ravaged by seven years of brutal and inefficient military rule. This he accomplished with signal success. He defused the threat of outright war with Turkey, ensured that the army returned to the barracks, and, acknowledging the way in which opposition to the junta had brought together politicians of all politicial backgrounds, legalized the Communist Parry, which had been outlawed in 1947. He moved rapidly to legitimize his power through elections held in November 1974, in which he secured a sweeping victory. In December of the same year, a referendum on the future of the monarchy resulted in a 69 percent vote against the monarchy and the return of King Constantine.

Karamanlis' second premiership lasted from 1974 until 1980, when he was elected president. By this time he had achieved his main objective, early membership in the European Community, which Greece joined in January 1981. His failure to counter the populist appeal of Andreas Papandreou's Panhellenic Socialist Movement (PASOK) resulted in a stunning electoral victory for PASOK in 1981.

The smooth transfer of power from a right-wing government that had ruled for much of the postwar period to a radical (at the level of rhetoric at least) socialist one appeared to indicate that Greece's newly reestablished democratic institutions were firmly in place. During nearly a decade of socialist rule. Papandreou's promises of change and a dramatic reorientation in the country's domestic politics and external relations were not fulfilled. Ambitious plans to "socialize" key sections of industry failed to materialize, and the attempt to create a welfare state could be sustained only by enormous borrowing. Important reforms were, however, introduced in family law, and society was liberalized in other respects. It was testimony to Papandreou's ability to articulate both the aspirations and frustrations of much of the electorate that, despite a poor economic record and amid accusations of large-scale corruption in the higher reaches of his party, the conservative New Democracy Party only barely regained power in 1990. The new government, with Konstantinos Mitsotakis as prime minister, was committed to a policy of economic liberalism and the diminution of the powers of the state, but the problems that confronted it were formidable. The policies of rigid economics introduced by Mitsotakis and, in particular, proposals for the privatization of the large state sector were unpopular with much of the electorate.

In 1993 Papandrou's PASOK returned to power with a share of the vote only marginally smaller than it had received at the time of its electoral triumph in 1981. However, the underlying economic and infrastructural problems facing Greece remained, and Papandroeu was unable to halt the rising deficits, inflation, interest rates, and unemployment. With Papandroeu in his mid-seventies and in failing health, PASOK was divided over who should be his successor. By January 1996, Papandroeu was o incapacitated that he resigned; he died later that year. Konstantinos (Kostas) Simitis was elected the new prime minister by the PASOK parlamentary deputies.

Simitis, more a pragmatic reformist than an ideological socialist, tried to control state spending and even to privatize some state industries. Hoping to capitalize on his apparent popularity, he called for elections in September, barely defeating the New Democracy Party. In the late 1990s, Simitis's efforts to introduce some fundamental restructuring of Greece's economy—taxes, labour laws, privatization, and social benefits—had some success but also provoked resistance from many Greeks, Much of the impetus for reforming Greece's economy came from its membership in the European Union (EU). Although Greec initially failed to meet the requirements for joining the European Economic and Monetary Union, it adopted the euro, the EU's single currency, in 2001.

In its foreign relations, Greece continued to be preoccupied with disputes related to its EU membership. After years of resisting the establishment of an independent nation of Macedonia, Greece reluctantly agreed in September 1995 to recognize its existence under the name of The Former Yugoslav Republic of Macedonia. Relations between Albanians (both those in Albania and in Greece) and Greeks continued to be strained. When NATO bombed Serbia in 1999 in defense of the Kosova, Albanians, Greece refused to participate in the air attacks. Greece's centuries-old "cold war" with Turkey was further exacerbated by quarrels over Cyprus, oil-drilling rights in the Aegean, and airspace violations, However, earthquakes that devastated Turkey and Greece in the summer of 1999 led each country to provide rescue teams, resulting in a sudden thaw in their relations.

For later developments in the history of Greece, see the BRITANNICA BOOK OF THE YEAR. (R.R.M.C./J.S.Bo./Ed.)

BIBLIOGRAPHY

GENERAL WORKS. All aspects of the country are treated in GIENN E. CIRTS (ed.), Greez - 4 Country, Study, 4th ed. (1995). JOINN CAMPBELL and PHILIP SHERRARD, Modern Greece (1968), contains, besides useful historical surveys, valuable chapters on the Orthodox church, literature, and the economy, while paying attention to the values underprinning society, YORGOS A. KOURVETARIS) and BETTY A. DOBRATZ, A PROISE OF MODERNEY CONTROL OF MODERN CONTROL OF MODERNEY CONTROL OF MODERN CONTROL OF MODERNEY CONTROL O

Physical and human geography. One of the most extensive works on the geography of Greece is ALFRED PHILIPPSON, Die griechischen Landschaffen, 4 vol. (1950–58). B.C. DARRY et al., Greece, 3 vol. (1944–45), produced by the Naval Intelligence Division of Great Britain, contains much material of value on physical and economic geography, J.L. MYRLS, Dodcamese, 2nd ed. (1943), also produced by the Naval Intelligence Division, is a survey of the Dodcamese islands under Italian rule between 1912 and 1947.

Grece's geology is treated in a regional context in CLIFFORD E-MBIETO's (ed., Geomorphiology of Europe (1980), chapters [5-16, BFRER BIROT and EFAN DEESKI, LA Méditerranée et le Moyen-Orient, vol. 2, La Méditerranée et le Moyen-Orient (1955), offers details on physical structure and brief treatments of climate and vegetation. Individual aspects of the landscape are detail with in E.G. MARIOLOPOULOS, An Oulline of the Climate of Greece (1961; originally published in Greek, 1953). J.R. MORBILL, The Mountains of the Mediterranean World: An Environmental History (1992), includes the Pindus Mountains on one of the case studies. (C.D.S.)

Classic studies of Greece's people and customs include ERNES-TINE FRIED, Vasilika: A Village in Modern Greece (1962); and J.K. CAMPRELL, Honour, Family, and Patronage: A Study of Institutions and Moral Values in a Greek Montain Community (1964, reissued 1974). MCHAEL KENNY and DAVID I. KERTZER (eds.), Urban Life in Mediteranea Europe (1983), includes several essays on Greece, including a study of rural-urban migration. TIMOTITY WARE (KALLISTOS WARE), The Orthodox Crutzch, rev. 2nd ed. (1997), is a clear and concise account of the history and theology of the predominant religion in Greece.

The economy is covered by A.F. FRERIS, The Greek Economy in the Twentieth Century (1986); and FRESEPONI V. TSALIK), The Greek Economy: Sources of Growth in the Postwar Era (1991). Politics is dealt with in KEITH R. LEGG, Politics in Modern Greece (1969); and RICHARD CLOGG, Parties and Elections in Greece (1987).

The remarkable continuities in the Greek language are dis-

cussed in ROBERT BROWNING, Medieval and Modern Greek, 2nd ed. (1983). A comprehensive survey, beginning with the emergence in the 11th century AD of literature in a recognizably modern form of the language, is LINOS POLITIS (LINOS POLITÉS), A (R.R.M.C.) History of Modern Greek Literature (1973).

History. Greece during the Byzantine period (c. AD 300-c. JOHANNES KODER and FRIEDRICH HILD, Hellas und Theysalia (1976), provides a detailed regional historical and geographic survey and includes an extensive bibliography as well as a discussion of the historical and political evolution of the region. General surveys of the history of the Byzantine world all include information dealing with Greece at the appropriate junctures. The most useful are GEORGE OSTROGORSKY (GEORGIJE OSTRO-GORSKI), History of the Byzantine State, 2nd ed. (1968, reissued 1980: originally published in German, 1940); and J.M. HUSSEY. 1980; originally published in German, 1990; and J.M. HUSSEY, D.M. NICOL, and G. COWAN (eds.), *The Byzantine Empire*, 2nd ed., 2 vol. (1966-67), vol. 4 of *The Cambridge Medieval History*. A wealth of detail on the society and economy of the late Roman world, as well as on the provincial administration of the Greek regions, is provided by A.H.M. JONES, The Later Roman Empire, 284-602: A Social Economic and Administrative Survey, 2 vol. (1964, reprinted 1986). The transition from late Roman to early Byzantine structures, the fate of urban society, and the effects of the disruptions of the 7th century are surveyed in J.F. HALDON, Byzantium in the Seventh Century: The Transformation of a Culture, rev. ed. (1997), with detailed discussion of a number of fundamental developments. Society and economy in the later period are treated in ALAN HARVEY, Economic Expansion in the Byzantine Empire, 900-1200 (1989), for the period to the Fourth Crusade: and ANGELIKI E. LAIOU-THOMADAKIS, Peasant Society in the Late Byzantine Empire (1977), for the period from about 1204 until the end of the empire. MICHAEL F. HENDY, Studies in the Byzantine Monetary Economy, 300-1450 (1985), presents a detailed collection of surveys of the physical geography, land use, and settlement patterns of the Balkans (as well as other regions of the empire), together with a discussion of the nature of the Byzantine economy, the fiscal administration, and related topics. NICOLAS OIKONOMIDÈS, Les Listes de préséance byzantines des IXe et Xe siècles (1972), presents the evidence for the development of the middle Byzantine provincial, fiscal, and administrative structures that evolved in Greece during this period. The most accessible materials for demography and population are PETER CHARANIS, "On the Demography of Medieval Greece: A Problem Solved," Balkan Studies, 20 (2):193-218 (1979); and PETER CHARANIS (compiler), Studies on the Demography of the Byzantine Empire (1972), a collection of articles.

Works dealing specifically with Greece include APOSTOLOS E. VACALOPOULOS, Origins of the Greek Nation, trans, from Greek (1970); and NICOLAS CHEETHAM, Mediaeval Greece (1981), both of which provide excellent general accounts, the former in particular presenting both the political, socioeconomic, and ethniclinguistic issues. English-language surveys of different regions are DONALD M. NICOL, The Despotate of Epiros, 1267-1479 (1984); DENIS A. ZAKYTHINOS (DIONYSIOS A. ZAKYTHÈNOS). Le Despotat grec de Morée, 2 vol., rev. and augmented by CHRYSSA MALTÉZOU (1975); and MICHAEL ANGOLD, A Byzantine Government in Exile: Government and Society Under the Laskarids of Nicaea, 1204-1261 (1974). Particular aspects of regional history are discussed in DAVID JACOBY, Recherches sur la Méditerranée orientale du XII^e au XV^e siècle: peuples, sociétés, économies (1979); and PETER TOPPING, "The Morea, 1311-1364," and "The Morea, 1364-1460," in KENNETH M. SETTON (ed.), A History of the Crusades, vol. 3 (1975), pp. 104-166, all of which deal with social and economic as well as political and historical problems connected with the Latin/Frankish presence in Greece. The roles of the Vlachs and Albanians are examined by T.J. WIN-NIFRITH, The Vlachs (1987); and ALAIN DUCELLIER, L'Albanie entre Byzance et Venise: X°-XV° siècles (1987). A useful and important survey of Byzantium and the Slavs, as well as the Vlachs and Albanians, is DIMITRI OBOLENSKI, The Byzantine Commonwealth: Eastern Europe, 500-1453 (1971, reissued 1982). A basic reference work that deals with all the topics referred to, sometimes in detail, and that also includes further references is ALEXANDER P. KAZHDAN (ed.), The Oxford Dictionary of Byzantium, 3 vol. (1991).

Greece under Ottoman rule, 1453-1831: ARNOLD TOYNBEE, The Greeks and Their Heritages (1981), is a stimulating survey of the whole range of Greek history from prehistoric times to the present day. One of the few scholarly studies in English of the dark age of Greek history, between the fall of Constantinople and the capture of Crete, is APOSTOLOS E. VACALOPOULOS (APOSTO-LOS E. VAKALOPOULOS), The Greek Nation, 1453-1669: The Cul-

tural and Economic Background of Modern Greek Society, trans. from Greek (1976). An overview of the critical four centuries of Ottoman rule is contained in D.A. ZAKYTHINOS (DIONYSIOS A. ZAKYTHÈNOS), The Making of Modern Greece: From Byzantium to Independence, trans. from Greek (1976). The crucial role of the church during the period is discussed in STEVEN RUNCIMAN. The Great Church in Cantivity A Study of the Patriarchate of Constantinople from the Eve of the Turkish Conquest to the Greek War of Independence (1968, reissued 1986). RICHARD CLOGG (ed. and trans.), The Movement for Greek Independence, 1770-1821 (1976), illustrates the emergence of the Greek national movement through contemporary documents; while G.P. HENDERSON, The Revival of Greek Thought, 1620-1830 (1970). focuses on the intellectual revival that preceded the outbreak of the war of independence in 1821. The war itself is covered in DOUGLAS DAKIN, The Greek Struggle for Independence. 1821-1833 (1973); and the diplomacy of the period is analyzed in c.w. CRAWLEY, The Question of Greek Independence: A Study of British Policy in the Near East, 1821-1833 (1930, reprinted 1973). The colourful story of the philhellene volunteers who fought alongside the insurgent Greeks is told by WILLIAM ST. CLAIR. That Greece Might Still Be Free: The Philhellenes in the War of Independence (1972). The independence movement is also traced in C.M. WOODHOUSE, Capodistria: The Founder of Greek Independence (1973), a study of the first president of Greece

Greece since 1831: RICHARD CLOGG, A Concise History of Greece (1992), an illustrated survey, focuses mainly on the 19th and 20th centuries, DOUGLAS DAKIN, The Unification of Greece, 1770-1923 (1972), is a detailed study of the gradual expansion of the Greek state. E.S. FORSTER, A Short History of Modern Greece, 1821-1956, 3rd ed. rev. and enlarged (1958, reprinted 1977), is a basic survey. Journal of Modern Greek Studies (semiannual), published by the Modern Greek Studies Association, is (since 1983) the premier publication for scholarship on modern Greece. The early years of King Otto's reign are studied in considerable detail in JOHN A. PETROPOULOS, Politics and Statecraft in the Kingdom of Greece, 1833-1843 (1968), CHARLES K. TUCKER-MAN, The Greeks of To-day, 3rd ed. rev. and corrected (1886), is a perceptive account of mid-19th century Greece written by the first U.S. minister to Greece. The Goudi coup of 1901, the first of many military interventions in the political process in the 20th century, is the subject of S. VICTOR PAPACOSMA. The Military in Greek Politics (1977). The meddling of Britain and France in Greece's internal affairs during the First World War is treated by GEORGE B. LEON, Greece and the Great Powers, 1914-1917 (1974); while MICHAEL LLEWELLYN SMITH, Ionian Vision. Greece in Asia Minor, 1919-1922 (1973, reissued 1998), thoroughly treats the disastrous Anatolian entanglement, GEORGE TH. MAVROGORDATOS, Stillborn Republic: Social Coalitions and Party Strategies in Greece, 1922-1936 (1983), provides an indispensable guide to the complex politics of the interwar period. The impact of the Axis occupation is investigated by MARK MAZOW-ER, Inside Hitler's Greece: The Experience of Occupation, 1941-44 (1993, reissued 1995). A critical decade of foreign occupation, resistance, and civil war is the subject of C.M. WOOD-HOUSE, The Struggle for Greece, 1941-1949 (1976, reissued 1979), while his The Rise and Fall of the Greek Colonels (1985) analyzes one of the consequences of the civil war, the military dictatorship of 1967-74, C.M. WOODHOUSE, Karamanlis: The Restorer of Greek Democracy (1982), traces the political career of the politician who oversaw the return to democracy. The whirlwind rise to power in 1981 of Andreas Papandreou and his PASOK party is the subject of MICHALIS SPOURDALAKIS. The Rise of the Greek Socialist Party (1988). THANOS VEREMIS (THANOS VEREMÈS), The Military in Greek Politics: From Independence to Democracy (1997), is a survey of the often strained relations between Greece's military and civilian powers. Books that focus on Greece since the 1960s include LORING M. DAN-FORTH, The Macedonian Conflict: Nationalism in a Transnational World (1995), an account of an issue that continues to vex Greeks; DAVID HOLDEN, Greece Without Columns (1972), which is blunt and opinionated but perceptive; THEODORE C. KARIOTIS (ed.), The Greek Socialist Experiment: Papandreou's Greece, 1981-1989 (1992), a balanced collection of essays on this controversial period; DIMITRI CONSTAS and THEOFANIS G. STAVROLL (eds.), Greece Prepares for the Twenty-First Century (1995); VAN COUFOUDAKIS, HARRY J. PSOMIADES, and ANDRE GEROLY-MATOS (eds.), Greece and the New Balkans: Challenges and Opportunities (1999); and KOSTAS A. LAVDAS, The Europeanization of Greece: Interest Politics and the Crises of Integration (1997).

(R.R.M.C./J.S.Bo.)

Ancient Greek and Roman Civilizations

ncient Greek and Roman civilizations is used here loosely, as an overall term referring to the Aegean and ancient Greek civilizations and the civilizations of the Etruscans and the ancient Italic peoples as well as the ancient Roman civilization. All of these flourished on the continents of Europe and Asia from the Neolithic Period (New Stone Age) to the decline of the Western Roman Empire in the 5th century AD and are treated here. For coverage of related topics in the Macropædia and Micropædia, see the Propædia, section 912, and the Index. The article is divided into the following sections:

Aegean civilizations 205 Early Aegean civilizations 207 Early cultures The Bronze Age The decline of the early Aegean civilizations 213 The eruption of Thera (c. 1500) and the conquest of Crete (c. 1450) The end of the Bronze Age in the Aegean The people of the Aegean Bronze Age Ancient Greek civilization 218
The early Archaic period 218 The post-Mycenaean period and Leftkandi Colonization and city-state formation Early Archaic Greek civilization The later Archaic periods 223 The rise of the tyrants Sparta and Athens The world of the tyrants Classical Greek civilization 233 The Persian Wars The Athenian empire The Peloponnesian War Greek civilization in the 5th century The 4th century 248 To the King's Peace (386 BC) From 386 Bc to Philip II of Macedon The rise of Macedon Alexander the Great Greek civilization in the 4th century Conclusion 263 Hellenism 264 Political developments 264 Alexander's successors The mid-3rd century The coming of Rome (225-133)

The recovery of the empire and the establishment

Aegean civilizations

Hellenistic civilization 268

The adjective Aegean is traditionally used in reference to the Stone and Bronze Age civilizations that arose and flourished in the area of the Aegean Sea in the periods, respectively, about 7000-3000 BC and about 3000-1000 BC. The area consists of Crete, the Cyclades and some other

islands, and the Greek mainland, including the Peloponnese, central Greece, and Thessaly. The first high civilization on European soil, with stately palaces, fine craftsmanship, and writing, developed on the island of Crete. Later, the peoples of the mainland adapted the Cretan civilization to form their own, much as the Romans adapted the civilization of later Greece. The Bronze Age civilization of Crete has been called Minoan, after the legendary King Minos of Knossos, which was the chief city of the island throughout early times. The Bronze Age of the Cyclades is known as Cycladic, that of the mainland as Helladic, from Hellas, the Greek name for Greece. Early, middle, and late stages have been defined in each of these, with further subdivisions according to recognizable changes in the style of pottery and other products that are associated with each separate culture. The civilization that arose on the mainland under Cretan influence in the 16th century BC is called Mycenaean after Mycenae, which appears to have been one of its most important centres. The term Mycenaean is also sometimes used for the civilizations of the Aegean area as a whole from about 1400 BC onward. Dating of the Aegean Bronze Age. The dates that are suggested here are approximate and conventional. In a general way, they are based on correlations with Egypt, where, from the beginning of the Early Dynastic period (c. 2925 BC onward), a historical chronology can be established with a leeway of a few centuries and can be fixed within reasonably narrow limits after about 2000 BC. Bronze Age pottery from the Aegean has been found

Minoan Cycladic, and Helladic civilizations

Principal sites associated with Aegean civilizations

in Egypt in contexts that are datable, and many Egyptian objects have been recovered on the island of Crete.

Two important landmarks are fragments of Cretan not-

tery from the town at Kahun in the Fayyum, built for workers engaged in the construction of a pyramid for the pharaoh Sesostris II (ruled 1897-78), and a large quantity of Mycenaean pottery from the mainland found at Tell el-Amarna, site of Akhenaton's capital, and imported during his reign (c. 1350-34). Radiocarbon dates appear consistent with those based on correlations with Egypt. Objects found in 1982 in the Kaş-Ulu Burun shipwreck off the southern coast of Turkey, including the first known gold scarab of the Egyptian queen Nefertiti, reveal a tight web of interconnections in the later 14th century among Mycenaean Greece, Cyprus, Egypt, Palestine, Syria, and Africa. History of exploration. The poems of Homer, which reflect an epic tradition that absorbed many changes occurring in warfare and society between the 15th and the 8th century BC, describe warriors employing bronze weapons and objects such as helmets plated with tusks of wild boar that went out of use before the end of the Aegean Bronze Age. Massive Bronze Age defense walls survived at Mycenae and elsewhere on the mainland; they were called Cyclopean because, according to Greek tradition, the Cyclopes had built them. Apart from these Cyclopean walls, virtually nothing was known about the Aegean Bronze Age before the middle of the 19th century, when in 1876 a German archaeologist, Heinrich Schliemann, discovered unplundered royal shaft graves at Mycenae. He thought that the men buried in them were the Greek heroes of

Homer's siege of Troy. There are in fact many likenesses between Homer's descriptions and the armour, weapons, and war imagery found in these graves. The graves, spaning about 1600 to 1450 ac, contained princely gifts from an age when Greece, Crete, and Troy engaged in trade. Schlemann's discoveries led to intensive exploration of Bronze Age and earlier sites on the Greek mainland. On the island of Thera in 1866–67, before Schliemann, Ferdinand Fouqué, a French geologist, had already explored settlements of the Shaft Grave Period sealed in under a thick shroud of volcanic pumice and ash. He found houses, frescoes, pottery imported from as far as Cyprus, and well-preserved agricultural produce. Because Bronze Age Crete and Greece were not explored at the time, this important find lay fallow for a century.

Later in the 19th century, Christos Tsountas, a Greek archaeologist, dug cemeteries of earlier phases of the Bronze Age on other Cycladic islands and continued the work begun by Schliemann at Mycenae. At the end of the century, a British expedition excavated the important Bronze Age town of Phylakopi on Melos. When Crete eventually became independent of Turkish rule in 1898, attention was turned to Bronze Age sites there. In 1900 Arthur (later Sir Arthur) Evans, an English archaeologist, began to uncover the palace at Knossos, the largest Bronze Age centre of the island, discovering clay tabeles with the first positive evidence for Bronze Age writing in the Aegean. Greek, American, French, and Italian excavarors added further knowledge of the Cretan Bronze Age during the years that followed, and American and German expeditions opened

Bronze Age writing

Ecology of

the Aegean

new sites on the mainland. Inscribed clay tablets in the script called Linear B, such as those found at Knossos in Crete at the turn of the century, were recovered in Messenia in 1939 by the American archaeologist Carl W. Blegen; others have since come to light at Mycenae and elsewhere on the mainland. The belief that the language of these tablets was a very archaic form of Greek was established in 1952 by the English architect and cryptographer Michael Ventris, working with the linguist John Chadwick, though acceptance of this is not yet universal. In 1962 a large palace, destroyed by fire about 1450 BC at Zákros in eastern Crete, was discovered. In 1967 the Greek archaeologist Spyridon Marinatos followed up Fouqué's explorations with excavations at modern Akrotiri on the south coast of Thera. He uncovered a whole town buried under the volcanic eruption and so preserved in wonderful detail.

EARLY AEGEAN CIVILIZATIONS

Early cultures. Paleolithic (Old Stone Age). Chipped stone tools made by Paleolithic hunters have been found in many parts of mainland Greece, but none are yet recorded from Crete or the other islands. As elsewhere in Europe, the latest Lower Paleolithic industries evolved into Upper Paleolithic ones with diminutive stonework. The excavations of Thomas W. Jacobsen at the Franchthi Cave on the Bay of Argos showed that boats already sailed to the island of Melos north of Crete for obsidian, a volcanic glass invaluable for early tools, by about 13,000-11,000 BC and that the cultivation of hybrid grains, the domestication of animals, and organized community tuna hunts had already begun. Neolithic (New Stone Age). If radiocarbon dates are to

be trusted, agriculture was being practiced in some parts of the Aegean area as early as the 7th millennium. The first agriculturalists in the Aegean, like those of Anatolia and Palestine, may have been ignorant of the art of making fired clay vases-traces of agricultural settlements without pottery have been identified at several places in Thessaly and at Knossos in Crete. The island of Crete appears to have been uninhabited before this time, and the first agriculturalists must have reached it by sea from western Anatolia or from somewhere more distant. Other immigrants from the east may have brought agricultural techniques and ways of life to the mainland, where they mingled with the Upper Paleolithic hunting peoples. For human habitation the Aegean is one of the most favoured regions of the Mediterranean basin. Immigrants from the coastal areas of Anatolia, Syria, or Palestine would have found the climate and ecology similar to what they had known in their homelands. The olive and vine, sources of oil and wine, the staples of the Mediterranean diet, grow in most parts of the Aegean area and may have been native there. Water, which is a problem in the present century, was probably more abundant in early times when forests were more extensive than they are today.

Agricultural communities were eventually established in every part of Greece. They made pottery by hand and ground stones to shape edged tools, axes, adzes, and chisels. Wheat, barley, oats, millet, lentils, and peas were among the crops grown, supplementing wild grapes, pears, nuts, and honey. The inhabitants continued to hunt and fish, though they also raised cattle, sheep, goats, and pigs. Arrowheads of chipped stone were used on the mainland and in the Cyclades, but none is recorded from Crete, where bone points may have served to tip arrows. Another longrange weapon was the sling, and clay sling pellets were made in Thessaly where suitable beach pebbles were not available. In Crete, clubs were armed with stone heads as in Egypt and elsewhere in the Middle East in early times. Houses with rectangular rooms are attested at Knossos in Crete, at Saliagos in the Cyclades, and at Nea Nikomedia in Macedonia. Some Aegean communities, however, may have lived in circular huts of the kind found in predynastic Egypt and in early Syria and Cyprus. By the Middle Neolithic, there existed independent walled acropolis towns with specialized industries like potteries; Sesklo is an important site several acres in extent, with nearly 30 houses, a sophisticated gate, and striking red-and-white pottery. In the Late Neolithic, walled communities with

special big houses that had megarons (central halls), as at Dhimini, suggest social hierarchies and dominant chiefs. Several Thessalian settlements were surrounded by defense walls or ditches. Copper tools-simple, flat axes and

knives-were in use before the end of the Neolithic both in Crete and on the mainland.

The Bronze Age. The Early Bronze Age (c. 3000-2200). The transition from Neolithic to Bronze Age in the Aegean was marked by changes in pottery and other aspects of material culture. These changes may reflect the arrival in Crete and the Cyclades of new people from lands farther east bringing knowledge of metalworking with them. In Crete and the islands, the changes that inaugurated the Bronze Age were more or less contemporary with the beginning of dynastic times in Egypt. The Bronze Age in the Peloponnese appears to have begun later under the influence of settlers from the islands. The Bronze Age in central Greece and Thessaly may have begun later still. Evolved types of metal tools appear to have been current considerably before the end of the Neolithic there.

Flourishing metal-using cultures were established by the middle of the 3rd millennium in Crete, the Cycladic islands, and the southern part of the mainland. Each of these three cultures had its own distinctive characteristics; however, they had much in common, and their peoples may have spoken the same or similar non-Greek languages. Many place-names throughout the Aegean-notably ones ending in -nt- and -ss-, such as Corinth and Knossosseem to reflect a time when a group of related languages with probable Anatolian affinities was spoken there before the introduction of Greek. A large number of words came

to be adopted into Greek from this earlier language group. These Early Bronze Age peoples of the Aegean seem Early metal to have employed similar types of metal tools, including axes, adzes, and short daggers, but double axes may have been special to Crete. Tweezers were used for plucking facial hairs, and rectangular stone palettes for grinding face

paints with small pestles made of attractive veined stones or Spondylus shell.

Lerna and other settlements on the mainland were eventually surrounded by massive walls with projecting towers, and neighbouring islands like Aigina or Syros in the Cyclades also had towered walls with trap gates. Houses with several rooms were being constructed in most parts of the Aegean by this time, and buildings at Knossos and at Vasiliki in Crete have been identified as the residences of local rulers. The so-called House of Tiles at Lerna, destroyed by fire toward the end of the period, appears to have been an important focus for the community. A massive rectangle two stories high, with a roofed balcony upstairs, the structure takes its name from the baked clay tiles found in its ruins. These small, flat tiles are thought to have come from a sloping roof and may be the earliest roof tiles known. Similar tiles were recovered from a huge circular structure of the same period at neighbouring Tiryns, of which only a section has been excavated, as it lies deep below the level of the later Mycenaean palace there. It was evidently a public building of some kind.

Cretans in the Early Bronze Age buried their dead in communal tombs. These belonged to clans or extended families and might have remained in use for many generations. Traces of hundreds of burials have been noted in some of them. Caves and rock-shelters, as well as buildings of various kinds, were used as tombs. Circular tombs were characteristic of the Mesara region of southern Crete. They were built above ground, with low massive stone walls perhaps covered with logs and thatch or slabs. Some of the largest tombs, however, with a diameter of 40 feet (12 metres) or more inside, may have been vaulted in mud brick. Annexes with cult rooms were built in front of the entrances of some tombs, and others had chambers for offerings around the sides. When a tomb became full, a new floor was laid above the earlier burials, or parts of the tomb's annex were brought into use as burial chambers. Sometimes the remains of earlier burials were removed to separate buildings or enclosures nearby. Communal tombs at Mochlos on the north coast had rectangular compartments or rooms and flat roofs, such as those in contemporary houses. At Knossos, where the local rock

hurial practices was soft, artificial caves were dug to serve as tombs. Everywhere in Crete the dead were normally trussed into a tightly contracted position, knees to chin. Sometimes the bodies were then squeezed into large storage jars or small clay chests or coffins. There was evidently much ceremonial in connection with burial, and, apart from objects of personal use such as seals, jewelry, and weapons left with the dead, vases with offerings were regularly placed inside or outside the tombs.

In contrast to the Cretans, the people of the Cyclades during the earlier part of the Bronze Age builed their dead in small graves that held a single body or sometimes a pair. The graves were often grouped in family cemeteries, which might be surrounded by a wall. The bodies were placed in them lying on one side in a loosely flexed position. Some Cycladic graves were small stone-built chambers with an entrance, although the standard type consisted of a box (cist) made with large slabs set on edge and roofed with slabs. There were platforms near the cemeteries in some cases, perhaps for musical performances, dances, or rites.

Less is known about contemporary burials on the mainland. The graves there normally contained several bodies, which suggests that they belonged to families but not to large units, such as the clans that existed in Crete. Various types of mainland graves of this period are known, including chambers cut in the rock and stone-built tombs, such as those in the Cyclades. Circular cairns (heaps of stones), each covering several burials, on the island of Leucas in western Greece appear to go back to this time.

Pottery was still made by hand throughout the Aegean area. A useful type of vase first attested there at the beginning of the Early Bronze Age was a handled jug with a spout for pouring. Some of the earliest jugs from Crete have round bottoms and yellowish surfaces, as if they were copies of vessels made from gourds. Distinctive spouted bowls of oval shape nicknamed sauceboats were quite typical of the Early Bronze Age on the mainland and usually have a fine reddish or dark overall wash. Pottery with a similar wash and with the surface often deliberately mottled is found in Crete and is known as Vasiliki ware, after a site with a little "palace" where large amounts of it were recovered. The art of making stone vases flourished in the Cyclades from the beginning of the Bronze Age. The techniques used were simple and included boring with a hollow reed, which twirled an abrasive, either emery from Naxos or sand. The people of the Cyclades used their fine white marble not only for vases but also for remarkable figurines, mostly female but including men, some playing double pipes or seated on chairs with harps. While the majority of these figures are only a few inches high, some females are larger and a few are nearly life-size. Some have traces of painted decoration. These marble figures were often placed in graves, and groups of them have been found in sanctuaries, though whether they represented gods and goddesses is uncertain. They were exported to the mainland and Crete and may have been imitated there. Vessels of gold and silver were current in the Aegean by then, and a few have survived, including gold sauceboats of mainland type and gold and silver bowls from the islands. Gold and silver jewelry of this period, mostly from Crete, includes bracelets, necklaces, earrings, headbands, and hair ornaments of various kinds. Some of the finest of this early jewelry was found in communal tombs at Mochlos on the northern coast of Crete. The inspiration for it no doubt came from the east, and much of that from Mochlos, notably hairpins with flower heads, is reminiscent of jewelry from the royal tombs at Ur in Mesopotamia.

Seals came into use in the Aegean about the middle of the 4th millennium. Before the invention of locks and keys, seals were employed to stamp wet clay, which was used to secure doors or affix lids to storage jars or other containers. The design impressed by the seal might add the threat of magic to that of detection if the sealing was broken. Many seals resembling those current in Egypt and Syria have been recovered from early tombs in Crete. Some of these early Cretan seals were made of elephant tusk or hippopotamus tooth. Others were made of bone or soft, easily cut stones, such as serpentine and steattte. They were of various shapes, some of animals or birds

or their heads, others cylindrical, adapted from Syrian versions of early Mesopotamian cylinder seals. They were engraved with a variety of designs, including abstract patterns and pictures of animals, notably dangerous lions and scorpions or poisonous spiders (rogalidhas) of a species native to Crete. Seals appear to have been in use in the Cyclades and on the mainland during this period, but very few have been recovered there. A stone cylinder seal from Amorgos resembles early Syrian ones. Most Aegean seals of this period, however, even in Crete, may have been made of perishable wood. Clay seal impressions, preserved by fires that destroyed buildings at Lerna, including the palatial House of Tiles, look as if they had been stamped by wooden seals with intricate interlocking designs.

Pictures of boats with many oars or paddles were drawn among spirals (waves?) on clay vases of this period in the Cyclades and on the mainland. The boats have a high prow often surmounted by a fish ensign, the stern being low with the keel apparently projecting beyond it. Similar vessels, though with a single mast for a square sail in addition to oars, are represented on early Cretan seals. Ships of this kind would have been capable of voyages to Syria and Egypt, whence skills and fashions were reaching Crete along with imports such as Egyptian stone wases and

Syrian daggers.

End of the Early Bronze Age on the mainland (c. 2200-2000). The comparative unity of incipient civilization in the Aegean area was eventually shattered by new movements of people into the Cyclades and the southern part of the mainland. Toward the end of the 3rd millennium, many of the settlements on the mainland, such as that at Lerna, were destroyed by fire, and the houses built afterward were of a different type and more primitive. These new houses were long and narrow, only one story high. and apparently gable-roofed. The entrance was at one end. and there was often a small compartment, which might be semicircular (apsidal), at the other. The new houses were evidently built by foreign invaders settling in the places they had destroyed. Some of the previous inhabitants, however, may have survived as hewers of wood and drawers of water. A new formal dark, burnished pottery appeared, as well as a simple ware with a linear pattern on a light ground; sauceboats, however, disappeared. This pottery has many features in common with that of the succeeding Middle Bronze Age; thus there may be ethnic affinities. The site of the House of Tiles appears to have been reserved as sacred or unlucky ground, with a ring of large stones above its burnt ruins.

The Middle Bronze Age on the mainland (c. 2000-1550). The mainland was disrupted again about 2000 BC with new levels appearing at sites such as Lerna in the Argolid and Eutresis in Boeotia; there seem to be new burial habits on both coasts. Some scholars see an intrusion from the north of "Indo-Europeans," but this is a difficult, perplexing topic. Some handmade pottery may have Balkan affinities, and there is string-impressed ware at a few places that resembles in some ways the pottery of the Black Sea region. In any case, the newcomers apparently were pastoralists. Although not wealthy, they may have been one source for the appearance of the horse in Greece, an established fact before the Shaft Grave Period. Many scholars view this wave, which covered most of Greece, as representing "the coming of the Greeks"; others regard the Greek language as a rich amalgam formed within the confines of Greece and not imposed from outside. A new pottery appeared on the mainland: a class of gray burnished ware, wheel-made, with sharp angular shapes copied from those of metal vases. The polished gray surfaces of this "Minyan" ware (as it was named by Schliemann after the legendary inhabitants of Orchomenus in central Greece, where he first came upon it) look as if meant to imitate silver; later, some pieces were coloured red or yellow. After some time, "Matt-painted" pottery also appeared, again with simple linear patterns on a light ground. The traditional "long house," often apsidal, was the preferred architectural form; by the end of the period, some villages were walled.

The level of cultural attainment seems low, and not much metal circulated at first. The newcomers quickly

Minyan and Mattpainted pottery

Protective seals

Mainland

practices

burial

developed connections with the islands and Crete; they imported Cretan vases, and some local vases show mainland ships. Minyan and Matt-painted pottery has been found in the nearer islands and even as far as Crete and the Anatolian coast. Burials grew from single interments to larger "family" chambers at Eleusis in Attica and on both coasts; in Messenia, in parts of the Argolid, and at Marathon there appeared a novel kind of multiple burial, with individual cists (burial chambers) or pithoi (large earthenware jars), the whole cluster being covered by a single mound. These tumulus burials, which had already appeared earlier at Leucas in the Ionian Sea, may reflect Balkan practice. In Messenia a Late Bronze Age beehive, or tholos, tomb was cut into the older mound as though that particular burial place were special. By the end of the 17th century, the newcomers had taken their full place on a newly emerging international scene and were always to be in a special relation with the Cycladic islands. Crete. and, probably, Troy. Bronze knives and gold ornaments were found with some burials, and, by the time of the Mycenae Shaft Graves in the 16th century, a luxuriant style of native goldwork had been created.

The Cyclades. On the island of Cythera (Kíthira), between western Crete and the southern tip of the Peloponnese, a colony of Cretans appears to have replaced a settlement of people from the mainland toward the end of the 3rd millennium. In the 17th or 16th century, Cretan colonies were established at Triánda in Rhodes and at Miletus on the western coast of Anatolia. Later Greek legends seem to refer to colonies from Crete, if not from Knossos, in some of the Aegean islands. Much Cretan pottery found its way to the Cyclades and was also imitated there; but, although the Cycladic people adapted some fashions and ideas from Crete, they retained their own distinctive traditions. Cycladic vases are decorated with flowers, especially lilies and saffron crocus, with swallows, wild goats, and dolphins, and with warriors and strange griffins, in a lively, splashy, and colourful style. Frescoes at Ayía Iríni (Aghia Eirene) on Ceos (Kéa) show blue birds, a town, hunting, a girl picking flowers, myrtle branches, and a copper ingot, and those at Phylakopi on Melos depict women in clothes embroidered with birds, fine textiles, flying fish, and lily blossoms, At Akrotíri on Thera, a town buried under a volcanic eruption about 1500 BC, there are in almost every house fairly well-preserved frescoes displaying wonderful, flat, brightly coloured scenes of boxers, fishermen, antelopes, birds, and blue monkeys. The two most dramatic ones are the "naval" or "miniature" frescoes from the West House, showing themes of war and peace in a seaside-and-country setting with whole towns watching elaborate ships, and the elegantly drawn set in Xeste 3, of girls and women picking saffron crocus, wearing their finest gold and rock crystal jewelry and elegant costumes; they are accompanied by blue monkeys. The Theran paintings are the best surviving Aegean documents for clothing, architecture, ships, armament, and daily life.

The Shaft Grave Period on the mainland (c. 1600-1450). There are links between the Thera paintings and such items as earrings, necklaces, and metal vessels found in the royal Shaft Graves at Mycenae. Thera itself, however, had few valuables like metal; apparently the inhabitants had taken prized objects away. The Shaft Graves, in contrast, were packed with gold, silver, and bronzealmost nomadic in the obvious preference for portable gold and weapons. Two groups of Shaft Graves were discovered at Mycenae in different parts of a large cemetery area. The burials in them seem to have ranged over a period of 150 years, from shortly before about 1600 to the middle of the 15th century. Each group was eventually surrounded by a circular enclosure wall. The circle designated B, with the earliest burials, lay outside the limits of the later Bronze Age defenses, but the other circle, A, enclosing the richest burials in six large graves, was deliberately incorporated within them. The wealthy burials belonged to leading, if not royal, families of the place that would eventually supplant Knossos as the chief centre of the Aegean. Schliemann excavated the graves of Circle A in 1876, but it was not until 1951 that Circle B was noted. These graves are capacious shafts cut in the rock,

often with pebble floors and slab roofs. They were used for multiple burials over a course of at least several years, and the remains, including beef bones and oyster shells, give evidence of well-developed funeral rites. Both men and women were buried in the graves, many of which contained several bodies. After the bodies were placed in the graves, the stone-walled burial chambers were roofed with timbers, and the shafts above were filled again. Sometimes the remains of earlier burials seem to have been pushed aside to make room for later ones, but, if so, the shafts must have been laboriously reopened to admit new burials. Large stone slabs with carvings in flat relief had been set above some of the graves. The carvings include spiral designs and pictures of the dead riding in their chariots to war or to the hunt. They have vivid battle imagery-three stallions rearing, spears ground under chariot wheels, and a man falling headfirst from a chariot. In one case, the scene of a warrior driving a chariot over a fallen enemy encased in a shield seems to be reinforced by a scene just below it, a lion chasing a deer. This visual simile may be analogous to lion similes in Homeric epic. According to another interpretation, the dead were taking part in their own funeral games with chariot races as described in Homer. These tombstones provide the earliest evidence for chariots on the mainland.

A fantastic array of gold and silver cups, jewelry, and dress ornaments had been placed with the dead, especially with those in the graves of Circle A. Golden diadems and elaborate hairpins decked the heads of women. Beads in necklaces were of amethyst, probably from Egypt, and amber, from the Baltic. The men were buried with supplies of bronze weapons, including great slashing knives and spearheads and two kinds of rapier-like swords, a mainland version and a Cretan version. Several swords are ornamented with gold-plated hilts and pommels of polished stone, ivory, or gold; some have gold predators at the hilt gripping the blades in their mouths. The blades may be ornamented with running horses, flying griffins, shields in the shape of a figure eight, or even lilies running down from hilt to tip. The tremendous influence from Crete on these graves is visible in the metal cups, faience "sacral knots" (i.e., representations of a Cretan ritual object in the shape of a scarf with a looped knot and fringed ends), dolphin-appliquéd ostrich eggs, conch shells associated with ritual summoning, gold triple shrine facades, images of bulls with double axes between their horns, and imported pottery painted with plants. Beside them is an equal wealth of local art such as formal gold cups, gold worked in breathless surface patterns of lions, bulls, and plants, and dozens of lions twisted as ornament. There probably is a local iconography in the gold seals of duels, lion combat, chariot hunting, and a wounded lion trying to pull an arrow from his shoulder. Traveling artists may account for some of the similarities to Cycladic and Cretan art, but local armourers may also have wrought local metal into drinking cups. Covering the faces of some of the men were gold portrait masks showing them with beards and mustaches. In this they are like an amethyst "portrait" gem in Circle B of a bearded mature man. (Later studies of faces also seem to reserve the beard and mustache for important or powerful elders, although fashions change; servants and soldiers are normally beardless). Women's

the Theran paintings, and the jewelry is impressive. Some bronze dagger blades were inlaid with remarkable pictures or designs in other metals, chiefly gold and silver and electrum (a mixture of gold and silver) in various shades. Black niello was used as a background for these pictures or to heighten the incised detail. The most famous of the Shaft Grave daggers shows men armed with bows, spears, and great body shields, hunting a pride of lions; another has califie animals chasing wild fowl among papyrus flowers beside a silver stream. This technique of "painting in metals" appears to have originated in Syria, although the workmanship and style of the pictures on the Mycenae daggers look novel. Whereas other daggers and some metal cups with inlaid designs of this kind have been found on the mainland, none has yet been recovered

costume cannot be known from the remains, but it may

have had the same range of tunic, apron, and veil as in

Two groups of Shaft Graves Tholos

tombs

in Crete. But many of the treasures from the Shaft Graves are imports from Crete.

The Shaft Graves had so many metal vases, including huge bronze cauldrons (one marked with Linear signs), that clay vases were not much needed. Yet, the contemporary chamber tombs at Mycenae and many other sites have wonderful pottery that is both imported from Crete and made with local taste with spirals, ferns, and double axes. In this development one can observe the formation of a new Mycenaean Greek culture, as it assimilated styles from Crete and vet insisted on more traditional local habits. It is this tentative fusion of two cultural "languages of art," already in touch for two or three centuries, that gave a special impetus to the new Mycenaean world, rendering it flexible, receptive, and adventurous. The pottery, superior in technique, colour, and design, was attractive to other cultures and widely used as commercial containers for oils. Because it has been found in almost all coastal districts from Syria to Sardinia, it is a real aid to dating.

Along with the rich chamber tombs at Mycenae, certain families, perhaps princely, began building tholos, or beehive, tombs as early as the Shaft Grave Period, perhaps first in Messenia in the 16th century and then in many places in Greece by the middle of the 15th century. The tholos tomb has three parts: a narrow entranceway, or dromos, often lined with fieldstones and later with cut stones; a deep doorway, or stomion, covered over with one to three lintel blocks; and a circular chamber with a high vaulted or corbeled roof, the thalamos. When the facades are finely dressed with cut stones or recessed vertical panels, one may think of a Cretan connection: indeed, one of the tholos tombs at Peristeria has two Cretan "masons' marks," a branch and a double ax, cut into the facade to the left of the doorway. The influence of Crete on the southwest Peloponnese is marked. Perhaps a traditional memory of this connection is preserved in the Homeric Hymn to Apollo, which tells of the god kidnapping the crew of a ship trading from Knossos to Pylos to serve his new sanctuary at Delphi. Excavations at Delphi yielded a snout of a marble lion rhyton (libation vessel), matched best by a complete example at Knossos. The tholos tomb is always covered by a mound of earth, often kept in place by a peripheral stone ring, or krepis. Some tholoi were built on the surface of the land, but most were built in a deep pit excavated into the slope of a hillside. The stones that were overlapped in rings to form the vault in the corbeled system were laid with a narrower face inside, which locked each ring in place. The lintel blocks, often huge in size and weight, were dragged across the hill and dropped onto the corbel rings at the proper height; either a single huge block or two or three slabs next to each other provided the needed depth. Various systems were used to ease the weight on the lintel, such as narrow stone bars or an open relieving triangle sealed by a thin-cut screening stone. The whole vault was sealed with a keystone.

Most tholos tombs have collapsed, often when the lintel cracked and gave way, and their contents have largely been looted. Occasionally the robbers overlooked a pit sunk in the floor, like the rich burial at Vapheio near Sparta; sometimes a whole tomb survived unplundered, like the one at Dendra near Mycenae or that at Rutsi-Myrsinochorion in Messenia. Of the nine tholos tombs at Mycenae, two, the Treasury of Atreus and the Tomb of Clytemnestra, have splendidly dressed facades with engaged half columns in two tiers and coloured exotic stones; they may have been built early in the 14th century, although arguments are made for a 13th-century construction. The elaborate design of the facade may have been imitated from the impressive north facade of the inner court at the Cretan palace of Phaistos. The imagery might imply a continuing presence of the dead kings inside the tomb. Such tombs sometimes mark the gate or main road to a town, as classical tombs did, as though they were "ancestral watchers" or guardians. Tholos tombs were built from the 15th to the 13th century and imply a hierarchical command of labour, of the kind the palace exerted later, according to the Linear B documents. Possibly the capstone was not put in place until the dynast died. These structures could not be built quickly but were prepared with foresight.

While stone-built tholos tombs became the standard resting places for kings and princes in all parts of the mainland to which the Mycenaean civilization penetrated. the mass of the population changed from a custom of burial in single graves, whether in mounds or cemeteries or inside settlements, to the use of family vaults. In some regions, such as Messenia and the frontier area of Thessaly, families built small tholos tombs for themselves. The most common type of Mycenaean family tomb, however, was a rock-cut chamber with a dromos leading down to the entrance. The entrance was blocked with stones and the passage filled with earth after each burial. The rockcut tomb may have been developed in Messenia during the 16th century under Cretan influence, like the tholos tomb. In the Knossos region of Crete, rock-cut tombs had been in use for communal burials for many centuries before this. Whatever its origin, the idea of family burial in rock-cut tombs soon spread to Mycenae and other parts of the mainland. Some rock-cut tombs in Messenia and elsewhere were carved in the shape of the beehive vaults of tholos tombs. A few large rock-cut tombs, including some of this shape, were used for royal or princely burials

Period of the Early Palaces in Crete (c. 2000– 1700). Crete does not seem to have been affected by the movements of people into the Cyclades and the mainland at the end of the 3rd millennium, but important changes were taking place there. Great palaces of a distinctive type built around large rectangular open courts seem to have been constructed within a comparatively short time at the leading centres of Knossos, Phaistos, and Mallia. The art of writing is first attested for certain in Crete at the beginning of this Palatial Period. These developments in Crete anopear to have been the result of local evolution.

Crete advanced rapidly along the path of civilization during the period of the Early Palaces, while the mainland relapsed into comparative agricultural stagnation. The art of seal engraving made great strides in Crete. Hard stones, such as jasper and rock crystal, began to be employed for some of the finer seals. A new and much-favoured shape, which may have been adopted from Anatolia, was the signet with a stalk. Anatolian seals found their way to Crete, and impressions of them have been identified in a great deposit of clay sealings from the early palace at Phaistos. Cretan seal designs now included elegant abstract patterns of spirals and concentric circles neatly made with the drill as well as lifelike pictures of animals, birds, and insects, together with mythical beasts such as sphinxes and griffins adapted from Egyptian or Oriental models. Attractive hard stones, such as gabbro, were used by the Cretan vase makers, although they still used the softer chlorites and serpentines. Some of the fine stone vases from communal tombs in the Mesara region and at Mochlos may date from this period, rather than earlier, in the light of discoveries since 1950 in the early palace at Phaistos.

The fast potter's wheel began to come into use in Crete about the same time as in the Cyclades and on the mainland. Meanwhile, a revolution in the style of Cretan pottery was taking place. During the Early Bronze Age most of the finer vases everywhere in the Aegean area had been decorated with designs in dark, rather shiny paintshades of red, brown, and black-on a light surface. Toward the end of that period in Crete, however, there was a change to a "light-on-dark" style of decoration; the vases were given an overall wash of the shiny paint previously used for decoration, and designs were applied to this dark surface in white. This new light-on-dark fashion was also adopted, to some extent, in the Cyclades and on the mainland, but in Crete it was developed much further, and, from the beginning of the Palatial Period, decoration in white was regularly supplemented with red to create a striking polychrome effect. This kind of pottery, which flourished in Crete throughout the time of the first palaces and later (c. 2200 to 1600), is known as Kamáres ware from a sacred cave of that name on Mount Ida, where vases with fine polychrome decoration were recovered at the end of the 19th century. Most of the smaller vases in Crete, notably the drinking cups, now copy metal ones in their shapes and often in their molded or impressed decoration, and the exquisite "eggshell" ware, made in the Earliest writing in Crete

"Eggshell" ware

Destruc-

nalaces

tion of the

workshops of the great palaces, with walls as thin as those of metal vases and shiny black surfaces adorned with abstract flowerlike designs in a combination of white, red, and orange, is among the finest pottery ever produced in Greek lands. The imitations in caly suggest that vessels of precious metal—gold and silver—were in general use in the palaces of Crete by this time. A silver, two-handled goblet of this period was recovered from a tomb at Gournia in eastern Crete. Silver occurs in the Cyclades, and it was being mined during the Bronze Age near Laurum in Attica on the mainland.

There were many contacts between Crete and the rest of the Levant during this period. Scarabs and stone vessels from Egypt reached Crete and were imitated there. Cretan Kamáres ware was exported to Cyprus, Syria, and Egypt, where it has been found in tombs and on town sites. Letters recovered from the ruins of the city of Mari on the Euphrates, destroyed by Hammurabi about 1760, refer to objects of Cretan workmanship. It seems that Cretan metalworkers were already preeminent in the civilized world of the time. The daggers they made were of types ultimately derived from Syria, but they were exported to Cyprus in exchange, perhaps, for copper, although supplies existed in Crete. Westward, they may have reached Italy, where native copper daggers are of Cretan shapes and flint imitations of them seem to have been made. It was during this period that tin-bronze began to come into more general use in the Aegean, replacing copper or bronze made by adding arsenic, a process which was effective but dangerous for the craftsman who undertook it. Tin may have reached the Aegean first from Iran through Syria. although Etruria on the western coast of Italy was another possible source.

Burial in Crete was still normally in communal tombs, and many of the Early Bronze Age ones continued in use, but cemeteries of burials in storage jars are also in evidence at this time. No royal tombs of this period have been identified, however, and kings and queens may have been laid to rest, like their subjects, in the tombs of their clans or possibly even buried ceremonially at sea. A large rectangular building with many rooms or compartments in the cemetery area just outside the city at Mallia might have been the tomb of the royal clan there. The local inhabitants plundered it during the 19th century, and its modern name-Chrysolakkos ("Gold Hole")-suggests what they found. A gold cup and jewelry, including elaborate earrings and pendants, acquired by the British Museum in 1892 and allegedly from a Mycenaean tomb on the island of Aegina near Athens have been thought to be plunder from Chrysolakkos, although recent excavations on Aegina have indicated a wealthy and warlike community that could equally have produced these jewels. They are marked by an unusual style: one earring has a two-headed snake surrounding a pair of leashed hounds over squatting monkeys, with owls and discs hanging on soldered chains. The collection may have been made during the 17th century, after the destruction of the older palaces. French excavations there in the 1920s led to the recovery of similar jewelry, notably a gold dress-pin with flower head and a pendant in the form of a pair of bees (or wasps) facing each other over a disc, which may be meant for a honey cake. This pendant shows that the Cretan jewelers were masters of the art of hard soldering and could use it to fix wire (filigree) or minute globules of gold (granulation) to a background.

Life in the Cyclades seems to have continued much as it had in the Early Bronze Age. Yet, apart from signs scratched or painted on pottery from Phylakopi in Melos, there is little evidence of acquaintance with writing or the use of seals. Some time after the beginning of the period of the Early Palaces in Crete, Phylakopi was defended by a massive wall. Cretan Kamáres ware was exported to the islands of Melos, Coos, and Aegina and to Lerna and a few other coastal sites on the mainland, and mainland Minyan ware found its way to the islands and to Crete. The trade may partly reflect the trade in Melian obsidian, which may still have been in demand for cheap knives and razors, although metal ones were already in use in the Aegean area from the Early Bronze Age onward. Chamber

tombs cut in the rock at Phylakopi appear to go back to this period, but burial in slab-lined cists continued elsewhere in the islands. At some point the fortified settlement at Khalandriani on Syrus was destroyed by fire and abandoned, but Aegina, Ceos, and other fortified island towns flourished.

Period of the Late Palaces in Crete (c. 1700-1450). Various disasters occurred in Crete about the turn of the 18th and 17th centuries BC. The palaces at Knossos and Mallia were damaged, while that at Phaistos and a building that may have been the residence of a local ruler in a large settlement at Monastiráki west of Mount Ida were destroyed by fire. The palace at Phaistos had been so violently burned that an enormous layer of almost impenetrable vitrified mud brick formed an underpinning for the new palace built on top of it; it is a vivid testimony to massive destruction. What caused these destructions is uncertain. Accident, internal warfare, or foreign invasion are among possible agents. The damage at Knossos might have been caused by one of the many earthquakes that afflict the area. It has been suggested that Crete was first conquered by Greeks during this period or by people from Anatolia speaking another Indo-European language called Luwian and related to Hittite. There is, however, no strong evidence for an invasion of Crete at this time. The two or three centuries following these disasters were indeed the most flourishing of the Aegean Bronze Age, during which Cretan civilization reached its zenith. The palaces at Knossos, Phaistos, and Mallia were restored with greater splendour than before.

From the dimensions of the new and entirely rebuilt palace at Phaistos, it has been possible to calculate the unit of length used by the Cretan architects: a foot only a fraction shorter than the standard English foot. In plan, the later palaces were basically the same as the earlier ones, with agglomerations of rooms clustering around long, rectangular central courts oriented roughly from north to south either for ritual or for catching the best of the winter sun. Many parts of these palaces were two or three stories high. A section on the eastern side of that at Knossos, built into a cutting in a steep slope below the level of the central court and housing the royal living quarters, may have had five stories. Large areas of the palaces, especially at Knossos, were possibly reserved for cult. It is difficult to explain otherwise the beautiful ceremonial steps at Phaistos leading up to a blank wall; although there is no entrance, a personage could make a sudden appearance from the side and speak or show something to an assembly in the open space in front. The palaces often had a conjunction of

Vats and cists for storage in the west magazine of the second palace at Knossos, Crete.

Aegina treasure grand facades and storage quarters, perhaps for the first fruits of the harvest to be blessed in passing.

Wide, paved squares flanked the palaces, and around them spread extensive towns, which by this time if not earlier seem to have been unwalled. Unfortunately, a complete town around a palace has never yet been excavated, and the comparative wealth or population is not known. Cobbled streets with raised central paths of smooth squared blocks for the convenience of pedestrians ran through the towns. Surface water was carried away by covered drains, and skillfully jointed clay water pipes were found in the palace at Knossos.

Gourniá

The only settlement of this period that has been entirely excavated is a small town at Gourniá in eastern Crete. This was built on the slopes of a ridge overlooking the sea, on top of which stood a little "palace" with a small open court in the centre and a public square beside it on the sheltered landward side. Down the ridge from the palace toward the sea was a small shrine facing the end of a path that led to it from the main street. Even in a small town such as that at Gournia, many of the houses were evidently two stories high, and houses with three stories are denicted on faience inlays from the palace at Knossos assignable to the 17th century BC.

Palaikastro in eastern Crete is another important town with blocks of houses marked by coloured stone foundations, narrow streets with drains, and pottery of exceptional quality. Another town of great potential interest is Arkhanes near Knossos, where palace facades, early tholos tombs and later shaft-grave burials, and shrines have been discovered scattered through the countryside. Pyrgos, a controlling villa, and Kommos, a commercial town with fine architecture, roads, and ship sheds, also are indicative of power and wealth; the road and watchtower system is

beginning to be better known.

In palaces as well as houses, the lower parts of walls were still normally built of rough fieldstones held together with mud, the upper stories being continued in mud brick. Carefully squared and fitted blocks of limestone, however, were employed for some important facades. Now, as earlier, walls were often tied together with a framework of timbers set vertically and horizontally and joined by crossbeams running through them. There was also an extensive use of timber for columns and pillars and for the rafters supporting upper floors and roofs, which, it seems, were usually flat. Pictures of wooden columns show them with a characteristic downward taper, which may reflect an original custom of placing tree trunks upside down. The lower parts of the walls inside the palaces and great houses were often clothed with large slabs of attractively veined gypsum, a soft crystalline stone that outcrops in the region of Knossos and Phaistos. Gypsum was also much employed for pavements, but a hard lime plaster was more commonly used for coating walls and floors. Plastered walls were decorated with brightly coloured pictures, which may be an innovation of this period, since they are not yet attested for certain earlier in Crete. These pictures are described as frescoes because they were normally painted while the plaster was still damp, Lines impressed with string in the wet plaster helped to guide the artists. White, red-brown, or blue were usually chosen as a background, while yellow and black were among the other basic colours used. Many of these pictures, especially those from the palace at Knossos, were concerned with religion; they show elaborately dressed goddesses, together with sacred dances and ceremonies, such as bull leaping. which appears to have had a religious or magical basis. Yet scenes such as a frieze of partridges and hoopoes adorning a room in what seems to have been an inn for strangers opposite the palace at Knossos look entirely secular. Monkeys, imported from Egypt, are depicted more than once, along with native wild goats and extraordinarily lifelike flowers-rose, ivy, saffron crocus, lily, and papyrus-but often imaginary hybrids. Some frescoes may represent permanent magic gardens. The pictures ranged in scale from those with life-size figures, which might occupy most of the wall surface, to panels and friezes, including a class of miniatures with figures of men and women two to three inches (five to seven centimetres) high. Parts of some wall pictures at Knossos were in relief, and plaster reliefs of this kind are occasionally found elsewhere in Crete, Floors and ceilings might also carry painted decoration.

Their wall paintings were probably the finest achievements of the Cretan artists, but only battered or firediscoloured fragments of these have survived. The minor arts are better represented in the archaeological record. Now, if not earlier, hard rock crystal began to be used for making vases and seals, together with the volcanic glass, obsidian. A variety flecked with spots of white pumice, from Yiali (Glass Island), near Cos, was favoured for vases. Other fine stones imported for vase manufacture were Egyptian alabaster (calcite) and green and red marbles (antico rosso and lapis lacedaemonius) from the southern Peloponnese. Antique stone vases from Egypt might be adapted to local tastes by the addition of spouts and handles. Vessels with narrow necks were carved in two pieces that were afterward joined together, an example being a crystal libation vase from Zákros with the handle formed of crystal beads threaded on copper wire. A number of cult vases are carved with pictures in relief, including an octopus, a mountain shrine with birds perched on horns of consecration, altars in an enclosed courtyard, and wild goats and, on other vases, youths engaged in ritual competition, a ritual dance of some kind, and games, such as bull leaping, wrestling, and boxing, which apparently had magical or religious connotations. Soft stones, such as chlorite or serpentine, were used for making these vases, the surfaces of which were often coated with gold leaf, to judge from the scraps that have survived. This economical system of gilding was sometimes applied to seal stones. although solid gold and silver seals also occur. A class of gold signet rings has oval bezels engraved with ritual scenes that may be from the story of a goddess and her consort and include scenes of worship at an altar or a tree, with a shield or sacral knots as attributes, or dancing, Seals of other shapes, in a wide range of attractive stones, display a variety of designs, including animals, such as lions, bulls, and wild boars. Sometimes a bull is being attacked by a lion, or a wild goat is escaping or standing at bay before a hound. Birds, fish, and butterflies also figure on these seals, and most of the designs appear to be entirely secular in character. A class of gems crudely engraved with pictures of jars and leafy branches may have been rain charms, however.

Rings and

There is little evidence for Bronze Age sculpture in Crete. apart from a few small stone heads that may have come

Minoan frescoes

from statues with wooden bodies or a pair of clay feet perhaps supporting a dressed armature. Some bronze curls from the palace at Knossos appear to have adorned the head of a more than life-size wooden statue of a goddess. Figurines cast in solid bronze, though sometimes marred by casting defects, are often of great beauty. They mostly represent worshipers, both men and women, and were placed as votives in sanctuaries. Statuettes of bull leapers and perhaps of gods and goddesses were made of imported ivory in several pieces cunningly joined together by pins and dowels. Faience manufacture was presumably learned from Egypt. Exquisite faience plaques of animals, along with statuettes of goddesses or priestesses and small vases of the same material, appear to be products of the palace workshops at Knossos for shrine or ritual display.

The Late Palace Period seems to have been rich in metals. Although few gold and silver vessels have survived in Crete, many fine vessels in the Mycenae Shaft Graves may have been made by Cretan skilled workers. Even cooking vessels were now being made of copper or bronze, including huge cauldrons in which a sheep or goat could be boiled whole. Among a variety of serviceable bronze tools were axes, adzes, and double-bladed axes such as those of earlier times. The sockets of these were improved toward the end of the period from a circular to an oval shape, which prevented twisting of the haft. New tools current by then included long bronze chisels and immense saws capable of slicing the gypsum required for paving and wall veneer, as well as for cutting timber. Helmets of copper or bronze are depicted on faience inlays from Knossos and on stone relief vases, but plate armour is attested only from the end of the 15th century. For defense, the Cretans of this time, like their Mycenaean and Cycladic contemporaries, appear to have relied on huge rectangular or eight-shaped shields of bull's hide. (Homer's description of the shield of Ajax as being "like a tower" preserves a memory of body shields of this kind.) Weapons included spears and daggers, as well as rapiers with long slender blades and short tangs for affixing wooden hilts. Massive pommels of attractive stones, such as rock crystal, or of gold-plated wood or ivory helped to balance the blades. Toward the end of the period, swords are found with strong, flanged hilts and short blades adapted for cutting as well as thrusting strokes. A remarkable set of weapons, often inlaid, enriched with gold, ivory, and designs, was created at Knossos at one or more brilliant sword workshops (which vanished after about 1400).

Signs scratched or painted on clay vases, not only in Crete but on the mainland and in the islands, from about the middle of the 3rd millennium onward may reflect acquaintance with writing among the peoples of the Aegean area. The first positive evidence for the use of writing in the Aegean, however, is found in Crete at the beginning of the Palatial Period-about 2000 or somewhat later. This earliest Cretan writing is known as pictographic or hieroglyphic because its signs are pictures of animals or things: the system appears to be of Cretan origin, even if it was inspired by Egypt or Syria. During the period of the Early Palaces and while the Cretan hieroglyphic script was still in use, a simplified linear script was being scratched on clay tablets at Phaistos. A more evolved script with linear signs of this kind is attested in various parts of Crete and was known in the Cyclades during the Late Palace Period. It is known as Linear A to distinguish it from the variety of script (Linear B) current both in Crete and on the mainland from the end of the 15th century (see below). Most of what has survived of Aegean Bronze Age writing is on clay tablets of the kind used in Syria and Mesopotamia in early times. Ink was, however, used to write Linear A inscriptions around the insides of two · clay cups from Knossos, and the bulk of what was written in the Aegean during the Bronze Age may have been in ink on some kind of paper made from papyrus, as in Egypt, or from palm leaves, as later Greek tradition hints. The two standard forms of tablets are the long narrow "palm leaf" for short transactions and the tall rectangular "page," which often is a summary or inclusive list. The Knossos tablets supply records of transactions involving personnel, cattle, sheep, goats, oils and spices, wool and textiles, weapons (including arrows, swords, and issues of chariots with armour), stored treasures, and religious offerings. They seem to reflect a period when the former palaces of the several districts were no longer standing, or powerful, but when the surrounding lands still produced agricultural goods that were taxed or tithed at Knossos

THE DECLINE OF THE EARLY AEGEAN CIVILIZATIONS

The eruption of Thera (c. 1500) and the conquest of Crete (c. 1450). Cretan civilization reached its highest peak between about 1600 and the later 15th century. An important change of fashion that began about 1600 in Crete was the abandonment of the "light-on-dark" style of vase decoration of Kamáres tradition in favour of a return to "dark-on-light." The new-style Cretan pottery, with attractive designs of spirals, grasses, ferns, and flowers in shiny black or brown paint, was soon to inspire the development of Mycenaean pottery on the mainland. This flourishing period in Crete, however, ended in a series of disasters. About 1500 the volcano on the island of Thera, long, it seems, quiescent, erupted to bury the settlements there under many feet of pumice and ash. The story of Atlantis, if Plato did not invent it, may reflect some Egyptian record of this eruption, one of the most stupendous of historical times. Knossos was shattered by a succession of earthquakes that preceded or accompanied the eruption, while great waves resulting from it appear to have damaged settlements along the northern coast of Crete. Ash identified as coming from the eruption has been found in coastal sites as far away as Israel and Sardis in Anatolia. The wind may have been blowing from the south or west. Later Greek traditions, such as the story of Deucalion's flood, may enshrine a memory of similar waves that swept the coasts of the mainland at this time. Some Cretan settlements might have been wrecked by the blast from the eruption, although Thera lies about 70 miles (110 kilometres) away from Crete. Whatever the damage caused, it appears to have been soon repaired and not to have disrupted the course of local culture. Damages to pastures and livestock were apparently minimal. Similarly, in the Cyclades there are few signs of any gap in occupation as a result of the eruption. The settlements on Thera, however, lay buried deep in pumice. The largest of these, at Akrotiri, opened by excavations since 1967, offers a unique picture of a Bronze Age town. The walls of its houses stand in places two stories high, with paintings miraculously preserved on them, and the floors with storage jars and other objects are as they were left when the inhabitants escaped from the eruption or from the earthquake that is thought to have preceded it. The wonderful preservation of delicate frescoes and of foodstuffs, from snails to olives to grain, makes Thera a tantalizing closed deposit of Aegean life. Many houses have flagstone floors upstairs, with columns supporting the roof, and rooms with multiple windows. Below there are storage bays filled with jars, looms, medicine chests, and grain and oil stores. There is delightful local pottery with swallows, dolphins, wild goats, and caper and saffron plants. The wall paintings have a garden quality and may often have religious associations or celebrate festivals and seasons, city or country life, and sea voyaging. Only a small part of the town has been excavated. The work has been slowed by the engineering problems of keeping the two- or three-story houses from collapsing and crushing the painted walls and delicate contents sealed from damage for centuries.

After the eruption, Crete appears to have enjoyed comparative prosperity for a time, while the influence of Cretan civilization continued to spread on the mainland. Alongside vases with plant and flower designs, the Cretan potters began to decorate others in an attractive marine style, with octopuses and other sea creatures. The marine style may have originated at Knossos, but vases with this type of decoration, many of them of a ritual character, were exported all over Crete, as well as to the Cyclades and the mainland. About the middle of the 15th century, however, a generation or so after the eruption of Thera, most of the important sites in central and southern Crete were destroyed by fire. Destruction was not confined to

Linear A and Linear B

marine

palaces and towns but extended to country houses, farms, and rural shrines. Many settlements were never inhabited again, such as that at Mochlos, where excavators found the remains of numbers of people who had perished in the destruction. The site of the destroyed town at Gournia was eventually occupied by a scatter of houses, but the palace there was not rebuilt. The large palaces at Mallia and Zákros were also destroyed by fire and afterward abandoned.

A new social order. The fact that palaces and country houses, centres of landed estates, were not rebuilt suggests a total overthrow of the existing social order. A number of magnificent stone ritual vases and bronze tools have been recovered from the ruins of the palace at Zákros in excavations since 1962, but virtually no gold or silver objects were found. Indeed, it looks as if the palaces and houses everywhere in Crete had been ransacked before they were destroyed. Of the four great palaces, only that at Knossos may have escaped serious damage at this time, but parts of the city there were wasted by fire. In the early days of Cretan exploration, it was taken for granted that such destruction was the result of war. Since the 1930s, however, it has been suggested that it was in some way caused by the eruption of Thera. The eruption, however, began and ended a generation or more before this horizon of destruction, while evidence of conquerors in Crete immediately after it has been found. The destruction appears to have been their work

The conquerors evidently came from the mainland and made their capital at Knossos, but they seem to have established another centre of power at Phaistos, and legend hints at a third centre at Kydonia (modern Khaniá) in western Crete. Vases of shapes already popular on the mainland, such as drinking cups with tall stems, became fashionable at Knossos after the conquest and eventually spread to other parts of the island. A rather stiff, formal "Palace Style" of vase decoration, using motifs derived from the earlier plant and marine styles, may reflect an adaptation of Cretan fashions to mainland tastes. The old clan tombs went out of use in the Knossos region and were replaced by rock-cut tombs. Some of these contain the burials of warriors and their families, accompanied by rich assortments of weapons and jewelry, resembling the military equipment of the Mycenae Shaft Graves and the mainland tholos tombs. There was a cemetery of similar rock-cut tombs, with richly furnished burials (the Tombe dei Nobili), at Phaistos. Tholos tombs sunk in the ground and covered by mounds appear to have been introduced to Crete from the mainland now. One, on the Kefala ridge north of the palace at Knossos, may have been built soon after the conquest. It has masons' marks like the one at Peristéria in Messenia.

The Linear B texts. Insight into the social order on Crete after the conquest can be gleaned from the Linear B tablets found at Knossos, where Linear B had replaced Linear A by the 14th century BC. The decipherment in 1952 of the Linear B tablets as Greek by Michael Ventris, working with John Chadwick (see above), has been widely accepted. Still, there are some skeptics who reject it; and, while most of these believe that the language of the tablets will prove to be Greek when (in their view) it is correctly deciphered, a minority think it will not. At the same time, among philologists who do accept the Ventris decipherment, there are a few who regard the language of the tablets as a form of Greek with little or no relation to the Greek of later times, which, in this minority view. was introduced into the Mycenaean world by new peoples of Greek speech at the end of the Bronze Age. The tablets have many personal names and place-names but very little connected descriptive Greek, making them hard to read; nonetheless, they are of enormous potential value. Knossos seems to have been the only Cretan centre with a genuine archive recording income, palace issues of expensive equipment like chariots and bronze corselets, and outlays on gifts to the gods (some of whom were Greek. some traditional Cretan), mainly in the form of donations of oil and cloth. The Knossos records are valuable in allowing reconstruction of farming practices, the wool industry, and military defense, as well as in providing lists of personnel and places scattered around the countryside of Crete that owed or brought sheep and produce to the palace. The bureaucratic apparatus seems to have been well organized and extensive, whereas the rest of Crete in the 14th and 13th centuries, though rebuilt after the earlier disasters and the abandonment of the 15th century and prosperous, does not give evidence of the same degree of control and record keeping. How far the countryside was subservient to Knossos is not known.

The fusion of cultures on Crete. The last decades of the 15th century and the first part of the 14th century saw a wonderful fusion of Cretan and mainland skills; the fabric and firing of pottery improved, and there were formidable and often elegant and richly ornamented bronze weapons in the warrior graves at Knossos and Phaistos. Sword hilts were sometimes sheathed in gold, and their pommels made of fine stones and ivory. Warriors were armed with large thrusting spears as well as throwing spears, or javelins; boar spears were used for hunting. Shields were painted on walls as well as hung there, and there were new bronze arrowheads and conical helmets with a plume knob and cheekpieces. The old mainland helmet plated with tusk plaques of the wild boar reached Crete, too, Bronze armour was issued by the palace, with chariots and pairs of horses; the transverse strokes on the cuirass ideogram on the tablets suggest a link with the transverse bronze bands of the armour suit from Dendra near Mycenae from about 1400 BC. There seems to have been a disciplined set of chariot squads, perhaps often composed of men from abroad, patrolling the island. It may be that a memory of this energetic military epoch is preserved in the Iliad, in the passages describing the exploits of the Cretan princes Idomeneus and Meriones. Gold rings from this period have a rich religious iconography of shrines and worshipers, and there are fine sealstones. About 1400 the fused customs or beliefs of the Cretan and Mycenaean worlds appear on the painted limestone sarcophagus from Avía Triadha, a small palace near Phaistos; depicted on one side are libations on the left and, probably, offerings to a dead man on the right. The other side shows a bull being sacrificed while a man is playing the double pipe. Pairs of women in chariots drawn by wild goats or griffins are represented on the ends. Historically the sarcophagus occupies a dividing line: Knossos was burned again after

There seems to be a marked difference in economic power or aesthetic achievement between the earlier (1600-1400) and the later (1400-1200) periods of Minoan, Cycladic, and Mycenaean cultures. Frescoes are dullermore repetitive, coarser in outline, and muddier in colour. The grand swords are no longer made, and rings and seals are simpler. Metal becomes rarer, and blue glass tends to replace lapis lazuli from the east. It is uncertain whether this decline in art reflects a change of governmental forms, a restriction on trade with Egypt and the east, a decrease of creative energy leading to an unimaginative reproduction of traditional patterns in familiar materials, or the loss of palace-controlled Cretan workshops that had supplied the earlier fine standards for the developing Greek world.

The mainland. While there are many signs of mainland influence in Crete in the period after about 1450, the conquest may have helped to spread Cretan fashions and techniques on the mainland through the medium of captive artisans sold as slaves. The earliest wall paintings on the mainland appear to date from this time and are thoroughly Cretan in style. The Mycenaean civilization of the mainland nevertheless remained very different from that of Crete. Mycenaean pottery is distinguishable from Cretan, and religious customs, such as worship in caves or hilltop sanctuaries, which continued in Crete, do not appear to have taken root on the mainland. The sphere of architecture, however, is continually impressive, as it had been in the older phase of tholos tombs.

The standard mainland palace of this period, although built with Cretan techniques, differed from the traditional Cretan palace centred around a large, rectangular court. The focal point of a mainland palace, such as that at Pylos (Pilos) in Messenia, was a great hall with the roof supported on four pillars and a vast circular central hearth. The hall was entered through an anteroom with a

The Knossos records

Mainland palaces

columned porch beyond it. This complex appears to be an adaptation of the type of longhouse found on the mainland since the end of the 5th millennium. The mainland palaces were painted in a manner derived from Cretan models, with large processional scenes and smaller scenes of men hunting boars or stags, of chariots, duels, and numerous battles; there are heraldic hounds, griffins, lions, sphinxes, and patterns with horses, argonaut shells, spirals, and rosettes. The whole is colourful but more imaginative in idea than expert in execution. After about 1400, a series of small acropolis palaces was built, usually with a simple megaron hall, as at Tiryns, in Late Helladic III A. These palaces developed into almost grandiose complexes by the later 13th century, with lower courses of well-dressed limestone and painted floors, surrounded by workshops and storerooms. The descriptions of palaces in Homer are evidently based on memories of palaces such as these, and what Homer calls the megaron corresponds to the great hall. A small palace with mainland features was built at Phylakopi on Melos in the Cyclades, and a more regular form on massive foundations at Ayía Triadha near Phaistos in Crete. A shrine there whose floor was painted with fish and octopods looks forward to the painted floors of mainland palaces, with dolphins and octopods at Tiryns and octopods and fish at Pylos.

The palaces on the mainland had a system of keeping records that was similar to the Cretan one. The archive at Pylos, excavated by Blegen in 1939 and again after World War II, is the only extensive one found so far, but Thebes also produced tablets in some numbers, and there were smaller groups at Mycenae and Tiryns. These tablets reflect the same range of interest as those at Knossos: they consist of lists of palace personnel and of persons in outlying towns in professions such as bronzesmith, shepherd, cowherd, or tree cutter. There are lists of landowners, women and children, and priests and "slaves of the god. as well as records of agricultural income, of the preparation of perfumed oil, and of sacrifices of animals to the gods and offerings of oil and cloth at different parts of the Pylian province. Systems of landownership and tenancy were fairly complicated, and the palace kept a close eye on all dues and exchanges of goods. The archive at Thebes has records of trade with neighbours, in Euboea, or at places like Sicvon in the Peloponnese and of contacts with western Crete; the commercial interests of the Pylos district seem to have been more internal.

By the late 20th century, only three palace systemsat Tiryns, Mycenae, and Pylos-were well excavated and understood. The Theban palace may yet emerge; workshops, storerooms, and an arsenal have been found in probes under the modern town. Athens and Sparta may have had palaces, now lost; Dendra-Midea in the Argolid had impressive walls; Orchomenos in Boeotia had at least a small megaron with frescoes. Private houses are known both at the palace centres and in nonpalatial places, and some private houses, like those at Mycenae, maintained their own records in Linear B. There is a certain likeness all across Greece in architectural techniques, pottery, frescoes, ivory, and jewelry, but local autonomy and distinct variations in design and workshop styles also are evident. Gifts no doubt were exchanged among the principal centres, and there was at least a partial network of roadways connecting one centre to another; much trading must also have been coastal.

The Greek mainland in the 14th and 13th centuries was densely populated with towns and villages, and cemeteries confirm the numbers. The state was organized under a king, wanax, with a military leader, rawaketa, and troops with chariot officers attached for patrolling the borders; there also were naval detachments. The people had certain powers and a council. The towns were organized hierarchims.

cally under local officials, like the later "kings," basileis. Eastward explorations. From the 15th century, the mainland Greeks explored eastward and replaced the Cretan settlers in such outpost towns as Triánda on Rhodes or Miletus on the coast of Anatolia. There are Hittle records that apparently mention the maneuvers and political medding of Greeks in coastal states; they refer to them under the name of Ahhíyawa, probably the equivalent to

Homer's Achaeans at Troy. These records, from the 15th through the 13th century, are confirmed archaeologically by finds from the cemetery at Panaz Tepe near Phocaea in the north to Müskebi near Halicarnassus in the south. Panaz Tepe has warrior equipment, and apparently the soldiers took native wives, for the Greeks were buried while the Anatolians were cremated in the same small tholos tombs. Mycenaean pottery and imitations of it appeared at Troy itself from the 15th century onward. The renowned "Trojan War" may sum up a series of relationships and conflicts spanning the entire Bronze Age, since some of the archaic equipment described in the poems is actually found in 15th- and 14th-century Anatolia. There also was extensive trade with the Levantine coast and Cynnis at least until all trade networks began to be disrupted after the Battle of Kadesh in the 13th century. The exports are far more visible than the reciprocal imports.

The end of the Bronze Age in the Aegean. From the middle of the 13th century, expensive fortification walls were constructed for the mainland palaces (except Pylos). which give testimony of tremendous skill in fitting large blocks of stone together without bonding, in designing sophisticated gates, and in protecting underground water supplies. At Tiryns the walls are marked by elegant setbacks, and at Mycenae the famous Lion Gate is ornamented with the sculpture of two lions, one on either side of a column. The gateway and walls on the Acropolis of Athens were also impressive, with postern gates and guard posts and roofed, sheltered water supplies, either from local springs or brought in by pipes. These walls may signal frictions between city-states such as marked classical Greece or represent a common fear of attack from enemies unknown to 20th-century investigators. It may be that the cost, in labour and hire, of these fortifications had serious effects on the economy. Yet the 13th-century palaces increased in size and complexity, their walls and floors being repainted. The tomb gifts did not decline in value, suggesting that local wealth was maintained, and, if the two columned tholos tombs at Mycenae, the Treasury of Atreus and the Tomb of Clytemnestra, were really built this late, as some scholars maintain, then dynastic resources were still potent. The palace workshops, controlling the production of blue glass paste jewelry, agate beads, or chariots and harness, also flourished until shortly before the end of the 13th century; these workshops had divine patrons, according to the texts. In the "private sector" outside the palace at Mycenae there was a shrine, apparently devoted to a popular cult that involved a fertility goddess, a sword goddess, and snakes,

Shifts in populations. Toward the end of the 13th century, the mainland palaces were burned, possibly within a short time of each other; the exception was Thebes in the north, which may have received a destructive blow slightly earlier. Mycenae and Tiryns continued to be inhabited and indeed had very rich and energetic periods of pottery production and trade in the 12th century; Pvlos was deserted, however, and Athens was inhabited but not wealthy. New centres, both of refuge and of independence, became conspicuous, such as Lefkandi on the inner shore of Euboea, south of Chalcis. The Cyclades, Crete, and, in the west, the Ionian islands such as Cephallenia experienced an increase in population. New expeditions eastward to Cyprus consisted of small groups who fortified military settlements around the coast. Anatolia may also have received new immigrants, as it had periodically since the 15th century, as far as Tarsus in Cilicia.

No completely satisfactory explanation for the collapse of the palace systems and the movements of populations has been found. Perhaps one must look toward a combination of factors such as climatic change and drought, havest failure, starwaiton, epidemic, civic unrest, and resentment of palace taxes. Contributing factors may also have been the breaking off of trade with the east after the clash of the Hittites and Egyptians at the Battle of Kadesh earlier in the 13th century, the presence of roving piratical bands of both local peoples and immigrants around the coasts of the eastern Mediterranean (known in the Egyptian records as the Peoples of the Sea) who were hired as temporary allies by several states, and general frictions caused by

Destruction of the mainland palaces

Hittite records

universally failing economies and alliances. At any rate, the stable states of the wealthy later Bronze Age, which had been bound by commercial exchanges and political alliances, gradually or swiftly collapsed into near chaos. By the end of the following Dark Age (lasting perhaps from 1100 to 1000 in some places, or 900 in others), new peoples had arrived and settled, as, for example, the Dorians in southern Greece and Crete and the southern Cyclades as far as Rhodes or the Phrygians in central Anatolia. Notable too is the fact that new late Hittite states had been formed in northern Syria at this time.

New foreign elements. Even before the end of the Bronze Age, there were occasional signs of new foreign elements in Greece, Crete, the islands, and Cyprus, such as exchanges of pottery and metalwork with Italy, Sardinia, the Balkans, and northern Greece and with regions like Epirus and other northern districts theretofore beyond the margins of the standard Mycenaean world. Dorian tribesmen as well as others may have moved into the weakened states and into the grazing lands to the south. They may have pushed the old inhabitants into flight or into isolated and linguistically separate hilltop areas like Arcadia. Occasionally single burials appear next to the family chamber tombs of traditional Mycenaean practice, along with an increase in cremation burial. Some alien gray pottery, pairs of long dress pins for securing women's untailored blanket garments, and the late introduction of iron and steel are further signs of new elements and evolving changes. Whether some of the "west Greek" elements in the new population were actually novel or had been present in Mycenaean society all along is obscured by the linguistic unity of the palace tablets; it may be that the Greek dialects that seem to have moved into place during the Dark Age, especially the Dorian dialects of the south, had been spoken but not written at an earlier stage by segments of the population.

The people of the Aegean Bronze Age. The Aegean populations after the Neolithic Period do not conform to a clear ethnic type. The men from small tribal organizations of early times seem to have chosen brides from outside the kin group, at distances from Anatolia to the Balkans and points south. Almost from the start one finds evidence of a variety of people-slender and stout, with round and long skulls, and of tall and medium height. Probably many of the ancient inhabitants of Greece and the islands looked as people in Greece do today-active, muscular, and of moderate height. From the evidence of the wall paintings, though these are often idealized, they seem largely to have had dark hair, dark or gray eyes, fine profiles, and slender figures. Detailed skeletal studies of burials in Grave Circle B at Mycenae have shown tall, rugged skeletons with large hands and feet, some arthritis and gallstones, and recurrent "family traits." The high average age at deathabout 36 years-may reflect fighting careers, for which the men may have been socially selected, fed, and trained. Their generally superior physical condition in comparison to that of "commoners" was perhaps the result of a better diet from childhood onward.

Dress. Clay figurines of about 2000 from Crete show men wearing a narrow codpiece with a belt or loincloth and bare above the waist. This was to remain the basic fashion for Cretan men throughout the Bronze Age. Cretan women wore short-sleeved jackets that left the breasts bare and ankle-length flounced skirts, although shorter skirts to just below the knees are also attested. Marble figurines of men from the Cyclades assigned to the Early Bronze Age have belts and narrow codpieces like those of the Cretans. There is little evidence for dress on the mainland until the time of the Mycenae Shaft Graves in the 16th century. A considerable variety of dress is represented from that time onward throughout the Aegean area, but it is difficult to recognize fashions peculiar to the mainland. Tasseled shorts worn by men shown on the Mycenae lion-hunt dagger are also attested in Crete at the time. A group of Aegean envoys painted on the walls of the tomb of Rekhmire, vizier of the Egyptian pharaoh Thutmose III (ruled 1504-1450), are wearing large codpieces of a type fashionable in Crete in the Shaft Grave Period; thus they may have been Cretan envoys. A second group of envoys painted on the walls of the same tomb at a somewhat later date, however, are wearing kilts without codpieces, as worn by men in paintings at Knossos after the mainland conquest of Crete, about 1450. This might reflect mainland envoys going to Egypt after the conquest and wearing a different type of dress from the Cretans, but kilts of this kind appear to be represented in Crete both before and after the conquest.

In addition, curious scaly cloaks and long single-piece robes are among a variety of ritual garments in Crete. Linen was known in Crete by the beginning of the Bronze Age, and fragments of it were recovered from the Mycenae Shaft Graves; however, in Crete, at any rate, clothes were mostly, it seems, made of wool, and wall paintings show them woven with colourful and intricate designs. including pictures of animals and birds and even musical instruments. One of the dyes used was purple crushed from murex shells. Cretan men wore knee boots and sandals with upturned toes. Men with leggings or greaves are represented in wall paintings on the mainland. Caps of various kinds appear on the heads of men, and high, pointed hats and tiaras on those of women and of gods and goddesses or their priests. Clay figurines of the Early Palace Period show Cretan women with elaborate hair arrangements. Women put jewelry in their hair, including strings of beads. Necklaces, earrings, bracelets, and armlets were displayed by men as well as women. Sealstones were carried on strings around the neck or on the wrist. Cretan men normally left their hair long but were clean-shaven. Beards and mustaches are attested on the mainland in the Shaft Grave Period and later.

The frescoes at Thera show a wonderful variety of costumes, including the Minoan bodice-jacket, the flounced skirt or apron worn thigh-length or ankle-length, a onepiece tunic with rich borders, diaphanous veils, and a marvelous profusion of gold earrings, necklaces, collars, bracelets, and anklets, and rock crystal and carnelian beads. The men wear a kilt or a tunic or a loincloth; "peasants" may wear sheepskin cloaks; soldiers have long capes, tower shields, and boar's-tusk helmets.

Society. The early villages show few signs of economic disparity between families, although at times the presence of big houses in the later Neolithic Period indicates domination by chiefs. The island communities of the 3rd millennium are not yet well known, though signs of maritime trade are conspicuous and the grave gifts of marble idols point to organized religious rites and some wealth. The existence of fortified communities and two-story special houses on the mainland may indicate that communities contributed to their welfare and that they were ruled by a dynast. In Crete two types of early towns are known, a communal one, as at Myrtos, and one dominated by a big house or houses, as at Vasiliki. By the time of the Early Palaces, after 2000, it is clear that some governing power in several provinces was able to call upon extensive labour for the construction of buildings, granaries, and roads. The likenesses among the palaces, moreover, suggests that social systems across Crete were similar, perhaps dictated in form by certain religious behaviours. The palaces combined facilities for agricultural storage and for community displays and festivals, perhaps regulated by trained families and priestesses or priests. The palaces suggest a reciprocal relationship between the inhabitants and the surrounding villages. In mainland Greece, dynasties controlled fortified acropolis centres with outlying towns dependent on princes. This system is recorded extensively in Greek myths with Bronze Age origins, which tell of kings, princesses, and heroes from a few reigning families. During the last phase of Mycenaean culture and presumably during the Dark Age, the power of the old families was dispersed to lower local rulers, basileis, and the systems of councils of elders and village headman were maintained

Trade. Foreign manufactures reaching the Aegean and especially Crete during the Bronze Age included Cypriot pottery, Mesopotamian and other Oriental cylinder seals, and Egyptian stone vases, ivories, and scarabs, while Cretan and eventually Mycenaean pottery is found in Egypt and elsewhere in the Levant.

Cretan

By the 14th and 13th centuries, Mycenaean pottery is found densely in the Levant; it is often accompanied by Cypriot pottery as though carried in Cypriot or Syrian ships. Mycenaean pottery not mixed with Cypriot pottery is found in Anatolia from Troy to Tarsus. Because there is almost nothing on the mainland in return, one may suppose that trade was carried on in archaeological invisibles, such as food, textiles, copper ores, and perhaps slaves or war captives (some are attested in the Linear B texts). Mycenaeans may also have exported technology, such as weapon making, or mercenaries. Crete and the mainland had to import tin for bronze, probably from Anatolia, and both used copper ores from Cyprus and other sources. Minoan contact seems to have reached Sicily and Sardinia, and metal ingots may have been brought back from the west. Silver-lead was produced in the Cyclades and Attica. The Kaş Ulu Burun shipwreck shows an extensive trade in glass ingots, often cobalt blue, as well. Ostrich eggs and stone for making vases were among imports to Crete from Egypt, and ivory came from there or from Syria. Amber from the Baltic reached the mainland in some quantity during the Shaft Grave Period and later but is rarely found in Crete. Exports from the Aegean may have included woolen goods, olive oil, and timber, as well as silver. In Crete, at any rate, foreign trade may have been largely under palace control, but a class of private merchants engaged in overseas commerce no doubt existed in the Aegean.

Transport. Ships with a mast and square sail in addition to oars or paddles were used in the Aegean from the Early Bronze Age. On land, goods were no doubt transported by pack animals or on poles slung between bearers; this principle was also adopted for passenger chairs, of which there are clay models. A model of a four-wheeled cart from Crete is datable to about 2000 or earlier. The wheels of such carts were evidently solid, and the carts were no doubt drawn by oxen. Horses may have been ridden in Crete by then, as they seem to be depicted on early Cretan seals. These horses could have come from the east, but a different breed was introduced into the mainland from the north at the beginning of the Middle Bronze Age, about 2000. The light spoke-wheeled chariot drawn by horses appears to have developed in Syria or northern Mesopotamia early in the 2nd millennium, but it spread rapidly throughout the Middle East because of its usefulness in war. Chariots are depicted on tombstones of the Mycenae Shaft Graves and on Cretan seals before the time of the mainland conquest, about 1450, Apart from warfare, they were used in the Aegean for hunting and probably for travel. During the latter part of the Bronze Age, terraces were built to support roads wide enough for wheeled vehicles both in Crete and on the mainland, Such roads were carried across streams on bridges, examples of which have survived in the region of Mycenae.

Carts and

chariots

Warfare. Short daggers of types derived from Syria were in use in the Aegean during the Bronze Age. Long rapiers, evolved from those in Crete, are found on the mainland by the time of the Mycenae Shaft Graves in the 16th century BC.

The traditional armour of the Shaft Grave Period-a shield shaped in the figure eight or a tower shield, a helmet often reinforced with boars' tusks, a thrusting spear, and a sword on a baldric in a tasseled scabbard-appears also in the Thera naval fresco and in the epics behind Homer's Iliad. Charioteers apparently wore a bronze tunic of thonged plates, sketched on the Knossos tablets and found in a chamber tomb at Dendra in the Argolid. Linen greaves appear in frescoes, and bronze greaves in graves. There were bronze wrist guards for archers. Many soldiers may have preferred quilted, padded protection in the summer because of the heat.

Short swords adapted for cutting as well as thrusting began to appear in the following century and may have been developed in connection with chariot warfare. Bronze armour and small, round shields more serviceable in chariots replaced the old Cretan body shields at approximately the same time. Bows and slings were probably used everywhere in the Aegean area, but, whereas arrowheads of flint and obsidian are found on the mainland, they are

virtually unknown in Crete, where arrows may have been tipped with bone or wood until the appearance of bronze arrowheads in the 15th century. Settlements on the mainland and in the Cyclades were defended by walls from the Early Bronze Age onward, and the town at Mallia in Crete appears to have been protected by a wall during the period of the Early Palaces; but, by the time of the Late Palaces, Cretan towns may have been unwalled. Faience inlays of the 17th century from Knossos, however, seem to show an attack on a walled town such as that depicted on a silverrelief vase from the Mycenae Shaft Graves. The attraction of the theme of the city by the sea, with vignettes of war and peace, landscape and water, is also apparent in the Thera naval fresco and the Master Sealing of Chania in western Crete, which shows a youth lording it over the rooftops of a town. Methods of warfare had become highly developed by the end of the Bronze Age, with improved weapons, complex and well-designed fortifications, exten-

sive use of chariots, and warships with rams. Religion. Little is known about religion in the Cyclades and on the mainland before the period when they came under strong Cretan influence. An open-air sanctuary filled with marble figurines on the island of Kéros (Káros) is assignable to the Early Bronze Age. In Crete during the Early Palace Period, there were many open-air sanctuaries on the tops of hills and mountains. Some of these had small shrines in them, and shrines with one or more rooms and benches for offerings and cult statues are found in the countryside and in the towns in Crete. Parts of the palaces and of large houses there were also set apart for cult. Shrines not unlike Cretan ones existed in settlements in the Cyclades and on the mainland in the Late Bronze Age; however, hilltop sanctuaries are not well attested there, and most of those in Crete appear to have gone out of use after the mainland conquest, about 1450. Caves also were used as sanctuaries in Crete, and cults in some of these persisted until the end of the Bronze Age and later.

The chief deity everywhere in the Aegean during the Bronze Age was evidently a goddess. Perhaps there were several goddesses with different names and attributes. The extant texts refer to a Potnia ("Lady" or "Mistress"), to whom they give several epithets like "horse" or "grain." Most mainland palaces have paintings of processions in

Developfortified

which people bring gifts to a goddess. On Thera, frescoes show girls picking saffron crocus and offering it in baskets to a seated goddess. Clay statues of goddesses, often with upraised arms and attributes such as horns of consecration, doves, snakes, or poppies have been found in Crete; these range in date from the 14th to the early 12th century, providing evidence of a strong tradition. A shrine with large clay goddesses, which once were stuccoed and painted, existed at Ayia Irini on the island of Ceos, and a smaller, later one at Phylakopi on Melos, with both male and female figurines. The shrine at Mycenae seems to have been devoted to powers of grain and the sword. A later shrine at Tiryns had small clay goddesses with upraised arms. Many cult statues may have been made of wood, and mythic traditions of simple wooden logs or planks (xoana) dropping from heaven or being found in thickets have become attached to several later sanctuaries.

The texts show a more elaborate set of divinities than do the surviving idols, with many later Greek divinities already in place, including Zeus, Poseidon, Athena, Artemis, Ares, Hermes, and Dionysus. The Cretan birth goddess Eleuthia and war goddess Eyno were transmitted to the mainland Greeks, and natural forces, like the winds, were occasionally worshiped. There can be no doubt about the continuity of religions and cult from the Late Bronze Age into later Greek times, as well as of the language itself. Some divinities, like the female Zeus and the female Poseidon figures known at Pylos, do not reappear in later times, however. The culture was reshaping itself as it passed from generation to generation.

The normal gifts to divinities were scented oils, textiles, and, in Greece at least, animal sacrifice of cattle, sheep, and pigs. The burial of a horse or a dog may either signify a sacrifice or simply express the attachment between the animal and its master. Two ideas about the realm of death existed, a rarer one of an overseas Elvsian paradise where the dead were restored to a new life of bodily blessed ease and a more common one, transmitted in the epic tradition, of a dark underground realm (Hades) inhabited by weak shades with poor memories. These two ideas, representing the Cretan and the Mycenaean tradition, were not fused but survived in separate sets of songs and tales.

The post-Mycenaean period and Lefkandi. The period

(M.S.F.H./E.D.T.V.)

Ancient Greek civilization

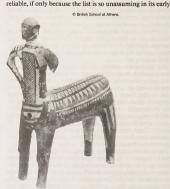

THE EARLY ARCHAIC PERIOD

between the catastrophic end of the Mycenaean civilization and about 900 BC is often called a Dark Age, It was a time about which Greeks of the Classical age had confused and actually false notions. Thucydides, the great ancient historian of the 5th century BC, wrote a sketch of Greek history from the Trojan War to his own day, in which he notoriously fails, in the appropriate chapter, to signal any kind of dramatic rupture. (He does, however, speak of Greece "settling down gradually" and colonizing Italy, Sicily, and what is now western Turkey. This surely implies that Greece was settling down after something,) Thucydides does indeed display sound knowledge of the series of migrations by which Greece was resettled in the post-Mycenaean period. The most famous of these was the "Dorian invasion," which the Greeks called, or connected with, the legendary "return of the descendants of Heracles." Although much about that invasion is problematic-it left little or no archaeological trace at the point in time where tradition puts it-the problems are of no concern here. Important for the understanding of the Archaic and Classical periods, however, is the powerful belief in Dorianism as a linguistic and religious concept. Thucydides casually but significantly mentions soldiers speaking the "Dorian dialect" in a narrative about ordinary military matters in the year 426: this is a surprisingly abstract way of looking at the subdivisions of the Greeks, because it would have been more natural for a 5th-century Greek to identify soldiers by cities. Equally important to the understanding of this period is the hostility to Dorians, usually on the part of Ionians, another linguistic and religious subgroup, whose most famous city was Athens. So extreme was this hostility that Dorians were prohibited from entering Ionian sanctuaries; extant today is a 5thcentury example of such a prohibition, an inscription from the island of Paros.

Phenomena such as the tension between Dorians and Ionians that have their origins in the Dark Age are a reminder that Greek civilization did not emerge either unannounced or uncontaminated by what had gone before. The Dark Age itself is beyond the scope of this article. One is bound to notice, however, that archaeological finds tend to call into question the whole concept of a Dark Age by showing that certain features of Greek civilization once thought not to antedate about 800 BC can actually be pushed back by as much as two centuries. One example. chosen for its relevance to the emergence of the Greek city-state, or polis (see below), will suffice. In 1981 archaeology pulled back the curtain on the "darkest" phase of all, the Protogeometric Period (c. 1075-900 BC), which takes its name from the geometric shapes painted on pottery. A grave, rich by the standards of any period, was uncovered at a site called Lefkandi on Euboea, the island along the eastern flank of Attica (the territory controlled by Athens). The grave, which dates to about 1000 BC, contains the (probably cremated) remains of a man and a woman. The large bronze vessel in which the man's ashes were deposited came from Cyprus, and the gold items buried with the woman are splendid and sophisticated in their workmanship. Remains of horses were found as well: the animals had been buried with their snaffle bits. The grave was within a large collapsed house, whose form anticipates that of the Greek temples two centuries later. Previously it had been thought that these temples were one of the first manifestations of the "monumentalizing" associated with the beginnings of the city-state. Thus this find, and those made in a set of nearby cemeteries in the years before 1980 attesting further contacts between Egypt and Cyprus between 1000 and 800 BC, are important evidence. They show that one corner of one island of Greece, at least, was neither impoverished nor isolated in a period usually thought to have been both. The difficulty is to know just how exceptional Lefkandi was, but in any view it has revised former ideas about what was and what was not possible at the beginning of the 1st millennium BC.

Colonization and city-state formation. The first "date" in Greek history is 776 BC, the year of the first Olympic Games. It was computed by a 5th-century-BC researcher called Hippias. This man originally came from Elis, a place in the western Peloponnese in whose territory Olympia itself is situated. This date and the list of early victors, transmitted by another literary tradition, are likely to be

The first Olympic Games

Centaur, terra-cotta, 10th century, from the site of Lefkandi, Euboea, Greece

The importance of the invasion

reaches. That is to say, local victors predominate, including some Messenians. Messene lost its independence to neighbouring Sparta during the course of the 8th century, and this fact is an additional guarantee of the reliability of the early Olympic victor list: Messenian victors would hardly have been invented at a time when Messene as a political entity had ceased to exist. Clearly, then, record keeping and organized activity involving more than one community and centring on a sanctuary, such as Olympia, go back to the early 8th century. (Such competitive activity is an example of what has been called "peer-polity interaction.") Records imply a degree of literacy, and here too the tradition about the 8th century has been confirmed by recent finds. A cup, bearing the inscription in Greek in the Euboean script "I am the cup of Nestor," can be securely dated to before 700 BC. It was found at an island site called Pithekoussai (Ischia) on the Bay of Naples.

The Euboeans, whose early overseas activity has already been remarked upon in connection with the discoveries at Lefkandi, were the prime movers in the organized and recorded phase of Greek colonization. (This point can be taken as absolutely certain because archaeology supports the literary tradition of the Roman historian Livy and others: Euboean pottery has been found both at Pithekoussai to the west and at the Turkish site of Al-Mina to the east.) This organized phase began in Italy c. 750 and in Sicily in 734 BC; its episodes were remembered, perhaps in writing, by the colonies themselves. The word "organized" needs to be stressed, because various considerations make it necessary to push back beyond this date the beginning of Greek colonization. First, it is clear from archaeological finds, such as the Lefkandi material, and from other new evidence that the Greeks had already, before 750 or 734, confronted and exchanged goods with the inhabitants of Italy and Sicily. Second, Thucydides says that Dark Age Athens sent colonies to Ionia, and archaeology bears this out-however much one discounts for propagandist exaggeration by the imperial Athens of Thucydides' own time of its prehistoric colonizing role. However, after the founding of Cumae (a mainland Italian offshoot of the island settlement of Pithekoussai) c. 750 BC and of Sicilian Naxos and Syracuse in 734 and 733, respectively, there was an explosion of colonies to all points of the compass. The only exceptions were those areas, such as pharaonic Egypt or inner Anatolia, where the inhabitants were too militarily and politically advanced to be easily overrun.

One may ask why the Greeks suddenly began to launch these overseas projects. It seems that commercial interests, greed, and sheer curiosity were the motivating forces. An older view, according to which Archaic Greece exported its surplus population because of an uncontrollable rise in population, must be regarded as largely discredited. In the first place, the earliest well-documented colonial operations were small-scale affairs, too small to make much difference to the situation of the sending community (the "metropolis," or mother city). That is certainly true of the colonization of Cyrene, in North Africa, from the island of Thera (Santorin): on this point an inscription has confirmed the classic account by the 5th-century Greek historian Herodotus. In the second place, population was not uncontrollable in principle: artificial means such as infanticide were available, not to mention more modern

Reasons for the colonization movement techniques like contraception. Considerations of this kind much reduce the evidential value of discoveries establishing, for example, that the number of graves in Attica and the Argolid (the area round Argos) increased dramatically in the later Dark Age or that there was a serious drought in 8th-century Attica (this is the admitted implication of a number of dried-up wells in the Athenian agora, or civic centre). In fact, no single explanation for the colonizing activity is plausible. Political difficulties at home might sometimes be a factor, as, for instance, at Sparta, which in the 8th century sent out a colony to Taras (Tarentum) in Italy as a way of getting rid of an unwanted half-caste group. Nor can one rule out simple craving for excitement and a desire to see the world. The lyric poetry of the energetic and high-strung poet Archilochus, a 7th-century Parian involved in the colonization of Thasos, shows the kind of lively minded individual who might be involved in the colonizing movement.

So far, the vague term "community" has been used for places that sent out colonies. Such vagueness is historically appropriate, because these places themselves were scarcely constituted as united entities, such as a city, or polis. For example, it is a curious fact that Corinth, which in 733 colonized Syracuse in Sicily, was itself scarcely a properly constituted polis in 733. (The formation of Corinth as a united entity is to be put in the second half of the 8th century, with precisely the colonization of Syracuse as its

first collective act.)

The name given to polis formation by the Greeks themselves was synoikismos, literally a "gathering together." Synoikismos could take one or both of two forms-it could be a physical concentration of the population in a single city or an act of purely political unification that allowed the population to continue living in a dispersed way. The classic discussion is by Thucydides, who distinguishes between the two kinds of synoikismos more carefully than do some of his modern critics. He makes the correct point that Attica was politically synoecized at an early date but not physically synoecized until 431 BC when Pericles as part of his war policy brought the large rural population behind the city walls of Athens. A more extreme instance of a polis that was never fully synoecized in the physical sense was Sparta, which, as Thucydides elsewhere says, remained "settled by villages in the old Greek way." It was an act of conscious arrogance, a way of claiming to be invulnerable from attack and not to need the walls that Thucydides again and again treats as the sign and guarantee of civilized polis life. The urban history of Sparta makes an interesting case history showing that Mycenaean Sparta was not so physically or psychologically secure as its Greek and Roman successors. The administrative centre of Mycenaean Sparta was probably in the Párnon Mountains at the excavated site of the Menelaion. Then Archaic and Classical Sparta moved down to the plain. Byzantine Sparta, more insecure, moved out of the plain again to perch on the site of Mistra on the opposite western mountain, Taygetos, Finally, modern Sparta is situated, once again peacefully and confidently, on its old

site on the plain of the river Eurotas. The enabling factors behind the beginnings of the Greek polis have been the subject of intense discussion. One approach connects the beginnings of the polis with the first monumental buildings, usually temples like the great early 8th-century temple of Hera on the island of Samos. The concentration of resources and effort required for such constructions presupposes the formation of self-conscious polis units and may actually have accelerated it. As stated above, however, the evidence from Lefkandi makes it hard to see the construction of such monumental buildings as a sufficient cause for the emergence of the polis, a process or event nobody has yet tried to date as early as 1000 BC. Another related theory argues that the birth of the Greek city was signaled by the placing of rural sanctuaries at the margins of the territory that a community sought to define as its own. This fits admirably a number of Peloponnesian sanctuaries; for instance, the temple complex of Hera staked out a claim, on the part of relatively distant Argos, to the plain stretching between city and sanctuary, and the Corinthian sanctuary on the promontory of Perachora, also dedicated to Hera, performed the same function. Yet there are difficulties. It seems that the Isthmia sanctuary, which at first sight seems a good candidate for another Corinthian rural sanctuary, was already operational as early as 900 BC, in the Protogeometric Period, and this date is surely too early for polis formation. Nor does the theory easily account for the rural temple of the goddess Aphaea in the middle of Aegina. The sanctuary is admittedly a long way from the town of Aegina, but Aegina is an island, and there is no obvious neighbour against whom territorial claims could plausibly have been asserted. Finally, a theory that has to treat Athens and Attica as in every respect exceptional is not satisfactory: the relation of Athens to Eleusis (the sanctuary on its western margins and the only possible candidate for a "rural sanctuary" in the required sense) is very different from the Peloponnesian cases already considered above. Fleusis was far more than a mere "outpost"; there was a tradition that it had once been an independent state.

A third theory attacks the problem of the beginnings of the polis through burial practice. In the 8th century (it is said) formal burial became more generally available, and this "democratization" of burial is evidence for a fundamentally new attitude toward society. The theory seeks to associate the new attitude with the growth of the polis. There is, however, insufficient archaeological and historical evidence for this view (which involves an implausible hypothesis that the process postulated was discontinuous and actually reversed for a brief period at a date later than the 8th century). Moreover, it is vulnerable to the converse objection as that raised against the second theory; the evidence for the third theory is almost exclusively Attic, and so, even if it were true, it would explain Athens and only Athens.

Fourth, one may consider a theory whose unspoken premise is a kind of "geographic determinism." Perhaps the Greek landscape itself, with its small alluvial plains often surrounded by defensible mountain systems, somehow prompted the formation of small and acrimonious poleis, endlessly going to war over boundaries. This view has its attractions, but the obvious objection is that, when Greeks went to more open areas such as Italy, Sicily, and North Africa, they seem to have taken their animosities with them. This in turn invites speculations of a psychologically determinist sort; one has to ask, without hope of an answer, whether the Greeks were naturally particularist.

A fifth enabling factor that should be borne in mind is the influence of the colonizing movement itself. The political structure of the metropolis, or sending city, may sometimes have been inchoate. The new colony, however, threatened by hostile native neighbours, rapidly had to 'get its act together" if it was to be a viable cell of Hellenism on foreign soil. This effort in turn affected the situation in the metropolis, because Greek colonies often kept close religious and social links with it. A 4th-century inscription, for instance, attests close ties between Miletus and its daughter city Olbia in the Black Sea region. Here, however, as so often in Greek history, generalization is dangerous; some mother-daughter relationships, like that between Corinth and Corcyra (Corfu), were bad virtually from the start.

A related factor is Phoenician influence (related, because the early Phoenicians were great colonizers, who must often have met trading Greeks). The Phoenician coast was settled by communities similar in many respects to the early Greek poleis. It is arguable that Phoenician influence, and Semitic influence generally, on early Greece has been seriously underrated.

Theories such as these are stimulating and may each contain a particle of truth. The better position, however, is that generalization itself is as yet premature; in particular, archaeologically based theoretical reconstructions need much more refining. All one can say in summary is that in roughly the same period-namely, the 8th century-a number of areas, such as Corinth and Megara, began to define their borders, deny autonomy to their constituent villages, and generally act as separate states. Attica's political synoecism, which occurred a little earlier, was complete perhaps around 900. Tempting though it is

beginnings of the polis to seek a single explanatory model for these very roughly contemporaneous processes, one should perhaps allow that different paths of development were followed in different areas, even in areas next door to each other. After all, the Archaic and Classical histories of mighty democratic imperial Athens, of the miserable polis of Megara which nevertheless colonized Byzantium, of wealthy, oligarchic Corinth, and of federal Boeotia were all very different even though Athens, Megara, Corinth, and Boeotia were close neighbours.

One is perhaps on firmer ground when one examines the evidence for prepolis aggregations of larger units, often religious in character. There are a number of such associations whose origins lie in the Dark Age and whose existence surely promoted some feeling of local and particularist identity among the participants. The Ionians in Anatolia formed themselves into a confederation of 12 communities, the Ionian Dodecapolis, with a common meeting place; and there were comparable groupings among the Dorian Greeks of Anatolia and even among the Carians (partially Hellenized non-Greeks) in the same part of the world. The central location for such organizations was characteristically small and insignificant. One poorly attested but intriguing early Archaic league was the "Calaurian Amphictyony" (an amphictyony was a religious league of "dwellers round about"). Calauria, the small island now called Póros, was not a place of any consequence in itself, but the league's seven members included Athens and Aegina, two major Greek poleis. The most famous and enduring such amphictyony, however, was the one that, originally from a distance, administered the affairs of the sanctuary of Delphi in central Greece. This sanctuary contained the most famous, though not the oldest, Greek oracle (the oldest was at Dodona); oracles were a mechanism by which divinely inspired utterances were produced in answer to specific questions. Finally, it is worth noting an adventurous suggestion that Lefkandi itself might have been the centre of some kind of religious amphictyony, but, if so, this would be an exception to the principle that religious centres tended themselves to be in-

significant, however mighty their participating members. Early Archaic Greek civilization. The sources. Before attempting to characterize Archaic Greece, one must admit candidly that the evidence is unsatisfactory. Only for Athens is anything like a proper political tradition known. and Athens' development toward the democracy of the 5th century was amazingly and untypically rapid by comparison with other states, many of which never became democratic at all. A tiny but salutary scrap of evidence makes this point: Thucydides in Book 2 of his History of the Peloponnesian War casually mentions a man called Evarchus as "tyrant" of a small northwestern Greek polis called Astacus in the 420s BC. But for this chance mention, one would never have guessed that tyranny could have existed or persisted in such a place so late or so long. Another difficulty is that, while a fair amount about the social structure of Classical Athens is known, some of it must go back to Archaic times; just how much is disputed.

There is a further complication. In both the political and the social spheres, one has to reckon-chiefly at Athens, but elsewhere too-with "invented tradition," a distorting element for which proper allowance is only now beginning to be made. Thus it seems that not just Lycurgus, the famous Spartan lawgiver (whose historicity was doubted even in antiquity), but even a reforming figure like Solon of Athens, who certainly existed in the 6th century and large fragments of whose poetry still survive, was in some respects what anthropologists call a "culture hero." Much was projected onto him anachronistically or just wrongly, and reformers in later generations established their credentials by claiming (if they were reactionaries) that they were trying to "get back to Solon" or (if they were democrats) that Solon was their founding father. Such errors should not induce too much pessimism: at Athens at least, individual aristocratic families preserved oral traditions, which affected the later literary records in ways that can be properly understood with the help of anthropological analogy. That is to say, not all the evidence so preserved is unusable, but it needs handling in special ways.

It has even been argued that social life, too, was creatively manipulated. Later Greek cities contained, alongside such transparent political institutions as the Popular Assembly and the Deliberative ("Probouleutic") Council, a more opaque set of institutions, ostensibly based on kinship groupings. The biggest and most basic of these groupings were the phylae, or "tribes," according to which the citizen body was subdivided. Thus all Dorian states had the same three tribes, and there were four Ionian tribes (although Ionian states were less conservative than Dorian, and one finds among them a greater readiness to innovate; late 6thcentury Athens, for example, switched from a four-tribe hereditary system of citizenship to a 10-tribe one based on simple residence as well as descent). Smaller subdivisions were the phratry, a word connected with a philological root meaning "brother," and the genos, a smaller cluster of families (oikoi). The existence of these groupings in historical times is beyond question; one finds them controlling citizen intake (as in the so-called "Demotionidai" inscription from the Attic village of Decelea, datable to as late as the early 4th century BC) and entering into complicated property arrangements. What has become a matter of debate, however, is the question of just how old they actually were. According to the most skeptical view, the whole apparatus of tribe and genos was an invention without any Dark Age history to legitimate it. This view, which rests partly on the near absence of the relevant kinship terminology in Homer, is not ultimately convincing in its hypothesis of a kind of complicated collective fraud on posterity. Yet it is right to allow for an element of conscious antiquarianism at certain periods (the 320s in Athens being one), which may well have affected specific traditions.

Society and values. The world of the colonizing states was aristocratic in the sense that a small number of exclusive clans within cities monopolized citizenship and political control. At Corinth, for example, citizenship was confined to the adult males of a single clan, the Bacchiadae. They perhaps numbered no more than a couple of hundred. At Athens there was a general class of Eupatridae, a word that just means "People of Good Descent"i.e., aristocrats. (The word may have had a simultaneous but narrower application to one single genos. This, however, is disputed, and, in any event, that hypothetical family was only one among many privileged genē. The case, therefore, is not analogous to that of the Bacchiadae.) It is unlikely that the Eupatridae were as rigidly defined as the Bacchiadae, and the negative tradition that Solon in the early 6th century deprived them of their exclusive claim to political office may just be the excessively formal and precise way in which later ancient commentators described a positive change by which power was made more

generally available than it had been before (see below), With regard to these same early Archaic times one hears for example, in the poetry of the 7th-century Boeotian Hesiod, of control, sometimes oppressively exercised, by basileis (singular basileus). This word is usually translated as "kings," and such titles as the Athenian basileus (an official, or archon, with a defined religious competence, conveniently but less correctly called the archon basileus by modern scholars) are then explained as survivals of an age of monarchy. This account in terms of fossilization certainly eases the awkwardness of explaining why, for instance, the wife of the archon basileus was held to be ritually married to the god Dionysus. The very existence of kingship in Geometric (as opposed to Mycenaean) Greece, however, has been challenged, and a case has been made (though not universally accepted) for seeing most of these Archaic basileis not as kings in any sense but as hereditary nobles. In the latter case, there is no great difference between these basileis and such aristocrats as the Bacchiadae

Life inside the Archaic Greek societies ruled by such families can be reconstructed only impressionistically and only at the top of the social scale; the evidence, to an extent unusual even in Greco-Roman antiquity, is essentially elitist in its bias. Aristocratic values were transmitted both vertically, by family oral traditions, and horizontally, by means of a crucial institution known as the symposium.

Bacchiadae and Eupatridae

The nature of the evidence

Religious

Symposia

gymnasia

and

or feast, for which (many literary scholars now believe) much surviving Archaic poetry was originally written. Perhaps much fine painted pottery was also intended for this market, though the social and artistic significance of such pottery is debated. Some scholars insist that the really wealthy would at all times have used gold and silver vessels, which, however, have not survived in any numbers because they have long ago been melted down. Symposia were eating and dining occasions with a strong ritual element; their existence is reflected in the marked emphasis, in the Homeric poems, on ostentatious feasting and formal banqueting as assertions of status (what have been called "feasts of merit"). Thus Sarpedon in Homer's Iliad reminds Glaucus that both of them are honoured with seats of honour and full cups in Lycia and with land (a sacred precinct, or temenos) to finance all the feasting. Symposia were confined to males (a reminder of the military ethos so prevalent in Homer); although when the institution was introduced, along with the vine, to Etruria-where much of the visual evidence comes from-it changed its character and became open to both sexes. The Greek symposium proper can be seen as an instrument of social control; it is a more tangible unit of social organization, and one with better-attested Homeric antecedents, than the problematic genë or phratries discussed above. There is much to be said for this suggestion, but the evidence

In Classical times, strong homosexual attachments were another way in which values were inculcated, passed on by the older man (the erastes) to the younger eromenos, or beloved. The gymnasium was the venue where such relationships typically developed. As with the symposium, there was an almost ritual element to it all; certain giftssuch as, for example, the gift of a hare-were thought especially appropriate. The date, however, at which Greek homosexuality became a central cultural institution is problematic; it is notoriously absent from the Homeric poems, a fact that some scholars explain as being the result of poetic reticence. The more plausible view is that homosexuality was in some way connected with the rise of the polis and was part of what has been called the "8th-century renaissance," If so, Homer's silence is after all significant: he does not mention it because in his time it was not yet important.

needs to be systematically collated and interpreted.

Both symposia and gymnasia in different ways mirrored or were preparatory to warfare (see below). Interpolis athletic competitions (such as the Olympic Games) are another reflection of warfare. Epinician poetry of the Classical period (that is, "victory poetry" like that of Pindar, whose epinician odes celebrate the athletic victories of aristocratic individuals) constantly uses the language of war, fighting, and victory. Indeed, one influential view of organized athletic competitions is that they are a restructuring of the instinct to hunt and kill.

With the great athletic festivals, which brought Greeks together at set intervals of years to Olympia and later to Delphi, Nemea, and the Isthmus (the four great Panhellenic, or "all-Greek," games), one passes from the internal organization of individual Greek societies to their interrelationships. Two kinds of powerful interrelationship have already been noted-that between colonizing city and daughter city and the shared membership of an

amphictyony. More generally, the basic institution in intercity relationships was that of "guest-friendship," or xenia. This was another area where ritual elements were present to such a marked degree that the whole institution has been called "ritualized friendship." The same aristocrats who drank and heard poetry together inside their own communities naturally expected to find comparable groups inside other states. They cemented their ties, which had perhaps been formed on initially casual or trading visits, with formal relationships of xenia. At some point quite early in the Archaic period this institution developed into something still more definite, the proxenia. Proxenoi were citizens of state A living in state A who looked after the interests of citizens of state B. The status of proxenos was surely in origin hereditary, but by Thucydides' time one hears of "voluntary proxenoi" (etheloproxenoi). The antiquity of the basic institution is not in doubt, however much the 5th-century Athenian empire may have exploited and reshaped it for its own political convenience; a 7th-century inscription from the island of Corcyra mentioning a proxenos from Locris is the earliest attestation of the institution.

Another way of institutionalizing relationships between the nationals of different states was epigamia, an arrangement by which the offspring of marriage were treated as citizens of the wife's polis if the husband settled there; and so was the husband. Athens, for example, granted enigamia to Euboea as late as the 5th century, a time when Athenian citizenship was fiercely protected. There are still earlier instances: usually one hears of epigamia when for one reason or another it was being suspended or denied. Thus, there was an early arrangement between the islands of Andros and Paros, which, Plutarch says, ended when relations went sour. More interesting is the statement, again by Plutarch, that there was no intermarriage between members of two of the villages, or demes, of Attica. Pallene and Hagnous. Far from being evidence that these places were somehow originally separate states, the prohibition was more like a ban on endogamy; in other words, the two communities were regarded-like members of a family-as being too close to be allowed to intermarry. Thus, both marriage itself and prohibition of marriage were ways of defining the relations between communities, including communities within a single large state like Attica, and of keeping those relations friendly.

The chief vehicle of interaction among poleis, however, was through warfare and through the formal suspension or renunciation of warfare by means of heavily ritualized treaties (one of the most common words for such a treaty is spondai, which literally means "libations" to the guaranteeing gods). The earliest surviving inscriptional peace treaty "for all time" dates from the 6th century and was found at Olympia. Nonetheless, there were surely agreements to limit warfare over strips of boundary land before that date. Archaeology may offer unexpected help in this matter: it is possible and plausible that some frontier zones were by tacit or explicit agreement left fallow. One such zone seems to have been the remote Skourta plain. which separates part of northern Attica from Boeotia; preliminary surface survey (i.e., the estimation of settlement patterns by gathering of potsherds) carried out in and after 1985 suggests that it was left-perhaps deliberatelyuncultivated in the Archaic period.

An important landmark in interstate military relations of the kind considered here was the Lelantine War. It was the earliest Greek war (after the mythical "Trojan War") that had any claim to be considered "general," in the sense that it involved distant allies on each side. Fought in perhaps the later 8th century between the two main communities of Euboea, Chalcis and Eretria, it took its name from the fertile Lelantine Plain, which separates the cities and includes the site of Lefkandi. (It is an interesting modern suggestion that Lefkandi itself is the site of Old Eretria, abandoned about 700 BC in favour of the classical site Eretria at the east end of the plain, perhaps as a consequence of Eretria's defeat in the war. This theory, however, needs to account for Herodotus' statement that at the early 6th-century entertainment of the suitors of Cleisthenes of Sicyon [see below] there was one Lysanias from Eretria, "then at the height of its prosperity.") Other faraway Greek states were somehow involved in the war; on this point Thucydides agrees with his great predecessor Herodotus. Thus Samos supported Chalcis and Miletus, Eretria. Given Euboean priority in colonization, it is natural to suppose that the links implied by the traditions about the Lelantine War were the result of Euboean overseas energy, but that energy would hardly have turned casual contacts into actual alliances without a preliminary network of guest-friendships. Whether the oracle at Delphi took sides in the war, as a modern speculation has it, is less certain, though there is no doubt that by some means wholly mysterious to the 20th century Delphi often provided updated information about possible colonial sites and even (as over Cyrene) gave the original stimulus to the colonizing act.

One can be more confident in denying the thoroughly

The Lelantine War

Xenia and proxenia

anachronistic notion that the Lelantine War shows the existence of "trade leagues" at this early date. Religious amphictyonies are one thing and trade leagues another; the evidence, such as it is, suggests that early trade was carried on by entrepreneurial aristocratic individuals, who no doubt exploited their guest-friendships and formed more such friendships during their travels. It is true, however, that such individuals tended to come from areas where arable land was restricted, and to this extent it is legitimate to speak in a generic way of those areas as having in a sense a more commercially minded population than others. One example of such an area is the Lelantine Plain, an exceptionally good piece of land on a notably barren and mountainous, though large, island. Herodotus described one such trader from the later Archaic period, Sostratus of Aegina, a man of fabulous wealth. Then in the early 1970s a remarkable inscription was found in Etruria-a dedication to Apollo in the name of Sostratus of Aegina. This discovery revealed that the source of his wealth was trade with Etruria and other parts of Italy. Aegina is an island whose estimated Classical population of about 40,000 was supported by land capable of supporting only about 4,000. One may quarrel with the first figure as too large and the second figure as too pessimistic (it makes insufficient allowance for the possibilities of highly intensive land use). Even after adjustment, however, it is clear that Aegina needed to trade in order to live. It is not surprising to find Sostratus' home city of Aegina included among the Greek communities allowed to trade at Naukratis in pharaonic Egypt; this arrangement is described by Herodotus, and the site has been explored archaeologically. Aegina was the only participating city of Greece proper, as opposed to places in the eastern Aegean.

THE LATER ARCHAIC PERIODS

The rise of the tyrants. Dealings with opulent Oriental civilizations were bound to produce disparities in wealth, and hence social conflicts, within the aristocracies of Greece. One function of institutions such as guestfriendship was no doubt to ensure the maintenance of the charmed circle of social and economic privilege. This system, however, presupposed a certain stability, whereas the rapid escalation of overseas activity in and after the 8th century was surely disruptive in that it gave a chance. or at least a grievance, to outsiders with the right gogetting skills and motivation. Not that one should imagine concentration of wealth taking place in the form most familiar to the 20th century-namely, coined money. Since 1951 the date of the earliest coinage has been fairly securely fixed at about 600 BC; the crucial discovery was the excavation and scientific examination of the foundation deposit of the Temple of Artemis at Ephesus in Anatolia. The first objects recognizably similar to coined money were found there at levels most scholars (there are a few doubters) accept as securely dated. Coinage did not arrive in Greece proper until well into the 6th century. There were, however, other ways of accumulating precious metals besides collecting it in coined form. Gold and silver can be worked into cups, plates, and vases or just held as bar or bullion. There is no getting round the clear implication of two poems of Solon (early 6th century) that, first, gold and silver were familiar metals and, second, wealth was now in the hands of arrivistes.

The first state in which the old aristocratic order began to break up was Corinth. The Bacchiadae had exploited Corinth's geographic position, which was favourable in ways rivaled only by that of the two Euboean cities already discussed. Like Chalcis, which supervised sea traffic between southern Greece and Macedonia but also had close links with Boeotia and Attica, Corinth controlled both a north-south route (the Isthmus of Corinth, in modern times pierced by the Corinth Canal) and an eastwest route. This second route was exploited in a special way. Corinth had two ports, Lechaeum to the west on the Gulf of Corinth and Cenchreae to the east on the Saronic Gulf. Between the two seas there was a haulage system, involving a rightly famous engineering feat, the so-called diolkos. The diolkos, which was excavated in the 1950s, was a line of grooved paving-stones across which goods could be dragged for transshipment (probably not the merchant ships themselves, though there is some evidence that warships, which were lighter, were so moved in emergencies). There is explicit information that the Bacchiadae had profited hugely from the harbour dues. As the Greek world expanded its mental and financial horizons. other Corinthian families grew envious. The result was the first firmly datable and well-authenticated Greek tyranny, or one-man rule by a usurper. This was the tyranny of Cypselus, who was only a partial Bacchiad.

Aristotle, in the 4th century, was to say that tyrannies arise when oligarchies disagree internally, and this analysis makes good sense in the Corinthian context. The evidence of an inscribed Athenian archon list, found in the 1930s and attesting a grandson of Cypselus in the 590s, settled an old debate about the date of Cypselus' coup: it must have happened about 650 (a conclusion for which there is other evidence) rather than at the much later date indicated by an alternative tradition. Cypselus and his son Periander ruled until about 585 BC; Periander's nephew and successor did not last long. Precisely what factor in 650 made possible the success of the partial outsider Cypselus is obscure; no Bacchiad foreign policy failure can be dated earlier than 650. General detestation for the Bacchiadae. however, is clear from an oracle preserved by Herodotus that "predicts" that Cypselus will bring dike, or justice, to Corinth after the rule of the power-monopolizing Bacchiadae. No doubt this oracle was fabricated after the event, but it is interesting as showing that nobody regretted the passing of the Bacchiadae.

Modern scholars have tried to look for more general factors behind Cypselus' success than a desire in a new world of wealth and opportunity to put an end to Bacchiad oppressiveness and exclusivity. One much-favoured explanation is military, but it must be said straightaway that the specific evidence for support of Cypselus by a newly emergent military class is virtually nonexistent. The background to military change, a change whose reality is undoubted, needs a word.

Aristocratic warfare, as described in the Homeric epics, puts much emphasis on individual prowess. Great warriors used chariots almost as a kind of taxi service to transport themselves to and from the battlefield, where they fought on foot with their social peers. The winner gained absolute power over the person and possessions of the vanquished, including the right to carry out ritual acts of corpse mutilation. This general picture is surely right, though it can be protested that Homer's singling out of individuals may be just literary spotlighting and that the masses played a respectably large part in the fighting described in the epics. There is some force in this objection and in the converse and related objection that in Archaic and Classical hoplite fighting (see below) individual duels were more prevalent than is allowed by scholars anxious to stress the collective character of hoplite combat. Still, a change in methods of fighting undoubtedly occurred in the course of the 7th century.

The change was to a block system of fighting, in which infantry soldiers equipped with heavy armour, or hopla (including helmet, breastplate, greaves, sword, spear, and a round shield attached to the left arm by a strap), fought, at least during part of an engagement, in something like coherent formation, each man's sword arm being guarded by the shield of the man on his right. This last feature produced a consequence commented on by Thucydidesnamely, a tendency of the sword bearer to drift to the right in the direction of the protection offered by his neighbour. For this reason the best troops were posted on the far right to act as anchor-men. The system, whose introduction is not commented on by any literary source, is depicted on vases in the course of the 7th century, though it is not possible to say whether it was a sudden technological revolution or something that evolved over decades. The second view seems preferable since the discovery in the 1950s of a fine bronze suit of heavy armour at Argos in a late 8th-century context.

Clearly, the change has social and political implications. Even when one acknowledges some continuation of individual skirmishing, much nonetheless depended on neighChange in methods of warfare

The earliest coinage

bours in the battle line standing their ground. An oath sworn by Athenian military recruits (ephēboi) in the 4th century includes clauses about not disgracing the sacred weapons, not deserting comrades, and not handing down a diminished fatherland (to posterity); the oath and the word ephēbe are 4th-century, but the institutionalizing of hoplite obligations and expectations is surely much older. Early land warfare can, in fact, be thought of as a symbolic expression of the Greek city's identity. This helps to explain the strong ritual elements in a hoplite battle, which typically began with a sacrifice and taking of omens and ended with victory dedications, often of bronze suits of armour, in some appropriate sanctuary. It is above all the heavily armed troops, not the lightly armed or the sailors in the fleet (nor even the cavalry, whose role in a typical battle was marginal), who were thought of as in a special sense representing the Classical polis. Thus at Classical Athens the 10-tribe citizen system determined the organization of the hoplite army but is much less important in the manning of the fleet.

The influential "hoplite theory" of the origin of tyranny seeks to explain one general phenomenon of the 7th century-namely, the beginning of tyranny-by reference to another, the introduction of hoplite weapons and tactics with their greater emphasis on a collective, corporatist ethos. Insofar as both phenomena represent reactions against aristocratic rule, it is reasonable loosely to associate the two, but it is important to realize that the theory, however seductive, is in its strict form a modern construction. In the first place, the connection is never made by intelligent ancient writers interested both in the mechanics and psychology of hoplite warfare on the one hand and in tyranny on the other. Thucydides, for instance, a military historian if ever there was one, saw tyranny primarily in economic terms. Aristotle does indeed say that the extension of the military base of a state is liable to produce a widening of the political franchise, but this comment has nothing specifically to do with tyranny. He explains tyranny elsewhere either as resulting from splits within oligarchies or by an anachronistic 4th-century reference to demagogic leadership, which, when combined with generalship, is liable to turn into tyranny (here he is surely thinking above all of Dionysius I of Syracuse). In the second place, it is discouraging for the hoplite theory that there is so little support for it in the best-attested case, that of Cypselid Corinth. Attempts have indeed been made to get around the natural implication of the evidence, but they are not convincing. For instance, the ancient statement that Cypselus had no bodyguard ought to be given its natural meaning, which is a denial of the

military factor; it ought not to be ingeniously twisted so as to imply that he did not need a bodyguard because (it is argued) he had the support of identifiable army groups. Furthermore, although it is true that Cypselus is called polemarch (which ought to mean a "leader in war"), it is suspicious that his activities in this capacity were entirely civil and judicial. Suspicion increases when one notes that polemarch was indeed the title of a magistrate in Classical Athens.

Other tyrannies are equally resistant to general explanations, except by circularity of reasoning. The Corinthian tyranny has been treated first in the present section because its dates are secure. There is, however, a more shadowy figure, Pheidon of Argos, who may have a claim to be earlier still and who has also been invoked as an exemplification of the military factor in the earliest tyrannies. Unfortunately, one ancient writer, Pausanias, puts him in the 8th century, while Herodotus puts him in the 6th. Most modern scholars emend the text of Pausanias and reidentify Herodotus' Pheidon as the grandson of the great man. This allows them to put Pheidon the tyrant in the 7th century and to associate him with a spectacular Argive defeat of Sparta at Hysiae in 669 BC. His success is then explained as the product of the newly available hoplite method of fighting. (The 8th-century suit of armour from Argos would in fact allow the connection between Pheidon and hoplites even without discarding Pausanias.) This construction assumes much that needs to be proved (see below), and the hoplite theory is in fact being invoked in order to give substance to Pheidon rather than Pheidon lending independent support to the theory.

Two other tyrannies date securely from the 7th century and perhaps happened in imitation of Cypselus; both arose in states immediately adjoining Corinth. Theagenes of Megara makes an appearance in history for three reasons: he slaughtered the flocks of the rich (an action incomprehensible without more background information than is available); he tried about 630 to help his son-in-law Cylon to power at Athens; and he built a fountain house that can still be seen off the "Road of the Spring-House" in modern Megara. The last two items reveal something interesting about the social and cultural character of established tyrannies (see below), but none of the three offers much support for the military or any other general theory of the cause of tyranny. At Sicyon the Orthagorid tyranny, whose most splendid member was the early 6th-century Cleisthenes, may have exploited the anti-Dorianism already noted as a permanent constituent of the mentality of some Greeks: but since the relevant action-a renaming of tribes-falls in the time of Cleisthenes himself, it is no help with the problem of why the first Sicyonian tyrant came to power at all. In any case, 'the main object of Cleisthenes' dislike seems to have been not Dorians in general but Argos in particular: the renaming is said to have been done to spite the Argives.

Notwithstanding the skepticism of what has been said above, some solid general points can be made about the tyrannies mentioned (Athens and Sparta followed peculiar paths of development and must be treated separately). First, these tyrannies have more in common than their roughly 7th-century dates: several of the most famous are situated around or near the Isthmus of Corinth. This surely suggests a partly geographic explanation; that is, there was an influx of new and subversive notions alongside the purely material goods that arrived at this central zone. Places with a more stagnant economic and social life, such as Boeotia and Thessaly, neither colonized nor experienced tyrannies. In fact, some version of Thucydides' economic account of the rise of tyranny may be right, though here too (as with the origins of the city-state or the motives behind acts of colonization) one must be prepared to accept that different causes work for different states and to allow for the simple influence of fashion and contagion.

Reflection on the places that avoided tyrannies leads to the second general point. Another way of looking at tyranny is to concentrate on its rarity and seek explanations for that. After all, there were hundreds of Greek states, many of them extremely small, which, as far as is

Pheidon of Argos

The rarity of tyranny known, never had tyrannies. The suggested explanation is that in places with small populations there was enough scope for office holding by most of the city's ambitious men to make it unnecessary for any of them to aspire to a tyranny. (One can add that certain places are known to have taken positive steps to ensure that regular office did not become a stepping-stone to tyranny. For example, a very early constitutional inscription shows that 7thcentury Drerus on Crete prohibited tenure of the office of kosmos-a local magistracy-until 10 years had elapsed since a man's last tenure.) This is a refreshing approach and surely contains some truth. Nonetheless, the qualification "as far as is known" is important: with regard to many places there is no better reason for saying that they avoided tyranny than for saying that they had it. Moreover, the view that tyranny was widespread may indeed be a misconception, although, if so, it was an ancient one: Thucydides himself says that tyrannies were established in many places. Finally, the psychological argument from satisfaction of ambition is only partly compelling: it was surely more rewarding in every way to be a tyrant than to be a Dreran kosmos.

Sparta and Athens. Prominent among the states that never experienced tyranny was Sparta, a fact noted even in antiquity. It was exceptional in this and in many other respects, some of which have already been noted: it sent out few colonies, only to Taras (Tarentum) in the 8th century and-in the prehistoric period-to the Aegean islands of Thera and Melos. It was unfortified and never fully synoecized in the physical sense. And it succeeded, exceptionally among Greek states, in subduing a comparably sized neighbour by force and holding it down for centuries. The neighbour was Messenia, which lost its independence to Sparta in the 8th century and did not regain it until the 360s. It was the Messenian factor above all that determined the peculiar development of Sparta, because it forced Spartans to adjust their institutions to deal with a permanently hostile subject population.

Despite Sparta's military prominence among Greek states, which is the primary fact about it, Sparta's development is especially difficult to trace. This is so partly because there are few Archaic or Classical Spartan inscriptions. Even more important, there is very little genuine Spartan history written by Spartans (there was no Spartan

Herodotus or Thucydides, though both men were deeply fascinated by Sparta, as indeed were most Greeks), And partly this is so because—a related point—"invented tradition" had been particularly active at Sparta. As early as the 5th century one finds "laconizers" in other states (the word derives from "Laconia," the name for the Spartan state, or Lacedaemon, and signifies cultural admiration for Sparta and its institutions). The Spartan tradition in European thought can be traced through the centuries up to modern times, though it has never amounted to a single easily definable set of ideas. In the intellectual world of the 4th century BC, when many of the most significant myths about Sparta seem to have been concocted, Sparta. chiefly under the influence of idealist philosophers seeking some solution to civic disorder, was virtually turned into a shorthand expression for a pure community free from stasis (internal dissension and fighting) with equality of land ownership and other utopian features that never existed in the historical Sparta or anywhere else. In the Roman period Sparta had become a tourist attraction, a place of uncouth, half-invented rituals. This was also the period when Sparta the living legend consciously traded on and exported fantasies about its great past (in the Hellenistic First Book of Maccabees one even finds the idea seriously put forward that the Jews and Spartans were somehow kin). If more is said about Athens than about Sparta in the present section, that is not because Athens was intrinsically more important but because the amount of usable evidence about it is incomparably greater.

By way of compensation for this lack of evidence about Sparta there are two items of cardinal importance: an extraordinary document about the early Spartan constitution and state, preserved by the Greek writer Plutarch (the "Great Rhetra"), and the poetry of the 7th-century Spartan poet Tyrtaeus. Tyrtaeus wrote poetry in elegiac couplets (alternating hexameter and pentameter lines) intended for symposia. Much of it is military in character and enshrines the hoplite ethic in a developed form at a time when Sparta and Argos were at each other's throats (a fragment of Tyrtaeus" poetry published in 1980 defi-nitley disproved modern skepticism about whether Sparta and Argos could have confronted each other militarily as early as the 660s).

The poetry of Tyrtaeus

Sparta had two kings, or basileis. If it is right that this title Panticapagun Tstrus Maccalin Colletis Sesamos Kytoros Anolionia * Ralagric Is Potidaea Laus AEGEAN -Cau Al-Mina Carthage Hadrumetum • Crete Cynrus GREEK SETTLEMENTS Taucheira 8 · 9th century BC Euhesperides . 8th century 8C 7th century BC • 6th century BC

merely denotes hereditary nobles with stated prerogatives, this was originally one of its less remarkable aspects. It is odd, however, that the number two should have been so permanently entrenched. In other respects the Sparta that emerged from the Dark Age had many standard features, such as a warrior assembly based on communal eating in "messes," syssitia (a system analogous to the symposium system), and a council of elders. Magistrates called ephors were unique to Sparta and its offshoots, but there is nothing intrinsically odd about formal magistracies.

The Rhetra is an alleged response by the Delphic oracle to the lawgiver Lycurgus around the 9th or 8th century BC. The Rhetra purports to define the powers of the various Spartan groups and individuals just mentioned. It begins, however, by saying that the tribes must be "tribed" (or "retained"; the Greek is a kind of pun) and the obes (a word for a locality) must be "obed." This is desperately obscure, but in an 8th-century context it ought to refer to some kind of political synoecism (Sparta, as stated, was never physically synoecized). The tribes and obes must be the units of civic organization. The Rhetra demands the setting up of a council with the kings and stipulates regular meetings for the Assembly (something not attested at Athens until far later). A crucial final clause seems to say firmly that the people, or damos, shall have the power. Yet a rider to the Rhetra, associated with the late 8thcentury kings Theopompus and Polydorus, says that, if the people choose crookedly, the elders and kings shall be dissolvers. A poem of Tyrtaeus echoes both parts of this document, rider as well as Rhetra.

The Rhetra is a precocious constitutional document, if it really dates to the 9th or early 8th century, and for this and other reasons (Delphi was not active and writing was not common much before the middle of the 8th century) it is common practice to date the whole document or pair of documents a century or two later. On this view, which is not here followed, the Rhetra itself, with its stipulation of powers for the (hoplite) damos, is a 7thcentury manifestation of hoplite assertiveness: in fact, it represents a kind of Spartan alternative to tyranny. The references to tribes and obes are then seen as part of a reform of the citizen body and of the army, comparable to and not much earlier than tribal changes elsewhere (see below for Cleisthenes). The rider then dates from an even later period, when Spartan military reverses called for a reactionary readjustment of the balance of power. This view, which involves down-dating Theopompus and Polydorus to the 7th century from the 8th and still more arbitrarily attributing to them the activity presupposed by the Rhetra rather than the rider, does too much violence to the best chronological evidence (that of Thucydides and Herodotus), and a view in terms of 8th-century political synoecism should be preferred. As for the alleged army reform, nothing can be said about it in detail. The best reconstruction is hardly more than a creative fabrication from Hellenistic evidence that dealt with a Spartan religious festival but had nothing straightforwardly to do with the army at all.

It was definitely in the 8th century that Sparta took the step which was to make it unique among Greek states. It had already, in the Dark Age, coerced into semisubject, or "perioikic," status a number of its more immediate neighbours. Then, in the second half of the 8th century, it undertook the wholesale conquest of Messenia (c. 735-715). One consequence, already noted, was the export of an unwanted group, the Partheniai, to Taras. These were sons of Spartan mothers and non-Spartan fathers, procreated during the absence in Messenia of the Spartan warrior elite. A still more important consequence of the conquest of Messenia, "good to plow and good to hoe" as Tyrtaeus put it, was the acquisition of a large tract of fertile land and the creation of a permanently servile labour force, the "helots," as the conquered Messenians were now called. The helots were state slaves, held down by force and fear. A 7th-century revolt by the Messenians (the "Second Messenian War") was put down only after decades of fighting and with the help (surely) of the new hoplite tactics. The relationship of hatred and exploitation (the helots handed over half of their produce to Sparta) was the determining feature in Spartan internal life. Spartan warrior peers (homoioi) were henceforth subjected to a rigorous military training, the agoge, to enable them to deal with the Messenian helots, whose agricultural labours provided the Spartans with the leisure for their military training and life-style-a notoriously vicious circle. The agoge and the Sparta that it produced can best be understood comparatively by reference to the kind of male initiation ceremonies and rituals found in other warrior societies. Up to the Second Messenian War, Sparta's political institutions and cultural life had been similar to those in other states. It had an artistic tradition of its own and produced or gave hospitality to such poets as Aleman, Terpander, and Tyrtaeus. But now Spartan institutions received a new, bleak, military orientation. Social sanctions like loss of citizen status were the consequence of cowardice in battle: a system of homosexual pair-bonding maintained the normal hoplite bonds at a level of ferocious intensity; and the economic surplus provided by the lots of land worked by the helots was used to finance the elite institution of the syssitia, with loss of full citizen status for men who could not meet their "mess bill." The agoge, however, transformed Sparta and set it apart from

other states. The helot factor affected more than Sparta's internal life. Again and again modifications were forced on Sparta in the sphere of foreign policy. It could not risk frequent military activity far from home, because this would entail leaving behind a large population of discontented helots (who outnumbered Spartans by seven to one). A solution, occasionally tried by adventurous Spartan commanders. was selective enfranchisement of helots. Yet this called for nerve that even the Spartans did not have; on one occasion 2,000 helots, who were promised freedom and were led garlanded round the temples, disappeared, and nobody ever found out what had happened to them. Some person or persons evidently had second thoughts. The Greek historian Xenophon, who was no enemy to Sparta, states that helots (according to the rebel Kinadon) would have liked to eat the Spartans raw, and incidents like this one explain why.

After the suppression of the Messenian revolt (perhaps not before 600), Sparta controlled much of the Peloponnese. In the 6th century it extended that control further, into Arcadia to the north, by diplomatic as well as by purely military means. On the diplomatic level, Sparta, the greatest of the Dorian states, deliberately played the anti-Dorian card in the mid-6th century in an attempt to win more allies. Sparta's Dorianism was unacceptable to some of its still-independent neighbours, whose mythology remembered a time when the Peloponnese had been ruled by Achaean kings such as Atreus, Agamemnon, and his son Orestes (in a period modern scholars would call Mycenaean). The central symbolic act recorded by tradition was the talismanic bringing home to Sparta of the bones of Orestes himself-a way for Sparta to claim that it was the successor of the old line of Atreus. The result was an alliance with Arcadian Tegea, which in turn inaugurated a network of such alliances, to which has been given the modern name of the Peloponnesian League. A valuable 5th-century inscription found in the 1970s concerning a community in Aetolia (north-central Greece) illuminated the obligations imposed by Sparta on its allies: above all, full military reciprocity-i.e., the requirement to defend Sparta when it was attacked, with similar guarantees offered by Sparta in return. Another, more obviously pragmatic, reason why Sparta attracted to itself allies in areas like Arcadia was surely fear of Argos. Archaic and Classical Argos never forgot the great age of Pheidon, and from time to time the Argives tried to reassert a claim to

hegemony in mythical terms of their own. In the same period (the middle of the 6th century) Sparta drew on its enhanced prestige and popularity in the Peloponnese to take its antipathy to tyranny a stage further: a papyrus fragment of what looks like a lost history supports Plutarch's statement that Sparta systematically deposed tyrants elsewhere in Greece-the tyrannies in Sicyon, Naxos, and perhaps even the Cypselid at Corinth (though this may be a confusion for a similarly named community

The Peloponnesian

Helots

called Cerinthus on Euboea). The most famous deposition was Sparta's forcible ending of the tyranny at Athens, Finally one must ask, however, what were Sparta's motives for this and other interventions. Perhaps part of the motive was genuine ideological dislike of tyranny; Sparta was to exploit this role as late as 431, when it entered the great Peloponnesian War as would-be liberator of Greece from the new "tyranny" in Greece-namely, the Athenian empire. Or Sparta may have been worried about the ambitions of Argos, with which certain tyrants, like the Athenian, had close connections. Or it may have longsightedly detected sympathy on the part of certain tyrants toward the growing power of Persia: it is true that Sparta made some kind of diplomatic arrangement with the threatened Lydian power of the Anatolian ruler Croesus not long before his defeat by Persia in 546. If suspicion of Persia was behind the deposition of the tyrants, Sparta was inconsistent in carrying out its anti-Persian policy; it did not help Croesus in his final showdown with Persia, nor did it help anti-Persian elements on Samos (see below), nor did it do much in the years immediately before the great Greek-Persian collision of 480-479 called the Persian War (it sent no help to the general rising of Ionia against Persia in 499 nor to Athens at the preliminary campaign of Marathon in 490). Inconsistency of diplomatic decision making on the part of Sparta is, however, always explicable for a reason already noticed-its helot problem.

Athens was also highly untypical in many respects. though perhaps what is most untypical about it is the relatively large amount of evidence available both about Athens as a city and imperial centre and about Attica, the territory surrounding and controlled by Athens. (This is a difficulty when one attempts to pass judgment on the issue of typicality versus untypicality in ancient and especially Archaic Greek history; it often is not known whether a given phenomenon is frequent or merely frequently attested. This kind of thing creates difficulties for what students of modern history call "exceptionalist" theories about particular states.) Even at Athens there is much that is not yet known; for instance, of the 140 villages, or demes, given a political definition by Cleisthenes

in 508, only a handful have been properly excavated, First, it is safe to say that Attica's huge size and favourable configuration made it unusual by any standards among Greek poleis. Its territory was far larger than that of Corinth or Megara; while Boeotia, though in control of a comparable area, resorted to the federal principle as a way of imposing unity. Like Corinth but unlike Thebes (the greatest city of Classical Boeotia), Athens had a splendid acropolis (citadel) that had its own water supply, a natural advantage making for early political centralization. And Athens was protected by four mountain systems offering a first line of defense. Second, Attica has a very long coastline jutting into the Aegean, a feature that invited it to become a maritime power (one may contrast it with Sparta, whose port of Gythion is far away to the south). This in turn was to compel Athens to import quantities of the ship-building timber it lacked, a major factor in Athenian imperial thinking. (It helps to explain its 5th-century interest in timber-rich Italy, Sicily, and Macedon.) Third, although Attica was rich in certain natural resources, such as precious metal for coinage-the silver of the Laurium mines in the east of Attica-and marble for building, its soil, suitable though it is for olive growing, is thin by comparison with that of Thessalv or Boeotia. This meant that when Athens' territory became more densely populated after the post-Mycenaean depopulation, which had affected all Greece, it had to look for outside sources of grain, and, to secure those sources, it had to act imperialistically. Some scholars have attempted to minimize Athens' dependence on or need for outside sources of grain and to bring down the date at which it began to draw on the granaries of southern Russia via the Black Sea (as it definitely did in the 4th century). Certainly, there were fertile areas of Attica proper, for instance near Marathon, and at many periods Athens directly controlled some politically marginal but economically productive areas such as the Oropus district to the north or the island of Lemnos. A case can also be made for saying that if Athenians had been

prepared to eat less wheat and more barley, Athens could have fed itself. Real needs, however, are sometimes less important than perceived needs, and for the understanding of Athenian imperial actions it is more important that its politicians believed (even if modern statisticians would say they were wrong) that internal sources of grain must be endlessly supplemented from abroad. Nor is it entirely plausible to dissociate Athens' 7th-century acquisition of Sigeum (see below) from the provisioning possibilities of the Black Sea region.

Unlike the Peloponnese, with its tradition of Dorian invasion from the north, Athens claimed to be "autochthonous"-that is, its inhabitants had occupied the same land forever. Like any such claim, it was largely fiction, but it helped to make up for Athens' relative poverty in religion and myth: it has nothing to compare with the great legends of Thebes (the Oedipus story) or the Peloponnese (Heracles; the house of Atreus). There was one hero, however, who could be regarded as specially Athenian, and that was Theseus, to whom the original political synoecism of Attica was attributed even by a hardheaded writer like Thucydides

At whatever date one puts this "Thesean" synoecism, or centralization (perhaps 900 would be safe), it seems that the late Dark Age in Attica saw the opposite process taking place at the physical level; that is, the villages and countryside of Attica were in effect "colonized" from the centre in the course of the 8th century. The process may not have been complete until even later. This explains why Athens was not one of the earliest colonizing powers: the possibility of "internal colonization" within Attica itself was (like Sparta's expansion into Messenia) an insurance against the kind of short-term food shortages that forced such places as Corinth and Thera to siphon off part of their male population.

In fact, Athens did acquire one notable overseas possession as early as 610 BC, the city of Sigeum on the way to the Black Sea. Yet as long as its neighbour Megara controlled Salamis, a large and strategically important island in the Saronic Gulf, the scope for long-distance Athenian naval operations was restricted; the excellent tripartite natural harbour of Piraeus was not safe for use until Salamis was firmly Athenian. Until then, Athens had to make do with the more open and less satisfactory port facilities of Phalerum, roughly in the region of the modern airport. Thus there was an obvious brake on naval expansion.

By the later 7th century then, Athens was looking abroad, and it is not surprising to find it experiencing some of the strains that in the 8th century had led to tyrannies elsewhere. Indeed, it narrowly escaped a first attempt at tyranny itself, that of Cylon, the Olympic victor (630s). The close connection between athletic success and military values has been noted; there was an equally close connection between athletic and political achievement, and not just in the Archaic age. Cylon was helped by his father-inlaw Theagenes of Megara, a fact that underlines, as does Megarian possession of Salamis until the 6th century, the lateness of Athens' growth to great power status: Classical Megara was a place of small consequence. That Cylon's attempt was a failure is interesting, but too little is known about his potential following to be able to say either that Athenian tyranny was an idea whose time had not yet come or that there is social and economic significance merely in the fact of his having made the attempt.

Cylon's attempt had two consequences for Athenian history. The first is certain but fortuitous: Cylon's followers were put to death in a treacherous and sacrilegious way, which was held to have incriminated his killers, notably Megacles, a member of the Alcmaeonid genos. Pollution attracted in this way is a slippery conception; it could wake or sleep, as Aeschylus put it. This particular pollution adhered even to persons who were not on their father's side members of the Alcmaeonid genos, such as the great 5thcentury leader Pericles, and was usually "woken up" for deliberate and political ends.

The other consequence may not be a consequence at all but a coincidence in time. It was not many years after the Cylon affair that the Athenian lawgiver Draco gave the city its first comprehensive law code (perhaps 621). Because of

Cylon

The distinctiveness of Athens

the code's extreme harshness, Draco's name has become a synonym for legal savagery. But the code (the purely political features of which are irrecoverably lost to the 20th century short of some lucky inscriptional find) was surely intended to define and so ameliorate conditions; the Athenian equivalents of the "bribe-eating basileis" of the Boeotian Hesiod's poem could still dispense a rough, but no longer arbitrary, justice. Further than that it is not safe to go; Draco's code, like that of the statesman and poet Solon (c. 630-560), was destroyed by antidemocrats in the late 5th century. A detailed constitution foisted on Draco has survived in the treatise called the Constitution of Athens, attributed to Aristotle and found on papyrus in 1890. This says much about the psychology of 411 BC and little about the situation in 621.

Whatever the connection between Cylon and Dracoand one must beware the trap of bringing all the meagre facts about the Archaic period into relation with each other-firmer grounds for postulating economic and social unrest in late 7th-century Attica are to be found in the poetry of Solon. Solon is the first European politician who speaks to the 20th century in a personal voice (Tyrtaeus reflects an ethos and an age). Like the other Archaic poets mentioned, Solon wrote for symposia, and his more frivolous poetry should not be lost sight of in preoccupation with what he wrote in self-justification. He was a man who enjoyed life and wanted to preserve rather

than destroy.

Solon's

laws

Solon's laws, passed in 594, were an answer to a crisis that has to be reconstructed largely from his response to it. Most scholars believe that Solon's laws continued to be available for consultation in the 5th and 4th centuries; this (as noted above) did not prevent distortion and manipulation. In any case, by the 4th century, the age of treatises like the Constitution of Athens and other works by local historians of Attica ("Atthidographers"), much about early Attica had been forgotten or was misunderstood. Above all, there was a crucial failure to understand the dependent status of those who worked on the land of Attica before Solon abolished that status, which was conceived of as a kind of obligation or debt; this abolition, or "shaking off of burdens," was the single most important thing Solon did (see below). When one divides Solon's work, as will be done here for convenience, into economic, political, and social components, one may fail to grasp the possibility that there was a unified vision organizing it all and that in this sense no one reform was paramount. Perhaps the poem of Solon's that sums up best what he stood for is a relatively neglected and not easily elucidated one, but an important one nonetheless, in which he seems to claim that nobody else could have done what he did and still have "kept the cream on the milk," That is to say, his was, in intention at least, a more just though still a stratified society that sought to retain the cooperation of its elite.

Solon canceled all "debt" (as stated, this cannot yet have been debt incurred in a monetary form). He also abolished enslavement for debt, pulling up the boundary markers. or horoi (see below), which indicated some sort of obligation. This act of pulling up the horoi was a sign that he had "freed the black earth." The men whose land was designated by these horoi were called "sixth-parters" (hektëmoroi) because they had to hand over one-sixth of their produce to the "few" or "the rich" to whom they were in some sense indebted. Solon's change was retrospective as well as prospective: he brought back people from overseas slavery who no longer spoke the Attic language (this is the evidence, hinted at above, for thinking that the problems facing Solon went back at least a generation, into the period of Draco or even Cylon).

Enslavement for debt was not an everyday occurrence in the world of Aristotle or Plutarch (although the concept never entirely disappeared in antiquity), and they seem to have misunderstood the nature of the debt or obligation that the horoi indicated. It is not only Aristotle and Plutarch who found the situation bewildering. It has seemed odd to modern scholars that mere defaulting on a conventional debt should result in loss of personal freedom. Hence they have been driven to the hypothesis that land in Archaic Greece was in a strong sense inalienable

and thus not available as security for a loan (of perhaps seed-corn or other goods in kind). Only the person of the "debtor" and members of his family could be put up as a kind of security. Incurable damage has, however, been done to this general theory by the independent dismantling of any idea that land in Archaic Greece was in fact inalienable (such Greek prohibitions on alienation as one hears of tend to date from late and semimythical contexts such as the 4th-century literary reworking of tradition about Sparta or from post-Archaic colonial contexts where the object of equal and indivisible land-portions was precisely to avoid the injustices and agricultural buying-up and asset stripping left behind at home).

Evidently then, some new approach is needed, and it can be found in the plausible idea that what Solon got rid of was something fundamentally different from ordinary debt. In fact, hektemorage was a kind of originally voluntary contractual arrangement whereby the small man gave his labour to the great man of the area, forfeiting a sixth of his produce and symbolically recognizing this subordination by accepting the installation of a horos on the land. In return the other perhaps provided physical protection. This would go back historically to the violent and uncertain Dark Age when Attica was being resettled and there was danger from cattle rustlers, pirates (nowhere in Attica is far from the sea), or just greedy neighbours. Alternatively, hektemorage may simply have been the contractual basis on which powerful men assigned land to cultivators in the 9th and 8th centuries, when Attica was being reclaimed after the previous impoverished period. As the 7th century wore on, however, there was scope in Attica for enrichment of an entirely new sort, involving concentration of precious metal in marketable or at least exchangeable form as a result of contacts with elegant, rich, and sophisticated new worlds across the sea. This produced more violent disparities of wealth and a motive for "cashing" the value of a defaulting labourer. On his part, the labourer may have felt that his low social status, once acceptable or inevitable, was no longer commensurate with his military value in the new hoplite age. So Solon's abolition of hektemorage was as much a social and political as an economic change.

This theory of the origin of hektemorage is attractive and explains much. It is disconcerting, however, that the best analogies that can be offered for such semi-contractual 'servitude for debt" are from older hierarchical civilizations dependent on highly organized exploitation of manmade irrigation systems (so-called "hydraulic economies"). It is hard to see who or what institution, in Geometric Attica, had the authority-in the absence of any kind of priest-king-to impose the hektemorage system generally throughout the large area of Attica, Nonetheless, one can accept that hektemorage was as much a matter of status as of economic obligation.

Solon's main political changes were first to introduce a Council of 400 members alongside the old "Thesean" council of elders known as the Areopagus, from the Hill of Ares next to the Acropolis, where it met. The functions of this new Council of Solon are uncertain, but that is no reason to doubt its historicity. Solon's Council is perhaps important not so much for itself as for what it anticipated-the replacement Council of Five Hundred, introduced by Cleisthenes at the end of the 6th century.

Second, Solon allowed appeal to the hēliaia, or popular law court. The composition of this body is the subject of fierce scholarly dispute; one view sees it as a new and wholly separate body of sworn jurors, enjoying even at this date a kind of sovereignty within the state. The more usual view is that the heliaia was the Assembly in its judicial capacity. This view is preferable: neither in Solon's time nor later is it plausible to posit large juries whose makeup or psychology was distinct from that of the political Assembly. In later times, such appeal to the people was regarded as particularly democratic. But this is just the kind of anachronism one must be careful of when estimating Solon: until pay for juries was introduced in the 460s, such juries could not be a buttress of democracy. Moreover, it would take a courageous peasant (there were no professional lawyers or speech writers as yet) to get up Solon's political reforms and articulately denounce a bribe-swallowing basileus, especially if-as seems possible-unsuccessful appeal could actually result in increase of sentence.

Third, Solon admitted to the Assembly the lowest economic "class" in the Athenian state, the thētes, whose status was henceforth defined in terms of agricultural produce. The quotes are necessary because investing such fixed economic statuses, or tele, with political significance was an innovation of Solon himself; that is, his fourth political reform was to make eligibility for all political office (not just the bare right of attending the Assembly) dependent on wealth and no longer exclusively on birth (a "timocratic" rather than an "aristocratic" system). Solon's four classes were the "five-hundred-bushel men," or pentakosiomedimnoi; the hippeis, or cavalry class; the zeugitai, or hoplites; and the thetes, the class that later provided most of the rowers for the fleet. Again, the immediate impact of the change need not have been cataclysmic; many of the older aristocracy (whether or not one should think of them as a closely defined group of "eupatridae"that is, "people of good descent") would still have been eligible for office even after the change. But there was also a need to cater to men who were outsiders in the technical sense of not belonging to the older genë: the name of one such excluded but high-status category of families has perhaps come down to the present, the so-called orgeones. Nor were Solon's four classes themselves entirely new (as indeed the Constitution of Athens actually admits in an aside). Thus there were horsemen and even hoplites before Solon, and thetes are mentioned in Homer. The phrase five-hundred-bushel men, which at first sight looks like a prosaic and unimaginative new coinage, acquired in 1968 a 9th-century archaeological analogue: a set of five model granaries was found in a female grave excavated in the Agora. It clearly was a pre-Solonian status symbol ("I was the daughter of a pentakosiomedimnos"). An interesting suggestion sees the four classes as originally religious in character: their members may have had allocated functions in the festivals of the synoecized Athenian state. This is not strictly provable but is plausible because the political and military life of Athens and Attica was at all times seen in religious terms.

Solon's

legislation

social

Solon's social legislation seems generally designed to reduce the primacy of the family and increase that of the community, or polis. To that extent it can be regarded as embryonically democratic. For instance, his laws on inheritance made it easier to leave property away from the family. He also legislated to restrict ostentatious mourning at funerals and to prevent spectacular burials, which were potentially a way for aristocratic families to assert their prestige. (And not just a potential way, either: a great noble called Cimon was buried later in the 6th century in true "Lefkandi style"-that is, close to the horses with which he had won three times at the Olympic games. This burial was surely in defiance of the Solonian rules.) As can be seen from the Antigone of the 5th-century tragic poet Sophocles, death and funerary ritual were always an area in which the family, and especially the women, had traditional functions. For the state to seek to regulate them was a major shift of emphasis.

The whole thrust of Solon's reforms was to define and enlarge the sphere of activity of the polis. He was concerned to recognize and increase the power of the ordinary Athenian thēte and hoplite, while containing without destroving the privileges of the aristocratic "cream." By uprooting the horoi, symbols of a kind of slavery, he created the Attica of independent smallholders one encounters as late as the 4th century. And he gave them political rights to match, "as much as was sufficient," as a poem of his puts it. One result of Solon's reforms cannot have been intentional: the abolition of hektemorage created, in modern terms, a "gap in the work force." From then on it was beneath the dignity of the emancipated Athenian to work for a master. Some other source of labour had to be found, and it was found in the form of chattel slaves from outside. That means that the whole edifice of culture and politics rested on the labour of men and women who by "right" of purchase or conquest had become mere things, mere domestic, agricultural, or mining equipment, and whose presence in Classical Attica rose into the tens of thousands. For by the 5th century, slave owning was not confined to the aristocratic few but had been extended to the descendants of that very class Solon had liberated from another kind of slavery.

Initially the Solonian solution was an economic failure. however true it is to attribute to him the economic shape of Classical Attica. Solon himself was almost, but not quite, a tyrant. The orthodox Greek tyrant was associated with redistribution of land and cancellation of debts. though this association was to a large extent a mere matter of popular perception because wholesale redistribution of land is extraordinarily rare in Greek history. Solon did cancel debts. He also redistributed the land in the sense that the former hektēmoroi now had control without encumbrance of the land they had previously worked with strings attached. He did not, however, redistribute all the land, because he left the rich in possession of the land the hektemoroi had previously worked for them. In this respect Solon's rule differed from tyranny. It also differed in his simple avoidance of the word; after his year of legislative activity he simply disappeared instead of supervising the implementation of that legislation. This was unfortunate for the former hektēmoroi, who needed to be supported in the early years. Growing olive trees, which were a staple of Attica, was an obvious recourse for the farmer in new possession of his own plot, but it takes 20 years for olive trees to reach maturity. Such farmers could hardly look for charity to their former masters, whose wealth and privilege Solon had curtailed. Instead they looked to a real tyrant, Peisistratus,

It took more than one attempt to establish the Peisistratid tyranny, but in its long final phase it lasted from 546 to 510. After the death of Peisistratus, the tyrant's son Hippias ruled from 527 to 510 with the assistance if not co-rule of his brother Hipparchus, who was assassi-

nated in 514

Hostility to the tyrants on the part of 5th-century informants like Herodotus makes it difficult to ascertain the truth about them. That they ruled with the acquiescence of the great nobles of Attica is suggested by a 5th-century archon list discovered in the 1930s, which shows that even the post-Peisistratid reformer Cleisthenes, a member on his father's side of the Alcmaeonid genos, was archon in the 520s. It is also suggested by the fact that Miltiades, a relative of the gorgeously buried Cimon (see above) went out to govern an outpost in the Thracian Chersonese, hardly against the wishes of the tyrants. Furthermore, even the Peisistratids did not confiscate property indiscriminately, though they did levy a tax of 5 percent. This enabled them to redistribute wealth to those who now needed it-that is, those who "had joined him through poverty after having their debts removed (by Solon)." Although a formally ambiguous expression, it must in common sense apply to pre-Solonian debtors, not creditors. How far Peisistratus, who seems to have started as a leader of one geographic faction, specifically mobilized hoplite support at the outset is uncertain, but such military backing is a little more plausible in his century than in the mid-7th century when the "Isthmus tyrants" were seizing power. (Peisistratus' position was, however, buttressed by bodyguards; here, for once, is a tyrant who in some ways fits Aristotle's otherwise excessively 4th-century model.) In any case, Peisistratus' introduction of "deme judges"-that is, judges who traveled round the villages of Attica dispensing something like uniform justice-was an important leveling step, both socially and geographically, and one should imagine this as an appeal to the goodwill of the hoplite and thetic classes. It also, in the longer term, anticipated (as did the well-attested road-building activity of the Peisistratids) the unification of Attica, which Cleisthenes was to carry much further.

Whether or not Peisistratus climbed to power with hoplite help, he surely strengthened Athens militarily in a way that must have involved hoplites. Indeed, the Peisistratid period ought to count as one of unequivocal military and diplomatic success, and literary suggestions otherwise should be discounted as products of aristocratic malice. In this period should be put the first firm evidence of Peisistratid tyranny

The

trireme

the tension between Athens and Sparta that was to determine much of Classical Greek history-namely. Athenian alliances not just with Sparta's enemy Argos but in 519 with Boeotian Plataea. (The Plataeans, faced with coercion from their bigger neighbour Thebes, sued for this alliance at the prompting of Sparta itself; this, however, is evidence of among other things Spartan-Athenian hostility because Sparta's motive, it was said, was to stir up trouble between Thebes and Athens.) Moreover, it may have been in the Peisistratid period that the sanctuary of Eleusis, near Athens' western border and always important for defensive and offensive as well as for purely religious reasons, was fortified. But this is controversial.

This is also the period in which Athens began to be an organized naval power: Salamis became definitively Athenian in the course of the 6th century (tradition credits its taking to both Solon and Peisistratus), with consequences already noted. The island was secured by the installation of what was probably Athens' first cleruchy, a settlement of Athenians with defense functions. Again, it is now that one finds definite mention of the first Athenian triremes, which formed a small private fleet in possession of Miltiades. The trireme, a late Archaic Corinthian invention, was a formidable weapon of war pulled by 170 rowers and carrying 30 other effectives. A full-sized working trireme, launched in Greece in 1987, proved beyond any further debate that triremes were operated by three banks of oars (rather than by three men to an oar). More generally, its size, technological sophistication, and visual impact make it possible to understand Classical Athens' psychological and actual domination of the seas. A proper Peisistratid navy is implied by the tradition that Peisistratus intervened on Naxos and "purified" the small but symbolically important island of Delos, a great Ionian centre. This purification involved ritual cleansing ceremonies and the digging up of graves. As with Eleusis, however, this was deliberate exploitation of religion for the purposes of political assertion.

Paul Lipke/Trireme Trust

The Greek trireme Olympias.

Elsewhere in Attica also, the Peisistratids interested themselves in organized religion. A literary text first published in 1982 states explicitly what was always probable, that Peisistratus actively supported the local cult of Artemis Brauronia in eastern Attica (the locality from which Peisistratus himself came) and so helped to make it the fully civic cult it is in Aristophanes' play Lysistrata. Too much however, should not be credited to Peisistratus; it has been protested that the relationship between local and city cults in Attica was always one of reciprocity and dialogue. Nevertheless, the explicit evidence about Peisistratus' care for his home cult of Brauron, and the permanent military importance of Eleusis on the way to Peisistratus' enemies in the Peloponnese, make it plausible to suppose a heightening of interest in these two particular sanctuaries precisely in the tyrannical period.

Peisistratid religious and artistic propaganda, and in particular the extent to which the evidence of painted pottery can be used by the political historian, is a modern scholarly battlefield. It has been suggested, on the basis of this sort of evidence, that Peisistratus deliberately identified himself

with Heracles, the legendary son of Zeus and Alcmene, and that this is reflected on vase paintings. Yet there are problems; it may be wrong, for reasons already noted, to accord to painted pottery the importance required for the theory. Certainly it needs to be proved that potters, not a numerous or powerful group at any time, had the kind of social standing that would give weight to their "views" as represented on vases, which price lists show were dirtcheap. In addition, there are particular difficulties about supposing that any man, tyrant or not, could at this early date get away with posing as a god. One is on firmer ground with the Peisistratid building program reflecting not only the tyrant's concern for the water supply (comparable to that shown by the Megarian tyrant) but including the construction of a colossal temple to Olympian Zeus (completed at the time of Hadrian). This and more conjectural buildings on the Acropolis were a direct anticipation of the 5th-century building program of imperial Athens. Unlike painted pottery, they could be commissioned only as a deliberate act by men with plentiful command of money and muscle.

The tyrant Hippias was expelled from Athens by the Spartans in 510. They no doubt hoped to replace him with a more compliant regime, true to their general policy, as described by Thucydides, of supporting oligarchies congenial to themselves. Oligarchy, or rule by the relatively wealthy few, however defined, and tyranny were in 510 the basic alternatives for a Greek state. The newly emancipated Athens of the last decade of the 6th century. however, reacted against its Spartan liberators and added a third member to the list of the political possibilitiesdemocracy. Spartan disappointment at this turn of events expressed itself not merely in unsuccessful armed interventions intended to install a prominent Athenian, Isagoras, as tyrant (506) and even to reinstate Hippias (c. 504) but also in attempts to persuade the world, and possibly themselves, that their relations with the Peisistratids had actually been good (hence another source of distortion in the tradition about the tyrants, who on this account emerged as friends, not enemies, of Sparta).

In 508, after a short period of old-fashioned aristocratic party struggles, the Athenian state was comprehensively reformed by Cleisthenes, whom Herodotus calls "the man who introduced the tribes and the democracy," in that order. The order is important. Cleisthenes' basic reform was to reorganize the entire citizen body into 10 new tribes, each of which was to contain elements drawn from the whole of Attica. These tribes, organized initially on nothing more than residence and not on the old four Ionian tribes based purely on descent, would from then on determine whether or not a man was Athenian and so fix his eligibility for military service. The tribes were also the key part of the mechanism for choosing the members of a new political and administrative Council of Five Hundred, whose function it was to prepare business for the Assembly. This Council, or Boule, insofar as it was drawn roughly equally from each tribe, could be said to involve all Attica for the first time in the political process: all 140 villages, or demes, were given a quota of councillors-as many as 22 supplied by one superdeme and as few as 1 or 2 by some tiny ones. An interesting case has been made for saying that this political aspect was secondary and that the Cleisthenic changes were in essence and intention a military reform. Herodotus, for example, remarks on the military effectiveness of the infant Cleisthenic state, which had to deal immediately and successfully with Boeotian and Euboean invasions. And there were arguably attempts, within the Cleisthenic system, to align demes from different trittyes (tribal thirds; see below) but the same tribe along the arterial roads leading to the city, perhaps with a view to easy tribal mobilization in the city centre. It is right that the political aspects of Cleisthenes (who was in fact far from producing democracy in the full sense) can too easily be overemphasized at the expense of the military; but the better view is that the new system had advantages on more than one level simultaneously.

One military result of Cleisthenes' changes is not in dispute: from 501 on, military command was vested in 10 stratēgoi, or commanders (the usual translation "generals" reforms of Cleisthenes obscures the important point that they were expected to command by sea as well as by land). Normally, each of the 10 tribes supplied one of these generals. They were always directly elected. Direct election for the strategia remained untouched by the tendency in subsequent decades to move in the general direction of appointment by lot. (Appointment by lot was more democratic than direct election because the outcome was less likely to be the result of manipulation, pressure, or a tendency to "deferential voting.") Even the Athenians were not prepared to sacrifice efficiency to democratic principle in this most crucial of areas. The number 10 remained sacrosanct and so (probably) did the "one tribe, one general" principle, though later in the 5th century, and in the 4th, it was possible for one tribe to supply two generals, one of whom was elected at the expense of the tribe whose candidate had polled the fewest votes. Again, the object was to ensure maximum efficiency: there might be two outstanding men in one tribe. Another peculiarity of the strategia to be explained in the same way, was that reelection, or "iteration," was possible. (Actually it is not quite certain that the strategia was unique in this respect; it is possible

The trittys

that iteration was possible for the archonship as well.) The Cleisthenic system was based on the trittys, or tribal "third." There were three kinds of trittys to each of the 10 tribes, the kinds being called "inland," "coastal," and "city." There were therefore 30 trittyes in all, and each of the 140 demes belonged to a trittys and a tribe. The numbers of demes in a tribe could and did vary greatly, but the tribes were kept roughly equal in population as far as one can see. (The last words represent an important qualification: it is just possible that the whole system was overhauled in 403 to take account of changes in settlement patterns effected by the great Peloponnesian War. In that case the evidence for deme quotas-evidence which is mostly derived from 4th-century or Hellenistic inscriptions-would not be strictly usable for the 6th or 5th centuries. But in fact there is just enough evidence from the 5th century to make the assumption of continuity plausible.) Each of the 10 tribes supplied 50 councillors to the new Council. In this way, even the remotest deme was involved in what happened in the city; Cleisthenes' solution can thus be seen in its political aspect as an attempt to deal with a characteristic problem of ancient states, which were mostly agriculturally based. That problem was to avoid the domination of city assemblies by the urban population. Cleisthenes' system gave an identity to the deme that it had not had before, even though the word dēmos just means "the people," hence "where the people live," hence "village" (the word and concept certainly predate Cleisthenes). Now it had a more precise sense: it was an entity with an identifiable body of demesmen and a right to representation in the Council.

The Cleisthenic deme was the primary unit for virtually all purposes. It was a social unit: to have been introduced to one's demesmen in an appropriate context was good evidence that one was a citizen. It was the primary agricultural unit-though it is disputed whether all settlement in Attica was "nucleated" (that is, whether all farms were clustered together around demes), as one view holds. In fact, there is much evidence for nonnucleated (i.e., isolated) settlement. It was, as stated, a legal unit-although deme judges were suspended from 510 to the 450s. It was a financial unit: temple accounts from the distant deme of Rhamnus date from well back in the 5th century. It was a political unit: as shown, it supplied councillors to the new Council and enjoyed a vigorous deme life of its own (though it seems that there was little overlap between deme careers and city careers). It was a military unit: not only did tribes train together, but a dedication by the demesmen of Rhamnus may show that they participated as a group in the conquest of Lemnos by Miltiades about 500 BC. (Another view puts this inscription in the years 475-450 and sees it as a dedication by cleruchs or a garrison.) Above all it was a religious unit: deme religious calendars, some of the most informative of them published in the 1960s and '70s, show a rich festival life integrated with that of the polis in a careful way so as to avoid overlap of dates. It has been suggested that the worship of Artemis of Brauron, a predominantly female affair, was somehow organized according to the 10-tribe system. Finally, and related to the last, it was a cultural unit: at the deme festival for Dionysus (the "Rural Dionysia") there were dramatic festivals, subsidized, as inscriptions show, by wealthy demesmen.

Cleisthenes seems also to have addressed himself to the definition of the Assembly, or Ecclesia. As seem, Solon admitted thieles to the Assembly, but Cleisthenes fixed the notional number of eligible Athenians (adult free male Athenians, that is) at 30,000. One-fith of this total, 6,000, was a quorum for certain important purposes, such as grants of citizenship.

grants of citizenship.

Cleisthenes' ulterior motive in all this must remain obscure in the absence of any corpus of poetry by the man himself, of any biographical tradition, and even of good documentary or historiographic evidence from anywhere near Cleisthenes' own time (the Constitution of Athens is

reasonably full, but it was written nearly 200 years later). That the tribal aspect of Cleisthenes' changes was central was recognized even in antiquity, but Herodotus' explanation, that he was imitating his maternal grandfuther, Cleisthenes of Sicyon, does not suffice as an explanation on its own. The question is why he should have been anxious that each Athenian tribe should be a kind of microcosm of all Attica. Politically, the tribe does feature in Athenian public life (for instance, tribal support in lawsuits was valuable, and each of the 10 tribes presided by rotation over the Council for one-tenth of the year. This is the socalled prytany system). But the tribe was not a voting unit like the Roman tribe-Athenian votes were recorded as expressions of individual opinion, not submerged in some larger electoral or legislative bloc-and the later political functions of tribes were not quite numerous enough to explain why Cleisthenes felt it necessary to subdivide them into "thirds" in the way he did.

Cleisthenes' changes should be seen in their context. First, the Attica he inherited had a relatively small number of militarily experienced fighters, many of them former Peisistratid mercenaries. It was essential that these be distributed among the tribes if the latter were to be militarily effective. (It is a corollary of this that one accepts that at some preliminary stage in Cleisthenes' reforms there was widespread granting of citizenship to residents of Attica whose status was precarious. There was surely plenty of immigration into prosperous Peisistratid Attica, not all of it military in character.) Second, in the late Archaic period tribal reform took place in other communities, some far removed from Attica in both character and geography. Cleisthenes' system looks subtle, theoretical, and innovatory in its decimal approach to political reform and its reorganization of "civic space," but there were precedents and parallels. For example, at Cyrene, three-quarters of a century after its colonization by Thera, there was stasis (political strife), which a reformer, called in from Mantinea on the mainland, settled by reorganizing Cyrene into three tribes. Again, at tyrannical or possibly posttyrannical Corinth, it seems (the evidence is some boundary markers published in 1968) that there was a tribal reorganization along trittys lines not dissimilar to, but earlier than, Cleisthenes' system. Finally, there is the Roman analogy: the new system of tribes and centuries, a system based partly on residence, replaced a purely gentilitial systemi.e., one based only on heredity. The word "century" is a clue: although the term signifies a voting unit, it is military in character. It is evident that tribal reform was a fairly general Archaic solution to the difficulties experienced by states with large numbers of immigrants. Such states needed the human resources these immigrants represented, but they could not admit them under the old rules. The rules had to be changed.

One may end with religion, which has been called a way of "constructing civic identity" in the ancient world, where religion was something embedded, not distinct. Cleisthenes was a decisive innovator in the social sphere, above all in the new role he allotted to the deme, but he did not dismantle the older social structures with their strong religious resonances. (The phratry, which was associated with Zeus and Apollo, continued to be an important regulator.)

The Ecclesia

Religion and social structure of citizenship; see above on the Demotionidai inscription.) His 10 new tribes were all named after heroes of Athenian or Salaminian myth, and these tribal heroes were objects of very active cult: this is in itself a recognition of a craving for a religiously defined identity. Nor did the old four lonian tribes altogether disappear as religious entities; they are mentioned in a sacrificial context in a late 5th-eentury inscription. The Cleisthenic Athenian state was still in many ways traditional, and it is above all in the religious sphere that one sees continuity even after Cleisthenes.

The world of the tyrants. If the earlier Archaic period was an age of hospitality, the later Archaic age was an age of patronage. Instead of individual or small-scale ventures exploiting relationships of xenia (hospitality), there was something like free internationalism. Not that the old xenia ties disappeared—on the contrary, they were solidized to the contrary of the contrary.

fied, above all by the tyrants themselves.

One very characteristic manifestation of this is intermarriage between the great houses of the tyrannical age, as between Cylon of Athens and Theagenes of Megara or between the family of Miltiades and that of Cypselus of Corinth (see above). The Cypselids also were on good terms with the tyranny of Thrasybulus of Miletus in Anatolia (an indication that the Lelantine War alignments had been reversed, though no explanation for this is available). The archetypal event of the Archaic age, however, was the 6th-century entertainment by Cleisthenes of Sicyon of the suitors for the hand of his daughter Agariste. This occasion, to doubt the actuality of which requires the dreariest sort of skepticism, looks back in some respects to the Homeric "suitors" of Penelope in the Odyssey. The novelty is that one is now in the world of the polis, and the suitors were men who had "something to be proud of either in their country or in themselves." They came from Italy (two of them, one from Sybaris, one from Siris). Epidamnus in northwestern Greece, Aetolia, Arcadia, Argos (the great-grandson of the great Pheidon), Eretria, Thessaly, and many other places. The winner was one of the two Athenians, Megacles the Alcmaeonid (the other Athenian, Hippocleides, had been well in front but lost the girl by dancing on a table with his legs in the air). Megacles' son by Agariste was the reformer Cleisthenes, named (as so often in Greece) after his grandfather. The suitors were made to perform in the gymnasia (if not too old, Herodotus says), but the decisive "match" at the Trial of the Suitors was held at the final banquet or symposium: proof of the centrality that athletics and communal banqueting had by now assumed.

Although some of the tyrants may (like the Athenian Peisistratids) have retained existing structures such as the archonship and so shown their respect for the status quo, the marriages even of the Peisistratids had politically defiant implications. They were more like pharaonic or Hellenistic sister marriage or like the close intermarrying in aristocratic families of the Roman Republic in that the tyrants had to take their wives only from strains as pure as their own. Yet in the tyrannical world the tyrant had no superiors or equals within his own state. More practically, such ties tended to guarantee political equilibrium. Another related feature that can be explained along similar lines was the practice of multiple marriages (Peisistratus had at least three wives). Breaking the normal social rules in this way had the function of placing the tyrant apart; it is an example of the games princes play.

A third aspect, both cause and consequence, of such intermariage is internationalism. There also were other factors that contributed to creating something like a common culture or koint. Some of these factors stemmed from an earlier period, such as that of the great Olympic Games (see above Colonization and city-state formation). Patronage of poets and artists was a newer phenomenon that helped to make the Greek world a koint through the movement of ideas and individuals from one tyrantical court to another. (The general point must not, however, be exaggerated: cities retained their distinctive cultures, and there were sharp differences of style between one tyrant and another. Even in antiquity the Peisstratids were distinguished from monsters of cruelty like Phalaris, tyrant of Sicilian Acragas.)

The poets Anacreon of Teos and Simonides of Ceos best exemplify the peripatetic life-style of the great cultural figures of the age. Both were brought to Athens by Hipparchus, the son of Peisistratus (Peisistratus himself did not summon poets and musicians to his court, perhaps preferring popular culture like the Dionysia and Panathenaic festivals). Anacreon had previously lived at the court of the splendid Polycrates, the 6th-century tyrant of Samos (who also patronized Ibycus, a native of Rhegium near Sicily); when Polycrates fell, Anacreon was dramatically rescued by Hipparchus, who sent a single fast ship to take him away. Simonides, after the fall of the Peisistratids. moved to the court of the Scopad rulers in Thessaly. Pindar and Bacchylides, the writers of 5th-century victory odes for young aristocrats, were the successors of poets like these. It would be wrong, however, to leave an impression that all the Archaic poets depended on the checkbooks of tyrants; on the contrary, the fragments of Alcaeus of Mytilene on Lesbos (c. 600 BC) include invective against the local tyrant Pittacus. And the poetry of his contemporary from the same island, Sappho, has no political content at all but is delicate and personal in character, concerned with themes of love and nature.

More tangible in their achievements, but less easily identified by name, are the tyrannical architects and sculptors, who imitated each other across long distances. The enormous Peisstratid temple of Olympian Zeus is thought to be a direct response to Polycrates' rebuilding of the temple of Hera at Samos, other huge efforts from the same period include a temple at Selinus in Sicily. This frenzied monumentalizing is surely competitive in character, and competition presupposes awareness. Again, Peisstratid interest in the water supply had a parallel not just in the activity of Theageness at Megara but in a great Polycratean aqueduct

at Samos, interestingly, built by a Megarian engineer. Such eastern Greek influences on thinking in the mainland imply a general Ionian intellectual primacy, which is most obvious in the sphere of speculative thinking. One 6th-century city above all, Miletus in Anatolia, produced a formidable cluster of thinkers (it is best to avoid the metaphor of a series, with its implication that intellectual progress was linear or organized). The cosmological theories of Thales, Anaximander, and Anaximenes are remarkable more for their method-a readiness to work with abstractions, such as water, or the unlimited, to which they accorded explanatory power-than for the actual solutions they reached. It is an interesting modern suggestion that all three were influenced by Persian or even ultimately Indian thought. The suggestion is especially plausible for Heraclitus (fl. 500 BC), because his native city of Ephesus, with its cult of Artemis (a goddess whose worship has features borrowed from that of her native counterpart Anahita) and its large Persian population, was alwaysdown to and including Roman times-especially open to Iranian influences.

This raises the general question of intellectual awareness of the Persian empire, which conquered the Lydian kingdom of Croesus about 546 BC and so inherited Lydian rule over the Greeks of the Asiatic coastal mainland. The poetry of another poet-philosopher, Xenophanes, from the Ionian city of Colophon, addressed itself to problems of religion and concluded that if horses had gods those gods would be horses, just as Ethiopian gods are black-skinned and Thracian gods have blue eyes. Xenophanes' awareness of the differences between cultures could plausibly be linked to the turnover of empires around him, even if there were no confirmation in the form of a poem describing a symposium at which men "sit drinking sweet wine and chewing chick-pea, and asking each other 'How old were you when the Mede came?' " (The Medes were the predecessors of the Persians, and the Greeks sometimes, as here, conflated the two.) In his "sympotic" aspectthat is, his emphasis on the symposium-Xenophanes was a child of his age; he was more unusual in his rejection, in another poem, of athletic values because of what he thought to be their coarsening effects. One way in which Persia influenced Greek thought was via individual refugees and refugee communities. Thus, Pherecydes of Syros has been seen as a theologian who emigrated from

Xenoph-

Anthropological reasons for intermarriage Anatolia to the west after Cyrus' arrival. (Whether there was a more general westward diaspora of Magi, members of the Persian religious caste, is disputable.) Whole communities left Anatolia under duress; some of them became famous in later philosophical history, such as Phocaea, which founded Elea in Italy, a place famous for philosophy, and Teos, which founded Abdera in northern Greece, the home of the 5th-century atomists Democritus and Leucippus. Finally, one must allow for a considerable Egyptian and western Semitic influence on Archaic Greek religion, political organization, and thought, though its precise extent and the means by which it was mediated await proper scientific treatment.

The greatest literary stimulus provided by neighbouring cultures like the Persian was in the field of ethnogra-phy and history. The "inquiries" (historiai) of Herodotus, from Asiatic Halicarnassus, will be discussed later, but they would not have been possible without the writings of Hecataeus, another Milesian (c. 500 BC), who treated both geography and myth in works that survive today only in fragmentary form. Hecataeus was a "logographer," a prose writer as opposed to the poets so far considered. The gradual move from verse to prose as an intellectual medium goes together with a shift from oral to written culture; but that second shift was not complete even in Athens until well into the 5th century, and there is a case for thinking that even then and in the "document-minded" 4th century "oral" and "written" attitudes coexisted.

Inquiries of Hecataeus' kind had a certain practical application: knowledge of the world, in the most literal sense of that phrase, was of obvious usefulness in a city like Miletus with its colonial connections (in the Black Sea region) and its long-distance trade. (A close connection with Sybaris in southern Italy is implied by Herodotus' story that, when Sybaris was destroyed in 510 BC, the Milesians collectively went into mourning; and Herodotus says that at the beginning of the Ionian revolt, in 500-499, Miletus was at the height of its prosperity.) When the time came to confront Persia politically, after 500, Hecataeus had the standing to suggest initiatives for shared Ionian defense. Surely this standing was conferred as much by what Hecataeus knew as by who he was. On the longer perspective, it was awareness of Persia that helped the Greeks, as it helped the Jews about the same time, to define themselves by opposition. The existence of a great and menacing culture perceived as importantly different was thus a factor in the formation of a common late Archaic Greek culture.

These political and ideological consequences of Archaic Greek thought can be seen as a kind of practical application of theory. The greatest applied scientific achievements of the Archaic period, however, were in the sphere of military technology-the trireme and the hoplite. Some Oriental influence can, it is true, be posited for each (Phoenician for the trireme, Assyrian for hoplite armour); but their refinement and effective use was Greek. The victories of the Persian Wars were won as much by the anonymous Archaic developers of the trireme and the hoplite as by the particular Greeks of 490 and 480-479.

CLASSICAL GREEK CIVILIZATION

The Persian Wars. Between 500 and 386 BC Persia was for the policy-making classes in the largest Greek states a constant preoccupation. (It is not known, however, how far down the social scale this preoccupation extended in reality.) Persia was never less than a subject for artistic and oratorical reference, and sometimes it actually determined foreign policy decisions. The situation for the far more numerous smaller states of mainland Greece was different inasmuch as a distinctive policy of their own *toward Persia or anybody else was hardly an option for most of the time. However, Eretria, by now a third-class power, had its own unsuccessful "war" with Persia in 490, and some very small cities and islands were proud to record on the "Serpent Column" (the victory dedication to Apollo at Delphi) their participation on the Greek side in the great war of 480-479. But, even at this exalted moment, choice of sides, Greek or Persian, could be seen, as it was by Herodotus, as having been determined either

by preference for local masters or by a desire to spite an equal and rival state next door. (He says this explicitly about Thessaly, which "Medized"-i.e., sided with the Persians-and its neighbour and enemy Phocis, which did not.) Nor is it obvious that for small Greek places the change to control by distant Persia would have made much day-to-day difference, judging from the experience of their kinsmen and counterparts in Anatolia or of the Jews (the other articulate Persian subject nation). Persia had no policy of dismantling the social structures of its subject communities or of driving their religions underground (though it has been held that the Persian king Xerxes tried to impose orthodoxy in a way that compelled some Magi to emigrate). Persia certainly had no motive for destroying the economies of the peoples in its empire. Naturally, it expected the ruling groups or individuals to guarantee payment of tribute and generally deferential behaviour, but then the Athenian and Spartan empires expected the same of their dependents. The Athenians, at least, were strikingly realistic and undogmatic about not demanding regimes that resembled their own democracy in more than the name.

But the experience of the Asiatic Greek cities was different again, because it was precisely here that the great confrontation between Greeks and Persians began, about 500 BC. The first phase of that confrontation was the "Ionian revolt" of the Asiatic Greeks against Persia (despite the word Ionian, other Asiatic Greeks joined in, from the Dorian cities to the south and from the so-called Aeolian cities to the north, and the Carians, not Greeks in the full sense at all, fought among the bravest). The puzzle is to explain why the revolt happened when it did, after nearly half a century of rule by the Achaemenid Persian kings (that is, since 546 when Cyrus the Great conquered them; his main successors were Cambyses [530-522], Darius I [522-486], Xerxes I [486-465], Artaxerxes I [465-424], and Darius II [423-404]). Too little is known about the details of Persian rule in Anatolia during the period 546-500 to say definitely that it was not oppressive, but, as stated above, Miletus, the centre of the revolt, was flourishing in 500.

The causes of the Ionian revolt are especially hard to determine because the revolt was a short-term failure. (Concessions were made after it, however, and its longerterm consequence, the Persian Wars proper, resulted in the establishment of a strong Athenian influence in western Anatolia alongside the Persian.) Defeats lead, especially in oral traditions, to recriminations: "Charges are brought on all sides," Herodotus says despairingly about the difficulty of finding out the truth about the crucial naval battle of Lade (495). Herodotus himself was contemptuously hostile, regarding the revolt as the "beginning of troubles". a phrase with a Homeric nuance-between Greeks and Persians. This is odd, because it is inconsistent with the whole thrust of his narrative, which regards the clash as an inevitability from a much earlier date; it is part of his general view that military monarchies like the Persian expand necessarily (hence his earlier inclusion of material about, for instance, Babylonia, Egypt, and Scythia, places previously attacked by Persia). The reasons for Herodotus' hostility have partly to do with anti-Milesian sentiment specifically in fellow-Ionian Samos, where he gathered some of his material (the Samians seem to have tried to represent the failure as due to the incompetence and ambitions of Milesian individuals), and partly with the generally Ionian character of the revolt (Herodotus' home town of Halicarnassus was partly Dorian, partly Carian). In addition, he was influenced by defeatist mainland Greek sources, particularly by Athenian informants who resented Athens' unsuccessful involvement on the rebel side. And he genuinely thought that the Persian-Greek conflict was a horrible thing, although mitigated, in his view, by the fact that Persians and Greeks, particularly Spartans, gradually came to know each other and respect each other's values. There were always Greeks who were attracted to a Persian life-style.

It should now be clear that Herodotus saw the revolt in terms of the ambitions of individuals (he singles out the Milesians Aristagoras and Histiaeus), and this must be

The Ionian

Causes of the Persian Wars part of the truth. But this must be supplemented by deeper explanations, because the rising was a very general affair.

A simple economic explanation, such as used to be fashionable, is no longer acceptable. Perhaps one should look
instead for military causes: Ionians disliked the military
service to which they were then compelled (they did not
even care much for the naval training they had to undergo,
in a better cause, before Lade). Persia not only expected
personal military service but punished attempts to evade
it, even at high social levels. Its method of organizing
defense and of raising occasional large armies (there was
no large Persian standing army) was analogous to the
method of later feudalism: "fiels" of land were granted
in exchange for political loyalty and for military service
when occasion required.

Here perhaps is a clue, which permits the resurrection of the economic explanation in another more sophisticated form. Grants of fuefs in Anatolia are well attested in the 5th and 4th centuries; in the pages of the Greek historian Xenophon (431–350) one finds the descendants of Medizing Greek families still installed on estates granted to their ancestors after 479 (and inscriptions show the same families were still there well into the Hellenistic period). Grants by Persia of good western Anatolian land to politically amenable Greeks, or to Iranians, made good political and military sense. Such gifts, however, were necessarily made at the expense of the poleis in whose territory the land so gifted had lain. In this, surely, were the makings

of a serious economic grievance. Politically, the Greeks did not like satranal control. This seems clear from the concessions made after the revolt ended in 494: the Persians Artaphernes and Mardonius granted a degree of autonomy by instituting a system of intercity arbitration; they abstained from financial reprisals and from demanding indemnities and merely exacted former levels of tribute, but after a more precise survey; and above all, Herodotus says, they "put down all the despots throughout Ionia, and in lieu of them established democracies." The meaning and even the truth of this last concession are alike disputed. Although there certainly were still tyrants in some Persian-held eastern Greek states in 480, some improvement on arbitrary one-man government is surely implied. Perhaps the answer is to be found in the formula recorded by a later literary source, the Greek historian Diodorus Siculus (fl. 1st century BC), who wrote that "they gave them back their laws." (When in 334 Alexander similarly claimed to restore to the Ionian and Aeolian cities their laws and democracies, he was largely indulging in propaganda.) Inscriptions, above all from Persian-occupied Anatolia in the 4th century, show that the cities in question held tribal meetings, enjoyed a measure of control over their own citizen intake, levied city taxes (subject to Persia's overriding tribute demands), and did indeed operate a system of intercity arbitration, How different all this was from the situation before 500 is beyond retrieval, but the continuity of civic structures and cults in eastern Greek states from the Archaic period to Classical times implies that in many respects the Persian takeover of 546 was not cataclysmic. For instance, one reads at the very end of Herodotus' history (concerning the year 479) of a temple on Asian soil to Demeter of Eleusis that had been brought over by the Ionians from Attica in the early Dark Age and was still going strong, presumably without a break. So the improvements introduced after 494 consisted in the increase, not in the outright introduction, of local self-determination within the satrapal framework.

In any case, one is left with the problem of why political unrest boiled over, if boil over it did, in precisely 500. A large part of the answer is to be found in the changes recently made at the Ionian mother city Athens by Cleisthenes. Local arrangements that may have seemed tolerable before the end of the century seemed less so in face of the new political order at Athens, an order that had moreover shown its military effectiveness. The hypothesis that the example of Cleisthenic Athens induced restlessness elsewhere is plausible not just for its kinsmen in Ionia, which can be supposed to have had good "colonial" communications with Athens, but even for the Peloponcommunications with Athens, but even for the Peloponnese, where in the first half of the 5th century Sparta had to deal with persistent disaffection (see below).

Communication between Athens and Ionia in this period is, however, first firmly attested in the other direction, not to Ionia but from it. In 499 the Milesian tyrant Aristagoras arrived in Athens and Sparta (and perhaps at other places too, such as Argos) asking for help. The Athenians agreed, while the Spartans under their king Cleomenes (who ruled from 519 to shortly before 490) did not, thus showing, as Herodotus says, that "it seems indeed to be easier to deceive a multitude than one man." This is out of line with Herodotus' otherwise favourable assessment of Cleisthenic democracy and should be put down to particular hostility to the revolt and its consequences for Athens. The Athenians sent 20 ships. This was a major undertaking. considering Athens' resources and commitments; in 489 (when Athens' fleet was surely bigger than it had been a decade earlier) Athens had only 70 ships, of which 20 were borrowed from Corinth. The reason Athens had borrowed these ships from Corinth (actually it was a sale at nominal charge) was Athens' war, or series of wars, with Aegina, which had caused it to build a fleet. Corinth and Athens. both of which had naval outlets in the Saronic Gulf, had a shared interest in containing the power of Aegina, the greatest other power in that gulf, the "star in the Dorian Sea," as Pindar was to call Aegina. The Athenian-Aeginetan struggle, which may actually have continued after the Battle of Salamis in 480, having begun well back in the late 6th century with a shadowy precursor in the mythical period, meant that the Athenian help sent to Ionia was risky and heroic.

On a longer perspective the struggle against Aegina helped to make Athens a naval power through simple peer-polity pressure. Ancient versions of the Athenian ship-building program, however, put too much onto the Aeginetan factor, usually out of malice against the great Athenian politician Themistocles and reluctance to give him credit for anticipating the eventual arrival of the Persian armada of 480. The better tradition allows Themistocles an archonship in 493, during which he started the walls of the Piraeus, turning it into a defensible harbour, and so first "dared to say that the Athenians must make the sea their domain" (as Thucydides puts it with forgivable exaggeration). The Ionian revolt had failed disastrously, Miletus having been sacked in 494, and it was clear that the Persian finger was now pointed at Athens and that Darius wanted revenge for the assistance it had sent. The result was the Marathon campaign.

Sparta did not participate in the Battle of Marathon, Spartan policy toward Persia in particular, and its foreign policy in general in the years 546-490, is at first sight indecisive. Having expelled the pro-Persian Peisistratids, Sparta not only tried to put them back a few years later but declined to help the Ionians in 499. The reason given by Cleomenes on that occasion, after a glance at the position of the Persian capital Susa on the map, was that it was outrageous to ask a Spartan army to go three months' journey from the sea. This is a colourful way of saying that it was a tall order to ask Sparta to go to the help of distant Greeks, with few of whom it had kinship ties. The Spartans who had made the original, admittedly ineffective, alliance with Croesus against the Persians had not been so timid. But that was when the Persian threat had scarcely appeared over the horizon. In 490 the reason for Spartan nonappearance at Marathon was a religious scruple: the Spartans had to wait until the Moon was full, probably because this was the sacred month of a festival, There is no good reason to doubt this, though it has been argued that there were special reasons why Sparta's leadership was halfhearted in the 490s and that it should be related to the scattered evidence for helot trouble at precisely this time.

Cleomens' own career ended in disgrace not long before Marathon. It has been suggested that he fell foul of the domestic authorities at Sparta (who always had the power to discipline the kings) because he made promises to the helots: he proposed freedom in exchange for military service. If so, this must have been late in his career; the reply to Aristagoras in 499 looks straightforward. In any case, Athenian support of Ionia the theory rests largely on the equally speculative theory that replaces the religious explanation for Spartan absence from Marathon with a political one. To say this is not to deny the permanent threat posed by the helots, still less to deny that Spartan equivocation can often be explained in terms of it

Cleamenes

Large claims have been made for the statesmanship of Cleomenes, but his vision does not seem to have gone beyond the narrow issue of "What is best for Sparta?" For instance, Cleomenes crushed the old enemy Argos, then resurgent, at the great battle of Sepeia (near Tiryns) in 494. He was too shrewd, however, to destroy it completely, realizing that dislike of Argos was one of the factors that kept Sparta's Peloponnesian allies loyal. Argos was left to the control of a group described as "slaves" (hardly literally that, perhaps really members of surrounding subject communities), which was thoroughly traditional Spartan behaviour on Cleomenes' part. He surely does not deserve to rank as a forward-looking "Panhellenist"-that is, as a supra-Spartan enemy of Persia. While it is true that he did act on one occasion against Medizers on Aegina, he did so only at the 11th hour, perhaps as late as 491. Even by the criterion of Sparta's local interests, Cleomenes, or more fairly Sparta's treatment of Cleomenes, had bad results. Cleomenes' offer of some kind of new deal to the Arcadians (better substantiated than his dealings with the helots) came to nothing with his spectacular death; he went insane (it was alleged), was imprisoned, and committed suicide. Some Arcadian states were certainly disaffected in the 470s and 460s and perhaps even anticipated 4th-century developments by forming a (numismatically attested) league of their own. It is also tempting to link the new pattern of forces in the Peloponnese, which enabled Argos to recover sufficiently to conquer Mycenae (460s) while Sparta was preoccupied elsewhere, with the activities of Cleomenes toward the end of his life and the expectations he had aroused only to disappoint. (Another plausible factor in Arcadia then, as in Ionia in 500 BC, was the unsettling effect of Cleisthenic democracy at Athens.) At least one can say that Spartan worries about Arcadia were relevant to the "Great Refusal" of leadership in 479, which made possible the Athenian empire.

Athens was not entirely alone in its fight against the Persians at the Battle of Marathon in 490 BC. Plataea fought beside Athens, true to the alliance of 519, and the Tomb of the Plataeans, excavated in 1966, probably commemorates the place where they fell. Eretria, which had also sent help to the Ionian revolt, had already been pounced on and destroyed. The reasons for the Persian choice of Marathon, as given by Herodotus, were proximity to Eretria (that is, the Persians wanted a short line of communications) and the good cavalry terrain there. He does not add, however, that a third powerful motive was political. The deposed Peisistratid tyrant Hippias, now a bitter old man, accompanied the Persian forces. (The Peisistratids came originally from eastern Attica.) Cleisthenes, in implementing his democratic reforms after the fall of the tyrants, had perhaps tried to break up old sources of political influence in this region. For instance, Rhamnus, a little to the north of Marathon and a vital coastal garrison site in Classical and Hellenistic times, seems to have been anomalously attributed to a city trittys; and an ancient local organization known as the Marathonian "Four Cities," or Tetrapolis, was broken up among more than one of the new tribes. Reasonably or unreasonably, Hippias was obviously hoping to establish a kind of political bridgehead here by appealing to old bonds of clientship.

The Athenians, however, marched out immediately under Miltiades, who had been recalled a year or two earlier from the Chersonese to help Athens meet the danger. Then, perhaps when the Persian cavalry was temporarily absent, they attacked the Persians "at a run." This last detail impressed itself on the tradition, as it undoubtedly impressed the waiting Persians, and the discovery of Persian arrowheads in the Athenian burial mound makes it possible to supply the explanation that had eluded Herodotus. The Athenian advance was evidently achieved under a hail of arrows; and the quicker the dangerous ground was covered, the better.

The Athenian victory was overwhelming; there were 6,400 Persian casualties to 192 Athenian. It was an important victory for two reasons. First, it showed what lethal damage hoplites could do to Persian forces: this encouraging message was not missed by the Spartans who arrived to view the corpses and departed with patronizing congratulations to the Athenians. Second and more important, it was a propaganda victory, celebrated in all the available media. Marathon soon became an almost mythical event. The Athenian Treasury at Delphi was built out of the spoils of the battle. An ambitious conjecture seeks to equate the 192 Marathon dead with the 192 equestrian figures on the Parthenon frieze. The horses on the frieze would be a difficulty if the idea was to recall the battle in a literal way, because the battle was definitely not a cavalry affair; but it has been ingeniously suggested that the horses were intended to suggest "heroic" status in the technical sense of "hero," or demigod. Heroic cult often involved horses (as perhaps at Lefkandi), and heroic funerals regularly included equestrian events. This interpretation, however, poses problems for two reasons: the frieze was partially destroyed in the 17th century and reconstruction depends on old drawings, and the evidence for actual heroization of the Marathonian dead is late.

Still, there is no doubting the symbolic significance of Marathon, or the way in which well after the Persian Wars the victory was exploited in epigram and painting. For instance, there was a famous rendition of the Battle of Marathon in the "Painted Colonnade" at Athens (now lost), which was perhaps commissioned by Miltiades' son Cimon. This was celebratory artistic propaganda, with a far clearer message than that of the Peisitratids. The Battle of Marathon and the Persian Wars must be recognized as an artistic watershed. There was admittedly something splendid about the gesture of sending help to the Ionian revolt, and it has been suggested accordingly that early 5th-century depictions on vases of Theseus attacking the Amazons (inhabitants of Anatolia) may be a coded allusion to Athens' Asiatic adventure of the 490s. The vindictive Athenian treatment of the playwright Phrynichus for referring in a play to the fall of Miletus shows, however, that the Ionian revolt was a dangerous subject, not lightly to be treated by pot painters. Marathon was the beginning of an epoch that lasted for centuries, during which Athens asserted its claim to uniqueness on the basis of two things: its achievements in the Persian Wars and (in and after the 4th century) its cultural primacy.

Meanwhile the Persians retreated, and Darius died, to be succeeded in 486 by Xerxes. No Greek could have doubted that Marathon, for all its symbolic importance. was not the end of the matter and that Xerxes would

return with a much larger invasion force. The internal Athenian reaction to this latest military success of the Cleisthenic democracy was to take the development of that democracy a stage further. First, a change was made in the method of appointment to the chief magistracy, the archonship. From then on the archons were appointed by lot from a preliminary elected list instead of being directly elected, as the strategoi continued to be. There were nine archons and a secretary. Three of the archons had special functions: the basileus, or "king"; the polemarchos, originally a military commander (though after the institution of the Cleisthenic strategoi, military authority passed to this new panel of 10); and the "eponymous archon," who gave his name to the year. Interpretation of the significance of the change varies according to the view taken of the importance of the archonship itself in the period 508-487; perhaps it was a young man's office and of no great consequence. The period is patchily documented, however, and in any case it would be eccentric to query the distinction of some of the names preserved. The point has a bearing on the composition and authority of the ancient Council of the Areopagus, which was recruited from former archons. The role of the Areopagus was to be much reduced in the late 460s, and if the archonship was after all not especially prestigious, then the importance of that subsequent attack on the Areopagus would be correspondingly reduced. A more substantial reason for thinking that the archonship

Appointment of archons

The Battle of Marathon The reform of 487 was probably the first time that lot or "sortition" had been used, though it is possible that Cleis-tenes, or even Solon, used it as a device for distributing posts equitably among basically elected magistrates. This would not be unthinkable in the 6th century, when the Athenian state still contained so many aristocratic features; after all, the Romans used sortition in this way, not as a consciously "democratic" procedure but as a way of resolving the competing claims of ambitious individuals.

There is a further slight uncertainty about the system of "sortition from an elected shortist." The usual and probably correct view is that this system was discarded, not long after 457, for the archonship and other offices appointed to by lot in favour of unqualified sortition. But there is enough evidence for the survival of the preliminary stage of election to have encouraged a theory that the hybrid system continued in use down to the 4th century. This, if true, would have serious implications for our picture of Athenian democracy, but the best evidence for the hybrid system is in untypically conservative contexts, such as

appointment to deme priesthoods.

A further novelty of the early 480s was the first ostracism.

This was a way of getting rid of a man for 10 years without depriving him of his property. First, a vote was taken as to whether an ostracism should be held in principle; if the voters wanted one, a second vote was taken, and, if the total number of votes now cast exceeded 6,000, the "candidate" whose name appeared on the largest number of potsherds, or ostraca, went into this special sort of exile. An obstinate tradition associates the introduction of ostracism with Cleisthenes, but this hardly matters because the evidence is explicit that no ostracism was actually held until 487. The object of this very unusual political weapon has been much discussed; whereas some ancient writers considered it as a way of preventing a revival of the Peisistratid tyranny (hardly a real threat after 490), modern scholars see it as a device for settling policy disputes-that is, as a kind of ad hominem referendum. It is possible, however, to be too rational about ostracism; of the large numbers of ostraca that survive, not all have been completely published, but one can see that their content is sometimes abusive and sometimes obscene. One accuses Cimon of incest with his sister, another says that Pericles' father Xanthippus "does most wrong of all the polluted leaders." The idea of the politician-leader as polluting scapegoat is a recurrent one in Greek political invective, and it is perhaps in terms of invective, or the need for a religious safety valve, that ostracism can best he understood

Evidently, the Athenian demos was growing more bold. as the Constitution of Athens puts it. This was equally true in foreign affairs. The year after Marathon, Miltiades made an attack on the Aegean island of Paros, which anticipates the more systematic imperialism of the period after 479. And it is possible that the Athenian duel with Aegina continued into the 480s. But the event with the greatest implications for foreign policy was a sudden large increase in the output of the Laurium silver mines (actually in a region called Maronea). The evidence gives the crucial year as 483, but it is not known whether there was really a dramatic lucky strike just before that or whether this was merely the year when Athens decided how to spend the accumulated yield of several good years. One source does speak of "discovery" of mines, but the mining area had been worked since Mycenaean times, and the mines were certainly operational under the Peisistratids. It was decided to spend the windfall on building more triremes, bringing the total to 200 by 480, from the 70 attested for Miltiades' Parian expedition of 489. The precise method somehow involved the advancing of money to individuals, an interesting partial anticipation of the Classical system of "trierarchies." Trierarchs, who are not specifically attested before the middle of the century, were wealthy individuals who, as a kind of prestige-conferring tax payment, paid for the equipping of a trireme (the state

provided the hull). The source of the timber for this huge program is not known; perhaps local Attic or Euboean supplies supplemented Italian timber. Themistocles, who is credited with the essential decision to spend the money on ships rather than on a distribution among the citizens, had western interests that make the Italian hypothesis plausible. If this is right, the feat of transportation should be admired almost as much as the crash building program itself. One consequence of the rapidity of the program was that much of the timber must have been unseasoned; this is relevant to the Greek decision at the Battle of Salamis (480) to fight in narrow waters, where the resulting loss of speed (green timber makes ships heavier and slower) would matter less.

It was in Athens, then, that the most energetic action was taken. Xerxes had not lost sight of the old revenge motive, a motive that ought to have meant that Athens was the main or only target, but his aim this time wasas Herodotus correctly says-to turn Greece as a whole into another Persian province or satrapy. This called for a concerted Greek plan, and in 481 the key decisions were taken by a general Greek league formed against Persia. Quarrels like that between Athens and Aegina had to be set aside and help sought from distant or colonial Greeks such as the Cretans, Syracusans, and Corcyrans, whose extraordinarily large fleet of 60 ships (possibly developed against Adriatic piracy but also-surely-against Corinth) would be a prime asset. Corcyra, however, waited on events, and Crete stayed out altogether, while Syracuse and Sicily generally had barbarian enemies of their own to cope with, the Carthaginians. (Syracuse and other parts of Sicily were now under the tyranny of Gelon.) Greek writers found the parallel between the simultaneous threats to eastern and western Hellenism irresistible and represented Carthage as another Persia. It has, however, been suggested that the imperialistic ambitions of Carthage have been generally exaggerated by Greek writers eager to flatter their patrons, such as Gelon. The reality of the Battle of Himera, however, in which Gelon decisively defeated the Carthaginians, is not in doubt; like the Battle of Salamis, it was fought in 480, allegedly on the same day. Gelon did indeed have his own preoccupations. The Greeks may not have been altogether sorry: the tyrant Gelon would have been an ideologically awkward ally in a struggle for Greek freedom from arbitrary one-man rule.

Even without western Greek help, the Greek fleet numbered about 350 vssesls, amounting perhaps to a third of the Persian fleet. The size of the Persian land army is reckoned in millions by Herodotus, and all modern scholars can do is replace his guess by far lower ones.

Greek unity, though impressive, was not complete; conspicuous among the "Medizers" was Thebes, while Argos' neutrality amounted, in Herodotus' view, to Medism.

An inscription found in 1959, the so-called "Decree of Themistocles," purports to contain further detailed decisions made about this time regarding the evacuation of Attica and the mobilization of the fleet. But the writing is of the 4th century, and the whole text is probably not a re-inscribing of a genuine document but a patriotic concotton of the age in which it was written and erected.

An initial plan to defend Thessaly was soon abandoned as unrealistic. Instead the Greeks fell back on a zone at the northeastern end of Euboea, where they hoped to defend Thermopylae by land and Artemisium by sea. Herodotus, who is often accused of failing to realize the interconnectedness of these two holding operations, did in fact stress that the two were close enough for each set of defenders to know what was happening to the other.

The Spartans had sent their king Leonidas to Thermopylae with a force of 4,000 Peloponnesians, including 300 full Spartan citizens and perhaps a helot contingent as well. They were joined by some central Greeks, including Bocotians from Thespiae and Thebes. The pass at Thermopylae could not be held indefinitely, as Leonidas surely knew, but he also knew that an oracle had said that Sparta would be devastated unless one of its kings was killed. Loonidas' exact "strategy" has been debated as if it were a puzzle, but perhaps one should not go beyond the oracle. The king must die. Gelon and Carthage

Ostracism

Leonidas died, with his 300 Spartans (and the helots, Thespians, and Thebans, as should be remembered to the honour of all three). The other groups, Peloponnesians and central Greeks, were all dismissed. The naval action at Artemisium was inconclusive, the real damage to the Persian ships being done by a storm as they rounded Euboea. Whether or not the Decree of Themistocles is genuine. it is a fact that Attica was evacuated and the Athenian Acropolis sacked by the Persians. This sacrifice of their city, like the victory of Marathon, is one of the cardinal elements in Athenian celebration of the Persian Wars. The Persians destroyed the temples on the Acropolis and carried off the statues of Harmodius and Aristogiton, the two men who had assassinated the tyrant Hippias' brother Hipparchus in 514. The symbolic importance to Athens of what happened on the Acropolis in 480 is illustrated by the subsequent history of those statues: they were returned to Athens by Alexander the Great a century and a half later as part of his propaganda claim to be punishing the

The Battle

of Salamis

Persians for their 5th-century impiety, The Persians entered the narrows of Salamis, where Themistocles had insisted the Greeks should be stationed. and they were comprehensively defeated under the appalled eyes of Xerxes himself. This defeat is a "David and Goliath" encounter only in the general sense that the Persian empire was vastly greater, in size and resources, than the realm of its Greek opponents. It is said that the Greek ships were actually heavier and less easy to maneuver than those of their opponents. Yet this Persian advantage, and that conferred by the greater experience of the Phoenician sailors on the Persian side, were canceled out by the Greek advantages of position: a fight in the narrows would enable them to board and fight hand to hand. No doubt there was also a propaganda aspect. Themistocles had inscribed on the rocks of Euboea messages imploring the Ionians on the Persian side not to help in enslaving their Ionian kin. This looks forward to Athens' political exploitation, in the very near future, of its original role as Ionian mother city. For the moment it surely helped sap morale in the Persian fleet. Sound strategy might have dictated a Persian withdrawal, or an attempt to bypass Salamis and press on to the Isthmus of Corinth, before the battle had even begun. but the prestige of the Persian king was visibly at stake.

Xerxes returned home, but the Persian general Mardonius remained for a final encounter with the Greeks at Plataea. The Spartans under Pausanias, regent for the underage Spartan king, advanced from the Peloponnese via the Isthmus and Eleusis; there had once been a question of making a stand at the Isthmus for the defense of the Peloponnese, but Salamis had made that unnecessary. Again the Persians were defeated, but this time the battle was primarily won, as Aeschylus was to put it in his play Persians, "under the Dorian spear"-that is, under the leadership of hoplite Sparta. (The army, however, was a truly Pan-Greek one and included a large infantry force of Athenians.) As much glory was to attach to Plataea itself as to Sparta. A Hellenistic geographer said with some impatience of the Plataeans that they had nothing to say for themselves except that they were colonists of the Athenians (strictly false, but an illuminating exaggeration) and that the Persians were defeated on Plataean soil. A great commemorative festival was still celebrated at Plataea in Hellenistic and Roman times; a 3rd-century inscription discovered in 1971 mentions "the sacrifice in honour of Zeus the Liberator and the contest which the Greeks celebrate on the tombs of the heroes who fought against the barbarians for the liberty of the Greeks." After the residue of the Persian fleet had been defeated at Mycale, on the eastern side of the Aegean, the Greeks were saved-for the moment. The Persians had, after all, returned to Greece after the small-scale humiliation of Marathon in 490; thus there could be no immediate certainty that they would abandon their plans to conquer Greece after the far greater humiliations of 480 and 479. A leader was required in case the Persians returned.

The Athenian empire. The eastern Greeks of the islands and mainland felt themselves particularly vulnerable and appealed to the natural leader, Sparta. The Spartans' proposed solution was an unacceptable plan to evacuate Ionia and resettle its Greek inhabitants elsewhere; this would have been a remarkable usurpation of Athens' colonial or pseudocolonial role as well as a traumatic upheaval for the victims. Samos, Chios, Lesbos, and other islanders were received into the Greek alliance. The status of the mainlanders was temporarily left in suspense, though not for long: in early 478 Athens on its own account captured Sestus, still under precarious Persian control hitherto. In this it was assisted by "allies from Ionia and the Hellespont"-that is to say, including mainlanders. The authority for this statement, which should not be doubted, is Thucydides, the main guide for most of the next 70 years.

The capture of Sestus was one manifestation of Athenian independence from Spartan leadership, which had gone unquestioned by Athens in the Persian Wars of 480-479, except for one or two uneasy moments when it had seemed that Sparta was reluctant to go north of the Isthmus. Another manifestation was the energetic building in the early 470s of a proper set of walls for the city of Athens, an episode elaborately described by Thucydides to demonstrate the guile of Themistocles, who deceived the Spartans over the affair. Whether the walls were entirely new or a replacement for an Archaic circuit is disputed: Thucydides implies that there was a pre-existing circuit. but no trace of this has been established archaeologically. The Themistoclean circuit, on the other hand, does survive, although the solidity of the socle does not quite bear out Thucydides' dramatic picture of an impromptu "all hands to the pump" operation carried out with unprofessional materials. Sparta's reluctance to see Athens fortified and its anger-concealed but real-after the irreversible event show that even then, despite its cautious attitude to the mainland Ionians, Sparta was not happy to see Athens take over completely its own dominant military role. Or rather, some Spartans were unhappy, for it is a feature of this period that Sparta wobbled between isolationism and imperialism, if that is the right word for a goal pursued with such intermittent energy. This wobbling is best explained in factional terms, the details of which elude the 20th century as they did Thucydides. Thucydides disconcertingly juxtaposes the wall-building episode, with its clear implication of Spartan aggressiveness, with the bland statement that the Spartans were glad to be rid of the Persian war and considered the Athenians up to the job of leadership and well-disposed toward themselves. In fact, there is evidence in other literary sources for the first and more outward-looking policy, such as a report of an internal debate at Sparta about the general question of hegemony, as well as particular acts such as a Spartan attempt to expel Medizers from the Delphic amphictyonyi.e., pack it with its own supporters.

One easily identifiable factor in the formation of Spartan policy is a personal one: the ambitions of Pausanias, a young man flushed from his success at Plataea. Pausanias was one of those Spartans who wanted to see the impetus of the Persian Wars maintained; he conquered much of Cyprus (a temporary conquest) and laid siege to Byzantium. But his arrogance angered the other Greeks, "not least," Thucydides says, "the Ionians and the newly liberated populations." These now approached Athens in virtue of kinship, asking it to lead them. This was a crucial moment in 5th-century history; the immediate effect was to force the Spartans to recall Pausanias and put him on trial. He was charged with "Medism," and, though acquitted for the moment, he was replaced by Dorcis. Yet Dorcis and others like him lacked Pausanias' charisma, and Sparta sent out two more commanders. Pausanias went out again to Byzantium "in a private capacity," setting himself up as a tyrant to intrigue with Persia, but he was again recalled and starved to death after having taken sanctuary in the temple of Athena of the Brazen House in Sparta. (The end may not have come until late in the 470s.) The charge was again Medism, and there was some truth to this because the rewards given by Persia to Gongylus of Eretria, one of his collaborators, can be shown to have been historical. There was also a suspicion that Pausanias was organizing a rising of the helots, "and it was true," Thucydides says.

Despite its successes in 479, Sparta, then, was as much a

Emerging Athenian dence

prisoner of the helot problem as ever, and it could not rely on the loyalty of Arcadia or the Peloponnese generally: Mantinea and Elis had sent their contingents to the Battle of Plataea suspiciously late.

The Delian League

The most important consequence of the successful Greek appeal to Athens was the beginning of the Athenian empire, or Delian League (a modern expression). The appeal to Ionian kinship set the tone for the organization and for much of its subsequent history, though one can fairly complain that this does not emerge strongly enough from Thucydides, who always tends to underreport the religious or sentimental factor in Greek politics.

The Athenians first settled which allies should pay tribute in the form of money and which should provide ships; the details of this assessment were entrusted to the Athenian statesman and general Aristides. Tribute, the need for which was assumed rather than explained, was to be stored at Delos, which would also be the site of league meetings, or synods. Thucydides does not add that the choice of Delos, with its associations with Ionian Apollo, was essentially religious in motivation. Nor does he bring out more than the mercenary or revenge motive of the league (to get redress by devastating the king of Persia's territory). In fact, the mood at the league's founding was positive and solemn, with oaths and ceremonies cementing the act of liberation (478-477). It is unlikely that there was much "small print" to which allies had to subscribe. League meetings were to be held, almost certainly, in a single-chamber organization, in which Athens had only a single vote, though a weighty one; there were perhaps undertakings, subsumed in the general oath taking, about not deserting or refusing military contributions. Unfortunately there are no inscribed stelae, or pillars, as there are for the Second Athenian Confederacy a century later, recording precise pledges by Athens or (equally valuable) listing the members in the order of their enrollment. Apart from the big Ionian islands and some mainlanders, there were in fact Dorian members like Rhodes and Aeolians like Lesbos; there even were some non-Greeks on Cyprus, always a place with a large Semitic component, (Some Cypriot communities probably joined at the outset.) Some Thracian cities were surely enrolled very early. There was no doctrinaire insistence that the league should be exclusively maritime, though the facts of geography gave it this general character automatically. For instance, by midcentury it seems that (in the period of Athens' decade of control of Boeotia, 457-446) the land-locked cities of Orchomenus and Akraiphia were in some sense members. Nor was the league necessarily confined to the Aegean: in 413, financial contributions from Rhegium in the south of Italy, among other places, were handled by the imperial "Treasurers of the Greeks," No inscribed records of tribute exist before 454 BC; after that point, one has the intermittent assistance of the "Athenian Tribute Lists," actually the record of the one-sixtieth fraction paid to the goddess Athena. It should be stressed that until roughly the late 450s there are virtually no imperial inscriptions at all.

Such lack of evidence makes it difficult to show in detail the increasing oppressiveness of the Athenian empire in the second half of its existence (450-404), particularly in the 420s when policy was affected by demagogues like the notorious Cleon. There is simply too little comparative material from the first three decades, and, in the absence of documentary material and of detailed information like that provided by Thucydides for the Peloponnesian War of 431-404, one must infer what happened from the very sparse literary account Thucydides gives for the years 479-439 and from supplementary details provided by later writers. Although it is right to protest, against facile talk of the harsh imperialism of Cleon, that imperialism is never soft, an important but sometimes overlooked chapter of Thucydides is nonetheless explicit that Athens suffered a loss of goodwill through its excessive rigour.

By the middle of the 470s, Greek unity had not come too obviously apart, though the reluctant withdrawal of Sparta was ominous. Even so, at the Olympic Games of 476, an unusually political celebration (the first after the last of the Persian Wars and held in the honoured presence of the Athenian Themistocles), there were still victorious

competitors from Sparta, as well as from other Dorian states such as Argos and Aegina and from Italy and Sicily. Athens' capture of Eion on the Strymon, also in 476.

was perfectly in keeping with the ostensibly Panhellenic or anti-Persian program of the Delian League: Eion, an economically and strategically important site in northern Greece, was still held by a Persian commander. This, the first act of the league recorded by Thucydides, was undertaken by Cimon, the son of Militades.

Mounting Athenian aggression

The next act of Cimon and the Athenians, the attack on the island of Scyros, was considerably more dubious. Cimon expelled the "Dolopians" (i.e., the indigenous inhabitants) allegedly because they were pirates. Protection against piracy was surely as real a justification for the Delian League as protection against Persia and more general in its application (vulnerability to Persia was very much a matter of geographic position). That Athens was effective in this respect is suggested by the rash of evidence for recrudescent piracy in the early 4th century, when Athens no longer had the power to police the seas. Nonetheless, the treatment of these Dolopians, who were hardly a serious threat to peaceful commerce, certainly appears to have been an act of mere muscle flexing. The enterprise had a propagandist point as well: Cimon brought back the bones of Theseus from the island to Athens, where they were housed in a shrine built for them, somewhere in or near the Agora-perhaps to the east of it. (The site has not been discovered; the so-called "Theseum" is generally agreed to be a temple to Hephaestus.) This magnificent piece of theatre must have been in imitation of the Spartan treatment of the bones of Orestes: this is not surprising, because Cimon was perhaps the first identifiable "Laconizer," or admirer of Spartan values, in Athenian history. Theseus had a special significance not only for Cimon but for the Athenian empire in general. It was Theseus who, according to the myth, had founded the great Ionian festival at Delos called the Delia, which Athens was to revive with much pomp in 426.

More aggression followed, unequivocally directed against other Greeks: Carystus, at the southeastern end of Euboea, was forced to join the league. This was a steppingup of an Athenian involvement in Euboea that goes back to the 6th century, when Athens installed a cleruchy on Chalcis soon after the Cleisthenic reforms. In the middle of the century inscriptions show that wealthy Athenians possessed land on the Lelantine Plain, Such ownership by individual wealthy Athenians of land in the subject cities of the empire is a telling phenomenon, because the land was usually acquired in defiance of local rules: landowning was normally restricted to nationals of the state in which the land was situated. For Athenians to acquire such land, otherwise than by inheritance as a result of marriage to a non-Athenian, was an abuse, and inheritance of this kind was much less likely after a law of 451 restricting Athenian citizenship to persons of citizen descent on both sides. After 451 "mixed marriages" must have been far less common.

A still more sinister move was the reduction of Naxos, probably in the early 460s. Thucyclides equates the in-habitants' loss of freedom with "enslavement"—a strong metaphor. (The precise chronology of the whole period 479–439, and particularly the first 30 years, is uncertain, because Thucyclides gives no absolute dates and there are none from other sources before the events in the northern Aegean of 465. The chronology followed here is the orthodox one, but some scholars seek to down-date the attacks on Eion and Scyros to 469—leaving the 470s implausibly empty of known imperial action—and Naxos later still.)

The anti-Persian aspect of the league had not, however, been forgotten, in spite of all this activity against Greeks. In 467 Cimon won the great Battle of the Eurymedon River in Pamphylia (southern Anatolia), a naval victory that made a great impression both in Greece (where it was celebrated by the dedication of a bronze date palm, or phoinix, at Delphi: a punning reference to the defeated Phoenician fleet) and among waverers, outside Greece proper, who had not yet joined the league. Many new alies were now recruited, such as the trading city of Phaselis on the Lycian-Pamphylian border. A rare early imperial

The Battle of the Eurymedon River inscription of the late 460s details the judicial privileges accorded to Phaselis

Greek success in the east was followed by some mixed achievement under Cimon in the north. A quarrel arose in 465 with the wealthy and fertile northern Aegean island of Thasos about the island's trading stations and mines along the mainland area just opposite it, and Thasos revolted. The word "quarrel" is obviously a euphemism for a piece of naked economic aggression by Athens; all ancient states wished to get their hands on as much precious metal for coinage as possible. Thasos was reduced and forced to give up all of its mines and mainland possessions. A further attempt at this time to extend Athenian northern interest, the colonizing expedition sent to the Nine Ways. the site of the later Amphipolis, was less successful. If silver was one coveted commodity, ship-building timber was another, and the desire for the latter was a large part of Athens' motive for getting a foothold in the Amphipolis region. The Nine Ways operation is a reminder that colonizing activity did not cease with the end of the Archaic period: 10,000 settlers were sent. But the entire force was destroyed at Drabescus. This was probably the occasion for instituting state burial for war dead, a democratic measure that anticipated the reforms at the end of the 460s.

Thasos signaled changes in foreign policy alignments all over Greece. The Thasians had appealed to Sparta for help, asking it to invade Attica, and the Spartans secretly agreed to do so. According to Thucydides, they would have done it had they not been detained by a massive revolt of the helots, who had taken advantage of an earthquake to occupy the strong position of Ithome in Messenia, Ithome. together with the Acrocorinth, the citadel of Corinth, was described by a Hellenistic ruler as one of the "horns of the Peloponnesian ox" that a would-be conqueror had to seize. It is indeed possible that the occupiers of Ithome planned not only an act of secession but, in fact, an attack on the famously unravaged city of Sparta itself. The earthquake not only shook Spartan nerve but must also have had serious demographic effects, though how longterm these were is disputed.

The Spartan response to Thasos looked forward in its anti-Athenian aspect to the great Peloponnesian War of 431-404. It was one of three major episodes in the period up to that war when Sparta moved against Athens. The second was an aborted invasion of Athens under King Pleistoanax in 446. The third episode, in 440, revolved again around the issue of whether to intervene to prevent Athens disciplining a recalcitrant ally, this time Samos. The actual confrontation between Sparta and Athens did not happen in any of these cases. Among the reasons for this-apart from the helot revolt that took a decade for Sparta to put down-was the growing anti-Spartan restlessness in Arcadia. The Athenian Themistocles, who had fallen from favour at Athens and spent time in the Peloponnese after his ostracism (perhaps 471), might have been behind this, though attempts to associate him with particular "synoecizing" developments in the Arcadian cities (i.e., developments whereby small communities coalesced into a single city) are speculative. Nor need such synoecizing (if it happened at this time) necessarily have been democratic and thus evidence that the communities in question were following the Athenian model rather than the Spartan oligarchic one. The evidence of Athenian tragedy (the Suppliants of Aeschylus) cannot be pressed to yield secure allusions to Themistocles. Another reason was the continued revival of Argos; its population had now recovered from the defeat at Sepeia (494), and the temporarily exiled descendants of the casualties of Sepeia, the "sons of the slain" as Herodotus calls them, a naturally anti-Spartan group, were now back in control (after ousting the slaves). Argos is on record as fighting a battle in perhaps the 470s, together with Arcadian Tegea, against Sparta, which also had to cope with "all the Arcadians except the Mantineans" at a strictly undatable battle of Dipaieis (which, however, should be put earlier than the Ithome revolt).

The "secret" promise to Thasos was followed by a more open rebuff to Athens. Sparta had invited the Athenians to help with the siege of the helots on Ithome, but with its usual catastrophic indecision Sparta then dismissed the Athenian contingent on suspicion of "revolutionary tendencies." Athens reacted by allying itself with Argos and Thessalv, which was a blow to Spartan ambitions both in its obvious stronghold, the Peloponnese and in central Greece, an area into which one group of Spartans always seems to have wanted to expand.

This phase of foreign policy has to be somehow associated with internal change at Athens, the so-called Enhialtic reforms. In 462, together with the young Pericles, the reforms of Athenian statesman Ephialtes pushed through the decisive phase of the reforms, namely an assault on the powers of the Areopagus. These powers, except for a residual jurisdiction over homicide and some religious offenses, and perhaps a formal "guardianship of the laws," were redistributed among the Council of Five Hundred and the popular law courts. This is, in essence, the very bald and unhelpful account of our main source, the Constitution of Althens; there must have been more to it, but the problem is to know how much more. Probably the Areopagus ceased to hear crimes against the state, and such cases were transferred to the popular courts. Alternative interpretations of the inadequate evidence, however, are possible: there are a handful of recorded treason trials earlier than 462 in which a popular element does admittedly play a prominent part, and, although these can be explained away in various ways, it can be held that the transfer of jurisdictional power to the people occurred earlier than 462. Alternatively, it is possible that Ephialtes' reforms in this area involved a mere transfer of "first-instance" jurisdiction (i.e., jurisdiction over cases other than those on appeal) from the Areopagus to the Council of Five Hundred. This requires the assumption of an unattested early 5th-century reform transferring capital appeals to the

More radically, and generally, the jurisdiction of magistrates (archons) was much curtailed; they now conducted a mere preliminary hearing, and the main case went to a large popular jury. The authority to conduct inquiries into the qualifications for office of the archons themselves (the dokimasia procedure) and into their behaviour after their terms of office had expired (euthyna procedure) was also taken away from the Areopagus and given to the Council of Five Hundred. This principle of popular accountability seems new, though the statement in Aristotle's Politics, that the right of popular euthyna goes back in some sense to Solon, has its defenders.

There surely were other reforms. Certain features of the later democracy appeared after the rule of Cleisthenes but were in place by the Peloponnesian War; it is plausible to argue that they were introduced at this time, though there is a risk of circularity in characterizing Ephialtes as a comprehensive reformer by reference to strictly unattributed and undated changes. Thus, sortition for the Council of Five Hundred is not likely to have been earlier than 487, when the archonship ceased to be elective; but Athens imposed sortition for a comparable though smaller council on Ionian Erythrae in 453, surely not before there was sortition for the Council at Athens itself. Similarly, there is evidence for jury pay for the 460s (or less probably for the 450s), which makes it plausible to date Council pay, attested by 411, to the mid-century period also.

Taken together these reforms look like the result of careful thinking by particular individuals with a definite democratic philosophy. A case, however, can be made for seeing them all as part of a 30-year process, with a central action-filled phase, rather than as a single event. After all, the Areopagus was affected indirectly by the changes in the archonship in 487, though the archonship was formally opened to the zeugitai (the hoplite class) only in 457. But despite the great increase in work for the big popular juries and the granting to the courts of the right (which may go back to Ephialtes) to quash or uphold allegedly unconstitutional proposals, it is not likely that then or at any other time Athenians saw themselves as conferring sovereignty on the people's courts at the expense of the Assembly. The implied psychological distinction between juries of Athenians and political gatherings of the same Athenians is not a plausible one.

Ephialtes

Some of these changes were perhaps already in the air when the Spartans dismissed Cimon and his Athenians at Ithome, Cimon's absence seems to have given Ephialtes and Pericles their chance: the main Areopagus reform was passed at this time, and in 461 Cimon was ostracized. This rejection of Cimon, however, was a personal matter: he should not be seen as a "conservative" opponent of a reform that gave more power to the people and especially to the thetic class, which manned the fleet. For one thing, Cimon's victory at the Battle of the Eurymedon River was primarily a naval victory; for another, it was the Spartaloving Cimon and his hoplites who were dismissed by the Spartans from Ithome for their subversive tendencies. Most important of all, there is the general point that the interests of hoplites and thētes, now as at other normal times, coincided; both were denied the chance of standing for the archonship before 457 (the hoplites were admitted to it in that year). On the whole, it is the top two "Solonian" groups, the pentakosiomedimnoi and the cavalry class who were bracketed together on the one hand (as by Thucydides in one military context), while the zeugitai and thetes tended to be bracketed together on the other. No built-in class cleavage existed between the hoplite or zeugite class and the thētes, and attempts to exploit one, by advocating or offering a "hoplite franchise," were shortlived failures. Cimon then should not be seen as champion of "conservative" hoplites against "radical" thetes; this view is wrong because the interests of hoplites and thētes were indissolubly linked.

Athens' two new alliances, with Argos and Thessaly, were provocative (surely not just defensive), but they did not create direct danger of war. Far more serious was the friction at this time between Athens and Corinth, Corinth had made no move to help Sparta, as far as is known, at the time of the Ithome disaster but seems to have pursued expansionist goals of its own in the Peloponnese, perhaps at Argos' expense. Now that Athens and Argos were allied, this indirectly tended to damage Corinth's hitherto good relations with Athens. (Corinth had fought well at Salamis, as even Herodotus was aware, though very different stories were circulating on this topic after 460.) More relevant than this was Athens' ready reception of a third ally, Megara; like the Argives, the Megarians had also felt pressure from Corinth (one hears of a boundary dispute and a local war) and turned to Athens. This was the cause and beginning of the "violent hatred" between Corinth and Athens, which produced what modern scholars call the First Peloponnesian War,

The First Peloponnesian War (460-446) should probably be seen as essentially a conflict between Athens and Corinth, with occasional interventions by Sparta. Modern disagreement centres on the reasons why Sparta did not play a role: one line of explanation is purely military, invoking the difficulty of invading Attica while the mountains above Megara were policed by Athens; the other and more plausible view is that Sparta simply lacked the will to act consistently. Spartan inactivity should in any case not be exaggerated. There is a pattern to its interventions, which suggests that in this period, as at others, the "central Greek" lobby at Sparta, the closest thing to an identifiably imperialistic group to be found there, could sometimes prevail.

The first battle of the war, at Halieis in the Gulf of Argolis, was a Corinthian victory, but the next battle, at Cecryphalea (modern Angistrion), went Athens' way (459). Aegina, which was attacked and besieged in the same year, was reduced in the following year and forced to pay tribute, though some vague undertaking about autonomy may have been made; the alternative is to suppose a special clause about Aeginetan autonomy, or even a general autonomy clause, in the peace of 446, which ended the war. The alleged Athenian infringement of the autonomy of Aegina was one of the secondary causes of the main Peloponnesian War. In the meantime, the subjugation of Aegina, a great city of the Archaic age, whose proud Dorianism and traditions of seafaring and hospitality are stressed in lines of great beauty by Pindar in his Nemean Odes and elsewhere, was an event of cardinal importance. The pretense that Athens was merely leading a voluntary

association of willing Ionian cities in need of protection could hardly survive the reduction of Aegina.

The real scale of Athenian ambitions is shown by four other developments of this period. First, Athens undertook a great and disastrous expedition to Egypt (460-454), in ostensible continuance of the fight against Persia, Egypt, however, had always been a rich and desirable Persian satrapy, exploited by absentee Persian landowners; and thus an economic motive for Athens cannot be excluded. Second, Athens made an alliance (almost certainly in 457) with an inland half-Greek Sicilian city, Segesta, This prepared the ground for a more tangible western policy in the 440s. Third. Athens now built the Long Walls connecting it to Piraeus and thus the sea and making it possible to depend for the future on the produce of its empire if absolutely necessary. The walls, however, should not be thought of as purely defensive in view of the constant connection made by Thucydides between walls and dynamic sea power. Fourth, Athens made an alliance (the inscription is strictly undatable) with the Delphic Amphictyony in the middle of the century. This must be connected with the Athenian alliance made with Thessaly (see above) in 461, because Thessaly controlled a majority of Amphictyonic votes (always a reason why other states or rulers. like Philip of Macedon in the next century, were anxious to have a controlling interest in Thessaly). It is interesting that Athens should thus extend its religious propaganda to include the sanctuary of Apollo of Delphi (Apollo Pythios) as well as that of Apollo of Delos. The oracle was always a distinct entity from the sanctuary, but it cannot be accidental that about now the oracle, normally favourable to Sparta in this period and conspicuously so in 431, declared Athens an "eagle in the clouds for all time."

The central Greek line of Athenian expansion was bound to bring a collision with Sparta. It entered the war in 458 in response to an appeal by its "mother city" Doris, the city from which the primeval Dorians were believed to have set out to undertake the invasion of the Peloponnese. This tiny state in central Greece was currently experiencing difficulties with its neighbour Phocis. The religious and sentimental factor in Sparta's response was not negligible, but Sparta may have had other aims as well. There is evidence in Diodorus Siculus, a Greek historian of the 1st century BC, though not in Thucydides, that Boeotia was a target.

It was on their return from Doris that the Spartans finally came to blows with Athens at Tanagra in Boeotia (458). The battle was of large scale—one hears of Argive involvement on the Athenian side—but indecisive. The Athenians, however, followed it up with a victory at Oenophyta, which gave them control of Boeotia for a decade, an extremely important development passed over by Thucydides in half a dozen words. There was further aggressive Athenian action, first under the general Tolmides, who circumnavigated the Peloponnese (456) and perhaps settled the large number of Messenians at Naupactus alongside the original Naupactans, and second, under Pericles. who launched military expeditions in the Gulf of Corinth (454?). But the disastrous end to the adventure in Egypt (454) made Athens ready for a truce, and in 451 Athens came to terms with Sparta, while Argos concluded a 30years' peace with Sparta on its own account.

Athens resumed the war against Persia with hostilities on Cyprus, but Cimon's death there made diplomacy imperative in this sphere also. This is where one should place the Peace of Callias (449), mentioned by Diodorus but one of Thucydides' most famous omissions. Thucydides' subsequent narrative of the Peloponnesian War, however, presupposes it at a number of points, especially in the context of Greek dealings with Persia in 411. More generally, a peace is made likely by the history of the 440s and 430s, which records no more overt Athenian warfare against Persia and a certain restlessness inside the Athenian empire. (This absence of warfare may be due to other factors as well; it is possible that the Treasury of the League, to which various states in the Delian League paid tribute, was moved from Delos to Athens in 454, a centralizing gesture that may have caused alarm. But the move may have happened earlier.)

Athenian expansion

the First Peloponnesian War

Causes of

Peace of Callias

Nonliterary evidence also points in the direction of a peace: the evidence of inscriptions makes it probable that no tribute was levied in 448. Perhaps it was recognized that the struggle with Persia was over and with it the iustification for tribute; if so, the recognition was only momentary, because there was tribute again in 447, Furthermore, an inscription of the 420s appears to refer to a renewal of the peace on the death of Artaxerxes I. Finally, the commissioning of a new Temple of Athena Nike ("Victory"), and perhaps even of the Parthenon, may have been an aspect of the same mood. (The peace could be represented as a victory of a sort because it restricted the Persian king's naval movements.) Yet the close correlation of architectural with political history is to be avoided; antibarbarian artistic themes on Greek public buildings need no special explanation at any time in the 5th century. Against all this there are a few ancient allegations that the peace was a later forgery, an implausible idea because such diplomacy was a matter of public knowledge.

Despite the truce with Athens in 451, Sparta had not withdrawn into its Peloponnesian shell completely. In addition to its campaign in support of Doris, Sparta successfully intervened in central Greece in a "Second Sacred War" against Phocis, which, with the assistance of Athens, had gained control of Delphi. Sparta handed over Delphi to the Delphians, but this action was promptly neutralized by the Athenians, who restored the sanctuary to Phocis. Catastrophic revolts in Boeotia and Euboea (446), however, soon eroded that Athenian authority in central Greece of which the Delphic intervention was a manifestation

The tributary states had much cause to rebel. There was something ominous about the sheer physical scale of the first (in chronological order) of the stone blocks on which were carved, as a permanent record, the tribute payments due to Athena. The block, preserved in the Epigraphic Museum in Athens, is a towering 142 inches (3.61 metres) high and had plenty of room for many years of tribute. Evidently the Athenians of 454 expected the empire to go on indefinitely, despite the failure in Egypt, which must have made many observers reflect that peace with Persia could not be far away. Yet tribute, exactingly collected, as Thucydides says, was not the only grievance. It was not even the only economic grievance. In the period of the early Peloponnesian War there were, as inscriptions show, strict Athenian controls on the traffic of grain from the Black Sea, including "Guardians of the Hellespont." According to one view, these controls were a purely wartime expedient, but, given the state of the evidence, that charitable view is an abuse of the argument from silence; in any case, a prewar inscription does in fact attest a 10 percent tax on shipping from the Black Sea. Grain bound for Athens itself was probably exempt from this. Still in the economic sphere, resentment against Athenian ownership of land-whether collectively (the so-called cleruchy system, stepped up at the end of the 450s) or privately, by wealthy individuals-can legitimately be inferred from the self-denying promises made by Athens in the days of its 4th-century confederacy. In this category should be included sacred precincts (temenē) in allied states, marked out by horoi, or boundary stones, which indicated land that might be leased out to other wealthy Athenians.

Another interference in the internal affairs of tributepaying allies in the 4th century was the placement of garrisons and garrison commanders, attested as early as the Erythrae decree of 453. The same decree imposed a "democratic" constitution, according to a principle that the literary sources say was general Athenian policy. Yet it would be simplistic to think that such Athenian-influenced constitutions were necessarily a significant upholding of human rights. One must always ask what "democracy can have meant in a small community. At Erythrae, not only was the council less democratic than that at Athens (see above), but there also was a property qualification for jurors. And at exceedingly few places other than Athens does inscriptional evidence for amendments from the floor exist. In any case, there are significant exceptions (Samos, Mytilene, Chios, Miletus, Potidaea, and possibly Boeotia) to the generalization that Athens insisted on democracies.

What the allies thought of this is inscrutable. A statement by an Athenian speaker in Thucydides that the popular party everywhere supported Athens is matched by the reported view of another Thucydidean speaker that what the

allies wanted was freedom from interference of any kind. In the legal sphere the allies suffered from disabilities (such as the requirement to have certain types of cases heard in Athens). These were firmly maintained even in texts, such as the Phaselis decree, that accord specific limited legal privileges. Full legal privilege and status was reserved for full Athenians, a status whose definition was tightened by the citizenship law of Pericles in 451. Roman commentators pointed to Athenian (and Spartan) failure to integrate their subjects as citizens as the explanation of their more general failures as imperial powers. There is much in this; it is not an answer to say that there is no attested clamour for Athenian citizenship, when the allied view on so many points does not exist. Certainly, among the thousands disfranchised in the 440s by the new rules regarding citizenship, there must have been many immigrants from the empire. Colonial mother cities sometimes offered citizenship wholesale to their daughter communities. Imperial Athens borrowed many features of the colonial relationship, but not that one.

Boeotia revolted in 446 with help from Euboean exiles and Athens was forced to accept this political reversal after a military defeat at Boeotian Coronea. The revolt of Euboea itself followed. Pericles crossed over to deal with it but only precipitated a third revolt, that of Megara. This was a serious military crisis, and it was compounded by a Spartan invasion of Attica: King Pleistoanax got as far as Eleusis and the Thriasian plain, but, as mentioned above. the invasion was not carried through. Pleistoanax and Pericles seem to have struck a deal: Sparta would not interfere in Euboea or invade Attica in exchange for Athens' acquiescence in the loss of Boeotia, the Megarid, and certain Peloponnesian sites. An arrangement on these lines was formalized in a Thirty Years' Peace between Athens and Sparta, but it would be too optimistic to try to list all the terms. An essential undertaking was a renunciation of armed attacks if the other side was prepared to submit to arbitration. Athens could now deal with Euboea, and inscriptions have preserved the terms of the firm settlement imposed on individual communities there.

Athenian buoyancy was not deflated even by these failures. For in 443 it advertised a big colonial venture to Thurii in Italy and about the same time made alliances

The Athenian Empire at its greatest extent.

The Erythrae decree

ties

Western Greek communi-

with Rhegium in Italy and Leontini in Sicily (alliances renewed a decade later on surviving inscriptions).

renewed a decade later on surviving inscriptions). Since the Persian Wars the most splendid of the western Greek communities had been tyrannically ruled until the fall of Gelon's family, the Deinomenids of Syracuse, in 466/467, soon after the death of Gelon's brother Hieron and the fall of the tyrannical house of Theron at Acragas in 472. Syracuse enjoyed a moderate democracy thereafter, disturbed only by a native rebel, Ducetius, whom it took surprisingly long to put down. In Italy, where Rome was preoccupied with the neighbouring Volsci and Aequi for much of the century, Hellenism maintained itself vigorously: the temples of Paestum dating to the 5th century, like those of Acragas or Segesta, were comparable to anything in mainland Greece, and there were philosophers and the philosophical schools of Croton, Taras, and Elea (Velia), all in southern Italy. At Elea, south of Paestum, interesting portrait statues were discovered in the 1960s, which showed that the philosophical school there had a medical aspect to it: a cult of Apollo Oulios, a healing god, was looked after by a clan of Ouliadai (which was associated with the medical organization, though the exact relationship is obscure), and even the famous Parmenides, better known as a philosopher, is called Ouliades. Pythagoreanism, a philosophical school and religious brotherhood, flourished in southern Italy. In the early 5th century Pythagorean groups involved themselves in government, ruling Croton for a period. Nonetheless, there were tyrannies in southern Italy too, such as that of Anaxilas at Rhegium. Religious and social links with the Greek mainland were cultivated, above all by contacts with the sanctuary and games at Olympia and by patronage of poets like Pindar.

The Athenian-inspired Thurii project represented a fairly substantial mainland Greek encroachment on western soil; this and a mysterious Athenian colonizing effort in the Bay of Naples region, undertaken perhaps in the early 430s by a western expert, Diotimos, must have caused unease to western-oriented Corinth. (There is even a Spartan aspect: Thurii was soon engaged in warfare with Sparta's only historical colony, Taras.) Nonetheless, when Samos revolted from Athens in 440, it was Corinth that in a congress of the Peloponnesian League voted against intervention against Athens on behalf of Samos (Corinth's attitude had no doubt softened with the detachment of Megara from Athens). Sparta, however, seems to have wanted to stop Athens in its tracks, though in the end it was typically unwilling to press this line of policy home. At this point Thucydides' main narrative stops for five crucial years, at the end of which tension between Corinth and Athens was again high, on the eve of the great Peloponnesian War.

The Peloponnesian War. The causes of the main Peloponnesian War need to be traced at least to the early 430s, although if Thucydides was right in his general explanation for the war, namely Spartan fear of Athenian expansion, the development of the entire 5th century and indeed part of the 6th were relevant. In the early 430s Pericles led an expedition to the Black Sea, and about the same time Athens made an alliance with a place close to areas of traditional Corinthian influence, Acarnania. (On another view this belongs in the 450s.) In 437 Athens fulfilled an old ambition by founding a colony at Amphipolis, no doubt on a large scale, though figures for settlers do not exist. This was disconcertingly close to another outpost of Corinthian influence at Potidaea in the Chalcidice, and there is a possibility that Athens subjected Potidaea itself to financial pressure by the mid-430s. That city was an anomaly in being both tributary to Athens and simultaneously subject to direct rule by magistrates sent out annually by Corinth; it clearly was a sensitive spot in international relations. Thus to the west (Acarnania and other places) and northeast (Amphipolis, Potidaea) Corinth was being indirectly pressured by Athens, and this pressure was also felt in Corinth's own backyard, at Megara. Athens passed a series of measures (the "Megarian decrees") imposing an economic embargo on Megara for violations of sacred land. The religious aspect of the offense was reflected in the exclusions imposed: like murderers, the Megarians were banned from the Athenian

marketplace and the harbours in the Athenian empire. But one should not doubt that Athens caused and intended to cause economic hardship as well or that the decrees were the first move in securing Megara as a military asset, a line of policy further pursued in the years 431 to 424.

Reactions to all this, within the empire and outside it, are hard to gauge. Athens' savage reduction of Samos, a member of the Delian League, in 440-439, did not stop Mytilene and most of Lesbos from appealing at some time in the prewar period to Sparta for encouragement in a revolt they were meditating. No encouragement was given: Sparta was standing by the Thirty Years' Peace and should be given (a little) credit for doing so.

For the period from 443 to 411 a vastly more detailed narrative is possible than theretofore, but the reader should be warned that this freak of scale is due to one man, Thucydides, who imposed his view of events on posterity. It would, however, be artificial to write as if the information for this unique period were no better than that

available for any other.

The main precipitating causes of the war, thought of as a war between Athens and Sparta, actually concerned relations between Sparta's allies (rather than Sparta itself) and other smaller states with Athenian connections. The two "causes" that occupy the relevant parts of Thucydides' first, introductory book concern Corcyra and Potidaea. (Thucydides does not let his readers entirely lose sight of two other causes much discussed at the time-the Megarian decrees and the complaints of Aegina about its loss of autonomy. One 4th-century Athenian orator actually dropped a casual remark to the effect that "we went to war in 431 about Aegina.") Corcyra, which had quarreled with Corinth over the Corcyran colony of Epidamnus on the coast of Illyria (a colony in which Corinth also had an interest), appealed to Athens. Taking very seriously the western dimension to its foreign policy (it was about then that the alliances with Rhegium and Leontini were renewed), Athens voted at first for a purely defensive alliance and after a debate, fully recorded by Thucydides, sent a small peace-keeping force of 10 ships. This was, however, trebled, as a nervous afterthought; no political background is given for this move, which, moreover, emerges only subsequently and in passing during the narrative of events concerning Corcyra itself. (This is a small illustration of the important point that Thucydides' presentation unduly influenced modern views on the general issue of Athenian belligerence, as on so many other issues. A different narrative, by emphasizing the escalation of the Athenian commitment and making it the subject of another full debate, might have left a different impression.) In fact, Corinthian and Athenian ships had already come to blows before the reinforcements arrived.

Then at Potidaea, a Corinthian colony, the Athenians demanded that the Corinthian magistrates be sent home. Potidaea revolted, and an unofficial Corinthian force went out to help. Potidaea was laid under siege by Athens. None of this yet amounted to war with the Peloponnesian League as a whole, but the temperature was as high as it could be, short of that. A congress of Spartan allies was convoked to discuss grievances against Athens, and the decision was taken for war.

The other Spartan ally seeking to involve Sparta in a private feud with an enemy was Thebes, whose attack on its neighbour Plataea (an Athenian ally) in time of peace was retrospectively recognized by Sparta as an act of war guilt. Sparta should not have condoned it, nor should it have invaded Attica (despite the fact that Athens had placed a garrison in Plataea) so long as Athens was offering arbitration, as it seems it was. Thucydides vacillates between two events for the beginning of the war, the invasion of Plataea and the Spartan invasion of Attica. Both occurred

in 431, separated by a mere 80 days.

Athenian war strategy and the initial conduct of the war are presented by Thucydides very much in personal terms: the focus is on what Pericles, the dominant figure of this time, did or wanted. This method, like the Homeric emphasis on heroes, is to some extent literary spotlighting, for at no time was Pericles immune from criticism. In the 440s he had to deal with a major rival, Thucydides, son

Megarian decrees Pericles

of Melesias (not the historian), who was ostracized in 443. Even after that, in the poorly documented 430s (before Aristophanes and Thucydides provide information about individual figures of second- or third-rate significance), there are suggestions of tension, such as a partial ban on comedy (with its potential for exposure) and indications in the sources that Cleon was really not a successor of Pericles at all but a highly critical contemporary. The reasons for Pericles' ascendancy remain a secret, and this in itself makes it necessary to allow for a large element of "charismatic" leadership.

In the military sphere Thucydides is surely wrong to present Pericles as a one-man band. He says of Pericles that early in the war "the Athenians reproached him for not leading them out as their general should." If this sentence had survived in isolation, one would hardly have guessed that Pericles was one of the college of 10, subject to control and threat of deposition by the Assembly (Pericles was indeed deposed temporarily toward the end of his life). On the whole, however, Thucydides minimizes the degree to which Athenian generals enjoyed executive latitude, particularly in wartime; it may be suggested that the reason for this was his own exile, imposed in 424 as a punishment for failing, as commander in the region, to relieve Amphipolis. This impressed him deeply-and unduly-with the impotence and vulnerability of generals other than Pericles

The reproach of "not leading out the Athenians" provides useful insight into Periclean strategy, revealing it to have been largely reactive. Whereas Sparta's goal was to liberate Greece from tyranny, which required it to dismantle the Athenian empire, all Athens had to do was to avoid such demolition. In a way this suited neither side: initiative of the kind this demanded from Sparta was in short supply there (though never entirely absent). For the Athenians' part, the famously energetic and meddlesome population did not take kindly to the practical consequences of Periclean strategy that required it to evacuate Attica and move its population behind the fortified walls of Athens, to rely on accumulated capital reserves and on the fleet as an instrument to hold the empire firmly down, and to avoid adding to the empire during wartime. By these means the Athenians would eventually "win through" (the Greek word is neatly ambiguous as between victory and survival).

Actually the Athenian position was not and could not be so simple. For one, the agricultural evacuation of Attica was not as complete as it was to be after 413 when the Spartans occupied Decelea in northern Attica. Nor did Pericles altogether abandon Attica militarily: there were cavalry raids to harass the dispersed foot soldiers of the enemy and to keep up city morale. Holding the empire down and holding onto capital were potentially inconsistent aims in view of the great cost of siege warfare (there was no artillery before the 4th century to facilitate the taking of fortified cities by storm). The destruction of Samos had been expensive-a four-figure sum in talentsand the siege of Potidaea was to cost 2,000. Athens, even with coined reserves of 6,000 talents at the beginning of the war, could not afford many Potidaeas. Pericles can be criticized for not foreseeing this, with the evidence of Samos behind him.

Sparta came as a liberator. This too called for money and ships, but it had neither accumulated reserves like Athens nor a proper fleet. Persia was a possible source for both, but assistance from Persia might compromise Spartan "liberation theology." This was especially true if Sparta set foot in Anatolia, where there were Greeks with as much desire for liberation (whether from Athens or Persia or both: some communities paid tribute in both directions) as their mainland counterparts. A further difficulty lay in the kind of regime Sparta itself could be expected to impose if successful. One revealing reason for the failure of the big colony at Heraclea founded in 426 (see below), a project with a strongly anti-lonian and propagandist element, was the harsh and positively unjust behaviour of the Spartan governors, who frightend people away.

Again a few qualifications are in order. Money could be obtained from more acceptable sources than Persia—from the western Dorians, for instance. And subsidized piracy,

of which one hears a little in the 420s, was another solution to the naval problem. Against harsh governors like those at Heraclea one has to balance Brasidas, who was as good a fighter in the battle for the hearts and minds as in the conventional sense.

Sparta's invasion of Attica set the tone of the first half of the Archidamian War (431-421), named after the Spartan king Archidamus II, unfairly in view of the wariness he is said to have expressed at the outset. Athens moved its flocks from Attica across to Euboea, whose economic importance was thus raised further still. As if in recognition that this was a war brought about at the instance of Corinth, much early Athenian naval activity was devoted to stripping Corinth of assets in the northwest-of Sollium, Astacus, and Cephellenia. Yet there was also an Athenian raid on Methone in Messenia (the later Venetian strong point of Modon), foiled by Brasidas; a moraleboosting raid on the Megarid (such raids were repeated twice a year until 424); and some successful diplomacy in the north, where the Odrysian Thracians were won over. At the end of this first campaigning year, Pericles delivered an austere but moving speech honouring the fallen men, which has become known as the funeral oration of Pericles. This famous oration, however, is largely the work of Thucydides himself; it is a timeless personal tribute to Athenian power and institutional strength but not, as has been argued, a key to unlock Athenian civic ideology. The speech, as preserved, is not peculiarly enthusiastic about democracy as such and has perhaps been over-interpreted in the light of Athens' later cultural fame. In particular, the Thucydidean Pericles is usually taken to have said that Athens was an education to Greece, but in context he says merely that other Greeks would do well to profit from its political example.

The second year of the war, 430, began with another invasion of Attica. Thucydides, having scarcely brought the Peloponnesians into Attica, switches styles dramatically to record the outbreak of a dreadful plague at Athens. Although it cannot be securely identified with any known disease, this plague carried off one-third of the 14,000 hoplites and cavalry (there was a recurrence in 427). Pericles himself came down with the disease and died in 429, not, however, before leading a ravaging expedition against Epidaurus and other Peloponnesian places and defending himself against his critics. The speech Thucydides gives him for this occasion is as fine as the funeral speech, which has received so much more attention. It hints loftily at expansion to east and west of the kind that Pericles' initial strategy had appeared to rule out. It is possible that this speech is historical and that the purpose of attacking Epidaurus was to bar Corinth's eastern sea-lanes completely; Aegina had already been evacuated and repopulated by cleruchs in 430, perhaps as an initial step toward this end. In the north, Potidaea surrendered, and a cleruchy was installed here too, a further Corinthian setback.

Peloponnesian pressure on Plataea was stepped up in 429. A large expedition in the northwest under the Spartan Cnemus, who used barbarian as well as Greek forces in an effort to win back some of Corinth's losses, showed that there were adventurous thinkers before the northern operations of Brasidas later in the decade. It was, however, a failure, as was a Peloponnesian embassy to Persia asking for money and alliance. Intercepted by the king of the Odrysians, the ambassadors were handed over to Athens, where they were put to death with no pretense at trial. The Odrysians feature prominently at this time (but perhaps Thucydides' own family interests in Thrace have distorted the picture): the mass mobilization of a large Odrysian force, ostensibly in the Athenian interest, soon afterward caused general terror in Greece, but it came to nothing. There was more concrete encouragement for Athens in some naval successes of the great commander Phormion in the Gulf of Corinth.

It is perhaps surprising that it was only in 428 that a revolt within the Athenian empire gave Sparta the opportunity to implement its basic war aim of liberating Greece. This was the revolt of Mytilene on the island of Lesbos, to which Athens reacted with a prompt blockade. It was a shrewd Spartan move to summon the Mytileneans and

The cost of siege warfare

other injured Greeks to the Olympic Games at this point, thus emphasizing that one aspect of the war was the tension between Dorians and Ionians. (Athens was hardly formally excluded from the solemnities, but Olympia always had a Dorian flavour.) Alcidas, the Spartan commander sent to assist the Mytileneans, failed, however, to do anything for them. On its surrender (427) the city narrowly escaped the wholesale executions and enslavements Cleon had recommended, but only as a result of second thoughts on the part of the Assembly (these events and decisions form the context of the famous "Mytilene debate"). It is to the Athenians' credit that some of them were moved by the thought that their original decision was bloodthirsty.

There were no such doubters among the Spartans who supervised the final phase of Plataean 5th-century history. When the remaining Plataeans surrendered (some had already broken out to Athens), they were put to death to a man, after the "brief question" had been put to them, "Have you done anything for Sparta during the war?" This was a question that the Plataeans, despite some moving pleas, could answer only negatively. At least Cleomenes I in the 6th century and Agesilaus II in the 4th, both of whom applied much the same criterion as this in international affairs, made no pretense of being liberators of Greece. It is impossible for the modern reader to reflect on these two fully reported incidents at Mytilene and Plataea without coming to some general conclusions about Spartan behaviour; and Thucydides, too, was prompted to generalize in this fashion. His thoughts are attached to an account of civil strife at Corcyra, in the west, in 427. After a bloodbath, the democratic pro-Athenian faction prevailed over the oligarchical pro-Spartan party, with the Athenian commander Eurymedon making no attempt to stop it.

About this time the Athenians speculatively pursued their western interests, sending at first an expedition of 20 ships under Laches and Charoeades (c. 427) and then 40 more under Sophocles (not the tragedian), Pythodorus, and Eurymedon (426-425). This was a large force in total, given Athens' other commitments, but its goals are difficult to assess: both radical and conservative motives are given, such as the desire to give the sailors practice (not a ridiculous motive, but an inadequate one), to cut off grain shipments to the Peloponnese (by which Corinth is presumably meant), or even to see if the whole island of Sicily could be brought under control, whatever exactly that might entail. (In 424, after mostly halfhearted warfare, the Sicilians put aside their internal differences at a conference in Gela, of which the Pan-Sicilian Hermocrates was the hero. The Athenian commanders returned home to an undeserved disgrace: their mandate for outright conquest had hardly been clear, nor were their resources sufficient.) The attempt by the Athenian general Nicias to take Megara by military means (427) had more immediate

promise of success. It is possible that even the Spartans were uneasy at what the main events of 427, at Mytilene and Plataea, had done for their image: they had been ineffective and brutal. Perhaps in partial redress, but also in pursuit of a traditional line of policy, they issued a general invitation to participate in a large (10,000 strong) colony at Heraclea in Trachis at the southern approach to Thessaly. This colonizing effort had intelligible short-term military motives, namely, a felt need to gain a hold on the Thracian region-the only part of the Athenian empire reachable by land-and a desire to deny Athens access to its larder on Euboea. But Thessaly had always featured and was always to feature in ambitious Spartan thinking; and Sparta may already have had designs on the amphictyonic vote that one certainly finds Heraclea exercising in the 4th century. From the propaganda point of view, the exclusion of Ionians, Achaeans, and some others was telling. Sparta was presenting itself as a leader of Dorians, not just as a selfish promoter of Spartan interests. This was the redress offered to a Greek world well-disposed toward Sparta at the beginning of the war but now perhaps dismayed by the way things were going. It was a pity that the brutality of Spartan governors at Heraclea helped to ruin the project.

Athens' magnificent refounding, also in 426, of the Io-

nian festival of Apollo on the island of Delos, where the Delian League had been established in 478 Bc (see above The Athenian empire), must surely in part be seen as a response to Dorian Heraclea. (There were other motives too, such as desire for expiation for the plague, which had rayaged Athens a second time in the winter of 427-426.) Of the two great Panhellenic sanctuaries, Olympia had taken an ugly anti-Athenian look in 428, while the oracle of Delphi had actually approved the Heraclea colony. Athens, through Delos, was creating or inflating religious propaganda possibilities of its own. The same is true of an Athenian invitation to the Greeks at large, also (possibly) in the 420s, to bring offerings of firstfruits to Eleusis.

Land operations in the northwest occupied much of the purely military history of 426. They were conducted by one of the finest generals of the Peloponnesian War, the Athenian Demosthenes (no relation of Philip's 4th-century opponent). He was at first spectacularly unsuccessful in some ambitious campaigning, perhaps not sanctioned by the Assembly at all, in Aetolia, where his hoplites were nearly helpless against the light-armed tactics of the locals. He was, however, able to retrieve the position subsequently, in Amphilochia, in circumstances that brought further discredit on Sparta, whose commander deserted his Ambracian allies.

The decisive year in the Archidamian War was 425, Demosthenes, whose credit with the Assembly must now have been excellent, obtained permission to use a fleet round the Peloponnese. He and his troops used it to occupy the remote Messenian headland of Pylos, a prominence at the north end of the Bay of Navarino, and to fortify it. The Spartans foolishly reacted by landing a hoplite force on Sphacteria, the long island to the south of Pylos. This force of 420 men, about half of them full Spartan citizens, was cut off by the Athenians, who thus acquired a potentially valuable bargaining chip. Sparta sued for peace without reference to its allies (so much for liberation), but Cleon persuaded Athens to turn the offer down. Cleon made steep demands, including (in effect) the cession of Megara, showing that he-like Nicias in 427 and Demosthenes and Hippocrates in 424-grasped the strategic importance of Megara, even if the historian Thucvdides did not.

Thucydides disliked Cleon, as did another highly articulate contemporary, the playwright Aristophanes (see in particular his comedy Knights, of 425-424). The picture that emerges from their works of Cleon and figures like him as "new politicians," arising not from among the old or property-holding families but from the people, is largely a literary fiction. It was foisted on posterity by these ancient writers, who exaggerated the contrast between Pericles and his successors because they admired Pericles' style. In social background, political methods, and particular policies the difference was not great. The real change in Athenian politics came only with the loss of the empire in 404 and the resulting partial breakdown in the "consensus politics" that had prevailed hitherto (because all social classes stood equally to gain from the empire, which financed political pay, provided land for all, and cushioned the rich against the cost of furnishing the fleet).

There are two lines of policy one can safely associate with Cleon from evidence other than that of Thucydides. One is a large increase in the level of allied tribute (425-424) documented by an inscription. Inscriptions also show the necessity of the raise, proving, as they do, a serious shortfall in public finance (extensive "borrowing from Athena"-i.e., drawing on capital reserves). The other line of policy is an attempt, attested by Aristophanes, to draw Argos into the war in some way (its peace with Sparta was due to expire in 421, the year in which, unknown to Cleon in 425, the Archidamian War was to end).

By declining the diplomatic solution, Cleon found himself committed to a military one. He succeeded dramatically, capturing 120 full Spartans and taking them back to Athens. This operation, achieved partly with the use of light-armed troops, ensured that there would be no invasion of Attica in 424. Athens was free to establish a base on the island of Cythera south of Laconia and make a serious and initially successful attempt on Megara.

At this point the balance of the war began to tilt again

Demosthenes

Brasidas' gains for Sparta

in Sparta's favour: Brasidas arrived, on his way to the north, and saved Megara by a whisker. Moreover, an ultra-ambitious Athenian attempt to reinstate the midcentury position by annexing Boeotia failed at Delium; this was a major defeat of Athens by a Boeotian army whose key component was Theban. Meanwhile, Brasidas had reached the north, where he had won over Acanthus by a blend of cajolement and threats and where, too quick for Thucydides (the historian) to stop him, he had taken Amphipolis. From there he proceeded to capture Torone. An armistice between Athens and Sparta in 423 did not stop further northern places from falling into Brasidas' arms-almost literally: at Scione the inhabitants came out to greet him with garlands and generally received him "as though he had been an athlete" (a rare Thucydidean glimpse of a world other than war and politics). He briefly won over Mende as well, but Athens recovered it soon after; Cleon arrived in 422 and won back Torone too. The deaths of both Cleon and Brasidas in a battle for possession of Amphipolis removed two main obstacles to the peace that most Spartans had been wanting for several years-in fact, since Sphacteria. The imminent expiry of the Argive peace was another factor, as was the occupation of Cythera, which provided a base for deserting helots (it is surprising that Athens did not make more use of the Spartan fear of their helots, a far from secret weapon of war). The essence of the Peace of Nicias (421) was a return to the prewar situation: most wartime gains were to be returned. Sparta had resoundingly failed to destroy the Athenian empire, and in this sense Athens, whatever its financial and human losses, had won the war.

The Peace of Nicias was seen by Thucydides as an uneasy intermission between two phases of a single war. Corinth and Boeotia rejected the peace from the outset, and an energetic young Athenian politician, Alcibiades, tried to return to what may have been Themistocles' policy of stirring up trouble for Sparta inside the Peloponnese. Alcibiades' plans, like those of Themistocles, centred on Argos, once again a factor in Greek international politics after 421 and ambitious to revive mythical Dorian glories. An alliance of Athens, Argos, Elis, and Mantinea fought Sparta in 418 in the territory of Mantinea, Sparta, resolute in war as it was irresolute in politics, scored a crushing victory over its enemies. The shame of the Sphacteria surrender was wiped out in one day, and the Greek world was reminded of Spartan hoplite supremacy. If Athens, whose finances were now strong again, wanted outlets for its aggression, it would have to find them elsewhere than in the Peloponnese. It sought it first in Anatolia, second on Melos, and third in Sicily.

At some point after 425, when there was a routine renewal of the Peace of Callias, Athens began an entanglement in Anatolia with the Persian satrap Pissuthnes and subsequently with his natural son Amorges; it sent mercenary help to Pissuthnes and perhaps Amorges. If this involvement began while the Archidamian War was still in progress, it was inexplicable provocation to Persia except on the assumption that Athens was too short of cash to pay these troops itself (a 1,000-talent reserve had been set aside at the beginning of the war, but there was resistance to touching this). If the entanglement began in the period of the Peace of Nicias, it was still dangerous adventurism because nobody could say how long the peace with Sparta would last.

Thucydides says nothing about this Persian entanglement in its right place, despite its long-term importance: it was, after all, Persian intervention on the Spartan side that ultimately settled the outcome of the whole war. By contrast, because a great deal about Athens' expedition in 416 against ostensibly unoffending Melos. Although militarily trivial, the subjugation and harsh treatment of Melos certainly had moral implications, which Thucydides explores in the famous "Melian Dialogue." It shows that the Athenians, who had made one attempt on Melos in 42" under Nicias, still wanted to round off their Aegean empire irrespective of the Dorian "ancestry" of Melos. Thucydides' debate is framed in absolute terms, as if there were no question of provocation by Melos and the only issue were whether the weaker should submit to the stronger, as Melos in the end

had to do. Yet there are points to be noted. First, Melos may have contributed to the Spartan war fund as early as 426. Second, Athens had assessed Melos at the high sum of 15 talents in the context of the (admittedly optimistic) general increase of 425; there was a fugitive sense in which Melos, which did not pay this exorbitant sum, could be seen as a recalcitrant subject. This, however, is not a line pursued by Thucydides' Athenians in the "Melian Dialogue". Third, some Athenian subject allies joined in coercing Melos in 416, evidence that Ionians and Acolians could be mobilized against Dorians and perhaps even that they positively approved of all the implications of a notably ruthless action.

In 415 Athens turned to the third and most aggressive operation of the period, the great expedition against Sicily of 415-413, better known as the Sicilian disaster. The initial commanders were Alcibiades, Nicias, and Lamachus, but the expedition was weakened by the recall of Alcibiades to stand trial for impiety (he escaped and went to Sparta. which sent help to Syracuse at his suggestion). Originally conceived in perfectly acceptable terms (a force of 60 ships to help Ionians and non-Greeks against the rising power of Syracuse), the expedition as ultimately sent was too ambitious; it consisted of a huge fleet of 140 ships-100 of them Athenian-reinforced by an additional 60. Thucydides speaks impressively but unspecifically about the cost of the expedition (he does report at one point that the Syracusans had spent 2,000 talents); from an Athenian inscription one can see that in a single transaction 3,000 talents was set aside for Sicily. A major problem was cavalry: Athens sent 250 cavalrymen without horses, but mounts were secured locally in Sicily, bringing the total to 650. (Athens also sent 30 mounted archers.) This total was not bad for a state that had never been a strong cavalry power, but it was scarcely more than half of the 1,200 that Syracuse was able to field. Even Athens' early successes in the field, and there were some, were neutralized by this disparity: pursuit of the enemy by victorious Athenian infantry became a dangerous matter because of harassment by Syracusan cavalry. When the Spartan Gylippus arrived to help the Syracusans and Athens failed to wall in Syracuse, the Syracusan cavalry made the Athenian position intolerable: those who went out from their camps foraging for food often did not come back. Nicias himself was ill but was kept in post by the Athenians, a great mistake not compensated for by the arrival of first the more energetic Demosthenes and then Eurymedon. (Lamachus had been killed in action.) The final catastrophic sea battle in the Great Harbour of Syracuse was fought in cramped circumstances that did not allow the Athenian fleet enough freedom of maneuver. The expeditionary force was virtually annihilated, including its main commanders. The blow to Athens' morale and prestige was perhaps

greater than the strictly military reverse, for, with an astonishing capacity for replacement, Athens managed, after a crash building program, to achieve rough naval parity with the Peloponnesians. This was the more remarkable in view of difficulties at home. Already before the end came in Sicily, Sparta had reopened the Peloponnesian War. On the advice of Alcibiades, the Spartans had fortified Decelea (413) and, as a result, were able to occupy Attica. Athens, embarrassed economically for this and other reasons, decided to impose a 5 percent tax on shipping instead of the tribute (but the tribute was restored in 410). Denied the use of Attica, Athens drew more heavily on Euboea for food, and this is relevant to Euboea's revolt in 411. By then, however, there had also been revolts in the eastern Aegean and in Anatolia (413-412). As regards Anatolia, another factor is relevant: the king of Persia, angered by the Amorges affair, had decided to back Sparta. Representatives of his satraps Tissaphernes and Pharnabazus, as well as ambassadors from Chios and Erythrae, invited the Spartans to carry the war across to the eastern Aegean, This Sparta did, and in some long, drawn-out diplomacy it agreed to abandon all claim to Anatolia as part of a deal for money and a fleet; the money given was hardly lavish, and the fleet did not materialize at all (perhaps, as Thucydides hints, because Tissaphernes wanted to wear down both sides, but perhaps because it was needed

Melos and the "Melian Dialogue" The

oligarchic

revolution

for use against Egypt. There is papyrus evidence for a revolt from Persian authority at this time, 411). For Sparta's part, it is possible that its abandonment of Anatolia was not quite final: a treaty of 408 may have stipulated autonomy for the Ionian Greeks. Despite the reservations on both sides, the possibility of a joint victory of Sparta and Persia over Athens had at least been conjured briefly into existence. For the moment, however, the war went on.

Athens' military resilience after its defeats in Sicily was remarkable, but the political credibility of the radical democracy had been battered: the rich had lost money, the thētes had lost men, all classes had lost their illusions. This was a situation ready to be exploited by intellectual activists, who disliked the democracy anyway. Thucydides gives a brilliant picture of the oligarchic revolution of 411 (the "Regime of the Four Hundred" oligarchs), but he can perhaps be criticized for not bringing out the importance of this intellectual factor, stressing instead the general atmosphere of suspicion and terror. A complete analysis of the revolution ought, however, to allow for the influence, on oligarchic leaders like Antiphon and the less extreme Theramenes, and no doubt on others, of the subversive teaching of the sophists (rhetorically adept "experts" who professed to impart their knowledge of such politically useful skills as rhetoric, usually in exchange for money). Theramenes is said to have been a pupil of the sophist Prodicus of Ceos. Thucydides mentions sophists only once, and then not in the context of 411 at all. The first impetus to the revolution was given by Alcibiades, who certainly was a product of the sophistic age. His motives, however, were selfish and short-term (he was aiming to achieve his own recall from exile), and he abandoned the oligarchs when he failed to get what he wanted. Nor had Peisander and Phrynichos, two other leading oligarchs, always been hostile to democracy. It is certain, however, that there were some who held, as a matter of sincere theoretical conviction, that there were merits in a "hoplite franchise"-that is, an undemocratic constitution in which the thetes would be barred from attending the Assembly or serving as jurors). Such a view, insofar as it was elitist. would naturally be attractive to the cavalry class, and it is an appealing suggestion that the original coup d'état was staged at the deme site of Colonus precisely because of its associations with the cult of Poseidon Hippios, "Horsey" Poseidon. But distinctions between extreme and moderate factions among the oligarchy must be made: Theramenes and Cleitophon were among the moderates who sought to justify the new arrangements by reference to Solon and Cleisthenes, who were wrongly represented, at this time. as having excluded the thetes from the Assembly. (Perhaps they used the slogan "ancestral constitution," but a contemporary sophist, Thrasymachus, implies that it was on everybody's lips.) However erroneous such an appeal to Solon was with regard to the facts-it is a good example of "invented tradition"-it is undoubtedly true that members of this group behaved more moderately than some of the other oligarchs (Theramenes helped to overthrow the Four Hundred).

The Law Against Unconstitutional Proposals, a democratic safeguard, was abolished, as was pay for most kinds of political office, and the old Council of Five Hundred was to be replaced by an elected Council of Four Hundred. These changes and plans did not go unopposed. Despite its losses in Sicily, there was still a fleet, at Samos, which was not at all pleased with what was happening. And the hoplites themselves, whatever theoreticians may have wished for on their behalf, were as enthusiastic for democracy as the thētes. The fleet sent a message to demand that the democracy be restored, and the extreme oligarchs were overthrown in favour of a more moderate oligarchy, the regime of The Five Thousand. This regime probably denied to the thētes the right of voting in the Assembly and lawcourts, though this is controversial. In any case, it lasted a mere 10 months.

Full democracy was restored in 410, and a commission was set up to codify the law: it was evidently felt that constitutional history had been abused in 411 and that the abuse had been made possible through ignorance. Codification was to prevent a recurrence; it was expected to

take four months but was still incomplete after six years. A fresh start was to be made in 403

In 410 Athens had recovered sufficiently to win a battle against the Peloponnesian fleet at Cyzicus (this was a factor in the downfall of The Five Thousand), and the Spartans may have asked for peace; the offer, however, is not mentioned by Xenophon, who now replaces Thucydides as the main source. This was a remarkable reversal of the position in 413 when a Spartan victory must have seemed in sight. Athens, however, refused to come to terms.

Athenian success continued with further victories in the Hellespontine region, and Alcibiades, who had played a role in these victories, was able to return from exile in 407. He magnificently led the religious procession from Athens to Fleusis, thus atoning for, or giving the lie to, his alleged impiety in 415 when he was held to have joined in profaning the Sacred Mysteries. His subordinate Antiochus, however, lost the Battle of Notium in 406, which effectively ended Alcibiades' career. Athens managed yet another victory at Arginusae in 406. But the Athenian commanders, who failed to rescue survivors, were executed in an illegal mass trial. This was folly, and so was Athens' refusal of yet another Spartan peace offer after the battle. In this, as after the Battle of Cyzicus, it followed the advice of the demagogue Cleophon.

That a combination of Persia and Sparta could win the war easily can never have been in much doubt, even after the particular failures of trust and understanding in 411. The extra factor needed to bring it about was a combination of personalities. This happened quite suddenly after 408, with the emergence to prominence of a new Spartan. Lysander, and a new and extremely young Persian, the king's son Cyrus, sent to fight on Sparta's side. The two men got on instantly (it surely helped their relationship that Persia had made concessions, if make them it did, about the autonomy of the Greek cities). The result was the victory at the Battle of Notium and then, after the Athenian refusal of the peace offer after Arginusae, a final crushing defeat of Athens at Aegospotami (405). The Athenians were starved into surrender by Lysander (404). The Long Walls were demolished, the fleet was reduced to a token 12 ships, and the empire ceased to exist. Athens was to be governed by a Spartan-imposed oligarchy, the Thirty Tyrants.

Greek civilization in the 5th century. The effect of the Persian Wars on literature and art was obvious and immediate; the wars prompted such poetry as the Persians of Aeschylus and the dithyramb of Pindar praising the Athenians for laying the shining foundations of liberty and such art as the Athenian dedications at Delphi or the paintings in the Painted Colonnade at Athens itself. Less direct was the effect of the Persian Wars on philosophy. It has already been noted that famous centres of philosophy, such as Elea and Abdera, owed their existence to the Persian takeover of Ionia in 546. The thinkers for which those places were famous, Parmenides of Elea and Democritus from Abdera, were, however, products of the 5th century, and the title of "school" has been claimed both for the atomists of Abdera and for the Eleatics, who argued for the unreality of all change. A number of Ionian thinkers arrived at Athens after Xerxes' invasion, perhaps because 5th-century Ionia experienced relative material poverty and was thus no longer an agreeable place or perhaps because they had escaped from the Persian army, into which they had been conscripted. This has been suggested for Anaxagoras of Clazomenae, who impressed Socrates by identifying mind as the governing power of the universe. Another 5th-century Ionian who found his way to Athens was Hippodamus of Miletus, an eccentric political theorist, who made his own clothes and was famous for a theory of town planning. However, the laying out of cities on "orthogonal," or rectilinear, principles cannot quite be his invention (though he gave his name to such 'Hippodamian" plans): such layouts are already found in Italy in the Archaic period at places like Metapontum. Hippodamus, nevertheless, may have had a hand in the orderly rebuilding of the port of Piraeus after the Persian Wars and even in the new colony at Thurii in 443. (A tradition associating him with the planning of the new

return of Alcibiades

Hippodamus of Miletus city of Rhodes, almost at the end of the century, surely stretches his life span beyond belief.)

The more theoretical side of Hippodamus' political thought did not have much detectable effect on the world around him (he thought that communities should be divided into farmers, artisans, and warriors) except perhaps for his suggestion that a city of 10,000 souls, a myriandros polis, was the ideal size. This is the number of colonists allegedly sent out to Heraclea in Trachis by the Spartans; and the concept of the myriandros polis was to be very influential in the 4th century and Hellenistic period.

It has been plausibly claimed that there is a general link between the rise of a political system, namely democracy, and the self-critical speculative thinking that characterizes the Greeks in and to some extent before the 5th century. Democracy, it is held, was causally responsible for the growth of philosophy and science, in the sense that an atmosphere of rational political debate conduced to a more general insistence on argument and proof. To this it can be objected that there are already, in the Homeric poems, remarkable debates constructed on recognizable rhetorical principles. Great warriors needed to be persuasive speakers as well. But political accountability was a cardinal principle of the Ephialtic reforms at Athens in the late 460s. and it is certainly attractive to suppose that intellectual accountability was a parallel or consequent development.

A further difficulty in assessing the relationship between intellectual activities consists in the lopsided ways in which the relevant evidence has survived. First, little is extant from any centre other than Athens, and this inevitably means that a treatment of 5th-century culture tends to turn into a treatment of Athenian culture. One can note the problem but not solve it. Second, some literary genres have survived more intact than others. Attic tragedy and comedy survive in relative abundance (the tragedies of Aeschylus, Sophocles, and Euripides, and the comedies of Aristophanes). The study of philosophy before Plato is, by contrast, a matter of detective work conducted from fragments preserved by later writers, whose own faithfulness in quotation and transmission may be suspect because of their own prejudices. (Christian apologists have perhaps been too readily trusted in this matter by students of the "pre-Socratics," or predecessors and contemporaries

One set of texts that does survive in bulk and is neither Athenian in origin nor the work of poets is the Hippocratic corpus of medical writings. Hippocrates was a 5th-century native of the Dorian island of Cos, but the writings that have survived are probably not his personal work. Many of them contain references to northern Greek places such as Thasos and Abdera, a reminder that intellectual activity went on outside Athens. The most striking feature of these writings, apart from the exactness of their descriptive passages, is their rhetorically conditioned polemical character. It was necessary for the practicing doctor not merely to offer the best prognosis and cure but to disparage his rivals and show by aggressive and competitive argumentation that his own approach was superior. In fact, it seems that on one specific major medical issue the "professional" doctors did not fare as well as an amateur commentator, the historian Thucydides, who in his description of the great plague was aware, as they were not, of the concepts of acquired immunity and contagion. In other words, he thought empirically and they did not. A basically competitive attitude as well as reliance on rhetoric are features of much early prose writing; for example, Hecataeus was criticized by Herodotus, who was in turn criticized by implication, though never named, by Thucydides.

Such shared features are a reminder that the 5th century, before the systematization of the 4th century associated with Aristotle or the organized Alexandrian scholarship of the 3rd, did not yet make clear distinctions between literary genres. A distinction between prose and verse is perhaps implied by Thucydides' distinction between "poets" and "logographers," or writers of logoi (tales, accounts). His own writings, however, like those of Herodotus, show an affinity to poetry, specifically to the epic poems of Homer. Indeed, an indebtedness to epic poetry is common to both the writings of Thucydides and to the Attic tragedy of the 5th century (it seems preferable to speak of shared influence of epic poetry on both the writers of tragedy and Thucydides rather than of direct influence of tragedy on Thucydides).

Greek tragedy was not itself intended as an immediate contribution to political debate, though in its exploration of issues, sometimes by means of rapid question-andanswer dialogue, its debt to rhetoric is obvious (this is particularly true of some plays by Euripides, such as the Phoenician Women or the Suppliants, but also of some by Sophocles, such as Oedipus the King and Philoctetes). It is true that sometimes the choregoi, or rich men appointed by one of the archons to finance a particular play, were themselves politicians and that this is reflected in the plays produced. (Themistocles was choregos for Phrynichos, one of whose plays caused a political storm, and Pericles paid for the Persians of Aeschylus.) One play with a clear contemporary resonance in its choice of the Areopagus as a subtheme, the Eumenides of Aeschylus (458), however, had for its choregos a man otherwise unknown: nor is it agreed whether Aeschylus was endorsing the recent reforms or voicing reservations about them. Equally, the Suppliants of Euripides contains much in apparent praise of democratic institutions, but it also includes some harsh words for the kind of politician that the democracy tended to produce. Euripides' associations with the sophists (the oligarchs Cleitophon and Theramenes are specifically linked to him) are another reason why it is difficult to treat his Suppliants as a straightforward endorsement of democracy.

The views, political or otherwise, of playwrights themselves cannot be straightforwardly inferred from what they put into the mouths of their characters. But it must be significant that the festival of the Dionysia, at which the plays were produced, was designed to reinforce civic values and ideology in various ways: war orphans featured prominently in a demonstration of hoplite solidarity, and there was some kind of parade exhibiting the tribute of the subject allies-all this taking place before the plays were actually performed. Not even this, however, entailed that the content of the plays was necessarily expected to reinforce those civic values. The opposite may even (it has been argued) be true of some plays; for example, both the Ajax and the Philoctetes of Sophocles question the ethic of military obedience, and his Antigone stresses the paramount claims of family in the sphere of burial at a time when the polis had made large inroads in this area. In general, however, it is hard to believe that Sophocles, who was a friend of Pericles and served as strategos and

imperial treasurer, was a kind of subversive malcontent. The choregic system is one aspect of a (for this period) very unusual institution by which individuals paid for state projects. The 5th-century Athenian economy, though it continued to draw on the silver of Laurium and was underpinned by the more recently acquired assets of an organized empire, nevertheless looked to individuals to finance both necessary projects like triremes and strictly unnecessary ones like tragedies. It is worth asking whether such distinction between necessary and unnecessary projects is too sharp: there was a sense in which the trireme, a noble achievement of human technê (art or craft), was an object of legitimate pride, which might have its aesthetic aspect. That, at least, is the implication of Thucydides' unforgettable account of the rivalry between the trierarchs en route to Sicily in 415. Thucydides describes the splendid flotilla, for which publicly and privately no expense had been grudged, racing from Athens as far as Aegina out of sheer pride, joy, and enthusiasm.

The psychology of contributions of this sort, the so-called The liturgy liturgy system, was complicated. On the one hand, the system differed from the kind of tyrannical or individual patronage the poetry of Pindar shows still existed in, for example, 5th-century Sicily or at Dorian Cyrene, which still had a hereditary monarchy (the Battiads) until the second half of the 5th century. Athenians themselves liked to think that the system was somehow anonymous and that glory was brought on the city. That assumption was true of athletic as well as cultural success: Thucydides makes Alcibiades claim the military command in Sicily because

Medical writings

system

his Olympic chariot victories have brought glory on the city. Consistent with this, Athenian victors in the Panhellenic games were given free meals in the Prytaneium (the town hall), alongside the descendants of the tyrannicides Harmodius and Aristogiton. The evidence for this is an inscription of the 430s. On the other hand, the liturgy system was exploited for individual gain. Thus Alcibiades' plea for political recognition was an individual and traditional one, recalling the 7th-century Olympic victor Cylon, who also sought political success by his attempted tyrannical coup. It was not altogether surprising that Alcibiades' contemporaries suspected that he too was aiming at tyranny. Alcibiades, it may be felt, can be written off as an exception and an anachronism. Far less famous speakers, however, in tight situations in the lawcourts, made comparable reference to their individual expenditure on behalf of the state, one of them frankly admitting that his motive in spending more than was necessary was to take out a kind of insurance against forensic misfortune.

Individuals might pay for the equipping of triremes, or even (like Alcibiades) own their own trireme. They might even help finance buildings like the Stoa Poikile of Peisianax (a relative of Cimon). But a building program such as that undertaken after 449 called for the full resources of the imperial state. The architects commissioned, Callicrates, Ictinus, and Mnesicles, worked under the general supervision of the sculptor Phidias; most of these men had personal connections with Pericles himself and with aspects of Periclean policy (Callicrates, for example, was involved in the building of the Long Walls). The main works on the Acropolis were temples, but even the great ceremonial gateway of Mnesicles (the Propylaea) was a lavish and expensive effort, though a secular one. The financial history of these buildings can be reconstructed with the help of inscriptions, though firm evidence for the Parthenon is lacking. Nonetheless, an inscription shows that the chryselephantine (gold and ivory) cult statue of Athena by Phidias cost somewhere between 700 and 1,000 talents, and the Parthenon itself, which housed the statue, may have cost something in the same region.

From the accounts of the Erechtheum, the temple of Athena on the Acropolis (built 421-405), it is known that highly skilled slaves as well as metics (resident foreigners) participated in the work on the friezes and columns. The slaves, whose work on the building can hardly be distinguished from that of their free coworkers, received pavment like the rest (but the money was presumably handed over to their owners). These slaves and those used as agricultural and domestic workers (e.g., the occasional nursecompanions mentioned by 4th-century orators) can be placed at one end of a spectrum. At the other end are the mining slaves working in the thousands under dangerous and deplorable conditions. Their life expectancy was short. It has been held that only condemned criminals were used in the mines, but the evidence for such "condemnation to the mines" is Roman, not Classical Athenian, Slaves were thus necessary for the working of the economy in its mining and agriculture aspects, and they also provided skills for the architectural glorification of the Acropolis. It is disputed how much chattel slaves were needed as part of the infrastructure of Athenian life in that they provided the political classes, down to and including the thetes, with the leisure for politics and philosophy. The answer depends on population figures, which are far from certain; perhaps the total slave population approached six figures (the adult male population in 431 was 42,000). Probably many thētes did own slaves. Although slaves were used for military purposes only rarely, they might exceptionally have been enrolled in the fleet. Slaves were always considered a dangerous weapon of war, but they occasionally figure prominently in descriptions of political struggle within cities; for example, at Corcyra in 427 the slaves were promised freedom by both sides but went over to the democrats. One cannot adduce this as support for an interpretation of Greek politics in terms of class struggle because the democrats may simply have made the more handsome offers.

One Athenian group that can without absurdity be called an exploited productive class was the women. They were unusually restricted in their property rights even by comparison with the women in other Greek states (Spartan women are treated below). To some extent the peculiar Athenian disabilities were due to a desire on the part of the polis to ensure that estates did not become concentrated in few hands, thus undermining the democracy of smallholders. To this social and political end it was necessary that women should not inherit in their own right: an heiress was therefore obliged to marry her nearest male relative unless he found a dowry for her. The prevailing homosexual ethos of the gymnasia and of the symposium helped to reduce the cultural value attached to women and to the marriage bond.

Against all this, one has to place evidence showing that, whatever the rules, women did as a matter of fact make dedications and loans, at Athens as elsewhere, sometimes involving fairly large sums. And the orators appealed to the informal pressure of domestic female opinion; one 4th-century speaker in effect asked what the men would tell the women of their households if they acquitted a certain woman and declared that she was as worthy to hold a priesthood as they were. In fact, priesthoods were one area of public activity open to women at Athens; the priestess of Athena Nike was in some sense appointed by lot "from all the Athenian women," just like some post-Ephialtic magistrate. (Both the inscription appointing the priestess and the epitaph of the first incumbent are extant.) The Athenian priests and priestesses, however, did not have the political influence that their counterparts later had at Rome; only one anecdote attests a priestess as conscientious objector on a political issue (Theano, who refused to curse Alcibiades), and it is suspect. It is true that Athenian women had cults of their own, such as that of Artemis at Brauron, where young Athenian girls served the goddess in a ritual capacity as "little bears," Such activity, however, can be seen as merely a taming process, preparatory to marriage in the way that military initiation was preparatory to the male world of war and fighting.

Military technology remained surprisingly static in the 5th century. The 7th century, by contrast, had witnessed rapid innovations, such as the introduction of the hoplite and the trireme, which still were the basic instruments of war in the 5th. The 4th century was to be another period of military change, although some of the new features were already discernible in the period of the Peloponnesian War (such as the more intelligent use of light-armed troops, as in the northwest and at Sphacteria in the 420s; the more extensive use of mercenaries; and the deenened right wing in the formation of the hoplite army used at Delium). But it was the development of artillery that opened an epoch, and this invention did not predate the 4th century. It was first heard of in the context of Sicilian warfare against Carthage in the time of Dionysius I of Syracuse.

THE 4TH CENTURY

To the King's Peace (386 BC). Dionysius I of Syracuse (c. 430-367) can be seen as a transitional figure between the 5th century and the 4th and indeed between Classical and Hellenistic Greece. His career began in 405, after the seven troubled years in Sicily that followed the Athenian surrender in 413. For most of this period there was war with Carthage and internal convulsions that Carthage was constantly seeking to exploit. Sicily was always prone to tyranny and political instability, partly because the island was threatened by potentially hostile neighbours ready to encroach and partly because there was a large population of non-Greek indigenous inhabitants such as the forces mobilized by Ducetius (see above). Polis life never struck deep enough roots, and populations tended to be mixed and were too often transplanted. Immediately after the defeat of Athens, a radical democracy was installed in Syracuse, at the instigation of an extremist called Diocles. The leader of the moderate democrats, Hermocrates, who happened to be absent, was exiled in 410. He tried to return but was killed in 407 in an attempt (his enemies said) to establish a tyranny. Dionysius, who had been one of Hermocrates' followers (and married his daughter) seized sole power in 406. His tyranny lasted until his death in 367; it was mostly taken up by warfare, fought with flucMilitary

Slaves

tuating fortunes, against Carthage. Successes such as the capture of Motya in 397 were hard to consolidate, and none of several peace settlements was lasting. His significance lies elsewhere than in this inconclusive fighting. The first nontorsion artillery (i.e., artillery using mechanical means to winch back, by means of a ratchet, a bow of unusual solidity but of a basically conventional conception) is attested from the Sicily of this period. Torsion artillery, which used the additional power of twisted substances like sinew or women's hair to act as strings for the projection of the missile and which did not need the bow element at all, was introduced in the middle of the 4th century. Torsion-powered stone-throwing machines could be huge and could batter down massive and sophisticated fortifications. Lack of torsion artillery prevented Agesilaus in the 390s from taking fortified cities rapidly and so making progress in his invasion of Anatolia; possession of it, by contrast, helped Alexander later in the century to overrun the same area with relative ease. The preliminary discovery of nontorsion artillery in Dionysius' Sicily, however, was already a notable refinement on traditional siege technique.

In other military respects Dionysius looked to the future; his was essentially a military monarchy based on loval mercenary power. War, which included large-scale munitions manufacture, was essential to his economy. In addition to taking on the Carthaginians in Sicily, he fought Greeks in Italy, even destroying the city of Rhegium in 386. Dionysius wanted to unite Sicily and southern Italy under his personal rule, and one need look for no subtler motive than the prestige and booty accruing from it. The kind of military monarchy he established was a crucial precedent for later figures such as Jason of Thessalian Pherae or Philip II and Alexander III the Great of Macedon.

Dionysius is called archon (an ambiguous title that can mean ruler or magistrate) of Sicily in an Athenian inscription, but he was surely thought of as king or tyrant by his local subjects. In this use of titles he has been compared to the 4th-century "Spartocid" rulers of southern Russia, Leucon I and his son Satyrus II, who (as inscriptions show) called themselves archon when dealing with their Greek subjects but king when describing their authority over the

native population.

The Syracuse that produced Dionysius was a late 5thcentury polis both in the literal sense and in features, such as appointment to office by lot, that it had adopted from the Athenians whose invasion had just been so vigorously resisted. Dionysius himself was helped to power by Sparta, the polis that above all others remained uncompromisingly "classical" in its repeated refusal, in later times, to come to terms with the victorious Macedonians. It is a striking fact, and a further betrayal of the liberation propaganda with which Sparta had entered the Peloponnesian War, that it ended it by installing at Syracuse a tyrant who was to last for four decades; this fact was not missed by the Athenian writer Isocrates. The particular Spartans sent to help Dionysius are figures of secondary importance, but it is reasonable to see behind them the hand of Lysander, who is attested as having visited Dionysius. (There is no overwhelming reason to doubt this.)

Spartan policy immediately after the Peloponnesian War looks imperialistic in the full sense: one hears of tribute and of "decarchies," or juntas of 10, imposed by Lysander, as, for example, on Samos. The government of the Thirty Tyrants, actually a Spartan-supported oligarchy, imposed at Athens is characteristic of this short phase. The seizure, by the Athenian democrat Thrasybulus, of the frontier stronghold of Phyle in northern Attica, however, created a focus for refugees, who flocked to join him. The democrats marched south, and the extreme oligarch Critias was killed in fighting in the Piraeus. Opinion at Sparta softened, and Lysander's tough policy was reversed at Athens and elsewhere (one of the Spartan kings, Pausanias, was instrumental in this, though he himself narrowly escaped condemnation at a trial held in Sparta). This episode perhaps deserves to rank as a rare instance in which moral scruple, or at least a qualm about what the rest of the Greek world might consider unacceptable, determined a foreign policy decision by Sparta. By the end of 403, democracy was restored at Athens.

Arguably, Athenian democracy was not merely restored but comprehensively rethought at this moment. As part of a general codification of the laws, now entering its second phase (see above), it was made harder for the Assembly to legislate; instead the passing of laws (or nomoi), with the important exception of those pertaining to foreign policy. was entrusted to special panels of sworn jurors. The Assembly henceforth passed only decrees. Pay for attendance in the Assembly was introduced at this time, and the hillside meeting place, the Pnyx, was physically remodeled. making it easier to control admission. The Council of Five Hundred also may have been tampered with, if it is right that "bouleutic quotas"-that is, the total of councillors supplied by demes-were now altered to take account of changes in settlement patterns brought about by the Peloponnesian War. The case for discontinuity has, however, not been proved. Other post-403 changes, some not strictly datable, may be mentioned here. The Assembly no longer heard treason trials after about 350; perhaps this was because jury trial was cheaper now that the Assembly was paid. (Juries also were paid, but Assembly attendances were larger.) For the same financial reason, and perhaps also in the mid-4th century, a limit was imposed on the hitherto unrestricted number of meetings of the Assembly per prytany, or council month lasting one-tenth of the year: the limit imposed was at first three meetings, though this was later increased to four. Generals received more specialist functions in the course of the century; and financial officials, especially those in charge of funds for disbursing state pay, acquired great elected power. All this tended toward efficiency and professionalism but away from democracy. There is no doubt that the Athens of the 4th century was less democratic than the Athens of the 5th.

The restored Athenian democracy may have been less democratic in certain respects than that of the 5th century. but it was no less suspicious of, and hostile to, Sparta. These feelings, along with the straightforward hankering at all social levels for the benefits of empire (a strong and well-attested motive that should be emphasized), were to be exploited by Thebans at Athens in 395 in their appeal to Athens to join in war against Sparta. This war, called the Corinthian War (395-386) because much of it took place on Corinthian territory, was fought against Sparta by a coalition of Athens (with help from Persia), Boeotia, Corinth, and Argos. Sparta eventually won the war, but only after the Persians had switched support from Athens to Sparta. In fact, the winning side was the old combina-

tion that had proved victorious in the Peloponnesian War. The causes of the Corinthian War lie in the policies pursued by Sparta after its victory in 404. Persian participation on Athens' side needs a special explanation, which is to be found in two ultimately related sets of operations conducted by Sparta east of the Aegean. In 401 Lysander's old friend Cyrus, the younger brother of the new Persian king, Artaxerxes II (reigned 404-359), made an attempt on the throne with Spartan help. The expedition was a military failure; Cyrus was killed at the Battle of Cunaxa north of Babylon, and the Greek army had to be extricated and brought back to the Black Sea region. It became famous, however, because a participant, first as a soldier of fortune and after Cyrus' death as a commander of the Greek force, was Xenophon, who made these exploits the basis of his Anabasis or "March Up-country" of the Ten Thousand. Lysander's support of Cyrus provided grounds for a change of attitude toward Sparta on the part of the new Persian king. The battle, though a short-term failure, had long-term propaganda importance because it fixed in Greek minds the possibility of a better-organized "march up-country," a project that was to be preached by the Athenian orator Isocrates, planned by Philip of Macedon and realized by Alexander the Great.

Cyrus had been given help in the early stages of his revolt by some Greek cities of Anatolia. When the Persian Tissaphernes, the victor of Cunaxa, threatened reprisals against them, they appealed to Sparta, which sent out Thibron (400). This was the beginning of the second Spartan operation in Anatolia, related to the first because the Ten Thousand were eventually able to attach themselves to Thibron, having meanwhile been harried by Tissaphernes.

Corinthian

Syracuse and Sparta Thebes

Thibron's expedition was followed by that of Dercyllidas (399-397), but the most ambitious of all was led by the new Spartan king, Agesilaus, in 396. At the least (and Xenophon, a great admirer of the Spartan king, attributes to him some very grand ideas indeed) Agesilaus seems to have wanted to establish a zone of rebel satraps in western Anatolia. It is therefore not surprising that in 397 the Persians began to build a new fleet to deal with the menace of a Spartan army in Asia. (Sparta's help may, however, have had some technical justification if, as is possible, there had been diplomacy in 408 that renegotiated a more favourable position for the Ionian cities than they had been left in at the end of 411.) It may have been a further irritant that Sparta was helping another anti-Persian rebel in Egypt; the fact that Egypt maintained its independence of Persia until the 340s was a serious economic loss to the Persian landowners who had been exploiting it at a distance.

The Greece that Agesilaus had left behind was uneasy under its new Spartan masters, despite the glory of Sparta's victory over the Athenian fleet at Aegospotami (405), duly commemorated at Delphi, and the personal prestige of Lysander, who may even have received at this time some kind of cult at Samos (though perhaps only after his death in 395). In fact, Sparta was not even secure in its local dominance in Laconia and Messenia: the old helot problem recurred in 399 with the attempted revolt of Cinadon. A little farther away, Sparta's former Peloponnesian and extra-Peloponnesian allies were unhappy with what they saw as alarming extensions of Spartan territorial interests, though in fact some of these were very traditional.

The rise of One powerful Spartan enemy was Thebes, which had emerged much strengthened from the Peloponnesian War. After the expulsion of the Athenians in 446, Boeotia had reorganized itself federally; the detailed arrangements are preserved in a valuable papyrus account by the Oxyrhynchus Historian. After the destruction of Plataea in 427, Thebes took over Plataea's vote and some of its territory; this was one reason for Theban strength. Another lay in the depredations that the Thebans had been able to carry out in Attica as a result of the occupation of Decelea, When Agesilaus prepared to leave for Anatolia. he tried to sacrifice at Aulis "like Agamemnon" before the Trojan War; but the Boeotian federal magistrates stopped him. Although they had little to fear from a Spartan presence in Anatolia, hardly a normal object of Theban ambition, Theban alarm can be explained by developments nearer home.

> In central Greece in the early 390s, Sparta reinforced its position at Heraclea in Trachis and had a garrison at Thessalian Pharsalus. Initially, Lysander seems to have been at the back of this northward encroachment (good evidence connects him with Thrace and the Chalcidice). Yet because this was always a direction in which Sparta expanded if given the chance, Sparta did not pull out of central Greece during Lysander's temporary eclipse after 403. From the point of view of Thebes and Corinth, there was a risk of encirclement by Sparta. Another factor making for specifically Corinthian resentment may have been Sparta's interference in Corinth's colony, Syracuse. Unlike Thebes, Corinth had emerged badly from the Peloponnesian War; its prosperous middle class had been eroded, and this made possible a remarkable turn of events: Corinth and democratic Argos, in a unique if short-lived political experiment, became fully merged at this time. Argos, for its part, never needed much excuse to act against Sparta.

> By 395 then, all Sparta's enemies were ready and willing for war. The precipitating cause was a quarrel between Locris, abetted by Boeotia, and Phocis. When the Phocians appealed to Sparta, Lysander (now back in qualified favour at Sparta) invaded Boeotia. He was immediately killed at the battle of Haliartus, however, a grave military loss to Sparta. Agesilaus returned from Asia and fought two large-scale hoplite battles but could not prize the Athenian general Iphicrates out of Corinth, where for several years he established himself with mercenaries and lightarmed troops. At sea, more progress was made against Sparta: Pharnabazus and the Athenian commander Conon

won a decisive battle off Cnidus (southern Anatolia) in August 394. The war might well have ended at this point, especially since Sparta faced a renewed helot threat as a result of the occupation by Pharnabazus and Conon of the island of Cythera. It was this as much as anything that made Sparta offer peace terms in 392, which would have meant the final abandoning of its claims to Asia. Artaxerxes, however, had not yet forgiven the Spartans for supporting Cyrus, and the war continued. Nor was Athens vet in a mood for peace.

In the years immediately following 392, the Athenians made such nuisances of themselves in Anatolia under Thrasybulus, who revived a number of 5th-century Athenian imperial institutions, that Persia-which was anxious to end rebellions not just in Egypt but also in Cypruseventually realized where its true interest lay. Consequently, it changed its support to Sparta. The Spartans under Antalcidas now blockaded the Hellespont with help from Persia and Dionysius of Syracuse, and Athens was

once again starved into surrender.
