Harmony and melody. As noted above, melody and harmony were synonymous in classical Greek theory; the term harmony referred not to notes sounded simultaneously, but to the succession of notes, or the scale, out of which melody was formed. During classical antiquity and the European Middle Ages melodies were written that had an inner logic in terms of their scale, or mode, its important notes, and the melodic patterns associated with it. This is also true of many non-Western melodies. After the gradual evolution in Europe, through the polyphony of the late Middle Ages and the Renaissance, of the common practice, or classical, system of Western harmony, the inner logic of melodies was strongly affected by harmony. Because the ear can perceive harmonic patterns in certain groups of notes, even when sounded successively rather than simultaneously, melodies began to carry a strong implication of underlying harmonies. During this period there arose the conception that melody was the surface of harmony. Thus, for example, the partitas for unaccompanied violin by J.S. Bach, despite their melodic basis and lack of outright harmonic underpinning, clearly set forth their basic tonality and harmonic direction. This is achieved by a melodic style that includes frequent scale passages and arpeggiated chords (chord notes played successively, in melodic fashion, rather than simultaneously, as in a chord) that make clear to the listener the scales, harmonies, and keys belonging to the tonality of the composition. Through the 18th century and well into the 19th, melodies tended to be the bearers of their own harmonic implications. The above noted opening of Bee-

Melody as the harmonic surface

thoven's *Eroica Symphony* represents this practice at both its height and at the beginnings of its dissolution. The opening eight notes outline an unmistakable E♭ triad, and would do so even if they were sounded unharmonized; the ensuing plunge to the unexpected C♯ likewise indicates by its mere melodic shape the harmonic unrest arising at this juncture.

Nevertheless, melody in the hands of a composer seeking a genuine expressiveness must function with some degree of independence from its harmonic underpinning. The long, expressive dissonances in the vocal lines of Romantic composers not only heighten the passion sought after in the music but also specifically represent a seeking for a heightened independence of melody from harmony.

The shift of harmonic usage in the 20th century can be viewed partly as a marked change in relationships between melody and harmony. In Schoenberg's techniques, the generating force is the 12-tone row, which is primarily a melodic sequence out of which harmonies, as well as themes, are generated. Thus, it is possible to detect a reversal of the traditional relationship, whereby harmony has become the surface—or at least the final result—of melody.

Harmony in musical form. The chief problem of composition, in any style from ancient times to the present, is the creation of a form, or structure in which the principles of unity and contrast operate in some kind of equilibrium. The listener enters into this process by the use of his powers of recognition and of memory.

In purely melodic, modal music the form often derives from the inner logic of the melody in terms of the important notes and melodic patterns of the mode. In polyphonic music before the common practice period, musical form depended partly on the unity achieved by setting a piece in a given mode, partly on the use of musical themes, and partly on creating harmonic movement and tension toward stopping points, or cadences. During the common practice period—from Bach to Debussy—much of the creation of musical form took place through the organization of harmonies into keys and relationships between keys. Thus, the sonata forms of the 18th and early 19th centuries depended as much on the statement of a key, the movement to other key areas, and the eventual return to the same key as they did on themes and other melodic devices. The composer was likely, of course, to employ the two principles of melody and harmony simultaneously; the return to the tonic key late in the course of a movement was usually reinforced by a restatement of the initial themes. In certain works of Haydn and Mozart, the listener was often thrown off course purposely by the premature return of initial themes in an unexpected key; such devices served further to enhance the drama of the genuine recapitulation, or return to the main key.

By the 19th century, however, the power of harmony to suggest clear formal structures was greatly undermined by freer use of dissonance, which broke down the clarity with which a key was defined. Other customary procedures were also abandoned. Many of Schumann's songs do not return to the tonic, or home key, for the final cadence. The extended length of Wagner's music dramas, and their wide-ranging modulation, make it impossible to regard key as a unifying force. Mahler's *Ninth Symphony*, the first movement of which is in D major, ends with a movement in D flat major, and since the symphony lasts nearly 90 minutes, there seemed to Mahler to be no reason to pay any closer lip service to classical practices of unity of key. Such necessities, by the time of this symphony, had vanished from the musical language.

Avant-garde conceptions of harmony. The course of harmony after Wagner followed three distinct paths. (1) Within the broad outlines of tonality, composers explored the potential of chords of far greater complexity than the traditional triad. In doing so they often allowed unstable chords such as dominant sevenths to stand as self-sufficient entities, and they greatly increased the use of ambiguous chords such as augmented sixths and diminished sevenths to thicken or occasionally to blur the sense of a stable tonality. (2) Composers broke away from the classical system of tonality by using chords that, although clearly recognizable as derived from earlier harmonic practices, resolved in other than the expected direction. Some also went further afield by substituting for the major and minor scales unusual scales such as whole tone and Gypsy folk music scales, by using chords built out of fourths, and by utilizing polytonality. (3) Composers systematically abandoned tonality through Schoenberg's technique of granting equal importance to all 12 chromatic tones, rather than allowing one tone to predominate as tonic. When this was done, the concept of a single, predominant key centre vanished entirely in favour of atonality. In such cases, the traditional duality of consonance and dissonance also disappeared.

New ways of creating harmony

Among most "progressive" composers of the 20th century, atonality has been extensively explored. By far the greatest concern among avant-garde composers has been to revive contrapuntal writing, or composition stressing the combination of independent melodic lines. This was partly a reaction against the lush harmonies and lyricism of the Romantic period. During the common practice period any counterpoint that occurred was subordinated to the principles of traditional harmony. The 20th-century obsession with counterpoint tended to sweep aside concern with harmonic relationships beyond the incidental fact that clusters of notes in counterpoint are indeed heard simultaneously. In the music of the American Charles Ives, for example, many skeins of fully developed atonal, contrapuntal writing pass by simultaneously, producing momentary sonorities. Such sonorities may occasionally, and quite accidentally, be identical with recognizable harmonies; but these accidental sonorities have little to do with traditional harmonic organization. Similarly, the "tone-cluster" writing of another American innovator, Henry Cowell, whereby a pianist's forearm sounds every note it can depress at once, can hardly be analyzed as functional harmony in any sense.

Other developments, too, point to the dissolution of traditional attitudes toward harmony. The aleatory, or indeterminacy, experiments of John Cage, Earle Brown, and others assign part of the composer's melodic, harmonic, and rhythmic events to a specific performer at a specific instance. In such music any discussion of harmonic direction is irrelevant. Most importantly, the rise of electronic music, which breaks away from any traditional scales such as might be produced on "normal" instruments, can only with the greatest stretch of the imagination lend itself to considerations of harmony.

Yet, there is a possible analogy with traditional harmony in electronic music as its musical styles and languages take shape. In the works of Karlheinz Stockhausen, one of the electronic pioneers and a composer of enormous influence among his younger colleagues, there are organizational systems that point to a clear control and regulation of musical elements. The strict control of musical factors such as densities of sonority, rates of rhythmic change and of change in phrase structure, rates of change in the spread of sound in an auditorium through the use of carefully positioned and modulated loudspeakers point toward a new musical system that may possibly be analyzed in terms of a new, fundamentally different harmony.

Search for a new order

The dissolution of harmony in the "progressive" music of the 20th century was not a matter of anarchy replacing order. Actually, the common practice period is of relatively short duration against the entire history of harmony. Before Bach other rules existed. Such rules, in contrast to the later system of traditional harmony, depended not on the contrast of keys but on harmonic unity brought about by the use of a given mode. Since Debussy, similarly, harmonic styles have been dictated by new rules or by the desire of many composers to seek out new rules. And, as both the modal and the common practice systems of harmony evolved only after centuries, so is it also safe to predict that the seeming anarchy of much of 20th-century music represents a state of movement toward new harmonic precepts. The question at hand, moreover, is not one of the dissolution of harmony itself, for any notes sounded simultaneously produce a harmony—whether the notes be from traditional scales or from the infinity of musical pitches produceable through electronic means. The

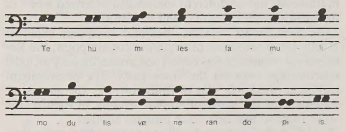
matter is, rather, the question of the uses to which these harmonies are put and the changing relations of harmony to musical structure.

An awareness of the value of harmony as pure, expressive sound persists among all composers of the present time. Some have pursued the atonal principles toward the point where harmonic sounds are totally dissonant (which is the same as saying that they are all consonant, because the contrast between consonance and dissonance disappears). Others have written works that consist of almost nothing but static, unadorned harmony—not necessarily harmoniousness. Such a work as Terry Riley's *In C*, for example, consists basically of a sustained triad on C (lasting, at the performer's option, anywhere from 30 minutes to several hours), over which fleeting dissonances are occasionally sounded, seldom more revolutionary than an F sharp or B flat. Here again, although one is more conscious of harmony in this work than of any other musical element, the harmony itself does not move or progress in the traditional sense; the sound exists, but not its function. Here one can discuss the work as pure consonance—which is the same, for lack of harmonic contrast, as pure dissonance.

Thus, in the 20th century the concepts basic to traditional harmony began to lose their importance. In counterpoint harmonies became the incidental result of the combination of melodic lines. New experiments with unusual harmonies (such as tone clusters, functionless in the traditional sense), the lessening of the tension between consonance and dissonance, and the creation of unprecedented harmonies by the use of computers have been the result of a search for new methods of musical organization. This in turn was the natural outgrowth of the blurring and final dissolution of the harmonic system that had prevailed for over two centuries in Western music. (A.Ri.)

COUNTERPOINT

A peculiarly Western phenomenon, counterpoint is the art of combining different melodic lines in a musical composition. It is the most characteristic element in Western music and a major distinguishing feature between the music of the West and that of the Orient and of primitive peoples.



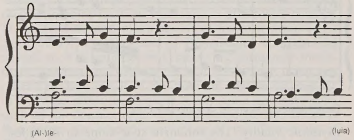
Counterpoint and polyphony distinguished

The word counterpoint is frequently used interchangeably with polyphony. This is not properly correct since polyphony refers generally to music consisting of two or more distinct melodic lines, while counterpoint refers to the compositional technique involved in the handling of these melodic lines. Good counterpoint requires two qualities: (1) a meaningful or harmonious relationship between the lines (a "vertical" consideration—*i.e.*, dealing with harmony), and (2) some degree of independence or individuality within the lines themselves (a "horizontal" consideration, dealing with melody). Musical theorists have tended to emphasize the vertical aspects of counterpoint, defining the combinations of notes that are consonances and dissonances, and prescribing where consonances and dissonances should occur in the strong and weak beats of musical metre. In contrast, composers, especially the great ones, have shown more interest in the horizontal aspects: the movement of the individual melodic lines and long-range relationships of musical design and texture, the balance between vertical and horizontal forces, existing between these lines. The freedoms taken by composers have in turn influenced theorists to revise their laws.

The word counterpoint is occasionally used by ethnomusicologists to describe aspects of heterophony—duplication of a basic melodic line, with certain differences of detail or of decoration, by the various performers. This usage is not entirely appropriate, for such instances as the singing of a single melody at parallel intervals (*e.g.*, one performer beginning on C, the other on G) lack the truly distinct or separate voice parts found in true polyphony and in counterpoint. Finally, contemporary theorists generally use the word counterpoint in a narrow sense for musical styles resembling those of Palestrina or Bach and emphasizing clear melodic relationships (*e.g.*, melodic imitation) between the voice parts.

Counterpoint can be considered more broadly, however, as an essential element in many styles within Western music. Composers in different periods have used counterpoint differently: in the Middle Ages they used it for the superimposing of different rhythmic groupings; in the Renaissance for melodic imitation; in the Baroque for contrasts between groups of instruments or voices; in the Classical period in conjunction with tonality, the organization of music in terms of key; in the Romantic in the combining of leitmotifs, or short melodic fragments; and in 20th-century music in the arrangement of isolated components of sound.

Counterpoint in the Middle Ages. The earliest examples of actual written counterpoint appear in the late 9th-century treatise *Musica enchiriadis*. Here a plainchant



Early organum; from *Musica enchiriadis* (*c.* 859).

Organum: the earliest counterpoint

melody, or "principal voice" (*vox principalis*), is combined with another part, "organal voice" (*vox organalis*), singing the same melody in parallel motion a perfect fourth or fifth below (*e.g.*, G or F below C). Such music was called organum, probably because it resembled the sound of contemporary organs. In the early 11th century the teacher and theorist Guido of Arezzo in his *Micrologus* described a variety of organum in which the accompanying or organal voice had become more individualized. In addition to moving parallel to the main voice, it included oblique (diverging or converging) motion and contrary (opposite) motion. In this era the organal voice remains melodically awkward and subservient to the chant voice, as though it were composed one note at a time simply to colour or ornament each note of the chant. Early organum is thus not far removed from heterophony. Until the end of the 11th century organum was written entirely in note-against-note style, described, in 1336, as *punctus contra punctum* (point against point—*i.e.*, note against note), hence the name counterpoint.

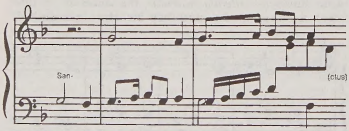
In the 12th century true polyphony comes into being; the melodic lines become individualized mostly by being given different rhythms. There emerges a hierarchy between the voice parts. The emphasis is upon the chant voice, which now becomes the lower part. Its notes are prolonged, or "held," and this part is now called the tenor, from the Latin *tenere*, to hold. The contrapuntal genius of the Middle Ages realizes itself mostly through the use of rhythmic contrasts between the different voice parts, and such contrasts gradually increase in complexity from *c.* 1100 to *c.* 1400. Around 1200 Pérotin, composer at Notre Dame in Paris who wrote some of the earliest music in three and four parts, superimposed different rhythmic modes (short fixed rhythmic patterns) in the voice parts. In his three-part *Alleluia Nativitas*, the voices are in different rhythmic modes, and they are also distinguished

Medieval rhythmic complexity

From *Alleluia Nativitas* by Pérotin.

by different phrase lengths, consisting of more or fewer repetitions of the rhythmic pattern. During the 13th century such contrasts were carried still further in the motet, a musical form usually in three voice parts, each in a different rhythmic mode. The theorist Franco of Cologne advocated the use of consonance at the beginning of each measure; such consonances (usually a chord made up of

the unison, fifth, and octave, such as C–G–C) served as fixed pillars in terms of which the horizontal extensions of different rhythmic lengths were like soaring arches of sound. The tenor voice part in the motets of the 14th and early 15th centuries was organized by huge rhythmic recurrences known as isorhythm (*i.e.*, the return throughout the piece of a complex rhythmic pattern, not necessarily in conjunction with the same pitches of the melody). During the 14th century, particularly in the works of Guillaume de Machaut, the upper voice part was sometimes displaced by a beat or more in respect to the other parts, giving it further rhythmic independence. In the late 14th century complicated syncopations (displaced accents) and the simultaneous use of different metres characterized some of the most complex counterpoint in history.



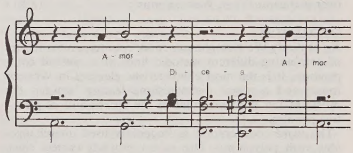
The Renaissance. If the medieval composer explored mostly the possibilities of rhythmic counterpoint, the Renaissance composer was concerned primarily with melodic relationships between the voice parts. The predominant technique used was that of imitation; *i.e.*, the successive statement of the same or similar melody in each of the voice parts so that one voice imitates another.

Imitation had appeared earlier in the Italian caccia and French *chace*, roundlike vocal forms of the 14th century, and in England in the 13th-century round, *Sumer is icumen in*. These compositions anticipate the Renaissance and also emphasize the rhythmic relationships typical of medieval counterpoint.

During the Renaissance the technique of imitation contributed to a new unity between the voices, as opposed to the hierarchy found in medieval counterpoint. Renaissance composers strove also for clear melodic relationships between voices; consequently imitations usually began on the same beat of a measure and were separated in pitch by simple intervals such as the fifth (as, C–G) or octave (as, C–C). The Renaissance theorists, among them Johannes Tinctoris and Gioseffo Zarlino, categorized dissonances according to type and governed each type by definite rhythmic and melodic restrictions.

Golden age of melodic counterpoint

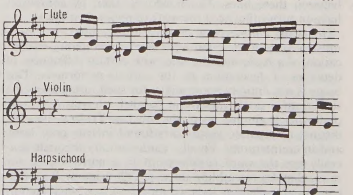
What is often proclaimed as the "golden age" of counterpoint—meaning melodic counterpoint—stretches from the late 15th to the late 16th century, from the Flemish master Jean d'Okeghem to the Spanish Tomás Luis de Victoria and the Elizabethan William Byrd. Its leading masters were Josquin des Prez, Giovanni Pierluigi da Palestrina, and Orlando di Lasso. The northern composers in particular showed a penchant for complex melodic relationships. Okeghem's *Missa prolationum* (*Prolation Mass*), for example, involves simultaneous canons in two pairs of voices. (In a canon, one melody is derived from another. It may be identical, as in a round, or it may be given various alterations, as of speed, or metre or omission of certain notes.) The most versatile craftsman of the Renaissance was Josquin, whose music displays a continual variety of contrapuntal ingenuities, including melodic imitation. His use of successive imitation in several voices, as in his *Missa da pacem* based on the chant melody "Da pacem" ("give peace"), is coupled with melodic smoothness and



From *Missa da Pacem* by Josquin des Prez.

rhythmic vitality. The imitative style came to its fullest flowering in the late 16th century not only in the masses and motets of di Lasso and Palestrina but also in secular songs such as the French chanson and Italian madrigal. It also flourished in instrumental music in such contrapuntal forms as fantasias, canzonas, and ricercari.

The Baroque period. During the 17th and early 18th centuries the pure linear—*i.e.*, melodic—counterpoint of the Renaissance, now called the first practice, was retained alongside the newer type of counterpoint known as the second practice. This latter type was characterized by a freer treatment of dissonances and a richer employment of tone colour. The new liberties with dissonance disturbed the conservative theorists of the time; but they were justified by their proponents on the ground that they allowed a more expressive treatment of the text. Still more distinct was a new use of tone colour. Although the individual melodic lines often resembled those of the Renaissance, they were intensified and made to stand out through differences of scoring or instrumentation. In figured bass compositions (in which a keyboard instrument improvised the harmonies over a given bass melody) the counterpoint was between the upper melody and the bass line. These stood out clearly from one another because of their differences of instrumental or vocal tone colour. Also significant at this time was the development of concerto-like scoring. In a concerto a soloist or group of instruments is contrasted with the entire orchestra. Hence concerto style emphasized contrasts between the numbers of performers, the high and low registers, and the tone colours of two or more performing groups. This was anticipated in some of the madrigals (Italian part-songs) of the late Renaissance, especially those of Luca Marenzio and Don Carlo Gesualdo, in which two or three voice parts in a high or low register were immediately answered by parts in a contrasting register. Giovanni Gabrieli of Venice expanded this principle in his *Symphoniae Sacrae* (*Sacred Symphonies*) by setting off choirs of voices or instruments, thus achieving a counterpoint of contrasting sonorities. Such concerto-like effects became an essential part of the later madrigals and operas of Claudio Monteverdi. In his madrigal *Lament of the Nymph*, a single soprano voice is pitted against three male voices, and both in turn against



Influence of the concerto

From *Lament of the Nymph* by Claudio Monteverdi.

an instrumental continuo (figured bass played, for example, by cello and harpsichord) in the background. This type of counterpoint was ideal for emphasizing dramatic-contrasts in the new forms of the opera and the oratorio. In these forms soloists, ensembles, and instrumental parts were opposed and combined in a great variety of ways by composers like Heinrich Schütz, Giacomo Carissimi, and Henry Purcell. In the late Baroque Arcangelo Corelli and Antonio Vivaldi added this style of dramatic contrasts to the purely instrumental contrasts of the concerto.The Baroque concerto culminated in the *Brandenburg Concertos* of J.S. Bach, which are characterized by a remarkable fusion of contrapuntal lines and instrumental colours.

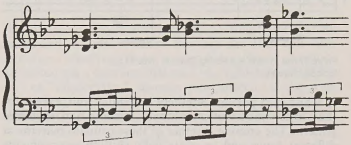
Bach's counterpoint has a retrospective side, which uses a mainly melodic approach. The fugue, a composition using the technique of melodic imitation, became highly developed in Bach's hands—*e.g.*, the fugues of the *Well-*

From *Brandenburg Concerto No. 5* by J.S. Bach.

Tempered Clavier and his final compendium of contrapuntal devices, *The Art of the Fugue*. A similar melodic, rather than tone-colour, approach occurs in works such as the *Inventions* and in the canons of the *Musical Offering*. These works are akin to "the first practice," the melodic counterpoint of the Renaissance, although in their use of dissonance and harmony they go considerably beyond Renaissance convention.

The Classical period. The turn from the Baroque to the Classical period in music was marked by the change from a luxuriant polyphonic to a relatively simple homophonic texture—*i.e.*, a texture of a single melodic line plus chordal accompaniment. Composers of the early Classical period (*c.* 1730–70) largely eschewed counterpoint altogether, drawing on it only when preparing church music in the "learned style," as the Renaissance style was then called. Many of the keyboard sonatas of Domenico Scarlatti and Carl Philipp Emanuel Bach, despite a basically homophonic approach, reveal a skillful interplay between the main melody and accompaniment. In the late Classical period (*c.* 1770–1820), especially in the music of the Viennese school of Haydn, Mozart, and Beethoven, there was an ever-increasing penetration of counterpoint into musical forms based on this homophonic style and its contrasts of tonality, or key (see above *Harmony*). This counterpoint in turn was tempered by the Classical style and musical forms. For example, although combined melodic lines are heard as counterpoint, together they can also be heard as a series of harmonies. In this way they form unified phrases in the homophonic style. This satisfied demands for symmetrical phrase lengths and clear-cut cadences, or stopping points, necessary to mark the sections of Classical forms such as the sonata.

Use of counterpoint by Haydn, Mozart, and Beethoven



Haydn underwent his contrapuntal "crisis," or movement toward counterpoint, during the 1770s, the period of *Sturm und Drang* ("Storm and Stress") in German literature, which had a deepening effect on other arts as well. Three of his *Sun Quartets* (1772) had fugues as final movements, and in the *Russian Quartets* (1781) Haydn proclaimed "an entirely new manner," in which the thematic material was to be more equally shared by all of the stringed instruments instead of being given to a single principal melody instrument. Haydn heard Handel's oratorios in London, which inspired him to write his own richly contrapuntal late oratorios, *The Creation* and *The Seasons*.

Mozart's discovery of the contrapuntal art of Bach and Handel impressed him so deeply that almost all of his later works were affected. The ensembles of the operas—*e.g.*, *Don Giovanni* and *Così fan tutte*—with their clear delineation of several characters through their vocal lines, only became possible because of his new feeling for counterpoint. And at one point in his *Jupiter Symphony* five different themes are stated simultaneously, singly, or in combination. Nevertheless the counterpoint is kept entirely subservient to the harmonies of the symphony's tonal design, or its use of keys. Each voice is also governed by an underlying phrase structure applied to all of them, so that the combined parts form unified musical phrases.

Beethoven began his career in Vienna under the tutelage of the noted contrapuntal theorist Johann Albrechtsberger, and this, coupled with his admiration for Handel, probably accounts for his lifetime interest in counterpoint. He drew upon counterpoint to create musical intensity, especially in the development section of sonata form (the form prominent in Classical symphonies and chamber music), as in the first movement of the *Razumovsky Quartet*, Opus 59, No. 1, for example. In his late sonatas and quartets, except for obvious fugal works such as the first movement of Opus 131, or the *Great Fugue*, Opus 133, almost every movement shows the interpenetration of the principles of counterpoint, which deals with melodic lines, and tonality, which deals with harmonies.

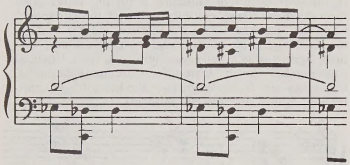
The Romantic period. Counterpoint in the 19th century had a retrospective side in addition to a characteristically Romantic style. Richard Wagner admired the counterpoint of Palestrina, and Johannes Brahms revered the Baroque masters. Felix Mendelssohn revived Bach's *St. Matthew Passion* in 1829, and this led to numerous Bach-like works, such as the organ sonatas of Mendelssohn and numerous organ works by Max Reger, as well as arrangements of Bach's works by Franz Liszt. Yet the true bent of Romantic composers was toward combinations of motives (small melodic fragments), use of motivic accompaniments against themes, and, later, of the combination of leitmotifs, or motives with significance beyond the music itself. The lieder (songs) of Franz Schubert were highly innovative because of their motivic accompaniments, which balance in interest the vocal part itself and contrapuntally interact with it. This technique is still more pronounced in the songs of Robert Schumann and Hugo Wolf. It is also the tendency in 19th-century opera. In the later operas of Giuseppe Verdi the voices often have a parlante character (imitating speech through music) while the orchestra defines the dramatic substance. This, too, is the principle of the Wagner music dramas, with their "speech-song" (*Sprechgesang*) in the voice balanced contrapuntally by the leitmotifs of the accompaniment. In *Tristan und Isolde* Wagner set the leitmotifs in counterpoint against one another. Similarly, in the Prelude to

Combinations of motives and leitmotifs

From *Siegfried* (Act III) by Richard Wagner.

Act III of *Siegfried*, a motive known as the "Need of the Gods" is cast against one associated with the "Valkyries." This results in a "counterpoint" of connotations and of emotions as well as in a musical counterpoint. In purely instrumental music a similar joining of motives previously heard separately is encountered in the finale of Hector Berlioz's *Symphonie fantastique* when the plainchant melody "Dies Irae" ("Day of Wrath") is heard together with the theme called "Round of Sabbath." Richard Strauss, in his tone poem *Ein Heldenleben (A Hero's Life)*, skillfully combines several themes taken from his earlier tone poems. And in the late symphonies of Gustav Mahler there is sometimes a complex of interwoven motives, each of which stands out contrapuntally through its presentation by a solo instrument.

In the 20th century Arnold Schoenberg carried this technique further, especially in his 12-tone works, which are based on a 12-tone row, or specific ordering of the 12 notes of the chromatic scale, arranged in such a way as to avoid a sense of tonality. In some 12-tone operas—*e.g.*, *Moses und Aron* by Schoenberg and *Lulu* by Alban Berg—there is but one tone row used in the entire work; nonetheless, several hours of music are spun out of it through a continual variety of thematic shapes and contrapuntal combinations.



The 20th century. The 20th century, like the 19th, has had its counterpoint inspired by earlier music. Anton Webern, for example, advocated a return to the forms of counterpoint used by Renaissance composers such as Heinrich Isaac, and in numerous of his own works (*e.g.*, *Symphonie*) he makes use of Renaissance contrapuntal devices such as simultaneous canons and retrograde movement between the voice parts—*i.e.*, one voice using the other's melody but with the notes in reverse order. Out of a similar return to Baroque forms came musical works such as the double fugue (a fugue based on two themes) that forms the second movement of the *Symphony of Psalms* by Igor Stravinsky.

But the use of older musical forms is no more of the essence of 20th-century counterpoint than it was of the 19th. A basic characteristic of 20th-century counterpoint is the separation of the voice parts into isolated entities of sound that are of themselves rather static. This may take the form of polytonality (the simultaneous use of two or more keys), using as static entities the notes of each key. It may also take the form of contrast of individual tone

Counterpoint of polytonality and tone colours

colour effects, rather than of melodies, found in much electronic music. (This use extends beyond the original definition of counterpoint simply as the combination of melodies.)

Richard Strauss's *Elektra* (1909) was one of the earliest works to make use of polytonality; in certain passages the instruments and voice parts are grouped into layers, each of which defines a different tonality, or key, although in this case all of the keys can also be interpreted as complicated aspects of the basic key. Stravinsky's *Three Pieces for String Quartet* (No. 1) suggests four keys at the same time: G, B, D, and A♭. In this particular work each instrument is limited throughout the piece to a few notes assigned to

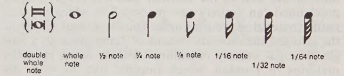
From *Three Pieces for String Quartet* (No. 1) by Igor Stravinsky.

it. Thus each part is absolutely individual and, except for the viola, consists of an ostinato melodic and rhythmic pattern. The coming together of these ostinato patterns at different times and in continually shifting arrangements suggests the effect of a mobile.Béla Bartók carried out a similar procedure in many of the short piano pieces of his *Mikrokosmos,* and in his *Fourth Quartet* (1928) he set apart tone clusters (chords built up in seconds, as C–D–E–F–G) in this way.

Turning now to a counterpoint purely of tone colours, *Intégrales* (1925) by Edgard Varèse presents 11-note "sound-clouds" in the wind instruments in opposition to the sounds of a large battery of percussion instruments. This approach probably grew directly out of earlier experiments with polytonality, but here tone colours, rather than keys or tones, are differentiated. Elliott Carter in his *Double Concerto* (1961) set apart two groups of instruments, one around a piano, another around a harpsichord, each with its distinctive tone colours and its own distinctive harmonic intervals or note combinations. In György Ligeti's *Atmospheres* every instrument in a symphony orchestra, including every string part, plays its own unique, melodic pattern; all of these parts coalesce into gigantic bands, or spectra, of tone colour that contrast with one another. In later experiments, the sound-producing groups are further set off by visual or spatial contrasts in the physical placement of performers; *e.g.,* Ramon Zupko's *Third Planet from the Sun,* 1970.

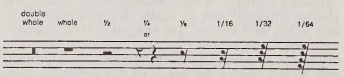
The literature of counterpoint. Most of the writings on counterpoint have sought to increase the student's skill in musical composition. From the 18th century onward, textbooks of counterpoint have recommended as a model usually Palestrina or Bach, and in some recent cases 20th-century composers. Medieval and Renaissance treatises also were originally intended for student guidance and reflect the taste and attitudes of their own time. Several 20th-century studies deal with the contrapuntal technique of a particular composer or group of composers.

(R.J.J.)



NOTATION

Broadly defined, musical notation is a visual record of heard or imagined musical sound, or a set of visual instructions for performance of music. It usually takes written or printed form and is a conscious, comparatively laborious process. Its use is occasioned by one of two motives: as an aid to memory or as communication. By extension of the former, it helps the shaping of a composition to a level of sophistication that is impossible in a purely oral tradition. By extension of the latter, it serves as a means of preserving music (although incompletely and imperfectly) over long periods of time, facilitates performance by others, and presents music in a form suitable for study and analysis.



The primary elements of musical sound are pitch, or the location of musical sound on the scale (hence interval, or distance, between notes); duration (hence rhythm, metre, tempo); timbre or tone colour; and volume (hence stress, attack). In practice, no notation can handle all of these elements with precision. Most cope with a selection of them in varying degrees of refinement. Some handle only a single pattern—*e.g.,* a melody, a rhythm; others handle several simultaneous patterns.

General principles of Western staff notation. The position of staff notation as the first notational system to be described in this article acknowledges its international acceptance in the 20th century. As an indirect result of colonization, of missionary activity, and of ethnomusicological research—not because of any innate superiority—it has become a common language among many musical cultures.

Pitch and duration. Staff notation, as it has developed, is essentially a graph. Its vertical axis is pitch, its horizontal axis, time; and note heads are dots plotting the graph's curve. The five horizontal lines of a musical staff function like horizontal rulings of graph paper, bar lines like vertical rulings. In practice, the system is far more complex and sophisticated than this. The vertical axis of pitch operates to represent melodic contour in music for a single instrument or voice; but when several staves are combined to form a score, the principle breaks down, each staff being a self-contained vertical system. Representation of time (duration) by horizontal spacing is used only in a very limited way. It is in reality made almost redundant because the symbol for a note gives the necessary information itself: not its absolute duration but its duration in relation to the notes around it. These symbols are as follows; each has half the duration of its neighbour to the left:

A system of "rests" measures silence in the same way:

A dot placed to the right of a note head increases by half the duration of that note. Such symbols when placed on a staff may indicate relative pitch and relative duration. In the grid, lines represent alternate notes of the scale and the spaces the intervening notes. Pitch and duration may be fixed by supplying two further indications: a clef and a tempo mark. The clef assigns a definite pitch to a given line of the staff; the first clef fixes the second line up as the G (g′) above middle C (c′):

Tempo and duration. The tempo mark is a sign that lies outside the staff. It appears above and may be a precise fixing of one duration ("♩ = 120 MM" means that the quarter note lasts $^1/_{120}$ of a minute, or one-half second), or it may be an approximate verbal indication setting tempo by reference to accepted conventions (allegro, or quickly; moderato, or moderate speed; etc.).

Staff notation is well adapted to two fundamental aspects of Western music: harmony and rhythm. For harmony, note symbols can easily be placed vertically together on a single stem, and these notes need not be all of the same

duration; or more than one stem may be used to indicate multiple melodic lines in the musical texture. For rhythm, the existence of an underlying regular pulse, or stress, must be indicated. This is achieved by two devices: the bar line and the time signature. The bar line primarily indicates a point of main stress. Bar lines are usually equally spaced as to duration, though there are numerous exceptions. A time signature indicates, first, the duration of the space between two bar lines (a measure, or bar); and, second, the subsidiary stress patterns within that space. A supplementary system for indicating stress is the device of linking successive notes together by beaming, or stroking. Two eighth notes may be linked together as shown in (a); four sixteenth notes (b); or a mixed group of values (c):

The function of a time signature

The implication of such grouping is generally that the first note carries a stress. Beaming thus may be used either to reinforce the stress patterns of the time signature (the metre) or to contradict it and set up a cross rhythm.

Accidentals. Staff notation rests firmly on the Western system of scales, within which all notes are assumed to be natural unless accidentals precede them or a key signature is in use. An accidental (♭, or flat; ♯, or sharp) is a temporary lowering or raising of pitch by a semitone; a key signature is the use of the same signs on a more permanent basis, valid to the end of a piece or until countermanded by a new signature. Another accidental, the natural (♮), cancels a previously indicated flat or sharp and may be used to alter one note or in a key signature to emphasize a key change. Any combination of sharps or flats is theoretically possible in a key signature, but the actual combinations are usually governed by the Western system of keys, or groups of interrelated notes and chords.

Auxiliary signs. Timbre and volume are specified through a variety of additional signs: symbols such as ≻ (stress) and ——— (increase in volume), and verbal instructions (frequently in Italian) such as forte (loud) and col legno (with the wood of the bow) placed above or below the staff wherever space permits. Additional symbols may also provide information about pitch and duration: the dot for staccato, the fermata, or hold sign (𝄐), the phrase mark, indications of amount of vibrato, and so forth. Other verbal instructions indicate the general manner of performance (pesante, "heavy"; cantabile, "songlike"; etc.) or expression (con dolore, "with suffering"; giocoso, "playfully"; etc.). Further, there are for each type of instrument certain technical signs, as for bowing, breathing, tonguing, or use of mutes.

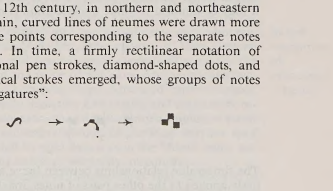
Types of musical "shorthand"

Other auxiliary signs are a kind of shorthand. Most important are symbols indicating notes not shown on the staff. An ornament sign may call for additional notes to be played within the value of a note. It may even delay the sounding of the main note. The precise meaning of such an ornament varies from one style of music to another and must be interpreted according to the conventions governing a particular style.

Comparable to the use of "shorthand" signs for ornaments is the system of placing arabic numerals beneath a bass line in keyboard music of the 17th and 18th centuries. A numeral, or "figure," signifies a harmonic (*i.e.*, a vertical) interval; thus a "6" indicates a note six degrees of the scale above a given bass note (A above C, for example). It is in itself an imprecise measurement, specifying neither whether the interval is major or minor nor in which octave register that upper note should be played. But the figures are governed by the same prevailing key signature as notes on the staff and can, like notes, carry their own accidentals. They are thus not an independent type of notation but a hybrid representation of interval/pitch that works in conjunction with staff notation. Its purpose is to indicate the harmonies implied by a bass line (even absence of figuring has a meaning) while at the same time leaving the player free to choose the precise notes to be played. The systems of letters and figures used by jazz musicians have this same imprecision; they are less dependent upon conjunction with staff notation but lack clear rhythmic significance unless allied to staff notation in at least a simplified form. They operate by defining a harmony in relation to the tonic chord (the chord built on the key note, or tonic) rather than by interval or pitch.

Evolution of Western staff notation. *Neumes.* Staff notation has its roots in the neumatic notations of plainchant and secular song of the 9th–12th century. Neumes were graphic signs indicating essentially the rise and fall of the voice. Their origin lies probably 1,000 years earlier in signs devised by Greek and Roman grammarians to guide declamation, such as ∕ *acutus* (high voice), ∖ *gravis* (low), and ∧ *circumflexus* (falling). The musical adaptations of these signs took many different regional forms. Unlike note symbols in staff notation, neumes, with two exceptions, comprised two, three, four, or more notes each and indicated their approximate relative pitches. Each comprised the notes belonging to a single syllable of text, though in florid chant the notes of a single syllable might be split up into several neumes:

Neumes were only a memory aid to singers who knew words and melody by heart. Between the 10th and 12th centuries, however, there occurred significant developments toward a notation that could be sight-read. "Heightened," or "diastematic," neumes were spaced on the page in relation to each other, so that an entire line of them formed a continuous graph of pitch over the words of text:



Sight-reading developments

Eventually, precision of pitch was further achieved by using horizontal scratched lines as a grid on which to space the neumes, so that degrees of the scale fell alternately on a line or in a space, and by colouring one line red to signify the pitch F and possibly another yellow to signify C—or by placing a letter F or C at the beginning of the appropriate line. Together, the two devices fixed the relative pitches of all notes by indicating where the semitones of the scale occurred (that is, immediately below the marked lines: E–F or B♮–C). In the 11th century two signs from a quite different system of notation (alphabetical notation; see below) were incorporated as accidentals before the pitch "B": b, the ancestor of ♭; ♮, the ancestor of ♮ and ♯, and also of the German "h," which refers to B♮. These two signs were progressively applied to other pitches in the following centuries. By the 13th century a four-line staff ruled entirely in black or red had become established, using stylized forms of the letters *f*, *c*, and *g* (ancestors of the modern 𝄢, 𝄡, and 𝄞) as clefs. For polyphonic music a five-line staff became standard by the 14th century, but keyboard music in some countries used six- or seven-line staves as late as the mid-17th century.

Adoption of the five-line staff

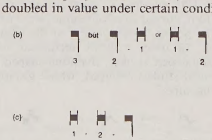
During the 12th century, in northern and northeastern France the thin, curved lines of neumes were drawn more thickly at the points corresponding to the separate notes within them. In time, a firmly rectilinear notation of heavy horizonal pen strokes, diamond-shaped dots, and hairline vertical strokes emerged, whose groups of notes are called "ligatures":

This was the notation of the troubadours' and trouvères' songs; also of plainchant from the 13th century to the present day. It was also used in 12th-century polyphony

for the upper voices, which were without text. Freed from syllabic considerations, the grouping of notes into ligatures took on rhythmic significance, specific groupings representing short, repeated patterns called rhythmic modes:

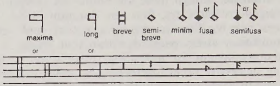
A ligature did not yet have a single, unvarying meaning. Its rhythmic pattern depended upon context.

Mensural notation. The freeing of ligatures from considerations of context occurred during the early 13th century. Time values for ligatures, single notes, and rests were codified around 1260 by the influential theorist Franco of Cologne. The notes then in use included the duple long, later called maxima ( ); long ( ); breve ( ); and semibreve ( ). In French music a shorter note value was created: the minim ( ).



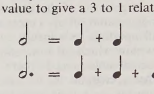
These note symbols provided the basis for notation from the late 13th to the late 15th century. This system, called mensural notation, was based on several fundamental principles that determined the value of a note relative to that of its neighbours. In the terminology of mensural notation a given note might be either perfect—*i.e.*, divided into three notes of the next lesser time value; or imperfect—*i.e.*, divided into two notes of the next lesser value. Thus, as in part (a) of the example below, a long might be perfect, containing three breves; or imperfect, containing two breves.

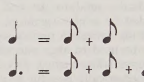
To determine which note symbols were perfect and imperfect for a given piece, special symbols were devised: , , , , , , , etc.



(Of these and survive, together with fractions such as , as modern time signatures.)

Specific rules provided for lengthening or shortening the value of notes in certain instances. To "imperfect" a long meant to shorten it by one-third of its value; this occurred when the long was preceded or followed by a breve or by notes equalling a breve in value, as shown in part (b) of the example below (for purposes of illustration, numbers have been placed under the notes showing their time value relative to the shortest note). Part (c) of the example shows another common alteration of time value: in a composition in which the long is perfect, a breve (brevis) preceding it may be doubled in value under certain conditions.



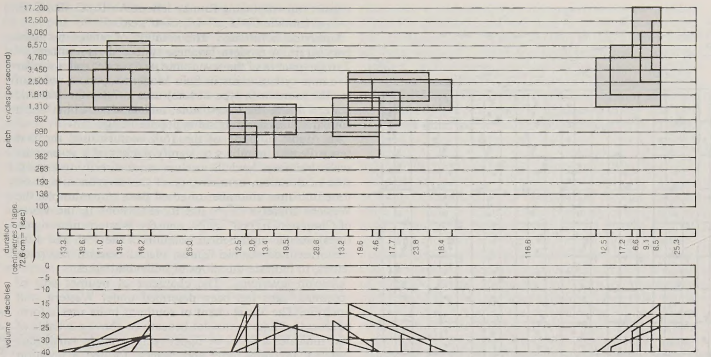


The time-value relationships between breve and long similarly applied to the other pairs of notes: maxima and long (longa); breve and semibreve (semibrevis); and semibreve and minim (minima).

As the system of mensural notation evolved, another device, coloration, came into use. If a composer wished to render a potentially perfect note imperfect, he could write it in red or as a hollow note (as , , or); these two devices had, however, various other, less common meanings. About 1400, hollow note shapes were adopted where full black notes had hitherto been used, and full black served as coloration. The notes then current and their corresponding rests were as follows:

Transition to modern staff notation. In 16th-century manuscripts and, later, in printed music, the diamond-headed notes became rounded. Ligatures were used less often in the later 15th century. The principles of perfection and imperfection gave way to the modern relationship of 2 to 1 between adjacent note values, with the dot adding an extra half value to give a 3 to 1 relationship.

Shorter note values were also introduced, and the old, longer ones became obsolete. Yet, because of a paradoxical survival from 15th-century practice, slow music has tended to be written in short values (*e.g.*, Beethoven's slow movements) and fast music in long values.



The bar line as a measure of metre arose first in 15th-century tablatures (notation showing playing position rather than pitch, as for lute). Barring entered staff notation in the 17th century, but regularly spaced barring became a practice only in the 18th century. Separate tempo indications, arising first in the 17th century, were verbally expressed; for example, adagio, largo, presto. The range of these terms greatly increased during the 18th and 19th centuries, and the metronome mark, an absolute indication of tempo, has never superseded them since its arrival in Beethoven's day. The bulk of the shorthand devices emerged during the 17th century, figured bass early in the century, the majority of ornamental signs later. Indications for loud and soft arose early in the century, expressed as words (forte, mezzoforte, piano) and later as abbreviations (*f, mf, p*). Graphic signs for dynamic and attack (staccato dot, crescendo mark, for example, and also phrase marking) appeared in the 18th century. A great proliferation of dynamic instructions and signs occurred in the late 19th and early 20th centuries.

Introduction of the bar line

20th-century notation. Two developments in musical style in the 20th century have placed great strain upon staff notation: integral serialism—in which the music is controlled by a mathematical system—and indeterminacy, or chance music. In the former, every note in a texture may have its individual dynamic marking and type of attack (for example, in Olivier Messiaen's *Mode de valeurs et d'intensités* and in parts of *Structures I* and *II* of Pierre Boulez). There may also be extensive use of unconventional playing techniques. Since staff notation indicates volume, attack, and technical effects in a comparatively clumsy manner, the written page becomes cluttered and unclear. In indeterminate and aleatory music (the latter type allowing the performer a limited degree of freedom), the notation must offer choices to the performer or be deliberately imprecise. Staff notation is for these purposes often too specific. In addition, electronic music, composed with such devices as graphs, mathematical symbols, and diagrams, is not easily translated into a readable "score" for publication.

Notation that offers the performer a choice

New systems. Notation, in face of this, has moved in two directions: toward adaptation of staff notation and

Page from the score of Stockhausen's *Electronic Study No. 2.*

toward the devising of new notational systems. Music using microtonal intervals (less than a semitone) has tended to adapt by modifying the standard accidental signs—meaning one-third sharp, two-thirds sharp, and so on (*e.g.*, in Krzysztof Penderecki's *Anaklasis*). So-called space time notation is a further adaptation that reasserts the graphic nature of staff notation. It abandons symbolic indication of note values and replaces it by the spacing of note heads horizontally on the staff, accompanied by an instruction such as "1 inch = 1 second." The principle may then be amplified by using different note heads (𝅝, 𝅗𝅥, ♩, etc.) to signify short, medium, and long sustaining of a note, thus obviating the use of rests, and by beaming together notes to be performed in one breath or bow (*e.g.*, Witold Lutosławski's *Trois poèmes d'Henri Michaux* and John Cage's *Music of Changes*).

Indeterminacy. Indeterminate music requires constant experimentation with notation. A composer may offer directions for one element of the music—as rhythm or pitch contour—and leave the performer to improvise the remaining elements. Or he may simply describe the general character of a passage by resorting to a specially designed symbol, a verbal description, or even an impressionistic drawing (as in Earle Brown's *Hodograph*). At the extreme, John Cage supplies "materials" (lines, dots, shapes) and leaves the performer to attach musical significance to them. For electronic music, published scores have so far adopted either strict graph form (Karlheinz Stockhausen, *Electronic Study II*) or pictorial form, using patterned drawings to represent different timbres (as in Henri Pousseur's *Electre* and Stockhausen's *Kontakte*).

Cage's "materials"

Adaptation to non-European music. Notations evolve with the musical styles they serve, and they reflect the underlying aesthetics of their own cultures. Thus staff notation is ill-equipped to cope with non-Western scales and tunings, with music to which the idea of the "note" (a stable, sustained pitch) is foreign, or with music whose subtlety lies as much in delicate gradations of volume or timbre as in pitch and rhythm. Ethnomusicologists have developed a range of supplementary symbols—*e.g.*, for notes of uncertain pitch, glissandi (slides), slight lengthening of a value, half-voiced notes, and other sounds. They have also experimented with staves of fewer or more lines. The Western system of proportional note values (for example, quarter note = half of a half note) does not easily cope with fine fluctuations of value; instead, constant changes of metronome tempo mark may be necessary. Among the most complex uses of staff notation in ethnomusicology are the transcriptions of Serbo-Croatian and Romanian folk song by the Hungarian composer Béla Bartók. Other transcribers have used graph paper to draw a curve of pitch against time. Many significant mechanical methods of transcription have been devised. The two most notable are the melograph, invented by the ethnomusicologist Charles Seeger, which traces a pitch/time graph immediately above a volume/time graph, and a device developed by Dahlbeck, which produces two similar graphs by means of a cathode-ray tube. These methods can reveal a level of interpretation by the performer that aural transcription into staff notation fails to bring out.

Other systems of notation. Written notations are to be found in the musical cultures of the Far East, Southeast Asia, South Asia, the Middle East, and the West. Early examples survive from Ancient Egypt and Greece. Notation may be classified into two broad categories: phonetic symbols—words, syllables, abbreviations of these, letters, and numbers; and graphic signs—accentual signs for the rise and fall of the voice (developing into neumelike "ecphonetic" signs), curves, lines, dots, and other symbols, perhaps originally depicting hand signs, and neumes. Symbols in both categories may denote simple sounds or stand for groups of successive sounds. In the West they are read in lines from left to right, whereas in the Orient many are read from right to left or vertically, in columns.

Major categories of notational systems

A second fundamental distinction is that between representational notations, which depict the sound of the music—leaving the player to produce that sound as he wishes—and tablatures, which instruct a player as to the technical means of producing a sound. Phonetic symbols play an important role in both types of notation, while graphic signs contribute mainly to representational nota-

Javanese *kraton* notation.

tions. A prime example of non-Western representational notation is the *kraton* notation used in music for the Javanese gamelan orchestra, its grid using the "graph" principle found also in Western staff notation but oriented at a 90° angle relative to the latter.

Verbal and syllabic notations. In oral traditions of music, solmization (the naming of each degree of a basic scale with a word or syllable) is important. The modern European sol-fa method ("do," "re," "mi," etc.) is such a system. The Indian syllables *sa, ṛi, ga, ma, pa, dha, ni* are similar, as are the Balinese *ding, dong, deng, dung, dang;* the ancient five-note Chinese scale *kung, shang, chiao, chih, yü;* and the Korean *tŏng, tung, tang, tong, ting;* and *rŏ, ru, ra, ro, ri* (the two sets being used for different instruments). Slightly different are the 12 chromatic Chinese *lü* syllables: each pitch bears the name of a bell—as *huang chung* ("yellow bell"), *ling chung* ("forest bell")—and its name is reduced to a syllable—*huang, ling, t'ai,* etc. Though primarily for reciting or singing as a melody is being learned, these syllables can be used to write down the notes of a melodic line (each appearing as a single ideogram in the Chinese examples) and thus form a simple syllabic pitch notation. Of the five Balinese syllables, only their vowels are used in written form—*i, o, e, u, a*—so that a letter notation results; this is still an abbreviated syllabic notation, not an alphabetical one.

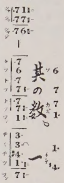
Notation for duration

In Western plainchant, abbreviated words were used to indicate duration (for example, *c* = *cito* or *celeriter* = "short" value) and direction of melodic movement (*l* = *levare,* and *s* = *sursum* = "upward"). In the notation of early Ethiopian church music a single letter or a pair of letters (short for a passage of text) signified a group of notes, even a complete melodic phrase. The drum syllables of North Indian music are a solmization of timbre (as *na, ta, dhin*) and often also of rhythmic patterns (as *tirikita, dhagina*) and can be written down to make a notation.

Alphabetical notations. Alphabets are historically a phenomenon of the Middle East, Europe, and the Indian subcontinent. Their ordering of letters provides a convenient reference system for the notes of musical scales in ascending or descending order. Alphabetical notations are among the most ancient musical scripts. Two Greek notations were of this type, the earlier using an archaic alphabet and the latter using the Classical Greek alphabet. Many comparable notations arose in the Middle Ages, and the modern note names, A to G, are an outgrowth of these.

The clefs of staff notations are a formalized survival. The system of pitch notation devised by the 19th-century German philosopher and scientist Hermann Helmholtz was derived from the Greek system, using dashes for octave register but employing Roman letters: A., B., C.–B., C–B, c–b, c′ (middle C)–b′, c″–b″, c‴–b‴, etc.

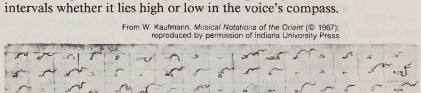
Numerical notations. The notation of pitches by numbers is rare. A modern Javanese system allots numbers 1–7 to the pitches of the seven-note *pelog* scale, and a similar five-note system exists in Bali. Modern Japanese notation for the samisen (a type of lute) uses 1–7 for the diatonic scale, 7 being the lowest note; and modern China has a similar system for publishing popular songs.



An Arabic notation of the 16th century used the first seven Persian numbers to signify pitches of a seven-note scale. Numbers lend themselves more directly to expression of duration, of metre, or of the division of a basic time unit into a number of equal parts (for example, the Western triplet $\overset{3}{\frown}$ and its extensions in the works of Chopin $\overset{11}{\frown}$ $\overset{21}{\frown}$; and the Western time signatures). Arabic alphabetical notation of the 13th and 14th centuries used Arabic figures, placed beneath the pitch letters, to indicate durations of individual notes.

Graphic notations. The character of neumes and of accentual signs has been described under Western staff notation. The Vedic chant of southern India uses a form of accentual notation: a dot beneath or above a syllable of text indicates a lower or upper reciting pitch. Analogous systems, involving dots and dashes, formed a notation for ancient Jewish cantillation and early Syrian Christian chanting. A more developed form ("ecphonetic" notation) was used for recitation of Byzantine liturgical chants. Besides simple signs for vocal inflection, it also had more elaborate, compound signs, such as

capable of signifying degrees of loudness and changes of voice production. The Western phrase mark and crescendo and decrescendo symbols are graphic signs of this type.



The dividing line between compound ecphonetic signs and neumes is slender. Neumes are concerned not with inflection of the voice between high, medium, and low but with groups of sung pitches rising and falling over a quite narrow range: a neume may represent a given pattern of intervals whether it lies high or low in the voice's compass.

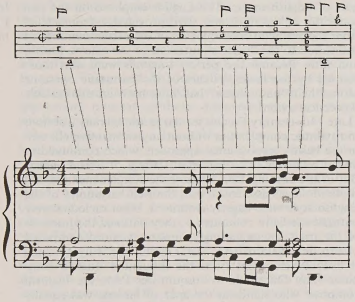
Neumes for a Tibetan Buddhist chant.

Neumes made up of curves, hooks, lines, and dots are found in Tibetan Buddhist chant books and in vocal notations for Japanese Buddhist chant, Nō plays, and *gagaku* (court music); and, in simplified form, they are used in Chinese notation in conjunction with pitch syllables.

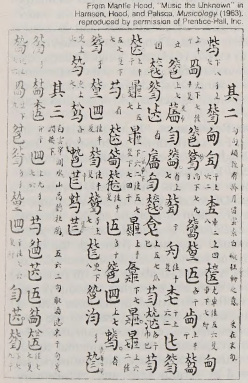
Tablatures. A tablature notates music as a series of playing positions. Hence a tablature for a plucked stringed instrument guides the player's fingers to the string he



By courtesy of Todaiji, Nara, Japan

Neume notation from the third part of the psalm of Upāli.

must pluck and to the fret at which the string should be stopped. Similarly, a tablature for a wind instrument guides a player's fingers to cover certain holes, and a tablature for percussion directs a player as to which drum to strike, which hand and stick to use, and what type of stroke to execute. Each single instruction in a tablature corresponds to one action by the performer. The order of his actions is automatically prescribed, and more precise rhythmic indication can be given quite easily as the length of time between successive actions—rests are unnecessary. Thus, a tablature for a plucked instrument requires signs for: each string, each fret, and possibly also each right-hand plucking finger, direction of stroke, and ancillary techniques such as harmonics, vibrato, and left-hand plucking. To indicate these, the tablature may use letters, numbers, and graphic signs. Thus 16th-century French lute tablatures indicate the strings (more properly the "courses") graphically as parallel horizontal lines, frets as letters, and right-hand fingering by dots:



From Francis Pilkington, Brian Jeffrey (ed.), *Complete Works for Solo Lute* (1970), by permission of Oxford University Press, London

Italian lute tablatures use numbers in place of letters.

The tablature for the Japanese koto zither is simpler in that its 13 strings are not stopped. The pitch of each string is indicated at the beginning of a tablature, and thereafter the strings are represented by numbers combined with graphic signs for special technical effects. The tablature for the Chinese *ch'in*, a zither whose strings are stopped, uses a combination of numbers (for strings and for stopping points) and ideograms (for other technical details). These are grouped close together in composite symbols. One composite symbol may contain an ideogram for the left-hand finger; a number for the stopping-point; another number for the string itself; an ideogram for the right-hand finger; and possibly an ideogram indicating loudness, legato, glissando, etc. German 16th-century lute tablature achieved economy of space by indicating string and fret as a single letter (as, *k* = first string stopped at third fret). No grid of lines was necessary. (I.Be.)

HISTORY OF WESTERN COMPOSITIONAL TECHNIQUES

Societal perspectives. Whether referring to the process or to the completed work, composition implies the creation of a unique musical event that may or may not be based on original musical materials. At certain cultural levels and in many non-Western societies, unique performance characteristics tend to assume greater significance than composition itself. In oral traditions, related variants of common origin often take the place of unalterable musical entities, so that tune families rather than single autonomous tunes form the collective repertoire. Where certain patterns of musical structure have gained broad recognition (as the ragas, or melody types, of India), musicians will as a rule rework such patterns extemporaneously though in accordance with prevailing conventions. Oral tradition

European music was communicated orally well into the Middle Ages and received important stimuli from a variety of oral traditions even after musical notation had developed to a high degree of precision. Indeed, the lower population strata, especially in rural areas, never abandoned the relative freedom that comes from reliance on the ear alone, and the sophisticated music of the upper strata, throughout its rapid evolution, rarely severed its connection with folk music altogether. Ultimately, the process of composition, as seen by the American musicologist Alan P. Merriam, does "not seem to differ radically between literate and non-literate peoples save in the question of writing." As a conscious act of social communication it always "involves learning, is subject to public acceptance and rejection, and is therefore a part of the broad learning process which contributes, in turn, to the processes of stability and change." Whether explicitly or not, composition is thus subject to rules that represent the stylistic consensus of a specific segment of society at a given stage of cultural development. During the Middle Ages, when man's natural instincts were held in particularly low esteem, musical compositions were often judged primarily in terms of their adherence to the rules. Hence, the supreme authority in matters musical was the *musicus* as theorist; only he was considered sufficiently conversant with musical science to vouchsafe its continued existence as the sonorous embodiment of universal truths. And it was because the metaphysical properties of numbers were allegedly embedded in the rules of composition that music, on a par with arithmetic, geometry, and astronomy, attained and retained an honorable place as a constituent member of the quadrivium, the more exalted of the two divisions of the seven liberal arts. Characteristically, music was not classified with grammar, rhetoric, and logic, the "rhetorical arts" gathered in the trivium. About 1300, musical composition as a mere craft was ranked by Johannes de Grocheo, a shrewd observer of the Parisian musical scene, with shoemaking and tanning.

Development of composition in the Middle Ages. The European written tradition, largely because it evolved under church auspices, de-emphasized rhythmic distinctiveness long after multipart music had superseded the monophonic plainchant. But multipart music might never have gone beyond the most primitive stages of counterpoint (see above *Counterpoint*) had it not been for the application of organized rhythm to musical structure in the late Middle Ages. This era witnessed the emergence of basic polyphonic concepts identified with European art music ever since. The precise measurement of musical time was simply an indispensable prerequisite for compositions in which separate, yet simultaneously sounded, melodic entities were combined in accordance with the medieval theorists' rules of consonance (specifying the

proper intervals to be used between voice parts, especially at points of musical repose). Toward the end of the 1st millennium of the Christian Era, church singers had grown accustomed to enhancing their chants through organum (see above *Harmony*). "Parallel" organum was followed, in turn, by "free" organum, which allowed the synchronized voice parts to utilize contrary melodic motion.

The decisive relationship between text and melody in early European music led to stylistic distinctions that have survived the ages. Thus, "syllabic" denotes a setting where one syllable corresponds to one note; "melismatic" refers to a phrase or composition employing several distinct pitches for the vocalization of a single syllable. Late medieval composers made clever use of these distinctions, including an intermediate "neumatic" style (Greek *pneuma*, "breath") to create ever more extensive polyphonic pieces. By the 12th century musicians at Notre-Dame in Paris, led by Léonin, the first polyphonic composer known by name, cultivated a type of melismatic organum that featured a highly florid upper part above a slow moving cantus firmus taken from a suitable plainchant melody. The melismatic sections alternated with strictly measured, or "discant," sections. This very effective procedure possibly was inspired by Middle Eastern practices with which the crusaders must have been well acquainted. In Eastern music, the rhythmically measured portions following the virtuoso singer's florid "outpouring of the soul" are nearly always played or at least supported by instruments. In the 13th century the clausula, a short, textless composition in discant style, tended to be dancelike in its systematic sectionalization, strongly suggesting instrumental derivation if not necessarily actual performance. The motet, a major genre of the medieval and Renaissance eras, was in its 13th-century form essentially a texted clausula, frequently employing two or three different texts in as many languages. This fact merely reinforces the suspicion that little distinction was made between vocal and instrumental composition in an era that so blithely based dancelike settings of erotic, in a few instances outright obscene, texts on a chant-derived cantus firmus. The point is not without its broader ramifications. For, brought up largely on 19th-century notions about the "purity" of church music, one easily overlooks the fact that even Bach and Mozart had few compunctions about the use of secular—in their cases mostly operatic—styles and specific tunes in church music. Over the centuries, the church has been the most important employer of composers and has offered far greater outlets for newly created music than any other social institution or category. Thus, composers of sacred music have had to satisfy the aesthetic needs and expectations of its highly differentiated "public." The church in turn repeatedly permitted the adaptation of promising secular types of composition, even though instrumental music, because of its more lascivious associations, remained suspect well into the 17th century.

Rhythmic contrast as a structural device

In accordance with medieval tendencies generally, Gothic polyphonic music was conceived in loosely connected separate layers. Thus, two-part motets could be converted into three-part motets, and Léonin's successor Pérotin expanded the organum to three and four parts. Inevitably, as their compositions gained in length and depth, musicians began to search for new integrative procedures. A system of six rhythmic modes (short, repeated rhythmic patterns) evolved rapidly. Pérotin used a single rhythmic mode for the multiple upper parts of his organums so that, separated from their cantus firmus, they resembled the conductus, a syllabic setting of a sacred text for two or three voices sharing the same basic rhythm. Finally, as organum faded into history, conductus-type motets were composed outright. Most prominent among the devices used to achieve structural integration in the 13th century were *color*, or melodic repetition without regard to rhythmic organization; *talea*, or rhythmic repetition without regard to pitch organization; and ostinato, or repetition of a relatively brief melodic-rhythmic pattern. Exchanges of melodic phrases between two or more parts in turn led to canon, a form in which all voice parts are derived from one tune—either by strict imitation of the basic melody or by manipulations stipulated in often quite sophisticated verbal instructions (canon = law). For instance, the canon *Ma fin est mon commencement (My End Is My Beginning)*, by Guillaume de Machaut, the leading French composer of the 14th century, demands the simultaneous performance of a melody and its retrograde version (the notes are sung in reverse order). French musicians of the 14th century were particularly partial tomisorhythm, which refers to repetition of the rhythmic organization of all the voices in a given compositional segment. It enjoyed considerable popularity for more than 100 years.

Melodic and rhythmic manipulation

Meanwhile, though somewhat eclipsed historically by the increasingly abstract nature of polyphony, the primacy of poetry was safeguarded in 13th-century music by the troubadours of southern France and their northern counterparts, the trouvères, as well as the German Minnesingers. These noble poet-composers created a rich tradition of purely monophonic secular song that furnished convenient points of departure for much of the secular polyphonic music in both 14th-century France and 15th-century Germany. By the beginning of the 15th century, European music had also begun to feel the impact of English music. The English emphasis on the rich sonorities of the third and sixth provided welcome relief from the aesthetic consequences of the earlier continental dedication to the "perfect" intervals of the octave, fourth, and fifth. Because the perfect intervals were also those formed by the lowest pitches of the harmonic overtone series, their "naturalness" had long been an unassailable theoretical axiom.

Impact of English music

Late 14th-century French secular music literally lost itself in rhythmic complexities without any substantive changes in the basic compositional approach, which continued to favour relatively brief three-part settings of lyrical poetry. But in the ensuing 15th century the simpler melodic and rhythmic ideas associated with the rich harmonies of the English style were eagerly embraced: often melodies were outright triadic in contour; *i.e.*, they outlined the intervals of the triad, an increasingly important chord composed of two linked thirds (*e.g.*, C-E-G). But the truly amazing stylistic development from the influential English composer John Dunstable to Josquin des Prez, the Flemish composer who stands at the apex of his era, was equally indebted to the flowing cantilenas, or lyric melodies, that characterized the top parts of Italian trecento music. If the French music of the waning Middle Ages was structured essentially from the bottom up, with relatively angular melodic and rhythmic patterns above the two-dimensional substructure of tenor and countertenor, its Italian counterparts were quite often monodically conceived; *i.e.*, a highly singable tune was sparingly yet effectively supported by a single lower voice. Indeed, the passion for melody, if need be to the detriment of other musical elements, has been a constant of Italian music. It sparked the *nuove musiche*, or "new music," of about 1600 and is exemplified in innumerable works of composers as diverse as Claudio Monteverdi (1567–1643) and Luigi Dallapiccola (1904–75). But it found its first major artistic expression in the city-states of northern Italy during the lifetimes of such 14th-century literary figures as Giovanni Boccaccio and Petrarch.

Composition in the Renaissance. During the latter part of the 15th century, French rhythmic sophistication, Italian cantilena, and English harmony finally found common ground in the style of Renaissance polyphony that, under the aegis of Flemish musicians, dominated Europe for nearly two centuries. Often referred to as modal because it retained the medieval system of melodic modes, Flemish polyphony was characterized by a highly developed sense of structure and textural integration. Although the older cantus firmus technique was never totally abandoned, Renaissance polyphony is identified above all with imitative part writing, inspired no doubt by earlier canonic procedures but devoid of their structural limitations. After a canonic or freely imitational beginning, each of the subunits of such a polyphonic piece proceeds unfettered by canonic restrictions, yet preserves the fundamental equality of the melodic lines in accordance with contrapuntal rules amply discussed by various 15th- and 16th-century theorists and ultimately codified by the Italian theorist

Gioseffo Zarlino. Through the works of Giovanni da Palestrina, the model composer of the Catholic Counter-Reformation, Renaissance modal counterpoint has influenced the teaching of musical composition to the present, suggesting the near perfection with which it conveys some fundamental aspects of the historic European ideal of composition as the art of lasting musical structures.

Changing conceptions of harmony

Whereas imitative polyphony affected virtually all 16th-century music, modal counterpoint was paramount in sacred pieces, specifically the motet and mass, probably because of its close kinship with the traditional modality of liturgical plainchant. In contrast, the beginnings of functional harmony (chordal relationships governed by primary and secondary tonal centres) manifested themselves first in the polyphonic French chanson; its Italian counterpart, the madrigal; and related secular types. Under the influence of less sophisticated music, such as that of the Italian frottola, a popular vocal genre, these secular polyphonic genres favoured rather simple bass lines highlighting a limited number of related harmonies. Thus, undisturbed by the theoretical writings from the pens of church-employed musicians, secular musical practice in the later Renaissance laid the foundations for the harmonic notions that were to dominate three centuries of Western art music. The increasing emotionalism of texts taken from the leading Italian poet of the 16th century, Torquato Tasso, and his immediate successors acted as a further stimulant, as Italian composers, searching for appropriate musical symbols, discovered the expressive possibilities of chordal progressions.

The Baroque period. Inevitably, the strong desire for heightened expression through harmony led at first to new, mostly chromatic, chord progressions. Eventually it precipitated the total abandonment of traditional polyphony about 1600 in the monodic experiments of the Florentine Camerata, a group of aristocratic connoisseurs seeking to emulate the Greek drama of antiquity. The accompaniment for these passionate and heroic solo recitations is based on a simple basso continuo. Only the bass part was written down; it was played by low, sustaining instruments bowed or blown, while plucked or keyboard instruments supplied the chords suggested by the bass and melody lines. The small figures used to indicate the proper harmonies gave the system the alternative name figured bass. Monody had its historical antecedents in mid-16th-century solo lute songs and in the plentiful arrangements of polyphonic vocal compositions for single voices accompanied by plucked instruments and for solo keyboard instruments. But it was the attempt to resurrect the spirit of antique drama in the late Renaissance that created the textural revolution that has been equated with the beginnings of modern music: the monodic style with its polarity of bass and melody lines and emphasis on chords superseded the equal-voiced polyphonic texture of Renaissance music. Monteverdi, the undisputed master of the monodic style, recognized the possibility of two basic approaches to composition: the first, or polyphonic, "practice" and the second, or monodic, "practice." Thus, with penetrating analytical insight he formulated the basic stylistic dialectic that has since governed the course of Western music.

Aesthetic and technical reorientation

The emergence of an essentially nonpolyphonic style went hand-in-hand with the rise of a variety of specifically instrumental idioms. Not only did accompanied vocal music offer instrumentalists various opportunities for improvisation; the basically chordal style also facilitated the emergence of virtuosity in the modern sense of the term, especially among keyboard artists. But as the singer and composer Giulio Caccini demonstrated in the preface to his influential collection *Le nuove musiche* (*The New Music;* 1602), singers, too, put their newly found freedom to good improvisational and ornamentational use. In short, after two centuries dominated by the highly structured, rationalistic polyphony of the Renaissance, the performing musician reiterated his creative rights. Inevitably, under such forceful pressures, the teaching of composition, previously tied to the laws of modal counterpoint, quickly shifted to the harmonic challenges of the figured bass.

Because the bass-oriented music of the 17th century relied primarily on chord progressions as fixed by the bass notes, it was structurally quite open-ended; *i.e.,* the new technique suited any number of formal patterns. Even so, the incipient rationalism that was to reach its peak in the 18th century soon led to the consolidation of broadly accepted structural types. Indeed, the very concept of musical "form," as generally understood from the late 17th century on, was intimately tied to the growing importance of instrumental music, which, in the absence of a text, had nothing to rely upon save its own organically developed laws. At least for a while, vocal music, which had been so largely responsible for the monodic revolution, continued to adhere to the Monteverdian principle that the words must act as "the mistress of harmony." Both melody and harmony, therefore, reflected often minute affective textual differentiations. And as late as the early 18th century similar musico-rhetorical considerations led to *Affektenlehre,* the theory of musical affects (emotions, feelings), developed primarily in Germany. Following this theory, German musicians dealt with composition systematically in terms of a specific but broadly adopted expressive vocabulary of melodic, rhythmic, and harmonic figures. Meanwhile, the Italians laid the foundations for such lasting categories of instrumental music as the symphony, the sonata, and the concerto. In each instance the structural outline was harmonically determined through juxtapositions of principal key areas acting as focal centres of tonality. As for tempo, the earliest 17th-century solo sonatas had relied on drastic short-range changes in accordance with a general predilection for "instant sensations." Subsequently, as musical composition fell in line with the prevailing rationalistic trend, tempo served above all as a means of differentiation between the various movements, or self-contained sections, that constituted the large-scale works of the Italian string school and of French and German instrumental composers as well. Texture, too, was used to provide contrast, particularly within a given movement, as in the concerto grosso with its alternation between small and large groups of players (concertino and tutti).

Emotional expressiveness

Interrelated with the spectacular rise and amazing vitality of instrumental music was its unprecedented variety. By the early 18th century, composers drew freely upon everything from contrapuntal forms like the fugue (an adaptation of the imitative techniques of the Renaissance motet within the context of functional harmony) to stylized popular dances, such as those that make up the suites and partitas of J.S. Bach. The figured bass era took full advantage of the possibilities of variety and contrast through judicious manipulations of all elements of composition. Whereas accompanied solo music pitted bass against treble (the latter often split up into two parts, as in the trio sonata), composers generally liked to juxtapose figured bass and polyphonic textures. Melodically, the far-flung phrases of Italian bel canto, the florid singing style characteristic of opera seria (17th- and 18th-century tragic opera), had little in common with the concise, symmetrically balanced phrases found in music of popular inspiration, whether in opera buffa (Italian comic opera) or the many types of dances. As for the latter, their impact on sophisticated 18th-century music is evident not only in many dance-inspired arias and concerto movements but also in certain polyphonic compositions. Both the chaconne and passacaglia, related polyphonic types, were based on dancelike ostinato patterns, often with specific harmonic implications. Perhaps the most famous example is Bach's "Chaconne" for solo violin, which concludes the *Partita in D Minor.*

Major structural developments of the Baroque

Even though the Baroque preoccupation with style worked somewhat to the detriment of structural definition, certain closed forms did gradually emerge. The da capo aria distinguished clearly between an initial section (A), a contrasting section (B), and the repeat (da capo) of the initial section, as a rule with improvised vocal embellishment. In instrumental music, the French opera overture began with a slow, stately introduction followed by a fast, often fugal movement, whereas its Italian counterpart had a tripartite fast-slow-fast scheme. Dance-based suite movements were binary in outline: the first of the two sections, each separately repeated, moved to the dom-

inant key (a fifth above the tonic or principal key) or to the relative key (*i.e.*, a minor third above the tonic in the case of a minor key); the second section, after some modulatory activity (*i.e.*, passing through several key areas), returned to the central key. Even more decisive in its far-reaching historical consequences was the structural organization of a number of the keyboard "sonatas" of the composer Domenico Scarlatti. These works consisted of single, essentially binary movements, the first section of which differentiated not only between two key areas but two contrasting thematic ideas as well.

The Classical period. The Classical era in music is compositionally defined by the balanced eclecticism of the late 18th- and early 19th-century Viennese "school" of Haydn, Mozart, Beethoven, and Schubert, who completely absorbed and individually fused or transformed the vast array of 18th-century textures and formal types. Expansion of the tripartite Italian overture had produced the basic three-movement scheme of the symphony even before the 18th century reached midpoint. Shortly thereafter, the minuet, borrowed from the dance suite, was inserted with increasing frequency as a fourth movement between the slow movement and the fast finale. The French opera overture in turn lent its slow introduction where needed for structural variety. Texturally, homophony (chordal texture) and polyphony soon assumed rather specific roles, with polyphonic writing usually reserved for the central or development section of the classical first-movement form. The organic fusion of a number of stylistic traits previously associated with strong and immediate contrast is exemplified by the obbligato accompaniment, the texture most typical of Viennese classicism. Here the relative equality of all the melodic parts in a given composition is ensured without denying the melodic supremacy of the treble and the harmonically decisive role of the bass. The evolution of this characteristic texture can be traced in the string quartets of Haydn. At first, following earlier 18th-century custom, Haydn wrote strictly treble-dominated compositions with a simplified bass (as compared with the more varied basso continuo); then, with the six *Sun Quartets*, Opus 20, dating from the early 1770s, he defied precedent and concluded each work with a fugue in the "learned style" of Handel. Finally, in his *Russian Quartets*, Opus 33, written, in his own words, "in a new manner," Haydn achieved the fusion of elements of both the learned and the treble-dominated styles. The result was a harmonically oriented, yet polyphonically animated, texture that was to affect both instrumental and vocal ensemble music for generations. It was also at this point, when compositional procedures reached a degree of stability and universality unmatched since Renaissance polyphony, that composition began to be taken seriously as a separate musicianly discipline. Johann Joseph Fux's famous *Gradus ad Parnassum* (*Steps to Parnassus*), published first in Latin in 1725 and subsequently in every important modern language, was still basically a didactic treatise on counterpoint abstracted from 16th-century practice. As such it served its purpose throughout the 18th century, while harmony continued to be taught as the art of accompaniment—*i.e.*, the improvised realization of a figured bass. But eventually the general fascination with comprehensive knowledge, sparked by the French *Encyclopédie*, inspired at first sporadic, then ever more numerous, volumes dealing progressively with all aspects of composition. During the ensuing 19th century the rapid institutionalization of musical education in the image of the National Conservatory of Music in Paris, created while the French Revolution was still raging, added further to the academic systematization of all musical studies along lines that have essentially remained in force. Thus the teaching of musical composition reflects to this day the biases of the 19th century, specifically its concern with functional harmony as the principal generative force in music—a doctrine first proclaimed in the 1720s in the name of nature (as being consistent with the harmonic overtone series) by the composer and theorist Jean-Philippe Rameau.

Integration of homophony and polyphony

Composition as an academic discipline

The Romantic period. With the onset of the Romantic era in the wake of the French Revolution, composers began to view their own role in society as well as the social function of their work, and hence also its aesthetic prerequisites, in a radically different light. With respect to social function, Beethoven was actually the first musician of stature to achieve emancipation in the sense that his work reflected, with relatively few exceptions, purely personal artistic concerns. He simply took it for granted that patrons would supply funds sufficient for him to pursue his creative career unfettered by financial worries. This attitude represents a total reversal of the basic assumptions of the preceding century, when composers were hired by and large to satisfy the musical needs of specific individuals or institutions.

The view of the composer as artist also changed. If during the Middle Ages the craft of musical composition had been evaluated largely in terms of its strict adherence to established rules, instinctiveness and spontaneity had remained suspect well into the Italian Renaissance. For a 15th-century composer-theorist like Johannes Tinctoris, the value of a musical composition depended on learned judgment as well as spontaneous reaction. Thus his admiration for certain composers of his time stemmed both from the happiness and from the enlightenment that he found in examining their music. But the Swiss theorist Henricus Glareanus, writing 70 years later, explicitly preferred natural talent to the most exquisite craftsmanship. The Renaissance was the first epoch in European intellectual history to recognize that the greatness of a composer rests upon his inherent talent and unique personal style, and that genius supersedes both experience and the observance of theoretical precepts. Likewise, it was the first era in which the process of composition was viewed as linked to powerful internal impulses. The rising tide of academicism notwithstanding, this basic attitude on the whole dominated the European scene more or less consistently from then on. According to E.T.A. Hoffmann, the early 19th-century poet, critic, and composer, "effective composition is nothing but the art of capturing with a higher strength, and fixing in the hieroglyphs of tones, what was received in the mind's unconscious *ecstasis*." And Romantic composers from Schumann and Chopin to Hugo Wolf and Gustav Mahler did in fact produce much of their very best creative work in precisely such a state of exaltation, in a few tragic instances (*e.g.*, Schumann and Wolf) to the ultimate detriment of their sanity.

The composer as genius

The aesthetic effects of this drastic change in conception of the composer's task and potential were immediate and far reaching. For one, every large-scale composition assumed artistic significance of a type previously accorded only a whole series of works, sometimes a composer's entire output. And, concomitantly, many leading composers of the 19th century wrote in considerably smaller quantities than their predecessors. But in exchange they revelled in idiomatic and structural peculiarities even in works that nominally fell into the same formal category. Thus, although "characteristic" symphonies alluding to nonmusical ideas occurred occasionally in the late 18th century, virtually every symphonic composition postdating Beethoven's *Symphony No. 3 in E Flat Major*, Opus 55 (*Eroica;* completed 1804), could be so designated. "Characteristic" works like Beethoven's *Symphony No. 6 in F Major*, Opus 68 (*Pastoral*: 1808), or his overture to Goethe's drama *Egmont* are but one step removed from the kind of characteristic scenes that make up the *Symphonie fantastique* of the French composer Hector Berlioz or, for that matter, Felix Mendelssohn's *Hebrides* (also known as *Fingal's Cave*), an overture unrelated to any particular drama, spoken or sung. Franz Liszt, in the free-wheeling forms of his symphonic poems, simply pursued the individualistic line to its ultimate consequences, severing whatever tenuous ties to traditional structures the works of his immediate predecessors had still maintained. The Romantic composer viewed himself basically as a poet who manipulated musical sounds instead of words. But if the composers catered to poetry, writing Lieder (German songs) and attempting to retell stories in instrumental works, the poets looked with awe and envy upon the composers' use of a language so utterly dissociated from material existence. "All art aspires to the condition of music," said Wordsworth. It is thus hardly surprising

Nonmusical allusions

that opera, whose extramusical connotations had in the past been responsible for some of the most daring stylistic innovations, rapidly incurred the disfavour of progressive composers. Although some, like Berlioz, Mendelssohn, and Schumann, tried their hands at an occasional opera, others, including Chopin, Liszt, and Brahms, felt no inclination whatever to compose for the stage. Instead, each developed personal idioms capable of a depth of expression that words could not match. Mendelssohn spoke indeed for many when he remarked that, as far as he was concerned, music was more precise in meaning than words.

As in the late Renaissance, harmony once again furnished the primary expressive means. In defining musical structure, too, harmonic and modulatory procedures predominated at the expense of the contrapuntal interplay of motives. Numerous Romantic composers excelled in concise forms of strong melodic-harmonic import, variously entitled Impromptu, Nocturne, Song Without Words, Ballade, Capriccio, Prelude, Étude, etc. The form of these works was nearly always tripartite, with a literal or modified repeat of the first part following a melodically and harmonically contrasting middle section. Works of larger scope often consisted of a series of relatively autonomous subunits tied together either by the same tune presented in different guises (as in variation sets) or by fairly literal recurrences of an initial musical idea (the rondo principle). Compositions of the Classical sonata-allegro type, to which motivic-contrapuntal development was essential, inevitably suffered from the Romantic love for pure, harmonically defined melody. Thus Tchaikovsky frankly admitted in 1878 that, although he could not complain of poverty of imagination or lack of inventive power, his lack of structural skill had frequently caused his "seams" to show: "there was no organic union between my individual episodes." Composers such as Tchaikovsky were indeed particularly successful with chainlike formations like the serenade or the ballet suite, which comprised a well-calculated number of carefully wrought smaller entities.

Interrelation of aesthetic, technique, and form

In the context of functional harmony, the Classical motivic-contrapuntal approach had no doubt been exploited in the last sonatas and string quartets of Beethoven to the very limits of its potential to define musical structure. The heroic image of Beethoven as one who had overcome every possible personal and artistic difficulty to achieve the highest aims of the art assumed well-nigh traumatic proportions among 19th-century musicians. Not only did composers ill equipped both by training and artistic temperament try to emulate him, but theorists from Adolf Bernhard Marx to Vincent d'Indy based treatises on his works. Thus, unwittingly the Classical Beethovenian inheritance turned into something of an aesthetic liability for Romantic composers swayed by the image of Beethoven and unable or unwilling to face the fact that their particular talents were totally unsuited for any further capitalization of his basic compositional procedures. Confronted with the task of writing in the Beethovenian manner, a great master like Schumann, who had created the near-perfect, totally Romantic suite *Carnaval,* Opus 9 (1835), was clearly out of his element: the development of his *Symphony No. 1 in B Flat Major,* Opus 38 (*Spring,* 1841), offers a prime example of the "rhythmic paralysis" that affected so many large-scale 19th-century works. That this symphony managed nevertheless to maintain itself in the concert repertoire, on the other hand, demonstrates the extent to which the best among the German composers compensated for obvious weaknesses in handling motivic development by sustaining above all constant harmonic interest. For their part, the French, always coloristically inclined, turned instrumentation into a principal compositional resource, so that in an unadorned piano transcription Berlioz' *Symphonie fantastique* retains little more than its basic contours. That by the end of the century virtuoso instrumentation had become universal practice is attested by any work of Richard Strauss or Gustav Mahler.

Characteristically, the most unique compositional achievement of the 19th century, that of Richard Wagner, was also the most eclectic. Wagner represents the apotheosis of Romanticism in music precisely because he fused into musico-poetic structures of unprecedented proportions virtually every musical resource that went before him. Seen in this light it may be more than mere coincidence that *Tristan und Isolde,* perhaps Wagner's most perfect music drama, begins with the same four notes that make up the motivic substance of four of Beethoven's string quartets (Opuses 130–133). Unlike most instrumental composers after Beethoven, the dramatist Wagner fully assimilated the motivic-contrapuntal process, even though his texture is principally determined by strong harmonic tensions and by a masterful use of instrumental colour in the vein of Berlioz and French grand opera. Just as he integrated diverse compositional techniques, Wagner also achieved a balance of musical and poetic elements so perfect that critics, both favourable and unfavourable, have never ceased to be puzzled by its aesthetic implications. How consciously Wagner proceeded is attested not only by his numerous theoretical writings but also by compositional sketches pointing in some instances to several stages of mutual adjustments involving music and text.

Wagner's fusion of counterpoint with late Romantic harmony

The 20th century. Wagner's highly expressive harmonic bequest could not but drive chromaticism eventually beyond the retaining confines of the idea of a central key, for the extensive use of chromatic chords tends to blur the listener's ability to perceive the basic harmonic relationships that define a key. In their nontonal compositional procedures, Arnold Schoenberg and his 20th-century second Viennese school abandoned the concept of key, using all notes freely without relating them to the system of functional harmony. They thus represent not so much a reaction to as a logical extension of Wagnerian principles. Wagner's compelling artistic personality certainly exercised near-magic powers over many of his younger contemporaries and successors, exceeding even Beethoven's spell. But others, too, contributed to "the music of the future." As Schoenberg was to point out in one of his remarkable essays, even Brahms, who looked upon himself as a conservative in the best sense of the term, was, historically speaking, a true "progressive," especially in his propensity for irregular phrasing and complex motivic manipulations.

The growth of political nationalism in the "peripheral" countries of Europe also had significant repercussions in musical composition. In the last half of the 19th century distinctive folk-music elements, previously totally unheeded by Europe's elitist musical cultures, found enthusiastic response in sophisticated circles, exerting an "exotic" attraction similar to that which had accounted earlier in the century for the Romantic infatuation with Eastern civilizations. Thus at a time when the exhaustion of Europe's "civilized" compositional resources appeared imminent, the "untutored" harmonies of the Russian composer Modest Mussorgsky—steeped in the spirit of Russian folk music and based on chord progressions alien to the standard harmonic usage of his day—helped breathe new life into a harmonic language about to succumb to redundant overdoses of functional chromaticism. Mussorgsky thus paved the way for the later whole-tone and pentatonic (five-note scale) experiments of Claude Debussy and Béla Bartók.

What was being questioned publicly in many quarters at the dawn of the 20th century was the evolutionistic view of Western art music as man's ultimate achievement in the realm of sound and its logical consequent that 19th-century harmony represented in turn music's most advanced stage of development. This increasing skepticism, given by the nature of late 19th-century music itself, was strongly reinforced by the growing awareness of historical compositional techniques that resulted from the mushrooming discoveries of musicological scholarship. Before long, all manner of pre-19th-century textures and structural principles were seized upon to counteract the type of self-defeating post-Wagnerianism—so tragically exemplified in several of the most ambitious works of Max Reger. The 20th-century search for fresh, flexible techniques extended far beyond the nontonal second Viennese school of Schoenberg. In historical perspective, Anton Webern's fascination with 15th-century canonic techniques, Paul Hindemith's predilection for both modal and early-18th-century polyphony, Igor Stravinsky's emulation of

Re-application of older techniques

Domenico Scarlatti, and, for that matter, Kurt Weill's reinterpretation of John Gay's *Beggar's Opera* (1728) represent but various individual and culturally conditioned manifestations of the same determination: to put the burden of history to positive use in a concerted effort to revitalize an art that seemed moribund by the time World War I changed the socio-economic and political physiognomy of Europe.

Historically, Schoenberg's formulation of the laws of composition with 12 tones—involving the consistent melodic and harmonic use of a specifically arranged sequence of the 12 notes of the chromatic scale—sprang in the early 1920s from the same obsession with textural and structural clarity that marked the postwar Neoclassical syndrome as a whole. Schoenberg himself may have considered his most fundamental contribution to musical history to be "the emancipation of dissonance"—a relativistic conception of intervals and chords that disregarded the careful regulation of dissonance characteristic of functional harmony. Actually, the 12-tone procedures he developed so consistently served to restore, to an extent far beyond that which Mahler had been able to achieve within the traditional harmonic framework, the primacy of motivic-contrapuntal development as a musical resource. Thus it was that the profusion of simultaneous melodies that animates Mahler's *Symphony No. 4 in G Major* (completed 1900) found its ultimate potential realized in Schoenberg's most uncompromising polyphonic work, the *Wind Quintet* (1924).

Possibly the most successful attempt to regenerate Beethovenian procedures without the total abandonment of functional tonality is represented by the string quartets and certain other instrumental compositions of Bartók. Drawing upon the rhythmic-melodic properties of Hungarian and Romanian folk music, Bartók produced a unique type of functionally extended harmony determined largely by the contrapuntal interaction of motives. Others, such as Charles Ives in the United States and, under the impact of South American popular music, Darius Milhaud in France, transcended traditional tonality by writing polytonally (in two or three keys simultaneously).

Whatever their specific approach, progressive 20th-century composers everywhere clearly gave precedence to melodic-rhythmic energies. Even instrumental colour was pressed into the service of melodic definition. Years before World War I Schoenberg had advocated in practice (*Five Orchestral Pieces*) and in theory (*Harmonielehre*, 1911; *Theory of Harmony*, 1947 [the English edition omits the pertinent chapter]) the idea of tone-colour melody, or *Klangfarbenmelodie*. But it was his pupil Webern who, in his mature works, divided the individual components of melodic phrases over several instruments as an imaginatively coloristic reinforcement of the complex polyphony that characterized his style. After World War II Webern's procedures were adopted enthusiastically by composers on both sides of the Atlantic. Living in increasingly automated societies, the post-Webern composers soon discovered total serialism, a manner of composition in which all musical parameters follow numerical rules laid down in the course of what has been called the precompositional process. Whereas Schoenberg's row technique merely fixed the sequence of the 12 pitches of the chromatic scale in accordance with the motivic context of a given piece, Webern had indeed begun to serialize rhythm and to some extent instrumentation, possibly under the influence of medieval isorhythmic techniques. But total serialization, as practiced by the post-Webernians, left little, if anything, to spontaneous inspiration, and the 1950s thus witnessed the closing of a creative circle initiated during the early Middle Ages when spontaneous inspiration was manifestly suspect. Perhaps inevitably, such a hermetically closed system of composition provoked reactions that moved the aesthetic pendulum violently to the extreme opposite position. Spur-of-the-moment action became the watchword in music as well as in life generally. Aleatory (chance-music) composition in its more radical manifestations provides only minimal guidelines for performers who are told to improvise freely within certain temporal or spatial limitations, or both.

Serialization of all elements

Thus, with the 20th century in its final quarter, Western man has returned, insofar as is possible, to the pretypographical stage when musical tradition was essentially oral. More than that, the relatively recent replacement of "the public," once essentially the cultural elite, by a whole host of publics to whom mutually exclusive types of composers cater with great solicitude, suggests that the private musical life of Western man in the immediate past is in the process of being transplanted by experiences serving, among other things, the identification of special group interests and needs. At the same time, novelty rather than originality has become the order of the day. Musical compositions, electronically recorded—more recently also electronically produced—and distributed as salable items by mass-oriented corporations, have attained the status of physical objects that are easily discarded and replaced. Still, there are those who try to transform the burdens of history into significant new forms of composition. A new eclecticism is in the making, destined perhaps to preserve a long tradition that has been among Western man's proudest achievements. (A.L.R./Ed.)

INSTRUMENTATION

Most authorities make little distinction between the words instrumentation and orchestration. Both deal with musical instruments and their capabilities of producing various timbres or colours. Orchestration is somewhat the narrower term since it is frequently used to describe the art of instrumentation as related to the symphony orchestra. Instrumentation, therefore, is the art of combining instruments in any sort of musical composition, including such diverse elements as the numerous combinations used in chamber groups, jazz bands, rock ensembles, ensembles employing chorus, symphonic bands, and, of course, the symphony orchestra. Included under this designation are the various instrumental groups that play non-Western music, such as the gamelan orchestras of Bali and Java and the traditional ensembles of India, Africa, the Far East, and the Middle East.

In Western music there are many standard or traditional groups. The modern symphony orchestra usually comprises the following instruments, although they are not necessarily used in every composition:

Constituents of the orchestra

1. Woodwinds: four flutes (one doubling, or duplicating the part of the piccolo), four oboes, English horn (cor anglais), three clarinets, bass clarinet, three bassoons, contrabassoon (double bassoon);

2. Brass: four trumpets, four or five French horns, three trombones, tuba;

3. Strings: two harps, first and second violins, violas, violoncellos, double basses;

4. Percussion; four timpani (played by one player) and at least three general percussion players.

The orchestra has arrived at this complement through centuries of evolution; the present size is needed to perform repertoire from the Baroque, Classical, Romantic, and Impressionistic periods, as well as the repertoire of the 20th century.

The various sections, with the exception of percussion, divide themselves in somewhat the same manner as a choir. The woodwinds, for example, divide into flutes (sopranos), oboes (altos), clarinets (tenors), and bassoons (basses), although this distinction must be greatly qualified. Instrumental range is larger than vocal range, and the clarinets of an orchestra may play higher than the flutes in a woodwind passage.

The standard instrumental groups of Western chamber music include the string quartet (two violins, viola, and violoncello), the woodwind quintet (flute, oboe, clarinet, French horn, and bassoon), the combinations employed in sonatas (one wind or stringed instrument with piano), and the brass quintet (frequently two trumpets, French horn, trombone, and tuba). In addition to these standard groups there are, however, hundreds of other possible combinations.

Other groups that deserve mention are those used in the popular music of the 20th century. The dance band, popular in the 1930s and 1940s, consisted of five saxophones, four trumpets, four trombones, double bass, piano, gui-

tar, and drums. The basic rock ensemble consists of two electric guitars, electric bass, electronic organ (doubling electric piano), drums, and frequently one or more singers. The concert band, which is particularly popular in North America, consists of mixed wind and percussion players totalling from about 40 to well beyond 100 players.

The music of the non-Western world is most frequently performed by groups of chamber music size. In this category would fall the music played by the Javanese gamelan orchestra (consisting mainly of tuned gongs and other metal instruments), Japanese *gagaku* music (performed on flutes, mouth organs, lutes, drums, and gongs), and Chinese music (with a traceable history of about 4,000 years) consisting of sacred, folk, chamber, and operatic music.

Types of instrumentation. The approach to the art of instrumentation is naturally greatly influenced by the type of group for which the composer is writing. He cannot treat a string quartet or a group of brass instruments in the same manner as he would a symphony orchestra. In general, the larger and more diverse the instrumental group, the more coloristic possibilities it presents to the composer. The smaller instrumental groups often have a sound character of their own, and the composer is challenged to find new and interesting ways to deal with this limitation.

The symphony orchestra has had definite traditions in relation to orchestration. The composer of the 18th century was likely to use the orchestral instruments at least part of the time in the following manner: the flutes doubling the same part as the first violins (frequently the melody); the oboes doubling the second violins or the first violins in octaves; the clarinets (by the end of the century) doubling the violas; and the bassoons doubling the violoncellos and double basses. French horns were often used as harmonic "filler" and in conjunction with every section of the orchestra because of their ability to blend easily with both stringed and wind instruments.

Development of wind instruments

These traditional doublings were not so often used in the orchestration of the 19th and 20th centuries because of the great improvement in the making of wind instruments and their consequent ability to function in a solo capacity. Wind instruments became used more and more for colouring; the flutes, for instance, were noted for their bright tone quality and great technical agility, the clarinets for all the aforementioned qualities, and the bassoons for their special tone quality. Brass instruments had to await the development of valves, which increased greatly the musical proficiency of brass players and overcame previous typecasting of these instruments as bugles and hunting horns.

String techniques. The string quartet has long been considered one of the greatest challenges to the composer because the contrast to be achieved by changing from one type of instrument when writing for a full orchestra is simply not available. The composer has had to rely on varying timbres to be arrived at by different playing techniques, such as pizzicato (plucking the strings), tremolo (the quick reiteration of the same tone), sul ponticello (bowing near the bridge of the instrument), sul tasto (bowing on the fingerboard), the use of harmonics (dividing the string in such a way as to produce a high flutelike tone), col legno (striking the strings with the wood of the bow), and many special bowing techniques.

Wind techniques. Special playing techniques also can alter the timbres of wind instruments. For instance, on many, tremolos can be played on two different notes.

Some wind instruments—and the flute is particularly agile in this respect—can produce harmonics. Flutter tonguing (produced by a rapid rolling movement of the tongue) is possible on most wind instruments; so are many other tonguing techniques that affect the quality of sound in orchestration.

Muting. The string mute is a device that softens the tone of the instrument. Muting is also used by brass instruments, particularly the trumpet and trombone, a development that took place in 20th-century popular music and then came into common use in all types of music.

Mutes—of which there are various kinds—provide the trumpet and trombone with a different tone colour. Mutes on woodwind instruments have been experimented with, but the results have not been satisfactory.

Percussion instrumentation. Percussion instruments have become a favourite source of colour for the 20th-century composer, both in the concert and popular fields. Instruments from all over the world are now commonly available and are divided into two categories: of definite and of indefinite pitch. The former include the xylophone, marimba, vibraphone, glockenspiel, timpani, and chimes. Instruments of indefinite pitch exist by the hundreds. Some of the more common ones are the snare drum, tenor drum, tom-tom, bass drum, bongos, Latin American *timbales*, many types of cymbals, maracas, claves, triangles, gongs, and temple blocks.

The availability of these instruments and the great improvement in percussion playing has resulted in an enormous increase in the number of compositions for percussion instruments. The percussion ensemble, a group of from four to eight players, is a chamber group that has existed only in the 20th century, particularly since the late 1940s. One of the interesting features of such an ensemble is that each player in it is capable of playing many instruments. An ensemble of four players, for instance, can easily handle 25 or 30 instruments, once again showing the rich palette available in a single composition.

Keyboard instrumentation. Since the 17th century, keyboard instruments have played an important role in orchestration. Those commonly available today are the harpsichord, celesta, organ (both pipe and electronic), and electric piano, in addition to the instrument for which most of the standard literature has been written—the piano. Keybord instruments vary greatly in the manner in which they produce a sound: the harpsichord has quills that pluck the strings; the piano has hammers that strike the strings; the celesta has hammers that strike a metal bar; the pipe organ sends air through a pipe; the electronic organ employs electronic oscillators to produce its sound. The resulting colours are naturally very different.

The piano, with its wide range (more than seven octaves), has been used in conjunction with virtually every instrument and instrumental combination. In the 18th century it gradually replaced the harpsichord as the common keyboard instrument because of the piano's ability to alter dynamics rapidly and its ability to sustain sounds. There is a vast amount of literature for the piano as the accompanying instrument in sonatas, partly because the piano can function as a "one-man orchestra." Many composers of the 20th century have discovered facets of the piano that had been previously ignored. The inside of the grand piano is a harplike body that has presented many new possibilities to the composer, such as the "prepared" piano. To prepare a piano, objects such as bolts, pennies, and erasers are inserted between the strings, thus producing many different sounds. The piano strings can be plucked or played with percussion mallets and can produce harmonics in the manner of non-keyboard stringed instruments, much to the dismay of piano tuners and traditional pianists.

The "prepared" piano

Electronic instrumentation. The electric piano is one of a number of instruments that have gained in popularity in recent times. These instruments either produce sound by means of electronic oscillators or are amplified acoustic instruments. The sound produced by ensembles playing this type of instrument is distinctive. The rock ensemble is the best known, but rock musicians are by no means the only instrumentalists to employ electric instruments. For the composer, amplified or electric instruments pose certain problems. Balances can be achieved or ruined simply by turning an amplifier up or down. The timbres produced by rock ensembles and other groups employing electronics are unusual for a number of reasons. The electric guitar has such devices as reverberation controls, "wa-wa" pedals, and filters that enable the performer to change timbre radically in the middle of a performance. Composers since the early 1960s, being much concerned with coloristic possibilities of instruments, have found the electronic ones most attractive.

Vocal instrumentation. The largest quantity of literature in Western music has been written for the chorus.

The choir, an instrument capable of great subtleties of colour, has been a favourite of composers for centuries. The range of most individual singing voices is rather limited. Choral singers, who usually have a limited amount of training, are capable of a range of about an octave and a fifth, which is considerably smaller than the range of individual instruments. Singers are usually not capable of singing wide leaps, that is to say, notes that are far apart in range. Great skill is required in the musical setting of the text in a choral work. Attention must be paid to the vocal qualities of vowel sounds as well as to the way in which the consonants are treated.

For centuries composers have been intrigued with the combination of voices and instruments, and many of the most important compositions in Western music have been written for chorus and orchestra. Almost every major composer of the past three centuries has written for choir and large instrumental ensembles.

The development of Western instrumentation. The development of the art of using instruments for their individual properties did not really begin in Western music until about 1600. The known history of musical instruments, however, has been traced back 40,000 years, although nothing is known about the music these early instruments produced. The Greeks left mostly musical theories and only a small amount of extant music. The Romans used instruments particularly in military bands, but, again, little is known of their specific use. The music of the Middle Ages and Renaissance was primarily vocal, although instruments were frequently used in compositions to accompany or reinforce the individual vocal line. Stringed, brass, woodwind, and percussion instruments were added not so much for their coloristic potential but because of their availability. Another practice in the Middle Ages was to make literal instrumental versions of vocal compositions, which, of course, has rather little in common with the modern art of instrumentation.

The Baroque period. Orchestration in a modern sense probably began in the 16th century with Giovanni Gabrieli, organist of St. Mark's in Venice. He was the first composer to sometimes designate specific instruments for each part in a composition, as in his *Sacrae symphoniae* (1597). Claudio Monteverdi made important contributions to the art of orchestration. His opera *Orfeo* was first performed at Mantua (now Mantova, Italy) in 1607 with an orchestra of about 40 instruments, including flutes, cornetts, trumpets, trombones, strings, and keyboard instruments. For the first time, a composer, in order to heighten certain dramatic moments, specified exactly which instruments were to be used.

Monteverdi's orchestra

The century after the first performance of *Orfeo* was characterized by a rise in the use of stringed instruments that were similar to the modern ones. Although that trend helped set the stage for the modern orchestra, it was not a period that made great strides in the art of orchestration: the prevalent practice of writing out only the melody and the bass line of a composition did not lend itself easily to creative scoring. By the end of the 17th century, however, the groundwork had been laid for new developments. Instruments and instrumentalists had improved steadily. Johann Sebastian Bach created works that occasionally exploited the coloristic capabilities of instruments but in a rather limited way. In some of Bach's music the stringed instruments are played pizzicato, although this practice had already been employed by Monteverdi. Bach also wrote for muted strings. Wind instruments were treated occasionally for their special sounds, although more frequently they were simply employed on a musical line that their range happened to fit.

Handel, whose life covered the same period as Bach's, had a keener sense of orchestral effect. He introduced the clarinet into his orchestra, although it was not to become standard until the 19th century, and in his operas Handel often used instrumental colour in a way that did not become common practice until much later. Jean-Philippe Rameau, the leading French composer of the 18th century, also contributed much to the development of orchestration. Rameau, like Handel, was principally famous as an opera composer, and the overtures and dances of his operas represent the most advanced uses of instruments during that period. Rameau was probably the first composer to treat each instrument of the orchestra as a separate entity, and he introduced interesting and unexpected passages for flutes, oboes, and bassoons.

By the middle of the 18th century the symphony orchestra was beginning to resemble the modern instrumental group, yet it was still considerably smaller. The orchestra at the court of Mannheim, Germany, consisted of 20 violins, four violas, four cellos, two double basses, two flutes, two oboes, two bassoons, four French horns, one trumpet, and kettledrums. Baroque composers frequently could not count on a fixed orchestra and therefore had to write the various parts so that they could be played on more than one instrument. The contrapuntal style that prevailed from the time of Monteverdi until the mid-18th century usually meant simply assigning instruments to each line in a composition; the basic consideration was whether that line stayed within the range of the chosen instrument. The fixed personnel of such orchestras as the Mannheim group, therefore, freed the composers to experiment with the capabilities of the instruments within the group. Musical style was also changing, the contrapuntal style of the Baroque giving way to a style that relied more heavily on melodic invention supported by harmony.

The court orchestra in Mannheim

One of the more important composers of the period between the Baroque and Classical eras was Johann Sebastian's son, Carl Philipp Emanuel Bach. In C.P.E. Bach's symphonies the strings become melodic instruments, and the winds—two flutes, two oboes, one or two bassoons, two horns—fill out chords and provide body to the orchestration.

The Classical period. The Classical era, which covers roughly the second half of the 18th century, is one of the most significant periods in the development of orchestration. The most talented composers of this period were Mozart and Haydn. Many important developments took place during this time. The orchestra became standardized. The Classical orchestra came to consist of strings (first and second violins, violas, violoncellos, and double basses), two flutes, two oboes, two clarinets, two bassoons, two or four French horns, two trumpets, and two timpani. Toward the end of his career, in the *London Symphonies*, Haydn introduced clarinets as part of the woodwind section, a change that was to be permanent. Haydn also introduced the following innovations: trumpets were used independently instead of always doubling the horns, cellos became separated from the double basses, and woodwind instruments were often given the main melodic line. In the *Military Symphony (No. 100)* Haydn introduced some percussion instruments not normally used in the orchestras of this time, namely, triangle, hand cymbals, and bass drum; and, what is still more unusual, they are employed in the second movement, which in the Classical tradition is normally the slow movement.

Standardization of the orchestra

In Haydn's music a method of composition appeared that had a bearing on orchestration. This consisted of the conscious use of musical motives; motive is defined in the *Harvard Dictionary of Music* as: "The briefest intelligible and self-contained fragment of a musical theme or subject." Perhaps the best known musical motive in Western music is the four-note group with which Beethoven's *Fifth Symphony* begins. These musical cells became the musical building blocks of the Classical period, particularly in the middle or development section of a movement, with the composer moving the musical motive from instrument to instrument and section to section, giving a new facet to the orchestration. The art of orchestration was thus becoming a major factor in the artistic quality of the music.

Mozart, too, was responsible for great strides in the creative use of instruments. His last two symphonies (*Nos. 40*, K. 550, and *41*, K. 551) are among the most beautifully orchestrated works of this or any period. For his 17 piano concertos, Mozart exhaustively explored the combination of piano and orchestra.

Mozart's special contribution

The Romantic period. Beethoven began his career under the influence of the Classical composers, particularly Haydn, but during his lifetime he transformed this heritage into the foundation of a new musical practice that was to

become known as Romanticism. The Classical composers for the most part attempted to orchestrate with a sense of grace and beauty. Beethoven occasionally made deliberate use of new, intense, often even harsh orchestral sounds. He also, in his later symphonies, augmented the orchestra with a piccolo, contrabassoon, and third and fourth horn. The *Ninth Symphony* has one passage calling for triangle, cymbals, and bass drum, a combination identified with the imitations of Turkish Janissary music in vogue in previous years, and the final movement calls for four vocal soloists and full chorus.

The Romantic era was characterized by great strides in the art of instrumentation, and, in fact, the use of instrumental colour became one of the most salient features of this music. The piano really came into its own as a source of interesting sonorities; the orchestra expanded in size and scope; new instruments were added; and old instruments were improved and made more versatile. The Romantic period saw the appearance of the first textbook on the subject of orchestration. It was the French composer Hector Berlioz' *Traité d'instrumentation et d'orchestration modernes* (1844; *Treatise on Instrumentation and Orchestration*, 1856). Berlioz was one of the most individual orchestrators in the history of music, and his *Symphonie fantastique* (1830) is one of the most remarkable pieces of music to come out of this era. Berlioz made use of colour to depict or suggest events in his music, which was frequently programmatic in character. He called on large forces to express his musical ideas, an idea that persisted throughout the 19th century and into the 20th. Berlioz' *Grande Messe des morts* (*Requiem*, 1837) calls for four flutes, two oboes, two English horns, four clarinets, 12 French horns, eight bassoons, 25 first violins, 25 second violins, 20 violas, 20 violoncellos, 18 double basses, eight pairs of timpani, four tam-tams (a type of gong), bass drum, and 10 pairs of cymbals; four brass choirs placed in various parts of the hall, each consisting of four trumpets, four trombones, two tubas, and four ophicleides (a large, now obsolete brass instrument); and a chorus of 80 sopranos, 80 altos, 60 tenors, and 70 basses. The coloristic ideas in Berlioz' music were carried on in various ways by other important 19th-century composers and reached a culmination in the music of the German composer Richard Strauss and the Austrian Gustav Mahler—both of whom demanded a virtuoso orchestra—and were orchestrated in a complex fashion, although Mahler was capable of very delicate effects.

First treatise on orchestration

Post-Romanticism and the 20th century. Claude Debussy in France was probably the most important composer of the Impressionistic era, which lasted roughly from 1880 until the turn of the century. The Impressionist composers attempted to describe scenes and evoke moods by the use of rich harmonies and a wide palette of timbre. No composer ever handled the colours of the orchestra with greater subtlety. Naturally, this is also dependent on his use of harmony, melody, and rhythm, but the dominant impression of a Debussy work is focussed on his use of orchestral instruments to create light and shadows. Works that exemplify his techniques are *Prélude à l'après-midi d'un faune* (*Prelude to the Afternoon of a Faun*; 1894), *Nocturnes* (1899), and *La Mer* (*The Sea*; 1905). In *Nocturnes*, he uses a wordless women's chorus as a section of the orchestra, functioning as another source of timbre rather than as the transmitter of a text.

The Impressionist school

Many of the composers who followed Debussy and Mahler brought about radical changes in the use of the orchestra. A good example of some of these changes is in *The Rite of Spring* (1913), by the Russian-born composer Igor Stravinsky. The strings frequently do not assume a dominant role but, rather, often play music that is subservient to the brass or woodwinds. Percussion instruments greatly increased in importance and have continued to do so. In 1931, Edgard Varèse composed an important work, *Ionisation*, for 13 percussion players, a landmark in the emergence of percussion instruments as equal partners in music.

The period between World War I and World War II was dominated by two main schools of composers with vastly differing results for orchestration. One was responsible for the Neoclassical style; the other, gathered around the Austrian composer Arnold Schoenberg, drew heavily on the Romantic movement for its direction. The Neoclassical composers sought to free music from the influence of Impressionism. Whereas the Impressionist and Romantic composers had frequently employed the instrumental forces at hand to create a deliberate sense of vagueness, the Neoclassical composers, beginning in about 1917 with a group in France known as Les Six, attempted to recreate the clarity of the Classical period by turning to models found in the popular music of the period, the music of the dance halls and cabarets. The Neoclassical composers also turned away somewhat from the orchestra as a medium, finding the forces of chamber music more suitable for their ideals. Neoclassical music returned to a clearer concept of "sections" in orchestration. The music of a composer such as Paul Hindemith in Germany is closer to the music of Mozart in its sense of instrumentation than it is to Romanticism or Impressionism.

The music of Schoenberg and his fellow Austrian Alban Berg drew heavily on the Romantic movement and eventually became known as Expressionism, which stressed inner experience. Emphasis on the inner man produced a music that was thick, dark, and intense.

In the first half of the 20th century electronic music emerged, although it did not become important until after 1950. The principal reasons for the inclusion here of electronic music are that electronic sounds, either taped or live, frequently are included in a composition combined with traditional instruments, and it has had a decided influence on orchestration. (For a treatment of historical and compositional aspects of electronic music, see MUSICAL FORMS AND GENRES: *Electronic music*.) By the 1960s many composers were writing works for electronic sounds and instruments. The electronic sounds provide a dimension to instrumentation never before possible. A number of things are noteworthy. Electronic sounds are capable of incredibly subtle changes of timbre, pitch, and mode of attack. When combined with traditional instruments they add a rich new spectrum of colour. This in turn has influenced the composer to attempt to produce "electronic" sounds with standard instruments. The result has been a great extension of the sound possibilities of Western instruments.

Importance of electronic music

Another 20th-century trend was away from large orchestras and toward chamber ensembles, often of nontraditional combinations. Compositions for such ensembles may excel in economy of means and explore individual instrumental timbres. To achieve this, unusual playing techniques may be required.

Non-Western instrumentation. Much of music outside the West has entirely different aesthetic aims; the music of the Hindu world, best known to the West through the classical music of India, provides an example. Indian music always has had strong ties with mythology and religion and thus produced an art that is as different from Western music as Hinduism is from Christianity. It achieves unity through similarity rather than through change and is based on a more purely sensual approach. Hindu music is divided, for example, into ragas, or melody types. The word raga means colour or mood. Combined with the ragas are *tālas*, or rhythmic patterns. The possible combinations of *tālas* and ragas are many, producing a music that is wonderfully subtle.

The instruments for this music consist of various drums made of terra-cotta, wood, or metal; cymbals also serve as percussion instruments. Probably the instrument best known to Western audiences is the tabla, a two-drum set capable of very subtle changes in sound. The two best known stringed instruments are the sitar (plucked) and the tamboura, a four-stringed instrument that provides the omnipresent drone accompaniment. In addition, there are various wind instruments, such as the bamboo flute and the *sheh'nai* (oboe).

Instruments of Indian and Balinese music

Balinese and Javanese music is centred on the gamelan orchestra, the instruments of which include the *saron* and *gender* metallophones (like xylophones but with metal, not wooden, keys), the *gambang kayu* xylophone, tuned gongs, flutes, and the *rebab*, a violin-like instrument with

two strings. All the instruments follow the same nuclear melody but elaborate it in different ways. The heavy reliance on tuned percussion instruments has given this music a brilliant quality that Western audiences have found extremely attractive. The gamelan orchestra, for instance, influenced Debussy, who first heard the music at the Paris Exposition in 1889.

The approach to instrumentation in the music of India and Bali is quite different from that of Western music. The concept of contrast created through the various "choirs" of the Western orchestra is not a primary concern. In Indian music a sameness of colour is created through the use of the drone played on the tamboura. This is not to say that this music is uncolourful but that a specific timbre is established for an entire composition. Since the time of Debussy, Western composers have come increasingly into contact with, in particular, the music of India, Bali, and Japan. A comparison of Balinese gamelan music with the *Sonatas and Interludes* for prepared piano by the 20th-century American composer John Cage shows how profound this influence can be.

Arrangement and transcription. A practice that has been much employed in the 20th century, although by no means confined to it, has been the writing of arrangements and transcriptions. Though little distinction is made between the two, there are, at least in current practice, differences. A transcription is essentially the adaptation of a composition for an instrument or instruments other than those for which it was originally written. An arrangement is a similar procedure, although the arranger often feels free to take musical liberties with elements of the original score. This is especially true of arrangements for jazz or rock groups and arrangements of popular compositions or songs from musical comedies.

In the 18th and 19th centuries, chamber and orchestral music was transcribed, or "arranged," for the piano for the purpose of study and, of course, for the pleasure of playing at home the music that had been heard at a concert. This practice has continued. Piano versions of many 18th- and 19th-century orchestral works exist in two- and four-hand arrangements. Another common practice is to reduce the orchestral parts of concertos to a keyboard version to enable students to study and play these works without an orchestra.

Piano versions of orchestral works

The symphonic band, despite its popularity in Great Britain and North America, was faced with a dearth of repertoire written specifically for it. In the past, one answer was to transcribe orchestral works for band, substituting particularly the clarinets, with their wide pitch range, for the strings of the symphony orchestra. The necessity for that substitution is no longer so great because in recent times composers have written much more music specifically for the symphonic band.

The dance band predominant in the 1930s and 1940s is treated roughly in the following way by arrangers: the saxophones carry the melody more frequently than the other sections; the trumpets provide embellishment or figures that work around the melody; the trombones either are combined with the trumpets or serve as a melodic instrument; the piano and guitar provide harmonic filler; and the double bass and drums set the rhythm.

The jazz or rock arranger has done much more than simply transcribe the keyboard version of a song. All forms of popular music in the 20th century have been involved in the art of improvising. Musicians working in this field almost always embellish the music as they perform it. The jazz or rock arranger in a sense improvises on manuscript paper. In making an arrangement for a group of musicians the arranger will embellish both the harmonic structure and the melody of the composition; or the arrangement will be worked out in rehearsal and memorized or written down later. Usually, the arranger keeps enough of the original material to enable the listener to recognize the source. His skill depends on how well he can manipulate the materials of the original and on his originality in scoring the composition for the group at his disposal. The men who work in this field are frequently composers of popular music themselves.

(D.Er.)

The recording of music

TYPES OF REPRODUCTION

The physical reproduction of music has been accomplished in three major ways, which can be designated the mechanical, the acoustical, and the electrical. In the mechanical, an automatic instrument, such as the barrel organ, plays music that has been built, or programmed, into the mechanism by the designer; the resulting sound is that of the apparatus. In the acoustical and electrical methods of reproduction, sonic vibrations themselves are captured in performance and reproduced—by purely mechanical means in the acoustical method and by the use of vacuum tubes, transistors, and other such devices in the electrical. In both cases, the resulting sound is expected to be that of the independent performance.

Mechanical, acoustical, and electrical methods

Until the end of the 19th century, music was reproduced primarily by means of the mechanical method. There are reports of other methods, probably based on the action of wind or forced air, dating as far back as about 1500 BC, in the 18th dynasty of ancient Egypt, when a colossal statue of the god Memnon at Thebes made some sort of sounds to greet his mother, the goddess of the dawn. (Toppled by an earthquake in the year 27, the statue seems to have lost this ability upon reconstruction.) Friar Roger Bacon is reported to have invented some sort of talking head in the Middle Ages, and Josef Faber created in Vienna in 1860 a talking man with ivory reeds for vocal cords, a rubber tongue and lips, and with a keyboard that altered the mouth cavity to control word formation. The most common technique, however, called for a human hand or clockwork to turn a cylinder embedded with pins that would strike or otherwise operate some sound-producing apparatus, such as the metal teeth of a music-box comb; the hammers, quills, or pipes of a keyboard instrument; or the clappers of a set of bells. Automatic carillons are known from the 1300s; automatic harpsichords and organs, from the 1500s. King Henry VIII of England owned an automatic virginal; his daughter Queen Elizabeth I in 1593 sent the sultan of Turkey an elaborate musical clock. Every six hours it played a tune on 16 chimes, followed by a two-trumpet tantara, then by an organ tune and performance by "a holly bushe full of birds and thrushes, which at the end of the musick did singe and shake theire winges." In the 19th century Queen Victoria of Great Britain owned a bustle that would play "God Save the Queen" when she sat down.

Some of the most illustrious composers in the history of music wrote for mechanical devices. Haydn wrote tunes for musical (pipe organ) clocks; Mozart wrote several pieces for mechanical organ; and Beethoven wrote his *Wellington's Victory* (or *Battle Symphony*) for the panharmonicon, a full mechanical orchestra invented by Johann Nepomuk Maelzel (Mälzel), a German musician who perfected the metronome.

At the end of the 19th century two inventions superseded the barrel-and-pin mechanism. One was the player piano, which used a perforated cardboard roll to control a stream of air that activated the piano's hammers. This had the advantage of enabling pianists to record their performances for future playback, and many virtuosos and composers took advantage of this device, among them Ignacy Paderewski, Edvard Grieg, Claude Debussy, and Sergey Rachmaninoff. Some composers, including Igor Stravinsky and Paul Hindemith, wrote music especially for the piano roll, using devices such as combinations of as many as 30 notes played simultaneously; while impossible for two hands, such chords could readily be played by the perforated paper.

The player piano

The second invention, which was to make obsolete all previous music-reproducing apparatuses (except in toys and cuckoo clocks), was the phonograph. (For the technology of musical reproduction, see SOUND: *Sound recording and reproduction.*)

THE INFLUENCE OF RECORDING

Composition. In 1967 a survey of hundreds of American composers indicated that they were almost unanimous in regarding the recordings of their works as being more

important than either printed publication or live performances. Through recordings, composers gained not only an easy familiarity with the music of others but also a new medium for their own works.

The contemporary American composer and teacher Milton Babbitt, in a conversation in 1965 with the Canadian pianist Glenn Gould (who maintained his own reputation largely by means of records and broadcasts, rather than by concert performances), said:

> We have all been affected as composers, as teachers, as musicians by recordings to an extent that cannot possibly be calculated as yet. . . . I don't think one can possibly exaggerate the extent to which the climate of music today is determined by the fact that the total Webern is available on records, that the total Schoenberg is becoming available.

The use of the record as a medium had superficial beginnings as early as 1904 in Ruggero Leoncavallo's song "Mattinata," specifically written for the record according to the label. Later, in 1925, Stravinsky composed a piano piece, *Serenade in A Major,* expressly for the record medium, though it is also perfectly capable of being performed live. Ottorino Respighi's *Pines of Rome* (1924) incorporates a recording of a nightingale's song in its third movement. Much more important use of recording as a medium occurred toward mid-century in works fundamentally relying on recorded tape, such as Edgard Varèse's *Poème électronique,* an 11-channel tape played through 425 speakers at the 1958 Brussels World Fair, and Morton Subotnick's *Silver Apples of the Moon* (1967), an electronic work playable only as a recording.

Teaching. In music education the phonograph was early adopted as a tool in teaching both serious students and laymen. Teachers who could not adequately illustrate musical examples at the piano found in records a means of demonstration. They could also bring entire orchestras into the classroom by means of the phonograph.

Recorded histories of music

In 1930 the *Columbia History of Music by Ear and Eye,* a phonographic survey that became popular in music history classes, enabled many students—as well as many of their teachers—to hear for the first time such instruments as viols, lutes, virginals, clavichords, and harpsichords together with the then little-known music written for them. A half dozen years later another educational recorded project, *L'Anthologie sonore,* added impetus to this specialized field. By the 1960s the Baroque music of the 17th and 18th centuries—as well as the earlier music of the Renaissance and medieval era—increasingly was recorded in performances using the instruments for which it was written. Such music found a wide audience beyond educational institutions; this audience was developed in large part by the phonograph.

By the late 20th century many conservatories, colleges, and universities, and even some secondary schools, had constructed recording studios to enable students to analyze their own performances or to rehear their own compositions.

Criticism. Records also enabled music critics to expand their knowledge and perspective of music and performance practices. Unfortunately, a record collection also allows reviewers to write on superficial differences between performances with very little expenditure of intellectual energy. New music has suffered especially from the resulting loss of the ability of many critics to expostulate on music for their readers.

Concerts. The impact of recordings on the concert hall has also been enormous, both for classical and for popular performances. Performers today can hardly hope to attract a concert audience if they have not produced distinguished recordings; usually, their audiences, both at home and abroad, consist of persons who know the performers' work through recordings. In the popular music field especially, many performers cannot compete in live appearances with recordings in which they depend heavily on technical aid. There are some who feel that the phonograph may cause the demise of live performance in the concert hall, which, if it survives at all, will do so for social rather than musical reasons. A possible indication of this trend is the disappearance of independent, nonacademic, nonprofessional classical music magazines in America; instead, there are record magazines. Their name changes are significant: *The American Record Guide,* established in 1935 as *The American Music Lover; High Fidelity,* established in 1951; and *Stereo Review,* established in 1958 as *Hi Fi/Music Review.* The record magazine is not a peculiarly American phenomenon; England has *The Gramophone* and *Records and Recording;* France, *Diapason* and *Harmonie;* Germany, *HiFi Stereophonie* and *Fono Forum;* Italy, *Discoteca Hi Fi;* Holland, *Luister;* Belgium, *Hi-Fi Musique;* Sweden, *Musikrevy;* and Japan, *Record Art/Record Geijutsu,* among many other periodical publications.

Musicology. The entire field of comparative musicology—*i.e.,* the study of the relationships between Western, non-Western, and primitive music—depends upon disc and tape recordings. Although the discipline may be traced to the 18th century, it did not emerge from a primitive state until it acquired phonographic tools. Primitive music is generally transmitted orally rather than through a written tradition, and as such its performance practices—certainly in rhythm and intonation—cannot be accurately transcribed into Western notation. Since World War II anthropologists and musicologists have visited the most remote parts of the world with tape machines to record aboriginal music before it was either tainted or wiped out by Western civilization. The most recent studies have been conducted as a race against time or more specifically against the transistor radio, a ubiquitous commodity that is homogenizing the world's musics.

THE ROLE OF THE PRODUCER

Although the record producer has at times become an equal partner with the musicians in creating the recorded performance of classical music, in the popular field he is frequently in total command. Here, in fact, the sounds produced by the musicians may simply be the raw material for the producer to work with; artificial sounds, overlays of sound upon sound, electronically introduced reverberation, multichannel effects with directional interplay and moving instruments, all may serve as vital ingredients of the recording. Paradoxically, as technological advancement brought the recording beyond the mere imitation of live performances, popular musicians began to bring complex electronic equipment into the concert halls to imitate the sounds of their recordings.

In productions of classical music, serious thought is given to whether the recording should faithfully capture the performance as heard from the optimum position in the concert hall or studio or whether the recording setup should be used to "enhance" the performance. Few question any longer the common practice of correcting actual mistakes. Ever since magnetic tape made detailed editing possible, extra takes have been made of sections in which musical problems are evident. The best taping of each section is spliced into a master tape. Even in recordings made during an actual concert, performers sometimes return to the hall afterward to emend any blemishes. The improvements in recorded performances made possible by tape splicing, however, often mislead audiences into anticipating the same perfection in live performances. Also, although tape editing facilitates the excision of poor passages that, while acceptable in the heat of a concert, would become irritating upon repeated hearings, it also has been said to hamper the continuity of the performance. It is unlikely, however, that a listener can spot the rare movement that has required no splicing from the majority that have. This alleged lack of continuity, however, was much worse when music had to be recorded in five-minute segments, for recordings at 78 revolutions per minute (rpm).

Microphone placement

Microphone placement has been perhaps the major criterion in separating the "natural" or "re-creative" from the "creative" technique of large-scale classical recordings. In a natural setup microphones are placed in the optimum positions in the hall—often directly over the conductor—in order to re-create the concert-hall or opera-house effect. In the natural arrangement the conductor is responsible for instrumental and vocal balances.

Some record-producing companies prefer to put microphones closer to the performers—this is called close-miking technique. Here the record producer—generally with the

final approval of the conductor or leader—is responsible for balances, for bringing out particular instrumental or vocal lines; in other words, the producer participates in the interpretation. Studio-made popular recordings—other than those of a lush semiclassical nature—have generally used the close-miking technique; in some cases, each performer in a small musical group is assigned his own microphone. In a close-miked symphonic recording session, as many as 18 microphones may be used: three for violins; one for cellos and basses (sometimes one for each); one each for woodwinds, brasses, timpani, snare drum and triangle, bass drum and cymbals, celesta or harp, and soloist; and from three to six for a chorus. Several separate recordings, or "tracks," each comprising the inputs of several microphones, generally are made at the same time, and the producer must balance the strength of these various inputs during the recording session. Until about 1960 two-track machines were ordinarily used; by 1970 eight-track recorders were in use, allowing much more subtle mixing of channels during the editing sessions subsequent to the actual recording. For popular music sessions 16-track recorders are sometimes used. For stereophony all the recording tracks must be edited and mixed to make the final two channels. The record producer also determines the degree of separation between those two channels, and during a dramatic recording—an opera, for example—he may function as stage director in guiding the performers around the aural stage.

In quadraphony (quadriphony), which has four channels and which, in disc format, unsuccessfully tried to find a market in the early 1970s, the controversy between natural and close-miked recordings persisted. In classical music, when the two rear channels were used mainly for hall ambience, the arguments centred on the placement of the two front channels. Some companies, however, began to use the four channels as equal partners even in the classics. Columbia, for example, sometimes placed the conductor in the middle of the orchestra, which was seated for optimum quadraphonic array rather than for optimum concert-hall effect. In the early 1970s several quadraphonic disc systems competed for prominence, most notably Columbia's SQ, Japan Victor Company's CD-4 (RCA's Quadradisc in the United States), and Sansui's RM (also called QS). Since they were incompatible systems, confused consumers, waiting for one to become standard, withheld their votes from all, and by the end of the decade the aural and aesthetic benefits of quadraphony had all but disappeared from the marketplace.

THE DEVELOPMENT OF MUSICAL RECORDING

In 1877 the U.S. inventor Thomas Alva Edison heard "Mary had a little lamb" emanate from a machine into which he had just spoken the ditty. It was the first time a recording of the human voice had been reproduced, and the event signalled the birth of the phonograph. There was, to be sure, a long gestation period.

Edison sent representatives, machines, and cylinders to Europe almost as soon as he had invented the phonograph, and between 1888 and 1894 recordings were made by such notables as Alfred, Lord Tennyson, Robert Browning, and even Johannes Brahms, who played a Hungarian rhapsody. The first "celebrity" recording, however, was made in Edison's West Orange, New Jersey, laboratories when the pianist Josef Hofmann, then a 12-year-old prodigy, paid a visit to Edison's studio in 1888. Hans von Bülow followed shortly after with a recording of a Chopin mazurka on the piano.

The first "celebrity" recordings

In 1894 Charles and Émile Pathé built a small phonograph factory in a suburb of Paris and began to record singers as eminent as Mary Garden. Within a decade their catalog boasted some 12,000 items, and their name became almost synonymous with the cylinder phonograph in Europe. Meanwhile, Emile Berliner, a German immigrant living in Washington, D.C., had filed a patent in 1887 for a "Gramophone," using a disc rather than a cylinder, and he began manufacturing Gramophones and discs in 1894. The disc had the commercial advantage of being more easily manufactured than the cylinders. One of his representatives established a branch in London, the Gramophone Company (in 1898), a branch in Berlin, Deutsche Grammophon AG, and one in France, the Compagnie Français du Gramophone, while Berliner's brother set up a disc-pressing facility in Hamburg. Most of Europe's recording industry thus was started by Berliner's representatives, and in the United States the small Berliner organization was to turn into the giant Victor company.

By the beginning of the 20th century, recording industries had been established in Germany, Austria, Russia, and Spain. Much of the managerial and technical talent, not to mention equipment, had been imported from America. (By 1970, the positions would be reversed, with Europe in command of most of the American market.)

During the 1890s recordings had become popular primarily through coin-in-the-slot phonographs in public places. Talent was incidental to the novelty of the apparatus; most of the recordings were of whistlers, bands, comic numbers, ditties, ethnic routines, and the like. In the first years of the 20th century, Victor and its affiliates raised cultural expectations with its Red Seal series (Red Label in Europe), particularly with discs made, beginning in 1902, by Enrico Caruso. By 1910 the vast majority of record sales—some estimates are as high as 85 percent—were classical.

The Red Label had been initiated in 1901 in Russia with some of the first 10-inch disc recordings made, and the basso Fyodor Chaliapin was among the first artists to record on the new Russian Red Label.

In 1902 Victor and another major label, Columbia, decided to help the development of the new industry by pooling their patents. Victor was thereby legally able to record on wax (which would then be electroplated) for the first time, and the new wax discs were then used in recording Caruso in Milan. Caruso's discs were a major catalyst in transforming the amusing gadget of a phonograph into a respected cultural phenomenon. That same year the new series received London-made recordings by stars of the Covent Garden opera house, primarily through the efforts of the Gramophone Company's music director, Landon Ronald, a bona fide serious musician and conductor who was able to convince his colleagues of the musical worth of the Gramophone. One instrumentalist also appeared in the new Red Label series, the violinist Jan Kubelík.

In the United States, Columbia followed suit in 1903 with its 10-inch Grand Opera Records, recording Metropolitan Opera stars. Shortly after, Victor began its own celebrity recording sessions of opera stars and others on 3½-minute 12-inch discs. Victor also made many of its associated European companies' Red Label recordings—which included Mary Garden singing music by Debussy with the composer at the piano—available in the United States on its Red Seal series. Columbia soon dropped its opera series when the recordings did not sell as well as songs and marches, but Victor saw an institutional value in the celebrity recordings. The prestige of the Red Seal influenced Victor's other products: "Victrola" became, in the popular mind, almost a generic term for the (disc) phonograph, and the company practically monopolized the quality-minded market for many years. Indeed, the total Western Hemisphere record market became virtually monopolized by Victor and Columbia, while their London affiliates controlled the rest of the world. The first major break did not come until World War I, when ties were severed with Deutsche Grammophon, which emerged after the war as the independent Deutsche Grammophon Gesellschaft (DGG).

Between 1907 and 1910 Columbia tried to approach Victor's cultural prominence by releasing records from Europe and later by reinstating its own recording sessions with operatic singers. Columbia also began issuing double-sided discs, as had already been done in Europe. Victor did not do so until 1923.

During the early days of recording, both the cylinder and the disc were produced acoustically rather than electronically. A singer would sing into a horn, and the accompanist behind him played a piano placed on a platform so that the rear of the instrument—with the back removed—would also be level with the horn. With the development of a sound box to be placed on violins and violas, small

orchestras could be used as accompaniment, but bassoons were required to play the cello part and a tuba the double bass part. It was an event worthy of a London newspaper announcement in 1904 when Kubelík made two records with his own Stradivarius, rather than on a violin with the sound box. When symphonic recordings came to be made, the wind and brass instruments still played or doubled the parts written for the lower strings, which could not be reproduced adequately. Although acoustical recordings were improved by the 1920s, the problems were not overcome until the introduction of the microphone and the consequent electrical recording process around 1925.

Birth of a mass medium

In the decade 1910–20, the phonograph became a truly mass medium for popular music, and recordings of large-scale orchestral works and other classical instrumental music proliferated. The rise of the popular record coincided in the United States with the new ragtime, popularized by Scott Joplin's rags at the turn of the century and sensationalized by Irving Berlin's "Alexander's Ragtime Band," written in 1910, which swept the country the following year. It stimulated an unprecedented dance craze at a time when the phonograph was becoming increasingly available. As the fad spread to millions who had never danced before, phonographs were sold to people who had never owned records before. Between 1914 and 1919 phonograph sales increased more than fivefold. In 1917 Victor issued the first jazz recordings, by the Original Dixieland Jass (sic) Band, but few major jazz releases appeared before the 1920s.

The first large-scale symphonic recording, Tchaikovsky's *Nutcracker Suite*, was issued in 1909 in England. The first attempt to record a concerto came the following year, also in London, when Wilhelm Backhaus recorded a cut version of the first movement of Grieg's *Piano Concerto*. In 1913 the first complete symphonies, Beethoven's *Fifth* and *Sixth*, were recorded in Germany under an anonymous conductor; later that year, a celebrity conductor, Arthur Nikisch, led a full-scale symphony for the first time, again the Beethoven *Fifth*. Solo instrumentalists vied with the opera singers for the record-buying public's affection, mainly by recording tidbits. In 1917 Victor began to record with a combination that was to prove its star classical music attraction for decades: Leopold Stokowski and the Philadelphia Orchestra.

The serious recording of serious music became a growing phenomenon as the phonograph matured during the early 1920s. Tidbits and orchestral snatches gave way to a spate of uncut symphonies, sonatas, quartets, and concerti; the music itself came to mean as much as its star performers, and the electrical recording process, from 1925 on, raised the quality of the recordings as well. But in the mid-1920s radio, which provided free music, developed, and this new factor, plus the worldwide economic depression of the 1930s, threw the phonograph industry into serious decline.

The companies realigned themselves. In 1929 the Radio Corporation of America (RCA) bought Victor. Later that year, Edison left the phonograph business he had created. In 1931 the English Columbia Graphophone Company divested itself of its near-defunct American progenitor and joined the Gramophone Company to form Electric and Musical Industries, Ltd. (EMI), bringing into the merger nearly every important European firm except DGG and its export label, Polydor. American Columbia was revived by its purchase, in 1938, by the Columbia Broadcasting System.

During the 1930s, as the American companies relied mainly on dance records in jukeboxes to satisfy a dwindled market, Europe supplied a slow but steady trickle of classical recordings. In 1931 the His Master's Voice (HMV) label in Great Britain began its "Society" issues: a limited public was asked to subscribe in advance to then esoteric releases—the complete Beethoven piano sonatas played by Artur Schnabel or Pablo Casals performing the Bach unaccompanied cello suites. A new British company, Decca, organized in 1929, also began to issue serious recordings. In the United States, Columbia began to record a number of distinguished orchestras, including those of New York City, Chicago, Cleveland, and Minneapolis. RCA retained its leadership, however, with the Philadelphia Orchestra under Eugene Ormandy, the Boston Symphony Orchestra under Serge Koussevitzky, and—perhaps the greatest orchestral combination ever assembled—the NBC Symphony under Arturo Toscanini, as well as with the violinist Jascha Heifetz and the pianist Vladimir Horowitz.

British Decca had a far-reaching role to play after World War II when its ffrr—full frequency range recording—became internationally known. The frequency range of discs had been dramatically extended, and Ernest Ansermet's recording of Stravinsky's *Petrushka* in the new process was to awaken the unsuspecting ears of many record collectors in 1946 to the future high fidelity, or "hi-fi," possibilities of the phonograph.

Two other developments in the late 1940s combined with the extended frequency range to produce a radical change in the development of recordings: magnetic recording and the first commercially successful long-playing (LP) record. In 1948 Columbia Records demonstrated 12-inch unbreakable vinyl discs that could play about 25 minutes of music per side. The standard shellac disc had revolved at 78 rpm, and a 12-inch disc had to be changed, automatically or manually, every five minutes, thus breaking up the continuity of longer works; the 12-inch LP, revolving at $33\frac{1}{3}$ rpm, could hold the average symphony, sonata, or quartet on a single side. And the vinyl discs had quieter surfaces than the shellac. Victor soon countered with its own microgroove records: seven-inch vinyl discs at 45 rpm. Each contained approximately as much music as a 12-inch 78-rpm disc, but the package was smaller. By 1950, a pattern had been set: 12-inch LPs for classical works and popular albums, 45s for individual popular songs. Extended-play 45s also were developed and successfully marketed. The LP opened up an entirely new market—not only newcomers but older record collectors who could see the advantage of the new technology and were willing to repurchase their collections as LPs. The 78-rpm shellac disc followed the cylinder into oblivion.

Tape had a major impact on recording starting in the late 1940s: anyone with a good recorder and microphone could become a record producer. Small companies sprang up in areas of music ignored by the giants: the esoteric and the avant-garde, the music of the periods before and after the highly popular Romantic classics of the 19th century. Chamber music, as well as Baroque works of the 18th century and earlier, which required paying fewer musicians than an entire symphony orchestra, flooded record stores and resulted in an unprecedented Baroque revival among music lovers. All-Vivaldi concerts were sold out, and Bach became a best-seller. Orchestral recordings of less familiar works—produced in a Europe that had been ravaged by World War II, where musicians' fees were minimal—crested the flood. New companies recorded for the first time many symphonies, quartets, masses, little-known operas, and many other once esoteric works, some of which were now available in competing versions. The more popular standard works, the symphonies of Beethoven, Brahms, and Tchaikovsky, became duplicated by the dozens. By the mid-1950s it seemed that most of the worthwhile musical output of Western civilization—and much from Asia and Africa—had been made available to the average home.

The stereo revolution

For a few owners of some deluxe tape recorders, a new listening experience was available by 1956: stereophonic tape recordings. Within two years stereo discs made their commercial appearance; every major U.S. company began issuing stereo discs by the end of 1958.

Now a new flood of records hit the market: notably popular were those that displayed the spectacular effects possible with stereo. It was again Decca/London that convinced the serious music lover of the musical benefits of stereo with the release in 1959 of Wagner's *Das Rheingold*, conducted by Georg (later Sir Georg) Solti, a pioneer work in the "creative" school of classical record production. Within a decade two complete recordings of Wagner's *Ring* cycle, comprising four complete operas on 19 discs, were available. Again, as with the advent of the LP, a technical advance spurred the record industry into recording an even greater repertoire than was available previously. By the late 1960s most American record com-

panies had discontinued their monaural recordings, except for "historical reissues."

The 1950s saw a rearrangement of record company alliances, as Europe began its strong invasion of America. By the 1970s not only did Europe own a sizable chunk of the American record industry, but it had taken over the recording, for the first time, of many of the most prestigious U.S. orchestras.

Another far-reaching phenomenon of the 1950s was Elvis Presley, a popular U.S. singer who inspired a new, militantly youth-oriented style of music: rock and roll. It generated a multitude of solo singers and groups as well as a teenage and subteen culture of rabid record buyers. The success of the British rock group the Beatles helped stimulate record sales in the 1960s to an all-time high. The sales of classical records, however, represented a declining portion of the total. It seemed that most people who wanted the standard classics had already bought them and that few new standard works of any length were being written. Rather than new classical recordings, re-releases were issued in new packages (*e.g.*, "Debussy's Greatest Hits") and in the new medium of tape. During the mid-1960s two small and conveniently packaged tape formats began a steady rise to popularity: the continuous-loop one-reel cartridge and the two-reel cassette. Each obviated the need for threading tape in order to play it. The cartridge first achieved consumer acceptance as an automobile accessory and was designed primarily as a playback-only format; the cassette configuration was first introduced in an inexpensive portable recorder player.

Cartridges, cassettes, and videotape

Cassettes had the advantage over continuous-loop cartridges in being rewindable and thus easier to control for selective "spotting" and for amateur recording. For nonselective music or music in which it is not necessary to start at the beginning—background music, for instance—the continuous-loop cartridge had the advantage of not having to be rewound at all. By the end of 1982 sales of recorded music on cassettes had overtaken those of LP discs in the United States.

Meanwhile, a new recording technique that boasted, among other things, a wider dynamic range had begun to revolutionize the market for quality recordings: the music was taped "digitally," via pulse-code modulation. Pioneered by the Denon label in Japan, it was most enthusiastically adopted by Cleveland-based Telarc Records in the late 1970s. Another small company, Sheffield Lab, had already been producing impressive-sounding results by recording directly onto disc, foregoing the tape stage entirely. These and other "audiophile" companies began to corner the quality market, while charging two to three times the price of standard discs for their products: by 1983 this had led more than 40 companies, including the major labels, to adopt audiophile, primarily digital, techniques for at least their new classical releases. The first true digital discs, called Compact Discs, played back with a laser as the "stylus," became available in Japan in 1982 and in Europe and the United States in 1983.

Video has continued to be used to record musical performances via several incompatible disc and tape formats. The first years of the medium demonstrated that the grafting of images onto music would become viable only with the emergence of genius comparable to that of the great composers themselves. (L.M.M.)

BIBLIOGRAPHY

Modern theories of musical meaning: ARTHUR SCHOPENHAUER, *Die Welt als Wille und Vorstellung* (1883; Eng. trans., *The World as Will and Idea*, 1961); and FRIEDRICH NIETZSCHE, "The Birth of Tragedy from the Spirit of Music," trans. by CLIFTON P. FADIMAN in *The Philosophy of Nietzsche* (1954). EDUARD HANSLICK, *Vom musikalisch Schönen* (1854; Eng. trans., *The Beautiful in Music*, 1957), remains the best single exposition of the formalist (or nonreferentialist) position in musical aesthetics. EDMUND GURNEY, *The Power of Sound* (1880, reprinted 1966), maintains a similar point of view but with considerably greater amplitude and subtlety. For background of the contemporary symbolist views of musical meaning, see ALFRED NORTH WHITEHEAD, *Symbolism* (1959); SUSANNE K. LANGER, "On Significance in Music," in *Philosophy in a New Key*, 2nd ed. (1951), and *Feeling and Form* (1953). LEONARD B. MEYER has made an important contribution to the aesthetics of music. His interest in the relevance of information theory to music has been evidenced in two articles: "Meaning in Music and Information Theory," *Journal of Aesthetics and Art Criticism*, 14:412–424 (1957), and "Some Remarks on Value and Greatness in Music," *ibid.*, 17:486–500 (1959), reprinted in his *Music, The Arts, and Ideas: Patterns and Predictions in Twentieth-Century Culture* (1967). JOHN DEWEY, *Art as Experience* (1934, reprinted 1959); and KARL JASPERS, *Von der Wahrheit* (1947; Eng. trans., *Truth and Symbol*, 1959), have given reinforcement to organic and symbolic theses, respectively. PETER LE HURAY and JAMES DAY (eds.), *Music and Aesthetics in the Eighteenth and Early-Nineteenth Centuries* (1981), expounds theories of musical aesthetics from the pre- and early-Romantic period. PETER KIVY, *The Corded Shell* (1981), is a study of the emotional expressivity of music.

Performance practice, styles, and musical forms: The best historical accounts of musical forms, styles, and performance practice are to be found in DONALD J. GROUT, *A History of Western Music* (1960); GUSTAVE REESE, *Music in the Middle Ages* (1940), and *Music in the Renaissance*, rev. ed. (1959); MANFRED F. BUKOFZER, *Music in the Baroque Era* (1947); ALFRED EINSTEIN, *Music in the Romantic Era* (1947); and WILLIAM W. AUSTIN, *Music in the 20th Century, from Debussy to Stravinsky* (1966). SIR DONALD FRANCIS TOVEY, *The Forms of Music* (1956), contains informative and engaging short pieces. ROBERT SCHUMANN, *On Music and Musicians*, ed. by KONRAD WOLFF (Eng. trans. 1947), is an example of the work by a 19th-century precursor of the phenomenon of the present-day composer-authors who have contributed to aesthetic theory by elucidating their own works and commentating on other composers and on the scene in general. See also IGOR STRAVINSKY, *Poetics of Music in the Form of Six Lessons* (1947); PAUL HINDEMITH, *A Composer's World* (1952); AARON COPLAND, *Music and Imagination* (1952). Discussion of music and film may be found in LEWIS JACOBS (ed.), *The Emergence of Film Art* (1969). Twelve-tone technique and varieties of serialism deriving from it are treated in ARNOLD SCHOENBERG, *Style and Idea* (1950); and RENÉ LEIBOWITZ, *Schoenberg, et son école* (1947; Eng. trans., *Schoenberg and His School*, 1949). Short pieces on electronic music appear often in periodical literature. HAROLD C. SCHONBERG, *Facing the Music* (1981), is a collection of performance-oriented articles. See also CAROL MACCLINTOCK (ed.), *Readings in the History of Music in Performance* (1979).

Musical sound: WILLEM A. VAN BERGEIJK, J.R. PIERCE, and E.A. DAVID, *Waves and the Ear* (1960); ARTHUR H. BENADE, *Horns, Strings and Harmony* (1960); CHARLES A. CULVER, *Musical Acoustics*, 4th ed. (1956); JOHN BACKUS, *The Acoustical Foundations of Music* (1969); JOHN MILLS, *A Fugue in Cycles and Bells* (1935); MAX F. MEYER, *How We Hear: How Tones Make Music* (1950); LLEWELYN S. LLOYD, *The Musical Ear* (1940); ALEXANDER WOOD, *The Physics of Music*, 6th ed. (1962); RENÉ DESCARTES, *Musicae compendium* (1650; Eng. trans., *Compendium of Music*, 1961); CORNELIS J. NEDERVEEN, *Acoustical Aspects of Woodwind Instruments* (1969).

Works on tuning and temperament include HERMANN VON HELMHOLTZ, *Die Lehre von den Tonempfindungen als physiologische Grundlage für die Theorie der Musik* (1862; Eng. trans. by ALEXANDER J. ELLIS, *On the Sensations of Tone*, 1875), still the classic treatment of the subject, with useful additional observations by the translator; J. MURRAY BARBOUR, *Tuning and Temperament: A Historical Survey* (1951), a comprehensive study of the theoretical aspects of the subject, with a good bibliography; LLEWELYN S. LLOYD and HUGH BOYLE, *Intervals, Scales and Temperaments* (1963), designed for the musician; PAUL C. GREENE, "Violin Intonation," *Journal of the Acoustical Society of America*, 9:43–44 (1937), disposes of the theory that violinists naturally play in just intonation; ROGER E. KIRK, "Tuning Preferences for Piano Unison Groups," *ibid.*, 31:1644–48 (1959), shows that musicians prefer groups of unison strings on the piano to be mistuned; D.W. MARTIN and W.D. WARD, "Subjective Evaluation of Musical Scale Temperament in Pianos," *ibid.*, 33:582–585 (1961), shows that musicians do not prefer just intonation to equal temperament; FRITZ A. KUTTNER and J. MURRAY BARBOUR, *The Theory of Classical Greek Music: Meantone Temperament in Theory and Practice*; and *The Theory and Practice of Just Intonation*, Musurgia Records, Theory Series A, No. 1–3. an opportunity to hear the three major tuning systems that preceded equal temperament, both in scales and chords and in actual music.

Criticism: The foundation for most of the subsequent developments in musical criticism was laid by SIR HENRY HADOW in his influential essay, "Music and Musical Criticism—A Discourse on Method." *Studies in Modern Music* (1892). This essay cleared the ground for two major inquiries into musical criticism: M.D. CLAVOCORESSI. *The Principles and Methods of Musical Criticism* (1923); and ERNEST NEWMAN, *A Musical Critic's Holiday* (1925). All these books consider the problem of criteria that now dominates the field of musical aesthetics.

Further contributions to the problem have been made by PAUL HINDEMITH in *A Composer's World* (1952); and by ARNOLD SCHOENBERG in *Style and Idea* (1950), containing a key essay, "Criteria for the Evaluation of Music." A later book that challenges the philosophical premises on which criticism is based is ALAN WALKER, *An Anatomy of Musical Criticism* (1966), an attempt to relate aesthetics to psychology. Important supplementary reading exists in the related field of musical analysis. The more significant books include: SIR DONALD FRANCIS TOVEY, *Essays in Musical Analysis*, 6 vol. (1935–39); HEINRICH SCHENKER, *Das Meisterwerk in der Musik*, 3 vol. (1926–29); DERYCK COOKE, *The Language of Music* (1959); and the analytical essay, "Mozart's Chamber Music" by HANS KELLER, in *The Mozart Companion*, ed. by H.C.R. LANDON and DONALD MITCHELL (1956). PAUL GRIFFITHS, *Modern Music: The Avant Garde Since 1945* (1981), is a history and criticism.

Performance: The best direct and concise account of the issues of performance is THURSTON DART, *The Interpretation of Music* (1954). Other general views of the subject are FREDERICK DORIAN, *The History of Music in Performance: The Art of Musical Interpretation from the Renaissance to Our Day* (1942, reprinted 1981); and ROBERT DONINGTON, *The Interpretation of Early Music*, 2nd ed. (1965), which, like Dart, includes a bibliography of sources. What bibliographic aids to individual performers exist are given in "Dictionaries and Encyclopedias of Musical Instruments, Makers, and Performers," in VINCENT H. DUCKLES, *Music References and Research Materials: An Annotated Bibliography*, 2nd ed., pp. 40–50 (1967). Certainly the most extensive bibliography ever published on the subject is KARY VINQUIST and NEAL ZASLAV (eds.), *Performance Practice: A Bibliography* 1971. Some book-length studies of particular aspects of musical performance are listed below. P. ALDRICH, *Rhythm in Seventeenth-Century Italian Monody* (1966); F.T. ARNOLD, *The Art of Accompaniment from a Thorough-Bass As Practised in the XVIIth and XVIIIth Centuries* (1931); J.H. BARBOUR, *Tuning and Temperament* (1951); D.D. BOYDEN, *The History of Violin Playing, from Its Origins to 1761 and Its Relationship to the Violin and Violin Music* (1965); WALTER EMERY, *Bach's Ornaments* (1953); R.E.M. HARDING, *Origins of Musical Time and Expression* (1938); WILFRID H. MELLERS, "Theory and Practice," in *François Couperin and the French Classical Tradition* (1950); FRITZ ROTHSCHILD, *The Lost Tradition in Music: Rhythm and Tempo in J.S. Bach's Time* (1953) and *Musical Performance in the Times of Mozart and Beethoven: The Lost Tradition in Music, Part II* (1961); DENIS W. STEVENS (ed.), *The Art of Ornamentation in the Renaissance and Baroque* (1967), a stereophonic record; HENRY PLEASANTS, *The Great Singers: From the Dawn of Opera to Our Own Time* (1966); and WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia* (1967).

Rhythm: CURT SACHS, *Rhythm and Tempo* (1953), the most comprehensive work on rhythm in music, ranges over many non-Western cultures as well as over the successive periods of Western musical history. Detailed rhythmical analyses of Western music since the 17th century appear in GROSVENOR W. COOPER and LEONARD B. MEYER, *The Rhythmic Structure of Music* (1960). Studies of special periods are available in CHARLES F. ABDY WILLIAMS, *The Aristoxenian Theory of Musical Rhythm* (1911); W.F. JACKSON KNIGHT, *St. Augustine's De Musica: A Synopsis* (1949); WILLIAM G. WAITE, *The Rhythm of Twelfth-Century Polyphony, Its Theory and Practice* (1954); PHILIP F. RADCLIFFE, "The Relation of Rhythm and Tonality in the Sixteenth Century," *Proc. R. Musical Assn.*, 57:73–97 (1931); and HENRY D. COWELL, *New Musical Resources* (1930, reprinted 1969). Particular applications of rhythm have been studied in CHARLES F. ABDY WILLIAMS, *The Rhythm of Song* (1925); and WILLIAM THOMSON, *The Rhythm of Speech* (1923). Aesthetic aspects are considered in MARGARET GLYN, *The Rhythmic Conception of Music* (1907); and MATHIS LUSSY, *Le Rythme musical*, 3rd ed. rev. (1897; abridged Eng. trans., *A Short Treatise on Musical Rhythm*, 1909). ÉMILE JAQUES-DALCROZE, *Le Rythme, la musique et l'éducation* (1920; Eng. trans., *Rhythm, Music and Education*, 1921), is the pioneer work in its aspect of the field; musical rhythm has been put in wider perspective by ELSIE FOGERTY in *Rhythm* (1937).

Scale: CURT SACHS, *The Wellsprings of Music*, ed. by JAAP KUNST (1965), a systematic study of rudimentary scale types throughout the world and their evolution; BRUNO NETTL, *Music in Primitive Culture* (1956), a concise and authoritative introduction to scale types and their geographical distribution; WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia* (1967), lucid summaries of scale systems in non-Western art-music traditions; JOHN L. DUNN, *The Structure of the Musical Scale* (1940), a thorough description of the diatonic scale; ANTOINE AUDA, *Les Gammes musicales* (1947), a classic, comprehensive study of the history of scales in Western art music.

Mode: GUSTAVE REESE, *Music in the Middle Ages* (1940), provides a competent account and critique of a wide variety of modal concepts prevailing during the Western Middle Ages and discusses their origins and repercussions. WILLI APEL, "The Tonality," in *Gregorian Chant*, ch. 3 (1958), describes thoroughly the system of church modes. EGON WELLESZ, *Eastern Elements in Western Chant: Studies in the Early History of Ecclesiastical Music* (1947, reprinted 1967), discusses the modal structure of the melodies of Byzantine hymns and compares them with those of the Western Church. ABRAHAM Z. IDELSOHN, *Jewish Music in Its Historical Development* (1929, reprinted 1967), an authoritative work on Jewish music, contains chapters on "The Modes of the Bible" and "The Modes of the Prayers." EGON WELLESZ (ed.), *The New Oxford History of Music*, vol. 1 (1957), includes the following chapters discussing modes: ARNOLD BAKE, "The Music of India," CARL H. KRAELING and LUCETTA MOWRY, "Music in the Bible," ERIC WERNER, "The Music of Post-Biblical Judaism," ISOBEL HENDERSON, "Ancient Greek Music," and HENRY G. FARMER, "The Music of Islam." MIECZYSLAW KOLINSKI, "Classification of Tonal Structures, Illustrated by a Comparative Chart of American Indian, African Negro, Afro-American and English-American Structures," *Studies in Ethnomusicology*, 1:38–76 (1961), comprises a new system of modal classification accommodating a wide range of Western and non-Western modal patterns. ROBERT LACHMANN, *Musik des Orients* (1929, reprinted 1966), is the first scholarly survey of the music of Eastern cultures.

Harmony: Two works by 20th-century composers that give considerable insight into the role of all musical elements in composition are PAUL HINDEMITH, *Unterweisung im Tonsatz* (1937–39; Eng. trans., *The Craft of Musical Composition*, 2 bks., 1941–42); and ARNOLD SCHOENBERG, *Harmonielehre*, 3rd ed. (1922; abridged Eng. translation, *Theory of Harmony*, 1948). Schoenberg's formulation of his 12-tone theories may be found in his *Style and Idea* (1950). Other theoretical works that trace the fluid state of harmony since the later 19th century are ELLIOTT ZUCKERMAN, *The First Hundred Years of Wagner's "Tristan"* (1964); HENRY COWELL, *New Musical Resources* (1930, reprinted 1968); and GEORGE PERLE, *Serial Composition and Atonality*, 2nd. ed. (1968). Standard textbooks based on the theories of Rameau are WALTER PISTON, *Harmony*, 3rd ed. (1962); and ROGER SESSIONS, *Harmonic Practice* (1951).

Counterpoint: General studies of the subject include HUGO RIEMANN, *History of Music Theory*, trans. by RAYMOND HAGGH (1962), rather outdated but still the most thorough summary of medieval and Renaissance theoretical studies on counterpoint; KNUD JEPPESEN, "Outline History of Contrapuntal Theory," in *Counterpoint*, pp. 3–53 (1939), the main theoretical views on the subject; GUSTAVE REESE, *Fourscore Classics of Music Literature* (1957), a synopsis of 80 theoretical sources, many of which deal with counterpoint; OLIVER STRUNK, *Source Readings in Music History* (1950), numerous excerpts from musical theorists on the subject of counterpoint.

Historical treatises on counterpoint include JOHANNES TINCTORIS, *Liber de arte contrapuncti* (1477; trans. by ALBERT SEAY, *The Art of Counterpoint*, 1961), a famous landmark, the first extensive outline of contrapuntal principles; GIOSEFFO ZARLINO, *Le istitutioni harmoniche* (1558; pt. 3 trans. by GUY MARCO and CLAUDE PALISCA as *The Art of Counterpoint*, 1968); THOMAS MORLEY, "Treating of Descant," *A Plain and Easy Introduction to Practical Music*, pt. 2 (1597; new ed. by R. ALEC HARMAN, 1952), a pupil-master discussion that offers firsthand information concerning the 16th-century approach to counterpoint; LODOVICO ZACCONI, *Prattica di musica*, pt. 2 (1622), one of the first presentations of the five species as a means of teaching counterpoint; JOHANN FUX, *Gradus ad Parnassum* (1725; trans. by ALFRED MANN and JOHN EDMUNDS, *Steps to Parnassus*, 1943), probably the most celebrated of all books on this subject; mainly concerned with the problems encountered in writing counterpoint.

Notation: WILLI APEL, *The Notation of Polyphonic Music, 900–1600*, 5th ed. (1961), a standard textbook, including staff notation and tablatures, and many facsimiles used as exercises for transcription; ERHARD KARKOSCHKA, *Das Schriftbild der neuen Musik* (1966), an excellently documented study of contemporary notation; WALTER KAUFMANN, *Musical Notations of the Orient: Notational Systems of Continental East, South and Central Asia* (1967); CARL PARRISH, *The Notation of Medieval Music* (1957), excellent facsimiles; EMANUEL WINTERNITZ, *Musical Autographs from Monteverdi to Hindemith* (1955), a study of musical handwriting, with many facsimiles.

Western compositional technique: Because most writings on musical composition were conceived as didactic treatises for would-be composers, their content has virtually no bearing on a better understanding of crucial aesthetic attitudes and mental processes. Instead, depending on the era from which they hail as well as the specific outlook of their authors, such treatises deal for the most part with contrapuntal rules, harmonic laws,

and the like. While numerous books of this type appeared through the ages, it was only with the creation of the educational institutions known as conservatories of music, following the lead of the National Conservatory of France established in the last years of the 18th century, that composition became a discipline formally taught and hence requiring comprehensive textbooks, including the theory of form and instrumentation. This profitable need was satisfied by the voluminous activities of 19th-century writers from J.J. Momigny and Anton Reicha to Vincent d'Indy in France and from Heinrich Christoph Koch to Hugo Riemann in Germany. Few of these books were translated into English, and they are of primary interest to the specialist. The following is a selection of easily accessible monographs and documentary collections with emphasis on firsthand testimonies of the creative artists themselves.

JACQUES BARZUN (ed.), *Pleasures of Music* (1951), a collection of writings about music, including many from the pens of men of literature; LEONARD BERNSTEIN, *The Joy of Music* (1959), contains Bernstein's seven "Omnibus" television scripts, including his excellent comments on sketch materials relating to Beethoven's *Fifth Symphony* and its ultimate realization; FREDERICK DORIAN, *The Musical Workshop* (1947), a discussion of various aspects of musical composition, including comments on creative procedures; HANNS EISLER, *Composing for the Films* (1947), rare insights into the problems of cinematographic music from a composer who, during his Hollywood years, tried to turn music into an integral aspect of film art; MAX GRAF, *From Beethoven to Shostakovich* (1947, reprinted 1969), a popular study of psychological processes involved in composition; MICHAEL HAMBURGER (ed. and trans.) *Beethoven: Letters, Journals and Conversations* (1960), a concise but well-chosen selection of Beethoven's own words concerning both specific compositions and the problems of the composer in general; LEJAREN A. HILLER, JR., and LEONARD M. ISAACSON, *Experimental Music* (1959), the first and still basic monograph dealing with the philosophy, procedures, and techniques of composition with an electronic computer; PAUL HINDEMITH, *A Composer's World* (1961), a leading 20th-century composer looks at various facets of the composer's world, including questions of musical perception, inspiration, technique, performance, and education; IRVING KOLODIN (ed.), *The Composer as Listener: A Guide to Music* (1958), excerpts from pertinent writings, including letters mostly by important composers of the 19th and early 20th centuries; EDWARD E. LOWINSKY, "Musical Genius: Evolution and Origins of a Concept," *Musical Quarterly*, 50:321–340, 476–495 (1964), excellent documentation of the evolution of a concept that has been associated through the ages more consistently with music than with any other form of artistic production; ALAN P. MERRIAM, *The Anthropology of Music* (1964), a comprehensive treatment of music in relation to culture, drawing upon fieldwork on every continent and at all social levels (see especially ch. 9, "The Process of Composition"); SAM MORGENSTERN (ed.), *Composers on Music: An Anthology of Composers' Writings from Palestrina to Copland* (1956), an excellent collection, mostly of letters, dealing with general and specific aspects of the composer's work; ERNEST NEWMAN, *The Unconscious Beethoven*, rev. ed. (1970), a fascinating, if not unproblematic, study of the successive stages of Beethoven's work as revealed in his sketches by one of Britain's most famous critics; GERTRUDE NORMAN and MIRIAM LUBELL SHRIFTE (eds.), *Letters of Composers: An Anthology, 1603–1945* (1946), one of the most comprehensive of several collections of composers' letters available in paperback; JOSEF RUFER, *Die Komposition mit zwölf Tönen* (1952, 2nd ed. 1966; Eng. trans., *Composition with Twelve Notes Related to One Another*, 1965), a cogent introduction to dodecaphonic aesthetics and technique by a dedicated Schoenberg disciple; WILLIAM RUSSO, *Jazz Composition and Orchestration* (1968), one of the very few serious treatments of a type of composition that has gained respectability only in recent years; ARNOLD SCHOENBERG, *Style and Idea* (1950), a discussion of Schoenberg's artistic motivation and procedures as well as those of the composers he admired most, including Brahms and Mahler; ROGER SESSIONS, *The Musical Experience of Composer, Performer, Listener* (1962), a discussion of fundamental musical problems by America's senior living composer; WILLIAM OLIVER STRUNK (ed.), *Source Readings in Music History from Classical Antiquity Through the Romantic Era* (1950), an indispensable collection of relevant excerpts from the writings of philosophers, musical theorists, and composers from Plato to Richard Wagner; DONALD FRANCIS TOVEY, *The Mainstream of Music, and Other Essays* (1961), a paperback reprint of some of the finest essays by the great British critic who discusses basic compositional issues. See also ERICH LEINSDORF, *The Composer's Advocate* (1981).

Instrumentation: WILLI APEL, *Harvard Dictionary of Music*, 2nd ed. rev. (1969), a good source on any musical subject; DONALD JAY GROUT, *A History of Western Music* (1960), the best general history of music to date; ADAM CARSE, *The History of Orchestration* (1925, reprinted 1964), a detailed look at the evolution of the orchestra and musical instruments; NICOLAS RIMSKY-KORSAKOV, *Principles of Orchestration, with Musical Examples Drawn from His Own Works*, ed. by MAXIMILIAN STEINBERG, I vol. (1964; orig. pub. in Russian, 1910), still one of the best texts for the serious student; ROMAIN GOLDRON, *Ancient and Oriental Music* (1968), examples of non-Western music and instruments.

Recording of music: ROLAND GELATT, *The Fabulous Phonograph*, 2nd rev. ed. (1977), a general history of the phonograph, particularly good on the complex corporate developments; OLIVER READ and WALTER L. WELCH, *From Tin Foil to Stereo*, 2nd ed. (1976), a scholarly and detailed phonographic history with much elucidation of technical matters; FREDERIC W. WILE, *Emile Berliner: Maker of the Microphone* (1926, reprinted 1974), an adulatory, but worthwhile, biography; FRED GAISBERG, *The Music Goes Round* (1942, reprinted 1977), an autobiographical account of the history of the phonograph by a man associated with Berliner from the earliest days (a valuable source despite many inaccuracies); MATTHEW JOSEPHSON, *Edison* (1959), a thoroughly researched biography of the inventor of the phonograph; JOSEPH BATTEN, *Joe Batten's Book: The Story of Sound Recording* (1956), another personal documentation of early phonographic history, not as far-ranging as Gaisberg's but with much unduplicated material. RUSSELL MILLER and ROGER BOAR, *The Incredible Music Machine* (1982), is a popular history.

The History of Western Music

All ancient civilizations entered historical times with a flourishing musical culture. That the earliest writers explained it in terms of legend and myth is evidence of the remote beginnings of the art of sound. Among the speculations about its origin, the more plausible are that it began as a primitive form of communication, that it grew out of a device to expedite communal labour, or that it originated as a powerful adjunct to religious ceremonies. While such theories must necessarily remain speculative, it is clear, despite the prehistoric musical artifacts found in central Europe, that the cradle of Western music was the fertile crescent cupping the eastern end of the Mediterranean Sea. There the Mesopotamian, Egyptian, and Hebrew nations, among others, evolved political, social cultures that were absorbed by the conquering Greeks and, in turn, by the Romans, who transported a relatively sophisticated art form back to western Europe.

In all of these early cultures the social functions of music were essentially the same since their climate, geographic location, cultural pace, and mutual influences produced many more social similarities than differences. The primary function of music was apparently religious, ranging from heightening the effect of "magic" to ennobling liturgies. The other musical occasions depicted in both pictures and written accounts were equally functional: stirring incitements to military zeal, soothing accompaniments to communal or solitary labour, heightening aids to dramatic spectacles, and enlivening backgrounds to social gatherings that involved either singing or dancing or both. In every case musical sounds were an adjunct either to bodily movement (dance, march, game, or work) or to song. Many centuries were to pass before pleasure in euphonious sound became an end in itself.

The establishment of Western musical traditions

ROOTS IN ANTIQUITY

Ancient Middle East and Egypt. The inhabitants of the Mesopotamian region around the Tigris and Euphrates rivers (the Sumerians, the Babylonians, and the Assyrians) flourished from *c.* 3500 to *c.* 500 BC. Their pictures and the few surviving artifacts indicate that they had instruments of every basic type—idiophones, whose sound is made by resonating as a whole; aerophones, which resonate a column of blown air; chordophones, with strings to be plucked or struck; and membranophones, made of stretched skins over a resonating body. An undecipherable hymn engraved in stone, dating from *c.* 800 BC, is evidence of a primitive system of musical notation.

The Egyptians, entering historical times about 500 years later than the Mesopotamians, enjoyed all of the same types of activities and instruments, as may be deduced from numerous written references to music as well as seen on many artifacts, especially the pictures preserved on pottery utensils.

The musical culture of the Hebrew peoples, recorded from about 2000 BC and documented primarily in the Old Testament, was more directly influential in the West because of its adoption and adaptation into the Christian liturgy. Because of the prohibition of Jewish religious law against the making of "graven images," there are very few surviving artifacts or pictures. Among the established practices of the temple service still current in the synagogue are the extensive use of the shofar (a ritualistic ram's-horn trumpet) and the singing of passages from the Pentateuch (the first five books of the Old Testament), prayers, and songs of praise.

Ancient Greece. Of the eastern Mediterranean cultures, it was undoubtedly that of the Greeks that furnished the most direct link with musical development in western Europe, by way of the Romans, who defeated them but adopted much of Greek culture intact. Entering historical times relatively late, *c.* 1000 BC, the Greeks soon dominated their neighbours and absorbed many elements of earlier cultures, which they modified and combined into an enlightened and sophisticated civilization. The two basic Greek religious cults—one devoted to Apollo, the other to Dionysus—became the prototypes for the two aesthetic poles, classical and romantic, that have contended throughout Western cultural history. The Apollonians were characterized by objectivity of expression, simplicity, and clarity, and their favoured instrument was the kithara, a type of lyre. The Dionysians, on the other hand, preferred the reed-blown aulos and were identified by subjectivity, emotional abandon, and sensuality.

Apollonian and Dionysiac expression

The prevailing doctrine of ethos, as explained by ancient Greek philosophers such as Plato and Aristotle, was based on the belief that music has a direct effect upon the soul and actions of mankind. As a result, the Greek political and social systems were intertwined with music, which had a primary role in the dramas of Aeschylus, Sophocles, Euripides, and Aristophanes. And the Grecian educational system was focused upon *musica* and *gymnastica*, the former referring to all cultural and intellectual studies, as distinguished from those related to physical training.

Origin of musical modes

To support its fundamental role in society, an intricate scientific rationale of music evolved, encompassing tuning, instruments, modes (melodic formulas based on certain scales), and rhythms. The 6th-century-BC philosopher and mathematician Pythagoras was the first to record the vibratory ratios that established the series of notes still used in Western music. From the total gamut of notes used were derived the various modes bearing the names of Grecian tribes—Dorian, Phrygian, Lydian, etc. The rhythmic system, deriving from poetry, was based on long–short relationships rather than strong–weak accentual metre. After Pythagoras, Aristoxenus was the major historian and theoretician of Greek music.

Ancient Rome. When the musical culture of the eastern Mediterranean was transplanted into the western Mediterranean by the returning Roman legions, it was inevitably modified by local tastes and traditions. In most cases, the resulting practices were more limited than their models. The diatonic (seven-note) scale, for example, became the standard, displacing the chromatic and enharmonic structures of the Grecian system. Of particular consequence was the new concept of metre as a series of equal durations, with emphasis being determined by accent (stress) rather than by duration.

An inventory of the musical heritage transplanted from the ancient East (particularly Greece) to Rome reveals the rich treasure inherited: an acoustical theory that accounted for the identification and classification of tones; a concept of tonal organization resulting in the system of modes; principles of rhythmic organization; basic principles of instrument construction; a system of notation that conveyed all necessary indications of pitch and duration; and a large repertory of melodies to serve as models for further composition.

THE MIDDLE AGES

Monophonic liturgical chant. With the decline of the Roman Empire, the institution destined to perpetuate and expand the musical heritage of antiquity was the Christian Church, but it was not a unified process. Many of the cultural centres of the Western church developed distinctive characteristics while sharing the common heritage of the Hebrew liturgy and Greek culture. In Milan, for example, metrical hymnody, as distinguished from the earlier practice of unmetred psalmody, was cultivated, particularly under the influence of the 4th-century Bishop Ambrose, who first attempted to codify the growing repertory of chants. This body of Milanese church music, therefore, came to be called Ambrosian chant. Somewhat later a unique style and repertory known as Mozarabic chant evolved in Spain, and in France the Gallican style prevailed.

Gregorian chant

But the mainstream of church music was the type of chant practiced in Rome. Beginning in the late 6th century, according to tradition, with Pope Gregory I, the vast number of traditional melodies that became the foundation for the later development of Western art music were codified and organized. A systematic organization of tonal materials also was gradually accomplished, resulting in the eight church modes. Each melody was assigned a specific function in the services of the liturgical year—some for the mass and some for the divine offices such as Matins, Vespers, and Compline. After a period of assimilation, the Gregorian chant repertory began a process of expansion in the 9th century, when the practice of troping originated. A trope is either a text or a melodic section added to a preexisting melody or a combination of text and music incorporated into existing liturgical music. It is not surprising that church musicians, after years of singing traditional chants, should want to express themselves by adding words to vocalized melodies. Perhaps the motive was more functional: the added syllables would make the long textless passages easier to remember. Tuotilo (died 915), a monk of St. Gall in Switzerland, is credited with the invention of tropes. Notker Balbulus (died 912) is notable for his association with the sequence, a long hymn that originated as a trope added to the final syllable of the Alleluia of the mass.

Development of polyphony. At the same time that the Gregorian repertory was being expanded by the interpolation of tropes and sequences, it was being further enriched by a revolutionary concept destined to give a new direction to the art of sound for hundreds of years. This concept was polyphony, or the simultaneous sounding of two or more melodic lines. The practice emerged gradually during the Dark Ages, and the lack of definite knowledge regarding its origin has brought forward several plausible theories: it resulted from singers with different natural vocal ranges singing at their most comfortable pitch levels; it was a practice of organists adopted by singers; or it came about when the repetition of a melody at a different pitch level was sung simultaneously with the original statement of the melody. Whatever motivated this dramatic departure from traditional monophony (music consisting of a single voice part), it was an established practice when it was described in *Musica enchiriadis* (*c.* 900), a manual for singers and one of the major musical documents of the Middle Ages. To a given plainsong, or *vox principalis,* a second voice (*vox organalis*) could be added at the interval (distance between notes) of a fourth or fifth (four or five steps) below. Music so performed was known as organum. While it may be assumed that the first attempts at polyphony involved only parallel motion at a set interval, the *Musica enchiriadis* describes and gives examples of two-part singing in similar (but not exactly parallel) and contrary movement—evidence that a considerable process of evolution had already taken place.

The beginnings of polyphony

The next major source of information was the *Micrologus,* written in the early 11th century by the Italian monk and musical theorist Guido of Arezzo. This work documented principles that were crucial to the further development of polyphony. Rhythmic independence was added to melodic independence, and the added voice might sing two or more tones to one in the original plainsong. During the half century after Guido's death, developments came more rapidly as the plainsong chant became the lower rather than the upper voice. After the emancipation of the organal part, *vox organalis,* its ultimate freedom was reached in the organums of the monastery of Saint-Martial in Limoges, France, where the plainsong part was reduced to the role of sustaining each tone while the organal part indulged in free melismata (groups of notes sung to a single syllable), either improvised or composed. This new style was called *organum purum.*

The Notre-Dame school. Early in the 12th century the centre of musical activity shifted to the church of Notre-Dame in Paris, where the French composer Léonin recorded in the *Magnus Liber Organi* ("Great Book of Organum") a collection of two-part organums for the entire church year. A generation later his successor, Pérotin, edited and revised the *Magnus Liber,* incorporating the rhythmic patterns already well-known in secular music and adding more than one part to the cantus firmus (the "given" or preexisting plainsong melody). When metre was applied to the original plainsong as well as to the *vox organalis,* the resulting form was called a clausula. Then, when words were provided for the added part or parts, a clausula became a motet. At first the words given to the motet were a commentary in Latin on the text of the original plainsong tenor (the voice part "holding" the cantus firmus; from Latin *tenere,* "to hold"). Later in the 13th century the added words were in French and secular in nature. Finally, each added part was given its own text, resulting in the classic Paris motet: a three-part composition consisting of a portion of plainchant (tenor) overlaid with two faster moving parts, each with its own secular text in French. At the same time another polyphonic form, the conductus, was flourishing. It differed from a motet in that its basic part was not plainsong and that all parts sang the same Latin text in note-against-note style. The conductus gradually disappeared with the rise of the motet, which apparently served both liturgical and secular functions.

The beginnings of the motet

Ars Nova. When the influential treatise *Ars Nova* ("New Art") by the composer Philippe de Vitry appeared early in the 14th century, the preceding epoch acquired its designation of Ars Antiqua (Old Art), for it was only in retrospect that the rapid developments of the century and a half from *c.* 1150 to *c.* 1300 could appear as antiquated. De Vitry recorded the innovations of his day, particularly

in the areas of metre and harmony. While 13th-century music had been organized around the triple "modal" rhythms derived from secular music and a harmonic vocabulary based on "perfect" consonances (unison, fourth, fifth, octave), the New Art of the 14th century used duple as well as triple divisions of the basic pulse and brought about a taste for harmonious intervals of thirds and sixths.

The musical centre of 14th-century Italy was Florence, where a blind organist, Francisco Landini, and his predecessors and contemporaries Giovanni da Cascia, Jacopo da Bologna, and Lorenzo and Ghirardello da Firenze were the leading composers of several new forms: madrigals (contrapuntal compositions for several voices), ballatas (similar to the French virelai), and caccias (three-voice songs using melodic imitation).

Monophonic secular song. Secular music undoubtedly flourished during the early Middle Ages, but, aside from sporadic references, the earliest accounts of such music in the Western world described the music of the goliards; these people were itinerant minor clerics and students who, from the 7th century on, roamed the land singing and playing topical songs dealing with love, war, famine, and other issues of the day. The emergence in France of a fully developed secular-musical tradition about the beginning of the 12th century is evidence that the art had been evolving continuously before that time. Partially motivated by the attitude of chivalry engendered by the Crusades, a new life-style began among the nobility of southern France. Calling themselves troubadours, they circulated among the leading courts of the region, devoting themselves to writing and singing poetry in the vernacular. The troubadour movement flourished in Provence during the 12th and 13th centuries. About the middle of the 12th century, noblemen of northern France, most notably Adam de La Halle, took up the pastime, calling themselves trouvères. In Germany a similar group known as Minnesingers, represented by Walther von der Vogelweide, began their activities about 1150 and continued for almost a century after their French counterparts had ceased composing. Late in the 13th century the burgher class in Germany began imitating the aristocratic Minnesingers. Calling themselves Meistersingers, they flourished for more than 500 years, organizing themselves into fraternities and following strict rules of poetry, music, and performance. The most famous of them, Hans Sachs, was immortalized in the 19th century in Richard Wagner's opera *Die Meistersinger von Nürnberg.* Relatively little is known of similar secular-musical activities in Italy, Spain, and England. Closely associated with the entertainments of the aristocratic dilettantes were the professional musicians of the peasant class called jongleurs and minstrels in France, *Gaukler* in Germany, and scops and gleemen in England.

Troubadours and Meistersingers

The musical style that had been established by the troubadours—which was monophonic, of limited range, and sectional in structure—was adopted by each of the succeeding groups. Of particular significance in view of its influence on polyphonic music was the metric system, which is based on six rhythmic modes. Supposedly derived from Greek poetic metres such as trochaic (long–short) and iambic (short–long), these modes brought about a prevailing triple metre in French music, while German poetry produced duple as well as triple metre. A great variety of formal patterns evolved, in which musical structure and poetic structure were closely related. The most characteristic was the ballade, which was called *Bar* form in Germany, with an AAB structure. This type, along with the rondeau (song for solo voice with choral refrain) and the similar virelai (an analogue of the Italian ballata), was destined to become a favoured form employed by composers of polyphony such as Guillaume de Machaut, the universally acknowledged master of French music of the Ars Nova period. Machaut also continued the composition of motets, organizing them around recurrent rhythmic patterns (isorhythm), a major structural technique of the age. The beginnings of an independent instrumental repertory during the 13th century are represented by the estampie, a monophonic dance form almost identical in style to the vocal secular music.

THE RENAISSANCE PERIOD

The term Renaissance, in spite of its various connotations, is difficult to apply to music. Borrowed from the visual arts and literature, the term is meaningful primarily as a chronological designation. Some historians date the beginning of the musical Renaissance at about 1400, some with the rise of imitative counterpoint, about 1450. Others relate it to the musical association with Humanistic poetry at the beginning of the 16th century, and still others reserve the term for the conscious attempt to recreate and imitate supposedly classical models that took place about 1600.

The court of Burgundy. No one line of demarcation is completely satisfactory, but, adhering to commonly accepted usage, one may conveniently accept as the beginning of the musical Renaissance the flourishing and secularization of music at the beginning of the 15th century, particularly at the court of Burgundy. Certainly many manifestations of a cultural renaissance were evident at the time: interest in preserving artifacts and literature of classical antiquity, the waning authority and influence of the church, the waxing Humanism, the burgeoning of urban centres and universities, and the growing economic affluence of the states of western Europe.

As one manifestation of their cultivation of elegant living, the aristocracy of both church and state vied with one another in maintaining resident musicians who could serve both chapel and banqueting hall. The frequent interchange of these musicians accounts for the rapid dissemination of new musical techniques and tastes. Partly because of economic advantages, Burgundy and its capital, Dijon, became the centre of European activity in music as well as the intellectual and artistic focus of northern Europe during the first half of the 15th century. Comprising most of eastern France and the Low Countries, the courts of Philip the Good and Charles the Bold attracted the leading musicians of western Europe. Prime among them was Guillaume Dufay, who had spent some time in Rome and Florence before settling in Cambrai about 1440. An important contemporary of Dufay was Gilles Binchois, who served at Dijon from about 1430 until 1460. The alliance of Burgundy with England accounted for the presence on the Continent of the English composer John Dunstable, who had a profound influence on Dufay. While the contributions of the English to the mainstream of continental music are sparsely documented, the differences in style between Dufay and his predecessor Machaut are partially accounted for by the new techniques and, especially, the richer harmonies adopted by the Burgundian composers from their English allies.

Rivalry between church and state in musical patronage

New religious musical forms. The social circumstances of the age determined that composers would devote their efforts to the mass, the motet, and the chanson (secular French song). During the first half of the 15th century, the mass became established as a unified polyphonic setting of the five main parts of the Ordinary of the mass (Kyrie, Gloria, Credo, Sanctus, Agnus Dei), with each movement based on either the relevant portion of plainsong or, reflecting the dawning Renaissance, a secular song such as the popular "L'Homme armé" ("The Armed Man") and "Se la face ay pale." Still reflecting medieval practices, the preexisting melody (or cantus firmus) was usually in the tenor (or lowest) part and in long, sustained tones, while the upper parts provided free elaboration. Dufay's nine complete settings of the mass, compared with Machaut's single setting, give a clear indication of the growing importance of the mass as a musical form. The motet became simply a setting of a Latin text from Scriptures or the liturgy in the prevailing polyphonic style of the time. It was no longer necessarily anchored to a plainsong tenor; the composer could give free reign to his invention, although some did, of course, resort to older techniques.

Importance of the mass

Secular music. It was in secular music that giant strides took place. While their chansons continued the tradition of rondeaux, virelais, and ballades, Dufay and his contemporaries added free forms divorced from the ordered patterns of the Ars Antiqua and Ars Nova periods.

Among the distinctive features of Burgundian musical style was the prevailing three-part texture, with melodic

and rhythmic interest centred in the top part. Because it was so typical of secular songs, this texture is commonly referred to as "ballade style" whether it appears in mass, motet, or chanson. Its possible stylistic implication is that a solo voice sang the upper melody, accompanied by instruments playing the lower parts, although no documents remain to establish exactly how the music was performed. There was probably no standard performing medium: all parts may have been sung; some or all may have been doubled by instruments; or there may have been one vocal part supported by instrumental accompaniment.

The Franco-Flemish school. A watershed in the history of music occurred about the middle of the 15th century. The fall of Constantinople in 1453 and the end of the Hundred Years' War at about the same time increased commerce from the East and affluence in the West. Most significant musically was the pervasive influence of musicians from the Low Countries, whose domination of the musical scene during the last half of the 15th century is reflected in the period designations the Netherlands school and the Franco-Flemish school. These musicians travelled and resided throughout Europe in response to their great demand at princely courts, including those of the Medici family in Florence and the Sforzas in Milan. Further dissemination of knowledge resulted from the invention and development of printing.

Travelling musicians at courts

The leading composers, whose patrons were now members of the civil aristocracy as well as princes of the church, were Jean d'Okeghem, Jakob Obrecht, and, especially, Josquin des Prez. D'Okeghem, born and trained in Flanders, spent most of his life in the service of the kings of France and was recognized by his contemporaries as the "Prince of Music." Obrecht remained near his birthplace in the Netherlands, going occasionally to Italy in the retinue of Duca Ercole I (Duke Hercules I) of Ferrara. More typical of the peripatetic Netherlanders was the career of Josquin, the most influential composer of the period. After training at St. Quentin, he served the Sforza family in Milan, the papal choir in Rome, Ercole I, and King Louis XII of France before returning to his native Flanders in 1516. These three composers and several contemporaries hastened the development of the musical techniques that became the basis of 16th-century practice and influenced succeeding developments.

Rather than the three parts typical of most Burgundian music, four parts became standard for vocal polyphony in the late 15th century. The fourth part was added below the tenor, increasing the total range and resulting in greater breadth of sound. The presence of the four parts also allowed for contrasts of texture such as the "duet style" so characteristic of Josquin, when the two upper parts might sing a passage alone and be echoed by the two lower parts alone. The emergence of the technique of imitation (one voice repeating recognizably a figure heard first in another voice) as the chief form-generating principle brought about more equality of parts. At the same time "familiar style," in which all parts move together in chords, provided a means of textural contrast. The great variety of rhythmic techniques that evolved during the 14th and early 15th centuries made possible a wide range of expression—from quiet tranquillity for sacred music to lively and spirited secular music. Knowledge of the musical practices comes not only from the thousands of surviving compositions but from informative treatises such as the 12 by the composer Johannes Tinctoris (1436–1511), one of which, *Terminorum musicae diffinitorium* (*c.* 1475), is the earliest printed dictionary of musical terms.

Wider range of expression through rhythmic developments

The chief forms of vocal music continued to be the mass, the motet, and the chanson, to which must be added other national types that developed during the 15th century—the villancico (secular poetry set for voice and lute or for three or four voices) in Spain and the frottola (a simple, chordal setting in three or four parts of an Italian text) in Italy. The emergence of the frottola in northern Italy led to the development of the Renaissance madrigal, which impelled that country to musical supremacy in Europe.

Instrumental music. At the same time, an independent instrumental idiom was evolving. While instruments had been in common usage throughout the Middle Ages, their function was primarily to double or to substitute for voices in vocal polyphonic music or to provide music for dancing. Techniques unsuitable for voices were doubtless part of an instrumentalist's musical vocabulary, but most such music was improvised rather than being written. Although there are a few sources of instrumental music dating from the 13th and 14th centuries, the earliest relatively extensive documentation comes from the 15th century, particularly from German sources, such as the *Buxheimer Orgelbuch* and Conrad Paumann's *Fundamentum organisandi* (*Fundamentals of Organ Playing*). The compositions in both collections are of two basic types, arrangements of vocal works and keyboard pieces entitled *Praeambulum* (*Prelude*).

During the course of the 16th century, instrumental music burgeoned rapidly, along with the continually developing idiomatically instrumental techniques, such as strongly accented rhythms, rapid repeated tones and figures, angular melodic lines involving wide intervallic skips, wide ranges, long, sustained tones and phrases, and much melodic ornamentation.

Musical forms. Dance forms, a continuation of a tradition unbroken since the beginnings of recorded music history, were most characteristically composed in pairs, although single dances as well as embryonic suites of three or more dances appeared. The pairs usually consisted of pieces in contrasting tempo and metre that often were unified by sharing a common melody. Common dance pairs included the pavane and galliard, the allemande and courante, and the basse danse and tourdion.

Preludes continued as a major form of organ music and were joined by the fantasia, the *intonazione,* and the toccata in a category frequently referred to as "free forms" because of the inconsistency and unpredictability of their structure and musical content—sections in imitative counterpoint, sections of sustained chords, sections in virtuoso figuration. If a distinction must be made, it might be said in very general terms that the fantasia tended to be more contrapuntal while the toccata (or "touch piece") featured passages designed to demonstrate the performer's agility, although the designations were freely interchangeable. To the same category belong the descriptive pieces such as *The King's Hunt,* which featured naive musical representations of natural sounds.

Fantasias and toccatas

The ricercar and the canzona, generally referred to as fugal forms because of their relationship to the principle of the fugue (that of melodic imitation), arose out of the growing understanding of and dependence on imitation as a unifying structural technique. Although these designations were applied to a great variety of pieces—some identical in style to the fantasia or prelude—the classic ricercar of the 16th century was virtually an instrumental motet, slow and churchlike in character and consisting of a number of sections, each utilizing imitation. The canzona followed the same structural principle but was a lively counterpart to the chanson, with the sections sometimes in contrasting tempo and metre. Cantus firmus compositions were based upon preexisting melody. During the 16th century most were designed for liturgical usage but were based upon both secular melodies and plainsong. In most cases the cantus firmus was sounded in long, sustained tones while the other part or parts added decorative contrapuntal lines. The organ mass, in which the choir and the organ alternated lines of the liturgical text, was a popular practice.

Variations also often used a preexisting melody but differed from cantus firmus compositions in that the melody was much shorter and was repeated a number of times, each time with different accompanying parts. The two basic types during the Renaissance were the plain, or melodic, variations and the ground. In the former, the chosen melody usually appeared in the top part and was varied in each repetition with ornamentation and melodic figuration or with changing accompaniments. The ground, or ground bass, was a simple melodic pattern sounded in the lowest part, which served as a foundation for imaginative figuration in the upper parts.

Solo and ensemble instruments. The four major vehicles for instrumental music of the period were the lute, the organ, stringed keyboard instruments, and instrumen-

tal ensembles. Most popular by far was the lute, which could produce the major elements of instrumental style except for long, sustained tones. Noteworthy composers of lute music included Luis Milán in Spain, Arnold Schlick in Germany, and John Dowland in England. The organ, because of its close association with liturgical music, continued to be an important instrument, and its literature includes all of the formal types except dances. Among the leading organ composers were the Germans Paumann, Schlick, and Paul Hofhaimer, the Italians Claudio Merulo and Andrea and Giovanni Gabrieli, the Spaniard Antonio de Cabezón, and the Englishman John Bull.

The two basic classes of stringed keyboard instruments were the harpsichord (virginals, spinet, clavecin, clavicembalo), with quill-plucked strings, and the clavichord, with strings struck by thin metal tongues. Keyboard instruments were highly capable of idiomatically instrumental effects and flourished, particularly in England, from the last half of the 16th century onward, thanks to the composers William Byrd, John Bull, and Orlando Gibbons. A major manuscript source of the keyboard works of these masters is the famous *Fitzwilliam Virginal Book* of the 17th century.

Instrumental ensembles of the Renaissance were not standardized, although consorts (groups) of viols, of woodwind instruments such as recorders and shawms (loud oboes), or of brass-family instruments such as the cornet and sackbut (early trombone) were common. More common, however, were mixed consorts of various types of instruments, depending on the players available. All types of instrumental forms were performed by ensembles except for the prelude and the toccata, which were essentially keyboard works. Representative composers included the Gabrielis and Gibbons.

Vocal music in the 16th century. At the beginning of the 16th century the style of vocal music was generally uniform because of the pervading influence of Netherlanders during the preceding half century. That uniformity persisted well into the late Renaissance but was gradually superseded by emerging national differences, new forms, and the increasing importance of Italy as a musical centre during the last half of the 16th century.

The rapid accumulation of new musical techniques and resources produced a wide vocabulary of artistic expression, and the invention of music printing helped the rapid dispersal of new techniques. In an age in which music was an essential social grace, composers wrote more secular music, in which fewer technical restrictions were in force and experimentation and novelty were applauded. Advances were particularly apparent in venturesome harmonies as chromaticism (the use of notes not belonging to the mode of the composition) sounded the death knell of the modal system.

Harmonic experiment

Liturgical practice dictated that the mass and the motet remain the chief forms of sacred vocal music. Compared with secular music, their style was conservative, but inevitably some of the newer secular techniques crept in and figured effectively in the music of the Counter-Reformation within the Roman Catholic Church.

Four distinct types of mass settings were established during the century. Two types were continuations of earlier practice: the tenor mass, in which the same cantus firmus served for all five portions of the Ordinary of the mass, and the plainsong mass, in which the cantus firmus (usually a corresponding section of plainsong) differed for each portion. Reflecting the more liberal attitudes of the Renaissance were the free mass, with no borrowed materials, and the parody mass, in which the entire polyphonic web was freely adapted from a motet or a secular composition. In all cases when a cantus firmus was used, the preexistent melody might appear in its original form or in paraphrased version, with tones added, omitted, or altered. As a result of the upheaval in the church caused by the Reformation, new forms derived from established models appeared in Protestant worship: the German Lutheran chorale (hymn tune, arranged from plainsong or a secular melody), the chorale motet, English anthems (Anglican form of motet) and services, and the psalm tunes in Calvinist areas.

Italy. While not young in a chronological sense, the musical life of Italy was reborn at the beginning of the 16th century after a century of relative dormancy. The frottola remained the prevailing secular form in northern Italy for the first three decades of the century.

When the humanistic poets, seeking a more refined expression, and the Netherlanders and composers trained by them, applying a more sophisticated musical technique, turned their efforts to the frottola, the result was the madrigal. The name was borrowed from the 14th-century form, but there was no resemblance in poetic or musical structure. Compared to the frottola, the earliest Renaissance madrigals, dating from about 1530, were characterized by quiet and restrained expression. Usually written for three or four voices, they were mostly homophonic (melody supported by chords) with occasional bits of imitation. Among the early madrigal composers were several Flemish composers resident in Italy, among them Adriaan Willaert, Jacques Arcadelt, and Philippe Verdelot. About 1560 the normal number of parts increased to five or six, and the texture became more consistently polyphonic. At the same time, more attention was given to expressive settings of the text, notably in the madrigals of Cipriano de Rore, Philippe de Monte, and the Gabrielis. During the last two decades of the century and continuing until the middle of the 17th century, the musical style of the madrigal changed appreciably. The late madrigals were of a very dramatic nature, featuring colouristic effects, vivid word-painting, and extensive chromaticism. Their declamatory character dictated a return to a more homophonic style. Noteworthy among the many composers of the late madrigal were Luca Marenzio, Don Carlo Gesualdo, and Claudio Monteverdi.

Birth of the madrigal

During the course of the century simpler secular forms, such as the villanella, the canzonetta, and the balletto, appeared in Italy, largely as a reaction against the refinement, complication, and sophistication of the madrigal. They reverted to the chordal style of the frottola, often with intentionally parodistic lyrics. The balletto was particularly distinguished by a refrain of nonsense syllables such as "fa la la."

England. Most of the Italian forms, along with their designations, were adopted by Elizabethan England during the last half of the 16th century. Most leading English composers, from William Byrd and Thomas Morley to John Wilbye, Thomas Weelkes, and Orlando Gibbons, contributed to the vast treasury of English secular music. Morley is particularly important as the editor of the most significant collection of English madrigals, the *Triumphes of Oriana,* published in 1603 and dedicated to Queen Elizabeth I (Oriana). These pieces correspond in style roughly to the middle-period Italian madrigal. English counterparts of the canzonetta and balletto were the canzonet and ballett. A late 16th-century innovation in both Italy and England was the ayre (air), a simple, chordal setting especially suitable for a solo voice with a lute or a consort of instruments playing the other parts. John Dowland and Thomas Campion were notable composers of ayres.

France. The French counterpart of Italian and English madrigals was the polyphonic chanson, a continuation of the chief medieval and early Renaissance form of secular music. Revitalized by composers such as Josquin, Clément Janequin, and Claudin de Sermisy, the chanson developed several distinctive features: a clearly delineated sectional structure with some repetition of sections, much vivid programmatic writing, and occasional use of irregular metric organization. The irregular metric structure, called *musique mesurée,* was used for maintaining faithfully the accentuation of the poetry and reflects the traditional primacy of textual over musical considerations in French music.

The chanson

Germany. The lied, or song, continued its 15th-century role as the chief secular form in Germanic areas, but it did not develop to the same extent as the madrigal and the chanson. Throughout the Renaissance it was relatively conservative in its adherence to the cantus firmus principle and its tendency toward chordal over contrapuntal texture. Following Heinrich Isaac in the 15th century, the major 16th-century lieder composers were Ludwig Senfl, Hans Leo Hassler, and Johann Hermann Schein. To all

national schools of the 16th century must be added the name of the Flemish composer Orlando di Lasso, who wrote in French, Italian, or German, depending on his current employment. The Spanish villancico was a flourishing popular form, but there was no Iberian equivalent to the madrigal, the chanson, or the lied.

The tonal era and after: 1600 to the present

The beginning of the 17th century was one of the most dramatic turning points in the history of music, even more so than the beginning of the Ars Nova and almost as revolutionary as the beginning of the 20th century. The winds of change had been felt several decades earlier, and the establishment of the new style required several decades after the turn of the century, but the year 1600 saw the performance of several works destined to change the course of music.

THE BAROQUE ERA

The spirit of the Baroque

Originally used in a derogatory sense of referring to something bizarre, degenerate, and abnormal, the term Baroque gradually acquired a positive connotation for the grandiose, dramatic, energetic spirit in art that prevailed during the period from about 1600 to about 1750. The new spirit required a vastly expanded musical vocabulary, and a rapid evolution of new techniques occurred, particularly in vocal music. Two distinct musical styles were recognized. One, the *prima prattica* (or *stile antico*), was the universal style of the 16th century, the culmination of two centuries of adherence to Flemish models. The other, called *seconda prattica*, or *stile moderno*, referred to the new theatrical style emanating from Italy.

The expanded vocabulary allowed for a clearer distinction between sacred and secular music as well as between vocal and instrumental idioms, and national differences became more pronounced. The tonal organization of music evolved also, as the medieval modes that had previously served as the basis of melody and harmony were gradually replaced, during the 17th century, by the system of tonality dominating Western music until about 1900: a system based on contrasting keys, or sets of interrelated notes and chords deriving from a major or minor scale. Viewing the period as a whole, two additional innovations most clearly distinguish it from the preceding Renaissance: concertato, or the contrast, combination, and alternation of voices and instruments, and basso continuo (thorough bass, figured bass), an accompaniment consisting of a low-pitched instrument, such as a violoncello or a bassoon, combined with a keyboard instrument or lute capable of harmonic elaboration.

Opera. Most typical of the emerging style were the dramatic productions of the Camerata, a group in Florence who were dedicated to recreating and imitating the musical ideals and practices of classical antiquity—in a sense, the musical manifestation of the Renaissance. Their guiding philosophy was the preeminence of textual over musical considerations; their belief was that the function of music was to heighten the dramatic impact of words. The musical result was monody: originally recitative (solo singing reflecting speech rhythms), later also arioso (more lyric than recitative) and aria (more elaborate song), accompanied by a basso continuo that could provide an innocuous background to a solo voice. Among the major figures in this revolutionary movement were Giulio Caccini and Jacopo Peri, both of whom composed operas based on the legend of Orpheus and Eurydice. Caccini also provided the name for the new movement with his publication of *Le nuove musiche*, a collection of solo songs with continuo accompaniment. The ideas and techniques conceived by the Camerata spread rapidly over Italy and, subsequently, all over Europe.

17th-century developments in Rome

Early Italian operatic schools. During the 1620s and 1630s the centre of operatic activity shifted from Florence to Rome, where several distinctive features developed: a chorus was used extensively, dancing was incorporated into the dramatic spectacle, and an overture in the style of a canzona became the accepted norm. A flourishing operatic activity developed a decade later in Venice, where the first public opera house was opened in 1637. Public taste began to influence operatic composition, and, as a result, several innovations, such as the extensive use of popular tunes, spectacular staging, and short, fanfare-like overtures, were introduced. The audience's desire for tuneful songs also contributed to the clear distinction between recitative and aria, which began with the Venetian school. Foremost among contemporary composers was Monteverdi, who had known of the activities of the Florentine Camerata while serving as musical director to the Gonzaga family in nearby Mantua. He adopted the new style for his later madrigals and wrote two operas, *Orfeo* (1607) and *L'Arianna* (1608), before moving to Venice in 1613. Francesco Cavalli and Antonio Cesti became the leading Venetian operatic composers after Monteverdi's death in 1643.

Neapolitan opera. The last major operatic centre to develop in Italy began its activities in the 1670s in Naples. Neapolitan opera seria, or serious opera, with characters from classical history or mythology, dominated Europe for a century. It was essentially a series of recitatives and arias, the latter mostly of the da capo type (ABA, the A section given improvised embellishment on its repetition) characterized by florid virtuosic singing. Other features were, first, the distinction between recitativo secco (dry recitative), accompanied by the continuo, and recitativo accompagnato, or stromentato, accompanied by the orchestra, and, second, the establishment of the Italian overture. Called a sinfonia, the overture in three parts (fast–slow–fast) evolved into the symphony during the 18th century. Alessandro Scarlatti was the most influential of the early Neapolitan operatic composers.

The joining of the French and Italian forms

France. During the same period, opera was introduced at courtly functions outside Italy. After Luigi Rossi's *Orfeo* was performed in Paris in 1647, the Italian form was gradually merged with the major French dramatic form, the ballet; the importance of dancing in French operas thereafter is not surprising. Another distinguishing feature was the French overture (a slow movement, a fast movement, and, occasionally, a return to the opening slow section), which, like the Italian overture, later had an independent life. The masters of French opera during the Baroque period were Jean-Baptiste Lully and his successor Jean-Philippe Rameau. Because of the social and political upheaval of the Thirty Years' War, there was less operatic activity in Germany than in France, and the activity that did occur was more completely dominated by the Italian style. Hamburg, Munich, Dresden, and Vienna were the major centres, with Reinhard Keiser and Georg Philipp Telemann as the most prolific composers.

England. The situation in England resembled that in France, since the English also had a flourishing musico-dramatic form, the masque, which gradually merged with Italian opera. Henry Purcell and John Blow were the chief composers of opera in English before Italian domination of serious opera became almost complete during the 18th century.

Cantata and oratorio. The leading Neapolitan opera composers also helped to establish the Baroque successor to the madrigal—the cantata—which originated as a secular form for solo voice with instrumental accompaniment. Giacomo Carissimi standardized the form as a short drama in verse consisting of two or more arias with their preceding recitatives. The cantata was introduced into France by one of Carissimi's students, Marc-Antoine Charpentier; Louis Nicolas Clérambault continued the tradition in the late Baroque period. With the fading stylistic distinction between sacred and secular music, the cantata was quickly converted to church purposes, particularly in Germany, where it became the chief decorative service music for the Lutheran Church. Dietrich Buxtehude and Johann Kuhnau were two of the leading composers of such church cantatas.

While the new concertato techniques were being applied to established forms of church music, such as the mass, service, motet, anthem, and chorale, new forms emerged that were clear departures from Renaissance styles and types. The oratorio and settings of the Passion story developed simultaneously with opera and on almost identical

lines, consisting of recitatives, arias, vocal ensembles, instrumental interludes, and choruses. Emilio del Cavaliere was the "founder" of the oratorio with his *La rappresentazione di anima e di corpo* (*The Representation of the Soul and the Body*). Produced in Rome in 1600, this work, unlike true oratorio, used actors and costumes. Carissimi and Alessandro Scarlatti were the chief Italian Baroque composers of oratorio, and Heinrich Schütz, a pupil of both Giovanni Gabrieli and Monteverdi in Venice, was the leading 17th-century German composer in this field.

Instrumental music. The new techniques of *Le nuove musiche* were to be heard in music for instruments, especially now that they participated in genres formerly written for unaccompanied voices (*e.g.,* the motet). The forms and mediums of instrumental music remained essentially the same but with considerably different emphasis. The lute, for example, lost status quickly with the rise of the harpsichord as the most common instrument for continuo accompaniment of dramatic productions. The organ, as the traditional church instrument, retained its position and assimilated the evolving forms.

Continuo instruments

Modification and expansion of older forms. Dance pairs of the Renaissance grew, about the middle of the 17th century, into dance suites consisting basically of four dances: allemande, courante, saraband, and gigue, with optional dances such as the gavotte, the bourrée, and the minuet sometimes inserted before the final movement. Variation forms—the chaconne (in which a set of harmonies or a bass theme is continuously repeated), the passacaglia (in which the theme is repeated but not necessarily in the bass), along with the ground bass and variations on well-known melodies—continued to be popular. Free forms also continued in the patterns of their Renaissance antecedents, while growing in dimension and inventiveness. The toccata, prelude, and fantasia were expanded into multisectional forms using the three basic instrumental textures—imitative counterpoint, chordal homophony, and virtuosic passage work—in combination, alternation, and contrast. The Renaissance fugal forms, chiefly the canzona and the ricercar, gradually evolved into the late Baroque fugue, and cantus firmus compositions continued to flourish as a result of their liturgical function.

The sonata and concerto. The major new categories of instrumental music during the Baroque period were the sonata and the concerto. Originally applied to instrumental ensemble pieces derived from the canzona, the term sonata became the designation for a form that was to dominate instrumental music from the mid-18th until the 20th century. In its keyboard manifestation, it was a binary (two-part) structure similar to a dance-suite movement. For small ensemble, it evolved into a series of independent movements (usually in a slow–fast–slow–fast arrangement) called a *sonata da chiesa* ("church sonata") or a dance suite called a *sonata da camera* ("chamber sonata"). Especially prominent was the trio sonata, for two violins (or flutes or oboes) and cello with continuo. Eventually, similar forms were adopted for orchestra (sinfonia or concerto), for orchestra with a small group of featured instruments (concerto grosso), or for a solo instrument with orchestra (solo concerto). The fundamental principle of the concerto was that of contrast of instrumental groups and musical textures.

Throughout the period, keyboard music flourished, notably in the hands of Jan Pieterszoon Sweelinck in the Netherlands, Johann Pachelbel and Johann Froberger in Germany, Girolamo Frescobaldi in Italy, and Domenico Scarlatti in Spain; in France the chief exponents included Rameau and François Couperin.

Instrumental ensemble music, both chamber and orchestral, was dominated by Italians, chiefly from Bologna, the Bolognese school producing such composers as Arcangelo Corelli, Antonio Vivaldi, and Giuseppe Tartini. Purcell in England and Couperin and Jean-Marie Leclair in France are representative of the many composers in other nations who were influenced by Italian models of instrumental ensemble music.

The late Baroque. The Baroque era reached its zenith in the work of Johann Sebastian Bach (1685–1750) and George Frideric Handel (1685–1759). Both were born in the same part of Germany; both were reared in the Lutheran Church; and both were primarily organists; but because of different environmental circumstances each became a master of different musical forms. Handel, because of his conditioning in Italy, was primarily a dramatic composer, writing opera, oratorio, and secular cantatas, mostly after he reached England. He also wrote quite extensively for orchestra and instrumental ensemble. Bach, by contrast, was influenced by his lifelong employment in the church and by his dedication as a teacher; his works thus include Passions, cantatas for church services, liturgical organ pieces, and harpsichord compositions, many instructional in purpose.

The primacy of Bach and Handel

In the works of both Handel and Bach changes in technique reached a culmination with the clear establishment of the tonal system, allowing for modulation from one key centre to another, primarily as a device for formal organization. Rich, chromatic harmonic language was both reason and result of such a change. The fusion of contrapuntal technique with homophonic style resulted in a distinctive hybrid texture that employed figured bass (homophony) as a foundation for two or more independent melodic lines (polyphony).

THE CLASSICAL PERIOD

The term classical

As in the case of the Renaissance, difficulties with terminology again arise with the label classical. Does it refer to a period of time, a distinctive musical style, an aesthetic attitude, an ideal standard, or an established norm? Again, the term was borrowed from the visual arts of the same epoch and is awkward when applied to music in that there were no known models from classical antiquity for composers to imitate. A full understanding of the term depends on a clear conception of the term romantic, for the two stand at opposite poles. Each represents a set of artistic ideals that has been in opposition to the other since both were recognized by early Grecian writers. As has been noted, the ancient Greek followers of Apollo established the ideal of classicism, whereas the cult of Dionysus produced the prototype of romanticism. A mixture of the two qualities has prevailed throughout recorded history, with first one and then the other in the ascendancy. Thus, there have been many "classic" and many "romantic" eras, but the labels have come to refer most specifically to the last half of the 18th century and the 19th century, respectively, because those periods represent most vividly the two tempers.

The social and political scene during the late 18th century was hardly a setting for a quiet, composed "classical" age in view of the prevailing revolutionary spirit and colonial rivalry. The revolutionary movement did have a direct effect on music in that "music for the masses" became a new ideal—music directly appealing to a large number of unsophisticated people who had previously been excluded from courtly entertainments.

Precursors of the Classical style. *The Rococo style galant.* As the pendulum swung from the predominantly romantic Baroque period toward the Classical period, there was an inevitable overlapping of the old and the new. While Bach was composing his intricate and erudite polyphony, his sons were reflecting a new ideal, the Rococo. Fostered by the court of the French king Louis XV, whose life-style was far less formal than that of his illustrious great grandfather, the Rococo ideal was artistic expression dedicated to elegance, frivolity, and gracefulness; a work of art must be delicate, playful, entertaining, and immediately appealing. The result was often artificial and unrealistic, but it succeeded in capturing the discreetly sentimental and hedonistic attitudes of the times. Powdered wigs, lace cuffs, and perfumed handkerchiefs for both sexes were other manifestations of the same playful spirit that produced music in the *style galant.*

The empfindsamer Stil. The German counterpart of the essentially French Rococo was the *empfindsamer Stil,* or "sentimental style," which flourished in the 1750s and 1760s. Its leading exponent was one of J.S. Bach's sons, Carl Philip Emanuel Bach, who served for a time at the court of Frederick the Great in Berlin. The distinguishing feature of this German reaction against Baroque profun-

dity was its concern with emotional feeling in the music itself, on the part of the performers and, hopefully, in the reaction of the audience. The French obsession with lightness, gracefulness, and decoration was countered by the German determination to affect sensibilities that were often more attuned to tears than to laughter. A late and less reserved manifestation of *Empfindsamkeit* was the *Sturm und Drang* ("storm and stress") movement in the arts during the 1770s and 1780s. The inclination toward the more intense personal expression of that movement was a harbinger of the coming Romantic period.

Consolidation of the Classical style. The fundamental changes in musical style that distinguished Classical from Baroque were inspired by Rococo ideals and refined and stabilized by the Classicists, particularly Joseph Haydn, Wolfgang Amadeus Mozart, Christoph Willibald Gluck, and the young Ludwig van Beethoven.

Central role of instrumental music

Stylistic elements. For the first time in the history of music, instrumental music became more important than vocal music. The orchestra and chamber groups, such as the string quartet, trio, and quintet, and the piano trio became standardized and replaced the heterogeneous trio sonata and other ensembles of the Baroque period. The basic duple and triple organization of metre remained unchanged, but rhythmic patterns tending toward more regularity and simplicity became the rule, producing the "tyranny of the bar line" that was to prevail for more than a century.

Melody was inclined to be more motivistic, tuneful, and epigrammatic, in contrast to the extended, figurative style of many Baroque melodies. Harmony was second only to melody as a focal element. Harmonic patterns that clearly established the tonal centre were the rule of the day.

As a reaction against the intricate polyphony of the later Baroque period, homophonic texture dominated by melody became the norm, but the accompanying patterns were different from those of the early Baroque, when monody supported by sustained chords was the prevailing style. In the late 18th century, figurations such as the Alberti bass (form of accompanying figure consisting of broken chords) and rhythmically enlivened repeated chords formed the typical textural patterns. Counterpoint was retained in some forms, however, and regained status particularly in development sections of works in sonata form.

Formal structure, a definitive aspect of classical style, was characterized by simplicity and clarity. Sectional forms (created by contrast and repetition of thematic materials, tonalities, and textures), variations, and the new principle of development (fragmentation, expansion, and modification of themes) were the established norms. Phrases of musical material became shorter and more clearly demarcated as well as more balanced and regular. A new concept of dynamic contrast also contributed to formal clarity. Shading from loud to soft or vice versa provided a dramatic means of building toward an expressive climax. Orchestration and instrumentation were closely allied to dynamic variation, and much more colour contrast and variety appeared in orchestral music, even though the ensemble was more standardized than formerly.

Sonata form. The pattern that served as the structural basis for most instrumental music of the classical period was the sonata. A large-scale work in several movements, it evolved from several Baroque predecessors, chiefly the Italian overture, the *sonata da chiesa*, and the concerto grosso. Depending on the medium of performance for which it was intended, it would be called, for example, a symphony, a concerto, a string quartet, a sextet, a trio. The designation sonata was reserved for a solo instrument or for an instrument accompanied by harpsichord or piano. Originally in three movements, the sonata became standardized as a four-movement form when a minuet was incorporated in the following sequence: (1) a serious allegro, (2) a slow, lyrical movement (andante or adagio), (3) a minuet and trio, and (4) a brilliant, vivacious finale. The internal structure of the first movement was so uniform that it acquired the designation sonata-allegro form; that is, the form employed in the allegro movement of a sonata, consisting basically of exposition, development, and recapitulation. The slower second movement is less structurally predictable. It is frequently a sectional form (for example, ABA, AABA, ABCA) or a set of variations. It may, even though in a slow tempo, be a sonata-allegro form, illustrating again the inconsistency of musical terminology. The third movement, usually omitted in the concerto and sometimes in other forms, is either a graceful minuet or a scherzo, a lively rhythmic form derived from the minuet. The structural pattern of the minuet had been fixed when it was established as the official court dance by Louis XIV in the mid-17th century. The last movement is frequently a rondo form, in which the principal theme recurs regularly between subordinate themes.

Instrumental music. *The symphony.* The most important and influential manifestation of the sonata form was that played by an orchestra—the symphony. During the 17th century the term sinfonia had been used for various kinds of instrumental music. "Sonata" was equally ambiguous. Late in the century, the designation sinfonia began to be confined to the Italian opera overture—a three-movement arrangement, fast–slow–fast. By the mid-18th century, opera overtures were being played independently in concerts. The insertion of the minuet between the last two movements resulted in the prototype of the Classical symphony.

During the waning Baroque period, vigorous advocates of the burgeoning Rococo and *Empfindsamkeit* ideals were active in Milan, Vienna, and Mannheim. In Milan, Giovanni Battista Sammartini began writing his symphonies, some 25 of them, in the 1730s. While employing the continuo of his models, Corelli and Giuseppe Torelli, the bithematic plan for his opening movements foreshadowed the exposition of the Classical symphonies. At about the same time, young composers in Vienna were experimenting with the new genre, thus laying the foundation for the later Viennese masters. The most famous and probably the most influential group was active in Mannheim in the court orchestra of Karl Theodor, the elector of the Palatinate. Their activity began in the 1740s, when Johann Stamitz became leader of the orchestra. His experiments with dynamic techniques—crescendo (increasing in loudness), diminuendo (decreasing in loudness), sforzando (special emphasis)—with homophonic textures featuring the first violins in virtuoso passages and with tremolo and other dramatic effects, became the hallmarks of the Mannheim style and served as models for his son Karl Stamitz and for composers in Vienna. Thanks to the fortuitous presence of certain instrumentalists as well as to benevolent patronage, the basic ensemble of the modern symphony orchestra was gradually established: violins, violas, violoncellos, and double basses; two flutes, two oboes, and two bassoons; two French horns and two tympani. Trumpets were added for festive occasions.

The Mannheim school

The concerto. Unlike the symphony, which had its origins in other forms, the Classical concerto grew directly out of the Baroque solo concerto and resembles it in that it is based on exchange of musical material between solo instrument or instruments and orchestra. While directly derived from the ritornello principle of the Baroque concerto (that of a recurrent musical passage when the soloists are silent), the internal structure of the first movement assimilated the developmental principle of sonata-allegro form. Pietro Locatelli and Giuseppe Tartini are especially notable for their numerous late-Baroque violin concerti.

Chamber music. While music for small instrumental ensembles had flourished for over 200 years previously, the late 18th century witnessed the establishment of chamber music in the modern sense of the term: music in sonata form for a small group of instruments with one player for each part. Replacing the trio sonata of the Baroque period, the most popular classical ensemble was a group of four stringed instruments—two violins, a viola, and a violoncello. Both the group itself and a sonata written for the group were called a string quartet. Among other popular ensembles were the string trio (violin, viola, and violoncello; or two violins and a violoncello) and the piano trio (violin, violoncello, and piano).

The keyboard sonata. The solo keyboard sonata was one of the most vital forms of the period, partly because

of the great increase in amateur performers resulting from the newly affluent middle class. The sonatas of Domenico Paradisi, of J.S. Bach's sons, and of Haydn and Mozart reflect the evolution from the one-movement, binary form of the Baroque period to the standard classical three-movement form. A four-movement form did not become popular until the time of Beethoven. A celebrated contemporary of Mozart, Muzio Clementi, composed more than 60 sonatas for the piano alone and half again as many for piano and violin or flute and strongly influenced the style of piano writing.

Clementi's 60 sonatas

Other instrumental forms. While the sonata was unquestionably the most important form of instrumental music during the period, several other types were cultivated. For orchestra and chamber ensemble, a suitelike work called variously divertimento, serenade, cassation, or notturno was popular for light entertainment, differing from the more serious symphonies, concerti, and sonatas (which were intended for attentive listening) in that the ensemble of instruments was inconsistent, unpredictable, and often unspecified. The number, types, and arrangements of movements were equally flexible, ranging from three to 10 or more, some in dance forms and others in forms suitable for a sonata. While nonsonata forms for solo instruments (particularly keyboard) occasionally bear these designations, the most popular smaller solo forms were sets of variations, individual dances or marches, fantasies, and small pieces that would have been appropriate as movements of sonatas. For some reason, composition for the organ dwindled drastically after the death of J.S. Bach, in 1750.

Vocal music. *Opera.* There was less distinction between Baroque and Classical opera than between instrumental styles of the two periods because opera, with musical interest centred on a solo voice, had been largely melodic-homophonic since its inception. Another reason for the continuity of operatic style throughout the 18th century was the universal domination by the Neapolitan opera seria. Even in Paris, where the Lully-Rameau tradition maintained its vitality, there was an Italian opera theatre. While there was some effective reform of certain aspects of Neapolitan style that had become decadent and some nationalistic reaction in the field of comic opera, nothing in the nature of serious opera challenged Neapolitan supremacy. As a result, the late 18th century was a period of great vitality in operatic composition.

Domination of opera seria

The distinguishing characteristics of Neapolitan opera seria reveal why it is little known and rarely heard today. It was a very conventionalized form, with artificial and overcomplex plots. There were usually six main characters representing three of each sex, with some of the male and female parts sung by castrati (emasculated male sopranos and contraltos). Each character was allotted a standardized number of arias in fairly standardized succession. Obviously, with such constant interruption of the action, dramatic truth received little if any consideration. The singers and the arias were the focus of the entire production, with little of musical interest in the parlando recitatives (*i.e.*, using speech rhythms), little use of chorus, and little function for the orchestra aside from providing a subordinate accompaniment.

Objections to the decadence and artificiality of the Neapolitan style, which had begun to appear as early as the 1720s, would have been fruitless had not a champion appeared to put suggestions and theories for reform into actual practice. Culminating the movement for reform was Christoph Willibald Gluck, who began his career in the 1740s by writing about 20 operas in the prevailing style. Then, beginning with *Orfeo ed Euridice* in 1762, he attempted to enhance both the dramatic and musical components of opera. Superfluous virtuosity and vocal display were drastically curtailed if not eliminated by providing music that reflected the emotional or dramatic situation. As a result of Gluck's reforms, opera moved toward a classical simplicity of style of which his and Mozart's works were the culmination.

A second challenge to established Neapolitan opera was emerging through comic opera in which the subject matter was light, sentimental, often topical, and satirical, reflecting both the social changes of the period and ridicule of serious opera. The music was engagingly tuneful, easy to perform and to comprehend. Comic opera had appeared during the 17th century but began its independent existence during the first half of the 18th century in Italy, where it was called the opera buffa. The French opéra comique evolved during the same period and was given new impetus by the *guerre des bouffons* ("war of the buffoons") of the early 1750s, when support of the Italian opera buffa company then performing in Paris exceeded that of the French heroic opera of Rameau. In England, ballad opera, beginning with *The Beggar's Opera* in 1728, followed a course of development similar in both period and style to that of the opéra comique. German singspiel grew out of translations and imitations of English ballad opera. Models that centred on Vienna adhered to the Italian style and culminated in Mozart's *The Abduction from the Seraglio* and *The Magic Flute*. Yet Mozart also brought the old Italian style to its zenith in *Le Nozze di Figaro* (*The Marriage of Figaro*), *Così fan tutte* (*Thus Do They All*), and *Don Giovanni*.

Comic opera

Other vocal music. Aside from opera, secular vocal music was composed for solo voice and chorus. But the production of solo songs and cantatas in other countries could not compare with the growing interest in the German lied, which flourished under C.P.E. Bach and later composers. The most extensive development of secular part-songs took place in England, where numerous catches and glees were written.

Large-scale sacred choral music of the period was strongly influenced by the prevailing operatic style. Except for the text, some passages from oratorios and passions are indistinguishable from an operatic excerpt. But the Handelian tradition combined with the Neapolitan style and culminated in Haydn's two noble oratorios, *The Creation* and *The Seasons*. Liturgical music, such as masses, motets, litanies, psalms, and canticles, also demonstrated that the same composers were writing for both church and theatre. In many instances the style was uniform for the two types, although the chorus naturally played a much greater role in church music.

THE ROMANTIC PERIOD

The beginning of the 19th century witnessed a change of both musical style and aesthetic attitude that has become identified as Romantic. The term romantic originated in German literature of the late 18th century, illustrating once again the overlapping of classical and romantic attitudes and ideals. The Franco-Swiss writer Mme de Staël articulated the new ideals of the movement in 1813 as original, modern, national, popular, derived from the soil, religion, and prevailing social institutions. Obviously, some of these proclaimed romantic ideals and purposes were the same as those of the 18th-century Classicists.

Establishment of the Romantic idiom. In defining classicism, it was suggested that the distinctive elements of musical romanticism embrace emotionalism, subjectivity, individualism, nationalism, and a preference for a certain type of subject matter. Emotionalism is reflected in the revelation of intensely personal feelings, indeed, the sentimentality that pervades 19th-century music. Subjectivity replaces the formalism of the Classical period, in that impulse and inspiration play a major role in the motivation of both composer and performer, and the listener's response is expected to be more sensory than intellectual. Closely related to subjectivity is the individualism reflected in the highly self-centred expression of composers of the period, as well as by the conviction that a composer's most personal thoughts and feelings are the ultimate artistic message. In contrast to the universality of musical style that prevailed during the 18th century, much 19th-century music is identifiable in terms of national origin. Nationalism—the consciousness of the distinctive features of a nation and the intent to reveal, emphasize, and glorify those features—played a prominent part in Romantic music, partly as a result of social and political developments. The subject matter favoured by Romantic composers is most apparent in vocal music, where words can convey the explicit theme, but instrumental music was also affected

Personal aspect of romanticism

by the Romantic attraction to national identification and to remoteness, strangeness, and fantasy, particularly to the fantastic aspects of medieval tales and legends.

Stylistic traits. During the 19th century, musical techniques and materials were rapidly enriched by new resources, all devoted to the ideal of emotional or dramatic expressiveness. The orchestra, the piano, the solo voice with piano accompaniment, and the opera were the four predominating mediums; chamber and choral music occupied a less central position. Duple and triple divisions of the measure remained the basis of metre, but there were occasional experiments with metric irregularity, and rhythm was recognized as one of the most effective agents of expressiveness in music. Strong rhythmic energy, frequently produced by dotted patterns, provided a vigorous force that could be enhanced by faster and faster tempi. Flaccid patterns in slower tempi provided for the requisite pensive or sorrowful moods.

Melodic style was determined on one hand by the vocal ideal of song, with long, lyric lines. On the other hand, the new idiomatic possibilities of instruments were being exploited. In either case, expressiveness was the governing ideal. Harmonic and tonal elements were gradually expanded during the century, with more chromaticism, enriched sonorities (seventh and ninth chords), and more nonharmonic tones resulting in a more flexible tonal scheme. Tonic and dominant chords (those based on the first and fifth notes of the key), were no longer the secure poles of tonal movement; frequent and remote modulations (changes from one key to another) contributed to the restlessness of key centres. Because musical interest was centred in melody and harmony, texture remained prevailingly homophonic, though counterpoint played a prominent role in developmental sections. Fugues and other imitative forms occurred as a result of studied archaism or for special effect, but the composers' preoccupation with direct and immediate expression led them to neglect the traditional polyphonic forms, with their inherent traditions and restraints.

Increasing importance of modulation

The Romantic abhorrence of formalism has frequently been exaggerated for the purposes of distinguishing between Classical and Romantic attitudes. Established patterns such as the sonata-allegro and rondo forms were subjected to many modifications and extensions, but musical coherence demands a judicious balance of unity and variety, so most compositions of the 19th century are still fairly clear-cut sectional, variational, or developmental forms. The distinctive new features are largely in the area of emphasis and dimension—symphonies lasting over an hour in contrast to the 20- to 30-minute standard of the Classical period. Instrumental colour and variety, as another aspect of expressiveness, was made possible by a greatly enlarged orchestra and figured prominently in the new sound ideal.

Beethoven as a transitional figure. The Janus-like figure who marked the transition from the Classical to the Romantic style was Beethoven, the first composer whose personality and character made a purposeful impact on the types and style of music he composed. Inspired by the revolutionary forces prevailing at the time, he declared himself a free artistic agent, with neither allegiance nor responsibility to any patron. His early works reflected the 18th-century acceptance of providing music on demand, and he applied his craftsmanship to supplying compositions in hope of financial reward. But in his later works, from about 1820 on, he declared his personal independence and wrote only what his imagination and inspiration dictated, thus establishing individuality, subjectivity, and emotional expression as the standard for Romantic composers. Yet the body of music he produced reflects the tastes of the 18th rather than the 19th century, in that he was attracted more by the absolute forms of instrumental music than by the dramatic and lyrical forms cultivated by the Romanticists. Symphonies, chamber music (particularly string quartets), and piano pieces (including 32 sonatas) far outweigh his one opera, one oratorio, one major mass, and assorted songs and part-songs. His lack of interest in dramatic vocal music reflects the classical side of his nature, though the expressive changes apparent in his instrumental works are evidence of his being the springboard to the Romantic epoch.

Opera. The opera remained a flourishing medium throughout the 19th century, and Italian opera continued as the dominant type during the first half of the century in the hands of Gioacchino Rossini, Vincenzo Bellini, and Gaetano Donizetti. The reforms instigated by Gluck were discernible, but enough of the genre's indigenous Italianate character remained to distinguish it from other national types. The man who, more than any other, personifies Italian opera of the period is Giuseppe Verdi (1813–1901), whose works are still among the most performed. Late in the century, the tendency toward even more realistic and topical subject matter produced the *verismo* ("realism") school of Ruggiero Leoncavallo, Pietro Mascagni, and Giacomo Puccini.

Meanwhile, German opera developed into the epitome of romantic subject matter and expressiveness, beginning in 1821 with the performance of *Der Freischütz* (*The Freeshooter*), by Carl Maria von Weber. Plots based on tales from Teutonic mythology and medieval legend that emphasized the mystical aspects of nature were a distinctive feature of Germanic operas and distinguished them from the more mundane Italianate plots. Richard Wagner (1813–83) crystallized the German Romantic ideal into the music drama, in which all aspects of the production—drama, music, design, performance—were intended to fuse into a manifestation of pure artistic expression in which no one element predominated over the others, as singing still tended to do in Italian opera. There was no development in Germany after Wagner comparable with the post-Verdi *verismo* group in Italy. Wagner's innovations—once again a readjustment of dramatic versus musical forces in musical theatre—were the point of departure for most German opera since his time, from Richard Strauss to the present.

Wagner's music drama

In Paris, the operatic centre of the world from late in the 18th century until well into the 19th, native composers were quick to sense the Gluckian changes in Italian opera as well as the new directions in Germany. Beginning with Rossini's *Guillaume Tell* in 1829 and crystallizing in the operas of Giacomo Meyerbeer in the 1830s and 1840s, French grand opera emerged as the most opulent and grandiose musico-dramatic spectacle of the first half of the century. During the later 19th century, opéra comique and grand opera merged to produce the prevailing French lyric opera. At the same time, opéra comique branched off in another direction to produce operettas, which developed into the musical comedies of the 20th century. Indigenous opera appeared in other regions, especially in Russia, Bohemia, and Scandinavia, as a result of nationalistic fervour.

Orchestral music. Reaching both a culmination and a turning point in the nine symphonies of Beethoven, orchestral music developed in two directions during the 19th century. On the one hand were composers who, because of their training and temperament, adhered primarily to Classical forms and ideals of absolute music. On the other hand were the composers seeking new realms of dramatic content, colour, and expressiveness. Even for the more conservative group, both the forms and the orchestra itself were greatly expanded during the century, but the total output of works was much smaller than in the Classical period. Romantic musical vocabulary replaced the Classical language in symphonies, of course, and programmatic content (*i.e.*, an extramusical image or story) was a frequent element.

New orchestral forms. The more progressive composers cultivated new musical types that represented the tastes and ideals of the Romantic period—the concert overture, the symphonic poem (later called tone poem), the symphonic suite, and symphonic variations. The concert overture, a direct development of overtures to dramatic works, was an attempt to reconcile the old classical demands for form with Romantic desire for programmatic content. It was usually a sonata-allegro form with picturesque themes designed to suggest (with the help of the title) characters, locations, or dramatic situations. Felix Mendelssohn's *Hebrides* overture and Brahms's *Tragic Overture* (completed 1880) are representatives of the genre. The symphonic

Programmatic and picturesque works

poem, foreshadowed in Hector Berlioz' *Symphonie fantastique* (completed 1830), was originated by Franz Liszt at midcentury as an orchestral work, usually in one movement, based on an extramusical idea such as a poem or a narrative. The futility of attempting to depict explicit events and attitudes in purely musical terms resulted in the demise of the form early in the 20th century after the many tone poems of Richard Strauss. The symphonic suite was one of three distinct types: (1) an outgrowth of 18th-century dance suites, divertimentos, or serenades, (2) the extension of the symphonic poem into a composite work of several movements of related programmatic nature, or (3) a group of selections from a dramatic work such as a ballet. Rimsky-Korsakov's *Scheherazade* represents the second type, and Tchaikovsky's *Nutcracker Suite* is typical of the third. While variations had appeared as movements of symphonies and concerti since the mid-18th century, they became an independent orchestral form during the last quarter of the 19th century. César Franck's *Variations symphoniques* (1885) is a good example of the type. Popular orchestral pieces, such as the waltzes of Johann Strauss, also flourished.

The mainstream of composers whose orchestral music reflected most clearly their allegiance to Classical forms and models—though conditioned by Romanticism, of course—is represented by Beethoven, Franz Schubert, Robert Schumann, Johannes Brahms, and Anton Bruckner. The more overtly Romantic contingent was centred around Berlioz, Liszt, Gustav Mahler, and Richard Strauss.

The movement toward national expression. A third group, chiefly nationalists who were reacting against Germanic domination of instrumental music as well as reflecting the sociopolitical developments of the era, combined features of both conservative and progressive camps, to which they added national characteristics. While there were manifestations of the movement in countries such as Hungary, Poland, Spain, and England, the most productive and outstanding of those who sought to reflect national distinctiveness were the Russian "Five"—César Cui, Mily Balakirev, Aleksandr Borodin, Modest Mussorgsky, and Nikolay Rimsky-Korsakov—the Bohemians Bedřich Smetana and Antonín Dvořák, and the Scandinavians Edvard Grieg, Carl Nielsen, and Jean Sibelius. French composers such as Camille Saint-Saëns, César Franck, and Vincent d'Indy were motivated by the same impulse of independence, but they could hardly be categorized as nationalists in the same sense as their eastern European colleagues, since there was less distinctive folk material from which to draw colourful materials and since they had been in the mainstream of musical development all along.

Piano music. One of the most popular media of the Romantic era, thanks to the rapid technical development of the instrument, was piano music. Another reason for the popularity of the piano was the growing demand for recreation and entertainment on the part of the newly affluent middle class. In tune with the taste of the times, small pieces of distinctive expressive character (hence, "character pieces") were the most popular type, either as single pieces or as parts of composite works. Stylized dances continued to be popular, but nationalistic types such as the polonaise and mazurka and the novel waltz replaced the staid minuets of the previous era. Sonatas continued to occupy serious composers, and sets of variations continued to flourish. The virtuosity of the violinist Niccolò Paganini and his contemporaries led to many studies, or études, designed to exhibit the performer's dexterity as well as the invention of the composer. Chopin, Schumann, Liszt, and Brahms were the major composers of piano music after Beethoven, but practically all composers of the time contributed to the literature.

Songs. The vocal counterpart of the keyboard character piece was the solo song with piano accompaniment. With the rise of the German romantic poetry of Goethe, Schiller, Heine, and others, about the beginning of the 19th century, the German lied ("song") flourished. After 1850, composers of other nations, especially France and Russia, also produced a song literature of universal appeal. A pioneer and certainly the most prolific composer of lieder was Schubert, who in his short life wrote more than 600 songs. His chief successors, in chronological order, were Karl Loewe, Mendelssohn, Schumann, Brahms, Hugo Wolf, and Richard Strauss.

Schubert's 600 lieder

Chamber and choral music. The great Viennese tradition of chamber music reached its zenith in the works of Beethoven and with the death of Schubert came temporarily to a close. The conciseness, unity, and balance that were basic to the Classical ideal were incompatible with the essence of musical Romanticism. When writing for instruments, the typical Romantic composer was inclined toward the colouristic effects and expressive possibilities of the orchestra. Chamber music continued to be written and performed, of course, but nowhere was it one of the primary interests of composers as it had been during the 18th century. Predictably, the more conservative composers, such as Mendelssohn, Schumann, and Brahms, were the chief composers of chamber music.

While the same musical vocabulary and style had served both church and opera house since the rise of dramatic music, the 19th century witnessed a separation of musical idioms according to function—sacred or secular. Music for use in church was generally conservative, especially after the "rediscovery" of Palestrina and systematic research into the reform of Gregorian chant. On the other hand, cantatas and popular part-songs produced for the many amateur choral societies incorporated as many of the new techniques as could be managed by the singers. There was some fusion of the two idioms in oratorios and in settings of liturgical texts for the concert hall or for special occasions. The requiem mass, with its vividly dramatic content, was attractive to Romantic composers, and Berlioz's and Verdi's settings remain as emotionally telling today as most operas of the period.

MODERN PERIOD

Diversity of styles. The striking changes in musical style that occurred about 1900 were a turning point in the history of Western music comparable to the dramatic transformation of the early 14th and early 17th centuries. But never before had the change been so rapid, and never before had there been such a diversity of resulting styles. The last decades of the 19th century witnessed what might be termed the diffusion of Romanticism, when significant departures from the current musical vocabulary appeared in the works of some nationalist composers and especially in the Impressionistic style represented in France by Claude Debussy and Maurice Ravel. The amorphous rhythmic patterns, the whole-tone scale, the concept of free relationship of adjacent harmonies, and the kaleidoscopic textures of musical Impressionism were musical manifestations of the aesthetic movements current in painting and literature.

The experimental works of Arnold Schoenberg and Igor Stravinsky about 1910 heralded a new epoch in music. Schoenberg was the pioneer when his adoption of the ideals of the Expressionist movement—like Impressionism an aesthetic development shared by other art forms—resulted in his discarding traditional harmonic concepts of consonance and dissonance and led to the development of atonality and 12-tone technique (in which all 12 tones of the octave are serialized, or given an ordered relationship). Stravinsky's revolutionary style, variously labelled "dynamism," "barbarism," or "primitivism," concentrated on metric imbalance and percussive dissonance and introduced a decade of extreme experimentation that coincided with World War I, a period of major social and political upheaval.

Stravinsky's innovations and experiments in Neoclassicism

In contrast with Schoenberg's and Stravinsky's experiments during the second decade of the century, another line of demarcation appeared about 1920 with a general return to the aesthetic ideals of the late 18th century. Following the leadership of Stravinsky, Paul Hindemith, Béla Bartók, and Sergey Prokofiev, among others, most prominent composers entered a Neoclassical period characterized by restraint of emotional content; simplification of materials, structures, and textures; a greater attention to craftsmanship; and a revival of concern for linear counterpoint rather than instrumental or harmonic colour. Baroque emphasis on counterpoint and Classical formal-

ism were now clothed in 20th-century melodic, harmonic, rhythmic, tonal, and orchestral idioms. The Expressionist followers of Schoenberg, most notably Alban Berg, continued in their preoccupation with serial techniques.

Neoclassicism continued as the dominant trend throughout the period from about 1920 until World War II, while many of the experimental techniques introduced during the revolutionary second decade of the century were gradually refined, modified, and assimilated into the accepted musical vocabulary. At the same time, experimentation continued alongside a tenacious conservatism that echoed Romantic ideals and styles. Nationalism also continued to flourish, reaching a level in some countries never achieved during the 19th century.

After World War II the two leading artistic attitudes tended to merge when the followers of Anton von Webern carried serial composition to such a rigorous extreme that its craftsmanship and intellectual orientation suggested Classicism rather than Expressionism. Shortly afterward, Stravinsky, the doyen of the Neoclassical group, began experimenting with serialism. Avant-garde music since that time has begun to employ the techniques made possible by technological developments in electronics.

Advent of electronic composition. Beginning about 1950, two leading groups began experimenting with electronic music, one in Cologne and the other in Paris. The product of the latter group was referred to as *musique concrète* in acknowledgement of the principle that preexisting, or "concrete," recorded sounds serve as the basis of all sonorities in the finished work. The basic sounds, which may be derived from any source—musical, natural, or mechanical—are modified electronically and arranged in any combination and succession suitable to the composer's purpose. The German group, led by Karlheinz Stockhausen, was concerned with a purer form of the medium in that its basic sounds are electrically generated instead of being recorded from sources external to the electronic apparatus. The two approaches share one connecting link with music of the past: all sounds have pitch, intensity, duration, and quality. All other concepts of musical organization have been discarded, including the necessity of a performer. Electronic compositions exist on a tape (or disc), and can be made audible by a speaker system. The dehumanizing of music has been carried several steps further by the use of mathematics and even of computers to determine the nature of sound materials—either electronic or that produced by more conventional means—and their organization. At the other extreme is aleatoric music, in which the performer is allowed to choose the manner and order of presentation of materials specified or simply suggested by the composer.

Computer music

Popular music. Another result of advances in electronics has been the tremendous growth of popular music during the 20th century. New techniques have made possible high-fidelity reproduction of sound and its widespread and rapid dissemination through radio, phonograph, tape recorder, and television. In addition, some of the instruments used in popular music have incorporated electronic amplification as well as sound production. While there has been a popular music as long as mankind has turned to singing and dancing for diversion and recreation, much of it was folk music and existed only as an oral tradition. But popular music in the modern sense originated in the late 18th century, when ballads made popular in ballad opera and dance music received wide circulation. The same types flourished throughout the 19th century and into the 20th, when a new direction was prompted by the emergence of jazz among blacks in the southern United States. After the original ragtime came jazz proper, swing, bebop, and rock in its numerous manifestations—punk, new wave, etc. Early in the century, the novelty of jazz rhythms and dominance of brass, woodwind, and percussion instruments over strings attracted some serious composers who occasionally incorporated suitable jazz idioms into their works. Since about 1930, the influence has worked in both directions, and popular music has gradually adopted techniques that originated in serious music. Regardless of the interaction of popular and serious music, the popularity of the former is one of the most significant musical developments of the 20th century, especially in view of the widening gulf between the serious composer and the potential audience.

Interaction of serious and popular idioms

It is impossible to arrive at a complete and objective description of a revolutionary movement while it is in progress; only a period of time can provide the necessary perspective. It can be acknowledged, however, that music has never before passed through a more anarchic phase than in the 20th century. The tremendous number and diversity of stylistic distinctions has precluded a characteristic designation for the first half of the century, but one must be forthcoming, for musicians of the future will need the terms modern and contemporary for their own times.

Despite the disproportionate publicity given to the most radical experiments, the majority of leading composers working today continue along the moderate path established in the late 1920s and 1930s. And, if one can rely on the lessons of history, the mainstream of music will continue to absorb those new techniques that contribute to expressiveness and communication while discarding that which is merely novel and sensational, so that music history will remain an evolutionary rather than a revolutionary process. Musical Forms and Genres

The term used for the structure of a musical composition is musical form; this term is regularly used in two senses: to denote a standard type, or genre, and to denote the procedures in a specific work. The nomenclature for the various musical formal types may be determined by the medium of performance, by the technique of composition, or by function.

Music rooted in the European tradition, its major forms and genres, and its outgrowths are the chief subject of this discussion. This type of music, it will be clear, is but one segment of the musical picture. Most other regions of the world also have highly developed musical forms and genres. Based on dissimilar cultures, aesthetics, and traditions, few of these bear much resemblance to Western music, and for most English-language readers they warrant a contextual treatment that will examine a number of aspects of their respective cultures. For a discussion of these, see the music sections of AFRICAN ARTS; AMERICAN PEOPLES, ARTS OF NATIVE; CENTRAL ASIAN ARTS; EAST ASIAN ARTS; ISLĀMIC ARTS; OCEANIC ARTS; SOUTH ASIAN ARTS; and SOUTHEAST ASIAN ARTS. The subject of rock music, a genre that sprang up in the United States during the mid-20th century, is treated separately. For a discussion of rock and its offshoots, see ROCK.

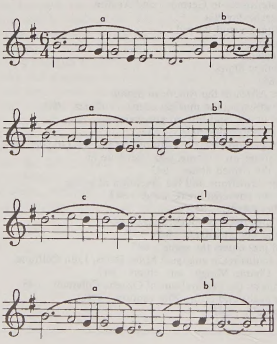
Development of musical form

PRINCIPLES OF MUSICAL FORM

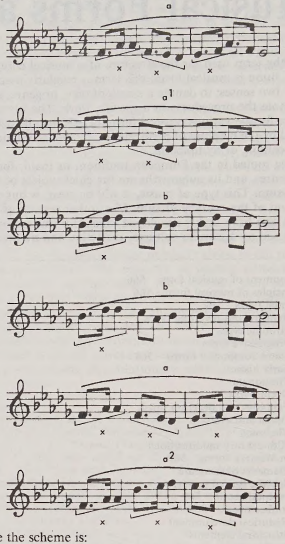
Music exists in time; as an aesthetician, Susanne K. Langer, put it in *Feeling and Form*, "music is time made audible." The proper perception of a musical work depends in the main on the ability to associate what is happening in the present with what has happened in the past and with what one expects will happen in the future. The frustration or fulfillment of such expectations and the resulting tensions and releases are basic to most musical works.

Musical form depends, therefore, on the disposition of certain structural units successively in time. The basic principles can be discerned from a brief consideration of melody, which may be defined as an organized succession of musical tones. This succession of tones consists of component parts, structural units, the principal of which is the phrase—a complete musical utterance, roughly corresponding to what can be sung or played in one breath or played with a single stroke of the bow. A melody, then, ordinarily consists of a succession of phrases, in which there may occur repetition (the same phrase repeated), contrast (a completely different phrase), or variation (the phrase altered, but in such a way that its identity remains perceptible). The relation between these component phrases is important for form. There may, for instance, be a complementary grouping of phrases as antecedent and consequent or "question and answer." The phrases may or may not be equal in length. Some writers, pressing the analogy between music and language, also distinguish larger groupings of phrases: into periods, sentences, paragraphs, and the like. Most musical forms are thus not only additive but also hierarchical: phrases are conjoined to produce a melody, which in turn may be a constituent part of a larger work. A melodic entity that functions as an element in a larger whole is called a theme.



Melody

Coherence may be produced by the use of a motive or figure, *i.e.*, short elements consisting ordinarily of two to four notes. But whereas the motive is usually characterized by a striking interval or rhythmic arrangement, the figure consists of entirely conventional elements (a scale segment, notes of a chord, etc.). Finally, coherence may also be achieved by the consistent use of a rhythmic pattern.



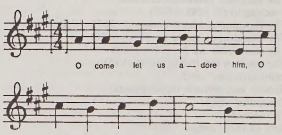
A few examples will serve to illustrate these points. The various phrases have been identified by slurs (phrase marks) and by lowercase letters (the exponential numbers designate variations), whereas larger groupings are designated by capital letters. In the hymn tune "Bethany," by Lowell Mason, shown below, the eight phrases may be grouped in pairs to produce the scheme:

a b a b¹ c c¹ a b¹
A A¹ B A¹ .

This four-phase arrangement with statement, repetition (here with variation at the cadence), contrast, and restatement is extremely common in the traditional and art music of the West.

Other schemes based on repetition and contrast abound. The famous "Largo" from Antonín Dvořák's *New World Symphony*, Opus 95, goes like this:

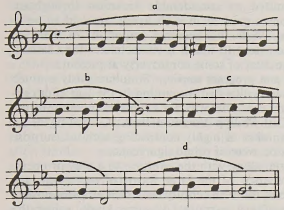
Here the scheme is:



a a¹ b b a a²
A B A¹

This common arrangement is known as three-part form. Coherence is provided by the use of a rhythmic motive,

(marked "x" in the second example).



A common device is melodic sequence, in which the phrase is repeated but in transposition, as in the refrain of the Christmas carol "O Come All Ye Faithful."

Different from the above procedures is an English traditional song, "How Should I Your True Love Know" (example follows). The phrase structure here is a b c d, so that there is no repetitive plan. Such a melody is said to be through-composed. In some through-composed melodies a rhythmic pattern may appear throughout to promote coherence.

Other elements contribute to formal organization in music. Among those having solely to do with pitch are range or register—whether most of the activity is high, low, or in the middle, or combinations of these, and whether the range of pitches used is large or small; types of melodic motion, whether conjunct (*i.e.*, by step along the scale) or

Function of pitch

disjunct (by leaps); and the use of different types of scales or modes. Factors included in music's temporal aspect include tempo, whether fast or slow, as well as duration; *i.e.,* whether individual notes are long or short (the gradually increasing use of constantly shorter note values, for instance, is associated with acceleration and accumulation, thus with increasing intensity). Among the harmonic aspects, there is key, or tonality (set of interrelated notes and chords, based on a major or minor scale), whereby the reassertion of a key following the intervention of other keys may produce an effect akin to the restatement of a phrase after a contrasting one has been heard; in this respect, cadences (sections giving the impression of conclusion) are of crucial importance in defining key. Still other factors include the use of dynamics (loud and soft); timbre, or tone colour, especially in the employment of unusual instruments or combinations of instruments; texture, whether monophonic (consisting of a single melodic line) or polyphonic (many-voiced), be it contrapuntal (having simultaneous independent melodic lines) or homophonic (one voice leading melodically, supported by chordal procedures); and, in vocal music, whether the text is set syllabically (one note to a syllable) or melismatically (many notes to a syllable).

FORMAL TYPES

Four basic types of musical forms are distinguished in ethnomusicology: iterative, the same phrase repeated over and over; reverting, with the restatement of a phrase after a contrasting one; strophic, a larger melodic entity repeated over and over to different strophes (stanzas) of a poetic text; and progressive, in which new melodic material is continuously presented (thus synonymous with through-composed). The following discussion deals first with Western and then with non-Western music.

Iterative and reverting types. Iterative types, not common in Western music, may be found in the recitation tones of Gregorian chant, in which, for example, each line of a psalm is sung to the same melodic formula. Far more common, however, are reverting types. In the Middle Ages there existed the fixed forms used in songs, such as the French ballade (a a b), virelai (A b b a A), and rondeau (A B a A a b A B), the Italian ballata (A b b a A) and the German bar form (a a b), where the patterns of repetition and contrast correspond to poetic forms. (In the representations of the reverting types in songs, lowercase letters refer to the same music set to different words, while capital letters indicate that both text and music are the same.) Since the Baroque period (*c.* 1600–*c.* 1750) there has been binary, or two-part form, such as a b. A variety of binary form particularly prominent in the dances of the 18th century is the rounded binary form, the two sections of which are a and b a (*i.e.,* with a final return to original material in the second section), each of which is repeated, part one being heard twice before part two begins: ‖ : a : ‖ ‖ : b a : ‖ (‖ : and : ‖ indicate the enclosed material is to be repeated).

Sonata form

Binary. The rounded binary form took on great importance in the late 18th century, when it was expanded and elaborated into what is known as sonata form (also called sonata-allegro or first movement form), which may be represented thus: ‖ : exposition : ‖ ‖ : development recapitulation : ‖ , whereby the kinship to the ‖ : a : ‖ ‖ : b a: ‖ structure of rounded binary form is clear. Ordinarily, in the exposition the principal musical themes are stated; in the development they are subjected to a process of working out and variation; and, finally, in the recapitulation they are restated. Sometimes the scheme is enlarged by adding a slow introduction before the exposition or a coda (concluding passage) at the end, or both. This formal principle, usually treated with a certain freedom, has been of basic importance in Western instrumental music since the mid-18th century.

Ternary. Another basic reverting type is ternary (three-part) form, a b a, also known as "song form" because of its frequent use in that genre, as well as in character pieces for piano. The form dominates the aria in late Baroque opera (the da capo aria, in which the final statement of a is not written out, but the performers simply follow the written instruction da capo, meaning "from the beginning," and repeat the first part). The da capo principle also appears in the instrumental minuet and scherzo with trio.

Rondo. On a larger scale are refrain schemes, in which contrasting episodes appear between statements of the refrain. In instrumental music this is found most often in a five-part arrangement, the rondo, frequently a b a c a b a; but many departures from the form occur, most common being the replacement of c by a development passage, usually based on the rondo theme. This important variant, known as the sonata-rondo, is particularly associated with Joseph Haydn. The refrain principle also appears in the rondeau of 18th-century French harpsichord music, in which there is no set limit to the number of episodes. The third movements of concertos, with the reversions of the tutti or ritornello (passage for full orchestra) and the intervening episodes for the solo instrument or instruments, are also of this type, as occasionally are large operatic arias.

Strophic types. The strophic type is seen in hymns and traditional ballads, in which different poetic strophes are set to the same melody. Thus, while the melody of a single stanza may accord with one of the reverting types, the hymn or ballad as a whole is strophic; this also applies to the fixed forms of medieval music and to many other types of song, simple and complex.

Theme and variation

The instrumental equivalent of the strophic type is variation (or theme and variation) form, in which a musical theme, often a complete melody with a harmonic accompaniment, is stated and then repeated a number of times, but with variations. A clear example of the relation between variation and strophic form is the chorale-partita of the Baroque era, a keyboard piece based on a hymn, with each varied statement of the hymn tune corresponding to a strophe of the hymn text. But the structure is more common in independent instrumental compositions, often of considerable dimensions (*e.g.,* Beethoven's *Diabelli Variations* for piano). In the Baroque a common type was the ostinato, or variations on a ground, in which the composition was built on a recurring melodic or harmonic pattern, generally in the bass, the accompanying parts being varied with each statement of the pattern, as in Bach's *Passacaglia and Fugue in C Minor* for organ or his "Chaconne" from the *Partita in D Minor* for unaccompanied violin. This procedure is also found in early operatic arias in the strophic variation form, in which each statement of the ostinato corresponds to a strophe of the aria's text. In the 19th century Brahms made impressive use of the ostinato (finales of the *Variations on a Theme by Haydn* and the *Symphony No. 4 in E Minor*).

Progressive types. The progressive type is common in songs and instrumental pieces of the 19th and 20th centuries but is also found in earlier music (*e.g.,* in the melodies used for the Gloria and Credo of the mass in plainchant) and in the prose, or sequence (*c.* 9th–*c.* 12th centuries), the phrases of which are arranged in pairs (a a b b c c d d, etc.), and its instrumental equivalent, the estampie. Polyphonic forms using a cantus firmus or basic melody (often a plainchant excerpt) also belong to the progressive type and include the liturgical organum, the early motet, and the conductus from the medieval era, as well as many chorale-preludes for organ of the Baroque. If, however, the cantus firmus itself is in one of the reverting forms, then the polyphonic setting will frequently follow suit.

The most important forms of Renaissance polyphony also belong to the progressive type, since the characteristic procedure was to give each line of the text its own musical phrase, as in the Renaissance motet and other types of secular polyphonic music. The same applies to the instrumental contrapuntal forms of the late Renaissance and Baroque: the ricercare, canzona, invention, and fugue. Other progressive types include intonations, preludes, toccatas, and fantasias for lute and keyboard of the 16th, 17th, and early 18th centuries, in which the thematic material consists primarily of figurative elements (scale passages, arpeggiated chords, trills, turns, and the like); in larger works of this kind—by Bach for instance—passages in fugal style are often also present. Finally, there is simple binary form (a b), often found in early dances and in large operatic arias of the Classical period (Mozart and Beethoven).

WESTERN COMPOUND FORMS

Early history. With the larger forms of instrumental music there are extended musical pieces, usually called movements, which in their succession and toiality make up a larger whole. An important unifying factor is key: a single key often dominates the work, others being used for contrast. This idea goes back at least to the Baroque, when two formal types were established: the first is the *sonata da camera,* or chamber sonata, consisting of a series of dances in the same key (also known as partita and, later, suite). By J.S. Bach's time (1685–1750) a set arrangement of dances was common: allemande (moderate duple time), courante or corrente (fast triple time), saraband (slow triple time), and gigue (fast duple or quadruple time), usually with some other dance inserted between the saraband and the gigue. The other type is the *sonata da chiesa,* or church sonata, which consists of four movements, again all in the same key, in a slow–fast–slow–fast succession. The distinction between the two types is explicit in Bach's sonatas and partitas for unaccompanied violin: the sonatas are in the "church" form, whereas the partitas are suites. Other large forms of Baroque music are the two types of overture: the French, in two parts, the first slow and stately, the second fast and fugal; and the Italian, in three movements in the succession fast–slow–fast, the middle movement usually in a different key. The instrumental concerto after 1700 usually employed the same scheme as the Italian overture.

The sonata. Around 1750 a combination of these types produced the forms most common in the standard repertory of concert music. The sonata became a piece for either a keyboard instrument or a solo instrument accompanied by keyboard. It ordinarily consisted either of three movements in the arrangement fast–slow–fast or of four, with a minuet inserted between the slow movement and the finale; but there are examples of two-movement sonatas, notably by Beethoven, and even of one-movement sonatas (*e.g.,* by Domenico Scarlatti, the Italian-born composer to the Spanish court). Usually all movements except the slow one (and sometimes the trio, as well) are in the same key. The first movement typically is cast in the sonata form, the slow movement in one of the reverting schemes (often ternary), and the finale either in sonata or rondo form; but variation form may appear in any of these movements.

This large form is also used in chamber music, particularly the string quartet, and in the large form of orchestral music, the symphony, both of which ordinarily have four movements. Notable exceptions to this are the late quartets of Beethoven as well as those of the 20th-century composer Béla Bartók, the latter in two instances using what is called the "arch form," a large reverting arrangement, A B C B A, each element being a separate movement; there are innumerable other exceptions. The concerto, on the other hand, adheres more to the older three-movement form. The various kinds of late 18th-century entertainment music (cassation, divertimento, nocturne, serenade, and the like) may employ any of a number of arrangements, ranging from three movements all the way to six or more.

Exceptions to sonata form

Cyclic form. Some authorities believe that since the 18th century such sonata-form compositions have been organized by the use of a few musical thematic motives, often submitted to considerable variation throughout. Compositions organized in such a way are said to be in cyclic form. While this becomes important in the 19th century, the extent to which it characterizes the Classical period is a matter of some controversy at present.

Fantasias and program music. Simultaneously a much freer form was cultivated, beginning in the late 18th century, the fantasia, primarily for keyboard, notably in the hands of Carl Philipp Emanuel Bach. Consisting of an indefinite number of highly contrasting sections, surprise and expression were of prime significance.

The fantasia, along with the overture to a play or opera, was the precursor of the large forms of orchestral program music of the 19th century, in which an extramusical content (usually a narrative of some kind), called the program, is expressed in the composition. There are two main types: the program symphony, associated with Hector Berlioz, in which the norms of symphonic form are for the most part preserved, and the symphonic poem, associated with Franz Liszt and Richard Strauss, in which the composer allows the extramusical subject matter to determine the structure of the composition. Some 19th-century concert overtures by German composers such as Felix Mendelssohn and Robert Schumann belong to this type of composition. Important here is the association of musical themes with aspects of the program, the themes being used throughout the work, often in varied forms.

The symphonic poem

Another arrangement is called the suite, which no longer consists exclusively of dances but also of instrumental pieces of all kinds. Usually some common element runs throughout: a cyclic theme may be used, as in Schumann's *Carnaval* or the Russian composer Modest Mussorgsky's *Pictures from an Exhibition,* or the music may originally have been intended for use with a play (Mendelssohn's music to *A Midsummer Night's Dream* or the Norwegian Edvard Grieg's for Henrik Ibsen's *Peer Gynt*).

Opera and oratorio. Among the large forms of vocal music, opera and oratorio are the most significant. Both are extended works in which a narrative is set to music. While an opera is performed in a theatre, an oratorio is a concert piece. Both may be either sacred or secular. A special type of oratorio is the Passion, the setting of New Testament accounts of Christ's crucifixion. The cantata may be regarded as a smaller form of oratorio.

Operas and oratorios ordinarily consist of several musical genres: recitative (imitating the manner of speech), aria, ensemble and choral pieces, often with instrumental interludes and an overture (most overtures of the late 18th and 19th centuries being cast in sonata form). Opera often includes ballets and large sectional finales at the ends of acts. With respect to the oratorio, Handel greatly increased the role of the chorus in his work with this genre (especially *Israel in Egypt*), an example seized upon by his successors. Oratorios also differ from operas in that they frequently make use of a *testo* (narrator), who relates the events of the action, usually set in recitative style. Stravinsky's *Oedipus Rex* (1927) combines the two traditions.

Whereas operas are usually composed as a series of enclosed musical forms, the German composer Richard Wagner devised a special kind, known as music drama, in which the music is continuous and in which the distinction between recitative, aria, and ensemble is largely eliminated. Instead, Wagner used a flexible melodic line which he referred to as "tone speech." Wagner also greatly increased the role of the orchestra, stressing the technique of thematic development and transformation borrowed from instrumental music and further associating each theme with an aspect of the operatic plot, such themes being known as leitmotivs ("leading motifs").

Wagner's new operatic form

The mass. Another large vocal form is the mass, the earliest polyphonic settings of which date from the 14th century. At first the mass was set in cantus firmus style, each movement built on the appropriate Gregorian chant melody, as in the mass of the French composer Guillaume de Machaut. In the 15th century a Burgundian composer, Guillaume Dufay, and his contemporaries developed the cyclic mass, in which a single cantus firmus was employed throughout. This idea was extended in the parody mass, built by elaborating thematic material taken from an ex-

isting polyphonic work, usually a motet or chanson; most 16th-century masses are of this kind. In the Baroque mass, each segment of the text is treated as an independent composition (aria, duet, chorus), similar to the procedure in a cantata or oratorio, except that no recitatives are used. J.S. Bach's *Mass in B Minor* is of this type.

In the 16th and 17th centuries, Monteverdi and others grouped madrigals into a kind of cycle around a particular subject; should a dramatic text be involved, the form is known as a madrigal comedy. In the 19th century and after, similarly grouped songs with piano accompaniment are known as a song cycle (*e.g.*, those by Beethoven, Schubert, and Schumann).

20th-century modifications. In the 20th century many composers have continued to use the traditional forms, although in other respects their work makes significant departures from what had been established. Others have virtually discarded them. Radically new elements have been introduced to serve as structural units: instead of the traditional phrases and motives, composers have come to employ what they call "sound events," combinations of textures, types of timbre, aggregates of different simultaneously sounding pitches, and the like. An early example is afforded by the notion of the melody of timbres—the *Klangfarbenmelodie* of Arnold Schoenberg and Anton von Webern. The broadest possible range is included in the conception of a sound event: not merely tones but also noises; in fact, sounds of all kinds. These sound events have been arranged in a complex manner. An important principle of organization has been serialism, originally applied only to pitch, so that the pitch content of the work is decided by reiterations of a series (set or row) of pitches that has been determined in advance (*e.g.*, in the 12-tone compositions of Schoenberg and Webern). Since 1945 the serial principle has been extended to other aspects of music as well: durations, dynamics, and types of attack and tempi, as in the music of the French composer Olivier Messiaen and the German Karlheinz Stockhausen. Other composers, including Stockhausen and the Greek Yannis Xenakis, have used numerical relationships to determine the structure of compositions mathematically. Still others have conceived of form as a dynamic interaction between contrasting and continually evolving sound events—the French composer Edgard Varèse and the American Elliott Carter. Simultaneously, there are works, such as those of the American John Cage, in which the form is not predetermined by the composer but left to chance, such pieces being called indeterminate or aleatoric. These statements apply particularly to electronic music.

"Sound events"

NON-WESTERN FORMS

Elements of structure. In many non-Western civilized cultures, such as those of India and Middle Eastern Islāmic countries, music for the most part is not written down in advance of the performance but improvised upon framework-like patterns. In effect a composition exists only in its performance. Problems are presented by the different scales and intervals, rhythmic patterns, timbres, inflections, and the like. Or, again, a type of polyphony known as heterophony may result from the discrepancies that occur when several different singers or players simultaneously vary the same melodic line. In Japanese *gagaku* music, in which improvisation is not a factor, the beats often vary in duration, producing what is known as "elastic rhythms," akin to the Western tempo rubato. Much non-Western music is functional: each piece has a specific purpose and is associated with certain events, actions, or situations, which often determine the musical structure.

Important elements of form in non-Western music are melody types and rhythmic patterns. By melody type is meant a melodic formula using a recognized scale, stressing particular tones and using specific configurations of intervals, which can provide the basis for a larger piece. In a given society or culture there ordinarily exists a large repertory of these melody types from which the musician, following convention, selects those for use in his rendition. The use of rhythmic patterns for form is seen, for instance, in colotomic structure, in which the composition is marked off in temporal entities by the differing but regularly recurring entrances of particular musical instruments in a set order.

Rhythmic patterns used for form

In the music of nonliterate cultures, simple iterative and strophic structures predominate. These are characterized by short phrases and the frequent use of alternation between a soloist and the group (the "call-and-response" pattern). Such pieces, often associated with dancing, usually belong to specific rituals of one kind or another.

In literate cultures comprehensive theoretical music systems often exist, with elaborate musical forms. Nonetheless, the conception of propriety, that each musical piece has a certain function, is dominant. While strophic forms continue to be important, as in the Indian *gat*, the *umui* religious chants of the Ryukyu Islands (both of which also use variation), and in the popular music of most cultures, there are also such large musical forms as those related to the Indian *rāgas*, the Arabic *maqāmāt* (melody types), and the music of the *gamelan* (gong and percussion ensembles) of Java and Bali.

Specific formal patterns. The term *rāga*, meaning colour or passion, refers not only to a scale but also to the melody type. It has given rise to several musical forms, among them the ancient northern *dhurpad* and the shorter type known as *khyāl* in the North and *kirtana* in the South. These may be vocal, instrumental, or both, the main performer or performers being accompanied by a drone played by a bass lute and by the reiteration of an extended rhythmic pattern (the *tāla*) by a drum. While much variety is possible, a typical formal arrangement includes a prelude which states the *rāga* (scale and melody type) in its simplest form and continues with a number of contrasting sections that differ in the degree of elaboration of the *rāga*, the register exploited, and the rapidity of the notes and figuration, usually reaching a climax near the end, in which daring variations on the *rāga* in the uppermost register are played or sung in very rapid tempo; the performance may conclude with a return to the character of the prelude. Interludes or linking passages, related to the prelude, are often present, so that an irregular reverting scheme results.

The Arabic *maqām*, roughly equivalent to the *rāga*, provides the basis, among others, for the *bashraf*, a reverting type not unlike the Western rondo, and the *nawba*, an extended multisectional performance with some resemblance to the suite. In Java and Bali particularly noteworthy is the *gending* (musical composition) for the *gamelan*, which may take one of several progressive sectional forms in which the colotomic principle is important: the large *gending agen*, usually bipartite, a slow movement followed by a fast one, and the shorter *gending gangsaran*, used as preludes and interludes. (F.E.Ki.)

Instrumental music

CHAMBER MUSIC

In its original sense chamber music refers to music composed for the home, as opposed to that written for the theatre or church; since the "home"—whether it be drawing room, reception hall, or palace chamber—may be assumed to be of limited size, the music is most often composed for a small ensemble, traditionally dispenses with a conductor, and permits no more than one player to a part. Music written for combinations of stringed or wind instruments, often with a keyboard (piano or harpsichord) as well, and music for voices with or without accompaniment have historically been included in the term.

An essential characteristic of chamber music results from the limited size of the performing group employed: it is intimate music, suited to the expression of subtle and refined musical ideas. Rich displays of varied instrumental colour, and striking effects produced by sheer sonority, play little part in chamber music. In place of those effects are refinement, economy of resources, and flawless acoustical balance.

This section discusses instrumental ensemble music written for groups of two to eight players with one player to a part, and in which stringed instruments and piano (or harpsichord) supply the principal interest.

Historical development. Instrumental music designed

for home use has existed since about the middle of the 15th century. It became customary in Germany to supply folk-song melodies with two or three countermelodies, to expand and elaborate the whole, and to arrange the result for groups of instruments; original melodies were given similar treatment. The instruments were not often specified, but on the basis of many paintings of the time one may assume that groups of viols of various sizes predominated.

A more important source of later chamber music is to be found in the arrangements of 16th-century chansons (songs of French origin composed usually for four voices on a variety of secular texts), some for voices and lute, others for lute alone. The typical chanson was characterized by contrasts in musical texture and often in metre; the effect of the whole was that of a short composition in several even shorter sections. That sectional form retained in the arrangements later became a striking feature.

The chanson travelled to Italy about 1525, became known as canzona, and was transcribed for organ. The earliest transcriptions differed from the French arrangements in treating the original chanson with greater freedom, adding ornaments and flourishes, and sometimes inserting new material. Soon original canzonas for organ, modelled on the transcriptions, and for small instrumental ensembles, were composed. One such type, characterized by elaborate figurations and ornamented melodies, became influential in England late in the 17th century and played a role in the works of Henry Purcell.

Development from dance suites

Parallel to the developments that led from the vocal chanson, in France, to the instrumental canzona, primarily in Italy, was the development of the dance suite. Early 16th-century dance tunes in all countries of western Europe usually had appeared in pairs: one was slow, stately in mood, and in duple metre (*i.e.,* with two beats to the measure); the other fast, lively in mood, usually in triple metre, and often melodically similar to the first. Through much of the 16th century, composers in the several countries sought to expand the dance pair into a unified dance suite. Suites based on variations of one movement appeared in England; suites in which each of four dances had its own rhythmic character, melodically based on the first dance, were written in Germany; sets of dances with no internal relationships to each other were common in Italy. The most influential steps were taken in France by composers for the lute or the clavecin (harpsichord). Consisting essentially of four dance forms that were then popular—the allemande, courante, sarabande, and gigue—the suites they composed were based on contrasting tempos, metres, and rhythmic patterns. The French version of the dance suite became the prototype for later chamber-music forms.

Toward the middle of the 17th century the two types of composition—one derived from the canzona and composed in sectional form, the other derived from the dance suite and consisting of several movements—appeared as works for small instrumental ensembles. In Italy small groups of stringed instruments were often employed in Roman Catholic churches to perform appropriate music; thus canzonas came to be widely used for church purposes. For church use the dance movements were omitted, and what came to be called a church sonata (*sonata da chiesa*) resulted. And a set of *sonate da chiesa* composed in 1667 by Giovanni Battista Vitali marked the beginning of the form as a separate entity.

Rosenmüller's chamber sonatas

In the same year Johann Rosenmüller, a German composer working in Venice, published a set of *Sonate da camera cioè Sinfonie . . .* (*Chamber Sonatas, that is, Symphonies . . .*), each consisting of four to six dance movements with an introductory movement (sinfonia) not in dance style. The development of chamber music for the remainder of the century centred upon these two types, *sonata da chiesa* and *sonata da camera.*

The first half of the 17th century was marked by considerable variety in the constitution of chamber-music groups. Compositions were commonly for one to four viols, or for combinations of viols and woodwind instruments, most often with a figured-bass accompaniment, a kind of musical shorthand, employed in virtually all music of the period about 1600 to 1750, in which the composer wrote a bass line and inserted figures and other symbols under certain notes. The figures indicated the nature of the desired chord to be improvised over the note—whether major or minor, whether in normal or in inverted position, and so on—and the figured-bass line was designed to be "realized" or played by a harmony instrument (such as a lute, organ, or harpsichord), often with a melody instrument (bass, cello, or bassoon) to reinforce the bass line. The bass line with its figures and the two instruments performing it were called basso continuo or simply continuo.

As early as 1622, the Italian composer Salomone Rossi had begun to specify two violins and *chittarone* (a large lute) in his dance sets; and soon similar combinations were adopted generally. A work written for two violins and bass (continuo) became known as a *sonata a tre* or "trio sonata"—even though four instruments (the three strings and the lute or harpsichord) were usually involved in the performance. Later in the 17th century works for one instrument and continuo appeared also and were called variously solo sonatas, duos, or *sonate a due.* The combinations of violin and continuo or cello and continuo were favoured, and sonatas for those combinations took regular places in the chamber-music field.

Works for two violins and continuo (with harpsichord and bass understood) virtually dominated the field until the middle of the 18th century. About that time the custom of serenading became popular; small groups of instrumentalists strolled the streets of Austrian and Italian cities, performing serenades and divertimenti. The keyboard instrument realizing the continuo proved unwieldy and was soon abandoned. To the three remaining strings a viola was added to fill out the harmonies, the bass was replaced by a cello, and the string quartet emerged. This new combination of two violins, viola, and cello was then adopted by composers of serious music, and from about 1750 the string quartet took its place as the principal medium for chamber music. Owing its development largely to the Austrian composer Joseph Haydn, it has reigned supreme to the present day. About 1760, other combinations for strings alone began to play important but relatively smaller roles in the field: the string trio (violin, viola, cello), string quintet (quartet plus a second viola), and string sextet (quintet plus a second cello) are chief among them.

Function of the harpsichord

Meanwhile, as the continuo principle gradually approached obsolescence, the harpsichord (which was superseded by the piano about 1770) took on a new function in chamber music. In works with continuo it had been an accompanying instrument, improvising its part according to the directions indicated in the figured bass; now the keyboard instrument became dominant in new combinations that included one to four strings. The most important of these is the piano trio (piano, violin, cello), the repertory of which includes works from Haydn to the present. Various combinations of piano and one instrument loom almost as large. Toward the end of the 18th century and extending through the 19th, the combinations of piano quartet (piano trio plus viola) and piano quintet (piano and string quartet) give rise to a small but significant repertory ornamented by composers such as Mozart, Beethoven, Brahms, and many others.

Finally, works for individual combinations exist in considerable number after about the 1780s. Representative compositions of that nonstandard group include the clarinet quintets (string quartet and clarinet) by Mozart (K. 581) and Brahms (Opus 115); the *Septet,* Opus 20 (violin, viola, cello, bass, clarinet, bassoon, and horn), by Beethoven; the *Octet,* Opus 166 (as in the septet plus a second violin), the *Trout Quintet,* Opus 114 (violin, viola, cello, bass, and piano), and the *String Quintet in C Major,* Opus 163 (two violins, viola, and two cellos), all by Schubert; and the *Horn Trio,* Opus 40 (violin, horn, and piano), by Brahms. Composers of the 20th century have written works for instrumental groups to which a voice is added.

Late Baroque period, c. 1675–1750. The work of Arcangelo Corelli (1653–1713) in standardizing the two major sonata types of his time had tremendous impact on chamber music. Corelli was of considerable influence on Henry

Purcell (*c.* 1659–95), the most important English composer of his time. Purcell's works include 22 trio sonatas closely allied to the *chiesa* type, and over a dozen "fancies" (that is, fantasies), works of a single movement largely in contrapuntal style for groups of three to seven viols. Another Italian Baroque composer of widespread influence, Antonio Vivaldi (1678–1741), in addition to several hundred concertos for various instruments and orchestra, composed some 75 chamber-music works. Of these, 12 trio sonatas, 16 sonatas for violin and continuo, and about 16 for various other instruments have entered the repertory.

Bach's contributions

The contributions of Johann Sebastian Bach (1685–1750) to development of chamber music were noteworthy. In all, Bach's chamber works include 18 sonatas for one instrument (nine for violin, three for viola da gamba, six for flute) and harpsichord, two separate trio sonatas, and two late works of an unusual nature; *Das musikalisches Opfer* (*The Musical Offering*) and *Die Kunst der Fuge* (*The Art of the Fugue*). Half of the sonatas require figured bass; the other half, with written-out keyboard parts, are essentially in three-voice counterpoint: one voice in the solo instrument and two in the keyboard part. *The Musical Offering* consists of 12 canons and fugues for various combinations of two to six instruments and a four-movement trio sonata; the whole is based on a theme given to Bach by Frederick the Great in 1747, upon which Bach improvised in the presence of the King, and which he later elaborated to constitute this "offering." The work reveals Bach's enormous technical skill and is filled with emotional intensity. *The Art of the Fugue,* Bach's last work, is a set of 19 fugues (the last unfinished) for two to four unspecified instruments. The work is based on one theme that is transformed in systematic fashion in successive movements, and employs two additional themes on occasion. The whole summarizes the contrapuntal practices of the past, contains profound spiritual symbolism, and is unique in music.

The 40-odd chamber works of George Frideric Handel (1685–1759), representing both *chiesa* and *camera* types, contain a wealth of melody and carefully worked-out fugal movements and are filled with the rhythmic drive that represents Handel at his best. Of these about 18 are solo sonatas (with continuo) for various instruments, and some 22 are trio sonatas.

Classical period, c. 1750–1825. The 83 string quartets (of which seven are single-movement arrangements of orchestral pieces titled *The Seven Words of Our Saviour on the Cross* and known as *The Seven Last Words*) by Joseph Haydn (1732–1809) constitute a series in which virtually the entire history of the string quartet is represented. Most of them appeared in sets of six, each under a separate opus number. The earliest sets, Opus 1 and 2, express merely the superficial and diverting elements of Rococo style—the fanciful, ornamental style that was prevalent in the 18th century. From Opus 3 onward the four-movement form is regularized, and in Opus 9 thematic materials begin to reveal details that point to the future. Opus 17 discloses a virtuosic element in its first-violin parts, and lower voices are given only a small share in the thematic work. The latter process comes to full expression in Opus 20, for now cello and viola are entrusted with thematic statements and the quartet style is close at hand.

Haydn's 83 quartets

After a nine-year interval (1772–81) Haydn introduced a "new manner" (his phrase) in the quartets of Opus 33; this resulted in the establishment of the principle of thematic development. Motive manipulation is basic to the texture, and the fully developed sonata form appears. Also in Opus 33 Haydn introduced the scherzo in place of the minuet, but did not continue that practice in later quartets.

The 33 quartets from Opus 50 onward (excepting Opus 51, *The Seven Last Words*) include the masterworks on which Haydn's reputation is so firmly founded. Of them 18 (Opus 50, 54, 55, 64) were composed during the time (*c.* 1786–90) Haydn was in close contact with Mozart and are characterized by an increasing use of chromaticism to produce poignant effects. The 15 quartets written after Mozart's death (Opus 71, 74, 76, 77, 103) return to the optimistic style that was innate, and they reveal an ever-increasing expressiveness and mastery of detail.

Haydn also composed more than 30 piano trios, eight violin sonatas, and over 60 string trios. While those works contain attractive melodies, they represent a minor aspect of the composer's activity.

Of the 26 string quartets written by Wolfgang Amadeus Mozart (1756–91) the qualities of the last 10 are such that they have virtually overshadowed the 16 earlier works. Six of the 10 reflect Mozart's first attempts to work in Haydn's "new manner" and reveal how successfully he adopted the principle. The last three, dedicated to King Frederick William II of Prussia, a competent cellist, show Mozart's ability to adapt to the interests of his potential patrons. Here the cello parts reveal something of the virtuosity required of the first violin. Taken together, the last 10 quartets are among Mozart's masterpieces.

Of Mozart's eight string quintets, three rise to supremacy. The *String Quintet in C Major,* K. 515 (K. stands for Köchel, a cataloger of Mozart's works), is a model of strength and delicacy, filled with moods reflecting grace and good humour, but also high dramatic tension. Its companion in G minor, K. 516, is characterized by the same strength but is the embodiment of anguish. Two years later Mozart composed the *Clarinet Quintet,* K. 581; now moods of grace, humour, and cheer prevail. The addition of the woodwind instrument enabled Mozart to achieve a high level of brilliance and colour throughout; the *Clarinet Quintet* is one of the monuments of the literature.

Exactly half of Mozart's 32 violin sonatas were composed before his 10th birthday; in them the violin parts do little more than accompany the piano. The last 16 move gradually to a true ensemble texture, which is fully attained in K. 454, K. 481, and K. 526. Two piano quartets, contrasting greatly in mood, are alike in containing a balance between piano and strings. His seven piano trios are somewhat like the violin sonatas in gradually reaching a true ensemble texture. Of the seven, one in B flat major (K. 502), one in E major (K. 542), and one in E flat major for clarinet, viola, and piano (K. 498) rise to greatness in variety of moods, balanced forms, and perfection of detail.

The backbone of the repertory

In the works of Ludwig van Beethoven (1770–1827) chamber-music composition takes a central place. His 17 string quartets constitute the backbone of the repertory. The first six take points of departure from the quartet style of Haydn's later works, but far exceed them in strength, occasional boisterousness, and variety of material. Five quartets of Beethoven's middle period represent a great increase in size, depth of expression, and formal freedom. The six last quartets include works that transcend conventional forms and textures. Development techniques and contrapuntal devices play more important roles here; forms are imaginative and fluid, movements are often thematically related, and a range of expression that uncovers new depths of the soul is here disclosed.

Beethoven's other chamber music, like the quartets, reveals a gradual increase in the power of the motive to generate thematic sections. This is especially true in the *Three Piano Trios,* Opus 1; the *String Trio in C Major,* Opus 9, No. 3; and the *String Quintet in C Major,* Opus 29. Particularly in the scherzo movements, which Beethoven employs in place of minuets, he generally begins with a one-measure motive, from which most of the thematic material is derived. The *Septet,* Opus 20, together with many of the violin sonatas, the cello sonatas, and a few miscellaneous works, occupy an intermediate stage in this development. Some are based on long melodies that are developed, others on short motives that are manipulated. In virtually every case, however, a masterpiece results.

Early Romantic period, c. 1825–55. Franz Schubert (1797–1828), in about 28 chamber-music works, at first modelled his compositions on those of the Classical period. His restless search for instrumental and harmonic colour soon took him beyond the bounds of Classical style and aligned him with the prophets of Romanticism. Of the eight works in which his mature mastery is so clearly revealed, all but one were composed after 1824. They include the last three string quartets, the *Trout Quintet* for piano and strings, an *Octet* for strings and winds, two piano trios, and the *String Quintet in C Major* with second cello added to the usual quartet.

Schubert's melodic flow

Less concerned with traditional formal structure than other composers of his stature, Schubert relied on unceasing melodic flow coupled with rare harmonic imagination. Typically a melodic section is repeated with changed harmonies, ranging far beyond the usual; the finale of the *Piano Trio in E Flat Major,* Opus 100, is an extreme example. But Schubert also had a keen sense of drama, as the *String Quartet No. 14 in D Minor* (*Death and the Maiden*) exhibits eloquently. Such characteristics (lyrical melody, harmonic variety, and drama) are wonderfully combined in Schubert's last large composition, the *String Quintet in C Major* with two cellos—probably the most perfect work of this composer's short life.

With Felix Mendelssohn (1809–47) a return to Classical ideals of form is seen, coupled, however, with Romantic enthusiasm. Of his about 24 chamber-music works, eight represent the composer at his best; these include five string quartets, two piano trios, and an *Octet* for eight strings. Mendelssohn's contributions include primarily a new kind of light and deft music, heard especially in his scherzos; a rich melodiousness that embraces all sections of the sonata-form movements (hence removing the element of thematic contrast on which musical conflict depends); and scrupulous attention to detail. The scherzo of the *String Quartet No. 4 in E Minor,* Opus 44, No. 2; that of the *String Octet in E Flat Major,* Opus 20; and the finale of the *String Quartet No. 3 in D Major,* Opus 44, No. 1, are among the finest representatives of Mendelssohn's enchanting style.

Robert Schumann (1810–56) represents the best aspects of early Romanticism; these include an interest in tone colour, melodiousness, a free approach to details of form, and subjective expression in which enthusiasm plays a large part. Twelve chamber-music works reflect those aspects in varying degrees. A set of pieces entitled *Märchenerzählungen* (*Fairy Tales*) for piano, clarinet, and viola illustrates the search for new tone colours; the *Piano Quintet,* in which the piano is combined with two violins, viola, and cello (possibly for the first time in the 19th century), does likewise. Three string quartets are melodious, dramatic, brusque, and dreamy in turn. In three piano trios, as in one piano quartet, Schumann's tendency to let the piano dominate the strings is sometimes seen. And in all those works his characteristic impulsiveness and tendency to alternate between forthright and moody expression is characteristic.

Late Romantic period, c. 1855–1900. In chamber music of the last half of the 19th century, only a few dozen works by composers other than Brahms survive in the repertory of the period. A piano quintet, one string quartet, and a single violin sonata by César Franck reveal that composer's fondness for cyclical form, in which successive movements are thematically linked, and for a structural scheme that is based on harmonic manipulation rather than melodic development. Bedřich Smetana (1824–84), in two string quartets and one piano trio, tended toward autobiographical expression in which Czech folk dances played a part. His first quartet, *Z mého života* (*From My Life*), is supplied with a program.

The work of Antonín Dvořák (1841–1904) represents a combination of the finest Romantic writing with a decidedly nationalistic flavour. Of about 30 works of chamber music, nine held an important place in the repertory; these include two string sextets, three quartets, two piano trios, a piano quartet, and a piano quintet. One of the string quartets, the *American,* Opus 96, purports to express Dvořák's impressions of American (including Indian) music. Another work, the *Piano Quintet,* Opus 81, marks a high point in the composer's use of attractive melody and rhythmic vitality; it, too, has Czech overtones. And the *Dumky Trio,* Opus 90, contains six dumky (a dumka being a Ukranian folk music form with moods alternating between melancholy and wild abandon); here the element of contrast is stressed to the utmost.

Aleksandr Borodin (1833–87), in the second of his two quartets, combined traces of Russian nationalism with expressions of pure lyricism. Peter Ilich Tchaikovsky (1840–93), with three string quartets (one of them containing the famous "Andante cantabile"), a string sextet, and a big-scale piano trio, often brought moments of orchestral sonority into his chamber music. The *Piano Trio,* Opus 50, is a virtuosic work in two movements—one a lengthy sonata form, and the other a set of brilliant variations—and is primarily elegiac in mood.

Preeminence of Brahms

It was Johannes Brahms (1833–97), however, who dominated the period. All of Brahms's 24 chamber-music works are highly successful; in all these works Brahms's characteristic balance of emotional and intellectual expression is clearly revealed. Rich sonorities, thick textures, and rhythmic complexity are present everywhere, and the forms are those of the Classical period, somewhat modified in the light of Brahms's temperament and expressive requirements.

Eloquent melodic writing is most characteristic of his earlier works, notably the *String Sextet No. 1 in B Flat Major,* Opus 18; the *Piano Quartet in G Minor,* Opus 25; and large portions of the *Piano Quintet,* Opus 34. Later works, by contrast, reveal Brahms's increasing concern with motivic and rhythmic development; as a consequence, lyricism plays a smaller role in such works as the two string quartets Opus 51, and the four late works with clarinet, namely the *Clarinet Trio,* Opus 114, the *Clarinet Quintet,* Opus 115, and the two sonatas Opus 120.

The 20th century. As in all times of stylistic change, considerable overlapping of styles occurred at the turn of the 20th century. In chamber music, several composers born in the 19th century carried the modified Late-Romantic style into the 20th. Among the French composers were Gabriel Fauré (1845–1924), who, with 10 works, is remembered primarily for a refined and controlled style that is rhythmically subtle; and Vincent d'Indy (1851–1931), represented by about eight works, who reflected the style of César Franck. Likewise the Hungarian Ernő Dohnányi (1877–1960) revealed the strong influence of Brahms in about six works noted for their outspoken melodiousness and contrapuntal excellence. The German Max Reger (1873–1916), with about 36 works, was primarily an exponent of chromatic writing in forms that are derived essentially from the 19th century.

The first step toward the new styles of the 20th century were taken in France by Claude Debussy (1862–1918); his one string quartet (1893) and three sonatas (late works) represent the Impressionistic style based on whole-tone harmony, of which he was an exponent. Somewhat similar are the string quartet and piano trio by Maurice Ravel (1875–1937), with a rich array of tremolos, forms based on repetition of melodic fragments, and many astringent harmonies. In England, on a different path are a string quartet and piano quintet by Sir Edward Elgar (1857–1934) and two string quartets, a string quintet, and a song cycle (*On Wenlock Edge* for tenor, string quartet, and piano) by Ralph Vaughan Williams (1872–1958). Elgar reveals an intensely personal style; Vaughan Williams uses English folk song, elusive harmonies, and strong rhythms.

Three major influences

The musical styles that have dominated the later 20th century are largely the work of three composers and their respective followers. The most influential was Arnold Schoenberg with his development of the "12-tone style"; but his earlier works were not yet representative of that style. A string sextet, *Verklärte Nacht* (*Transfigured Night*), transferred the form and content of the symphonic poem to the field of chamber music; two string quartets, Opus 7 and 10, are similarly post-Romantic in style, and the second includes a part for soprano voice. A set of 21 short poems for quasi-reciting voice and five instruments, *Pierrot Lunaire,* marked an intermediate stage; and four later works, including the third string quartet, saw the full development of the 12-tone style. In a fourth quartet and a few smaller works the system was carried to completion.

In the *Lyric Suite* for string quartet (1927) Alban Berg (1885–1935), also an Austrian and one of Schoenberg's pupils, brought elements of Romantic expression into the system. And another Austrian pupil, Anton von Webern (1883–1945), sought to develop utmost refinement and consistency, along with brevity. A string quartet, a quartet for violin, clarinet, saxophone, and piano, and a chamber concerto for nine instruments are the principal works that illustrate his methods of extreme economy in the use of

all materials. Webern's approach has been of maximum influence on many composers of the present day, and has led to the development of serial writing.

A completely different path was taken by the Hungarian Béla Bartók in six string quartets and a trio, *Contrasts,* for piano, violin, and clarinet. In those works the main thrust has been on harmony (including acrid dissonances that border on atonality), greatly rhythmic drive with many irregular rhythmic patterns (some of them based on eastern European folk song, in which field Bartók was an avid worker), and the development of new instrumental effects. Coupled with such technical elements are fervent expressiveness and, in the slow movements, great repose. The Bartók quartets are among the major chamber-music works of the 20th century.

The third principal influence, that of the Russian-born Igor Stravinsky (1882–1971), was felt perhaps less in chamber music than in orchestral, for Stravinsky composed fewer than a dozen works in the field. Five song cycles for voice and small groups of instruments, several short pieces for string quartet, and a pantomime, *The Soldier's Tale,* for narrator and seven instruments are varied in content and style. An *Octet* for wind instruments (1923) represents a deliberately impersonal style that requires no subjective interpretation on the part of the performers. And a *Septet* for three winds, three strings, and piano (1952) marks Stravinsky's adoption of serial writing, a style that he had consciously rejected earlier.

Other major contributions

The German Paul Hindemith (1895–1963), with seven string quartets and more than two dozen sonatas and other works, favoured polyphonic textures, an expanded harmonic scheme, and great rhythmic drive. His style in later works became less dissonant, more lyric, and was characterized by a general lightening of the thick counterpoint that had distinguished his work of the 1940s. His seven works called *Kammermusik* are for larger groups and so do not come within the scope of this article. The French composer Darius Milhaud, in about 18 string quartets, four quintets for various combinations, and a number of other works, for a time espoused the principles of polytonality, the device of employing several keys simultaneously. Characterized by moods that are often pungent, humorous, and even satirical, his works reveal a mixture of dissonant counterpoint, rhythmic flexibility, and graceful expression. His 14th and 15th quartets, independent works in their own right, may be performed simultaneously to form an octet.

Two Russian composers, Sergey Prokofiev (1891–1953) and Dmitry Shostakovich, are represented in the repertory by about 20 works adhering, in the main, to the forms and textures of the 19th century. Both men embrace the new harmonic techniques without departing entirely from Romantic expressiveness. Many of their compositions reveal a sense of humour. Of British composers, Sir William Walton, Lennox Berkeley, Alan Rawsthorne, and Benjamin Britten have made significant contributions to the medium.

The chamber music by American composers has in general reflected the international styles mentioned above. One exception is seen in two quartets, a piano trio, and several violin sonatas by Charles Ives (1874–1954), who maintained a style of great originality through his long lifetime. Another exception may be noted in the work of Ernest Bloch (1880–1959), Swiss by birth, but identified with the United States since about 1917. In five string quartets, two piano quintets, and a few smaller works, Bloch brought his Jewish heritage to expression in styles that are robust and varied.

American composers

Among the more prominent American composers, a few may be singled out for their notable contributions. Walter Piston, with four string quartets, a piano trio, a quintet for flute and strings, and a piano quintet, is perhaps the most eclectic; his works are basically Neoclassical and are distinguished by elegance and vitality. Roger Sessions, represented principally by two string quartets and a string quintet, has written in an austere, reserved, and strongly dissonant style. Quincy Porter (1897–1966) composed 10 string quartets, several quintets for various combinations, and smaller works; they are characterized by warm expressiveness achieved in textures that employ considerable repetition of short motives. The works of Roy Harris are distinguished by forms that depart from 19th-century models; three string quartets and a piano quintet are among his most significant works.

Aaron Copland may be mentioned for a piano trio; a sextet for clarinet, piano, and strings; a piano quartet; and a violin sonata. Those works include variously nationalistic allusions (including Jewish and Latin American), unresolved dissonance, and elements of serial style. William Schuman in four string quartets and smaller works discloses a strongly dissonant style that remains, nevertheless, within the tonal system; his works are rhythmically vital and express great energy.

Elliott Carter, Jr., is best represented by a cello sonata and two string quartets. He employs elements of serial writing, composes in a virtually free rhythmic manner, and employs new instrumental effects in the manner of Bartók; yet his style is a completely individual expression. Leon Kirchner has composed two string quartets, a violin sonata, and a piano trio; unmetrical rhythm is a striking characteristic of his style, along with a variety of harmonies ranging from purely diatonic to atonal, and warm expressiveness is usually present.

Latin-American composers

Among composers representing the countries of Central and South America, three have risen to international prominence. Heitor Villa-Lobos (1887–1959) was the outstanding exponent of Brazilian national idioms, including those of the indigenous Indians. In his many chamber-music works (10 string quartets, several piano trios, and a few sonatas are representative) Villa-Lobos gave expression to those idioms. Carlos Chávez (1899–1978) worked similarly with the idioms of Mexican Indians, but in several of his relatively few chamber-music works, Neoclassical style elements are prominent. Alberto Ginastera (1916–83), representing Argentina, stressed the element of rhythm to a high degree in a style that is thoroughly contemporary.

Structural elements. *Form.* A major distinction must be drawn between the prevailing musical forms of the period before about 1750 and those after that date. The earlier forms included primarily the *sonata da chiesa,* which emerged from the instrumental canzona, and the *sonata da camera,* which owed its origin to the dance suite. In the first of these, the several sections that had been taken over from the canzona were gradually extended, cadences (harmonic devices analogous to punctuation marks in prose) were confined largely to ends of sections, and the single-movement form soon dissolved into a set of movements of varying length, tempo, and metre. Toward the 1640s a tendency arose to standardize the number of movements and regularize the contrasts between them; soon a pattern of four movements arranged in slow–fast–slow–fast sequence, with textures based to a large extent on imitative or fugal writing, emerged. The Italian violinist-composer Arcangelo Corelli, with about 38 *sonate da chiesa,* was the most consistent in employing that pattern after about 1680.

Chamber and church sonatas

The other form, *sonata da camera,* remained less regular. Its parent, the dance suite, had most often contained four movements, but works of three to eight or more movements exist also. When the dance suite adopted the trio-sonata instrumentation and gradually became the *sonata da camera,* it at first maintained that irregularity. Soon, however, it was altered to include a nondance first movement (prelude, preamble, or *intrada*), after which a number of idealized dance forms followed. In keeping with its origin, the *sonata da camera* revealed a relationship to dance rhythms in its several movements (except the first), and homophonic style (*i.e.,* with a single melodic line supported by chords) dominated. The work of Corelli, embodied in 34 *sonate da camera,* again served as a model for later composers.

Toward the end of the 17th century the two forms began mutually to influence each other. The *sonata da chiesa,* with its serious moods set usually in contrapuntal texture (*i.e.,* employing counterpoint, the intertwining of independent melodic lines), adopted some of the lighter and more rhythmic aspects of its rival. Likewise, the *sonata da cam-*

era, light in its total mood and based on dance rhythms, often embodied contrapuntal devices and contained movements that were essentially imitative or fugal in texture and serious in mood. By the end of the 17th century the distinctions between the two types tended to disappear; soon the terms *chiesa* and *camera* were dropped, and the term *sonata a tre* or "trio sonata" prevailed to about 1750. The situation in regard to solo sonatas (for violin and continuo, for example) was similar; they, too, took on common characteristics derived from the contrasting trio-sonata types, and contained both dance metres and contrapuntal textures.

Pattern of the string quartet

The post-1750 forms, on the other hand, were based on different patterns. A standard pattern of a string quartet consisted of four movements, the first of which was most often cast in sonata form—three-part form containing an exposition of two contrasting melodic ideas, a transition (later elaborated to create a "development section"), and a recapitulation of the first part with changed harmonies. The second movement was generally in slow tempo and could represent one of several forms: another sonata form, a set consisting of theme and variations, or the like. Then followed a movement in triple metre (at first a minuet and later a faster version of that dance called a "scherzo") derived from the dance field and consisting actually of two such idealized dances; the second, called a "trio," usually lighter in texture, was followed by a recapitulation of the first dance. The last movement was a rondo (consisting of a regular alternation of two or more musical ideas, in the form A B A B A or A B A C A), or a set of variations, or even another sonata form. The whole represents a compound form called a "sonata," although post-1750 and pre-1750 sonatas have few structural elements in common.

The term sonata (in the post-1750 version) can be applied to most of the forms within the field of chamber music as well as to several outside that field. As seen in the compositions of a line of composers from Haydn in the late 18th century to Brahms in the late 19th and beyond, the piano trio, violin sonata, string quintet, and the others are all based essentially on the pattern that characterizes, above all, the string quartet. Even the symphony and the concerto of the post-1750 period are, in effect, sonatas for orchestra. Internal differences exist, of course; the piano trio and the violin sonata, for example, do not always include a dance-derived third movement, which the string quartet and symphony generally do. Conversely, the exposition of the symphony's first movement often contains more than two contrasting themes, and is often preceded by a massive introduction; and the recapitulation is often followed by a large concluding section or coda (literally, "tail"). Similarly, the first movement of a concerto (for piano and orchestra, say) is generally characterized by two expositions—one for the orchestra, the other for the solo instrument. In most other respects, the majority of the larger instrumental forms of the post-1750 period are closely related in their total structure.

Melody. The years about 1600, marking roughly the date when chamber music emerged as a separate branch, also mark one of the major turning points in the evolution of music. Virtually all the factors of music were affected by the developments of the time. A new system of melodic organization (the tonal system, with its major and minor scales) soon assumed a preeminent position; the principles of harmony were expanded and systematized; a texture based on the polarity between melody and bass (as opposed to one that had been largely the result of writing intertwined and independent melodies) came to the fore; and the figured bass or continuo was invented (albeit, a few decades earlier) to deal with the new texture. In those new developments all the musical factors continued to be mutually related; but they are considered separately here for the sake of clarity.

The melodies of the canzona, or sonata, at first continued to imitate vocal melodies; easily sung intervals, relatively slow tempos, and undulating stepwise contours were characteristic. Gradually composers began to consider the nature of the instruments they were using and to write melodies appropriate to those instruments. Soon the concept of instrumental idioms was developed; each instrument was given melodies appropriate to its structure. That development is seen most clearly in the many trio sonatas written by Corelli after about 1680.

Harmony as a system

With the emergence of systematized harmony, in which specific functions were given to chords according to their relationships to the tonic (the basic, or root, tone of a given scale), melodies became harmonically directed, moved from one harmonic goal to another, and began to take on regular periodic structure (in units of four measures, eight measures, and so on). Slow movements often adopted elements of vocal style, in which sharp contours were avoided, and the melody followed purely musical or aesthetic laws rather than the laws of textual declamation. The ever-increasing use of harmonic dissonance was reflected in melodic writing through the 18th and 19th centuries. Extreme leaps, angular contours, irregular rhythmic shapes—such characteristics became the common property of all composers.

Influence of tonality

Harmony. The complex of chords gradually evolved into the system of tonality. Central to that system is the idea that the triad on the first tone of the scale (*i.e.,* the tonic and the third and fifth intervals above it) determines the key or tonality (C major, D minor, and so on) around which other chords are grouped. Modulations (shifts to other key centres) became regularized: those to the dominant (the fifth note of the scale) and subdominant (an interval of a fifth below, or the fourth note of the scale) became the most important. In the period immediately before and after 1800, especially in the works of Beethoven and Schubert, modulations to the mediant and submediant (an interval of a third above and below the tonic, respectively) became characteristic. And throughout the 19th century, modulation to ever more remote keys was practiced assiduously. Further, chromatic tones—tones not related to the key centre (F sharp or D flat in a C major context, for example)—appeared in increasing numbers; and tones not part of the chord at a given moment (F in a triad on C, for example) were treated more freely. The consequence was a system in which tonality became so ambiguous that it ceased to serve any real function through long passages in the music. Chromatic harmony dominated much music of the late 19th century, and the steps from chromaticism to the atonal and serial systems of the 20th century, in which tonality was entirely abandoned, followed as a matter of course.

Texture. Similarly, the element of texture underwent a series of changes. Much music was composed in homophonic style, with a melody supported only by a few chords built above the continuo. Gradually, especially in the trio sonatas, an inner part came to imitate the upper melody to some extent; bits of figuration gave the two upper melodies a degree of independence, and eventually polyphonic texture, composed of two or more intertwining melodies, was restored. That texture reflected the harmonic developments of the time and came under the control of the tonal system with its dissonances, modulations, chromatic embellishments, and all the rest. Mixed textures, partly homophonic and partly polyphonic, became common also; but in general the uppermost melody dominated the structure well past the middle of the 18th century.

Toward the 1770s, with the string quartet an established grouping, increasing attention was given to the inner and lower parts. Viola and cello were occasionally given thematic material, the violins at times played accompanying parts, and detailed writing for all four instruments compensated for the absence of the continuo. The practice of improvising harmonies at the keyboard came to an end, and all parts were obbligati (that is, obligatory). Continued refinement in the writing and equal distribution of musical responsibility to all four instruments resulted in the so-called quartet style, in which the distinction between melody and accompaniment disappeared and no instrument dominated the others. From that point forward, the idea of a soloist in chamber music lost whatever validity it had had earlier; the performers in a chamber-music work became members of a group of equals.

Style. In style, too, there has been a continuing series

of changes. "Style" may be defined in this context as the sum of the devices—melodic, structural, harmonic, and all the rest—that a composer consistently employs, that a class of works regularly exhibits, or that a particular age finds most useful for its aesthetic purposes.

In this sense, the majority of chamber-music works composed before 1750 are monothematic in style; those after about 1750 are polythematic. The typical fast movement of a trio sonata, say, consists of a series of phrases largely similar in contour and mood and differentiated primarily by harmonic considerations; whereas the typical sonata-form movement is characterized by having two or more themes embodying sharp contrasts of mood and shape, and further contrasted by means of texture, instrumentation, and harmonic colour. Alternation of dramatic and lyric moods, further, is most often characteristic of post-1750 chamber music.

With the emergence of the string quartet and sonata form toward the middle of the 18th century, thematic materials most often took the shape of relatively long melodies—whatever their contour or mood. Those melodies were then manipulated or repeated in accord with harmonic principles and constituted sections in tonic, dominant, and so on. In the 1780s, and specifically in the quartets Opus 33 by Haydn, certain melodies were so constructed that they could, in effect, be broken apart into fragments or motives, each motive with its own distinctive shape. In the appropriate sections of sonata-form movements—namely, those that connected one thematic section with another, and the large transition that comprised the midsection of the form—the motives were treated separately, manipulated, combined in new ways, served to suggest yet other ideas to the composer; in short, they were "developed."

Thematic development

Such treatment of the motives led to the principle of thematic development and to the practice of motive manipulation. Begun by Haydn, carried forward notably by Beethoven and Brahms, and employed by virtually every other instrumental composer of the 19th century, the principle of thematic development is one of the chief distinguishing marks of late Classical and Romantic instrumental music. Beethoven, however, and after him many other major composers, employed the process somewhat differently from Haydn; he often began with a melodic or rhythmic motive, then let the themes themselves grow out of the motive manipulation.

The repertory of works for piano and strings also grew considerably from the late 18th century onward, and there was considerable modification in the role of the piano in that repertory. The keyboard instrument had entered the field, it will be remembered, after having played a century-long role as the improvising member of the continuo team, in which it provided accompaniments to the other instruments. When it emerged in its new role with written-out parts to play, it at first assumed a dominant position—in violin or cello sonatas and in piano trios alike. Many of the piano trios by Haydn are essentially sonatas for solo piano with accompaniments furnished by violin and cello; the latter often do little more than double the parts given to the pianist's right and left hands, respectively.

Evolution of role of piano

Gradually the string parts acquired a degree of independence and became obbligato parts. The final steps toward complete equality were taken across the interval from about 1790 to 1840, especially in the piano trios and quartets of Mozart and Beethoven and in Schumann's *Piano Quintet,* Opus 44 of 1842. In many of those works, particularly the later ones, the piano emerged as one-half of the tonal body with the two, three, or four stringed instruments providing the other half. Again, as in the string quartets, the concept of soloist versus accompanist has no validity in chamber music with piano. A keyboard player does not "accompany" the strings; he is an equal partner in the ensemble—which marks a major change from the role he played in the 17th and the first half of the 18th centuries.

Chamber music in the later 19th century became ever more affected by developments in the orchestral field. The rise of professional quartets in the time of Beethoven had the effect of moving chamber music from the confines of the home to the public concert stage. Composers took advantage of the virtuosic attainments of the best performers and wrote music with which the nonprofessional performer could not always cope. Effects requiring consummate technical ability became common; true virtuosity became a general requirement. Further, orchestral effects depending upon sheer volume of sound were often employed; the string quartets and piano trio of Tchaikovsky are examples. And with the rise of descriptive or program music in the orchestral field, extramusical or nationalistic elements sometimes entered chamber-music works; Smetana's autobiographical string quartet, *Z mého života* (*From My Life*), and certain of Dvořák's compositions containing Czech folk idioms and representing the Czech spirit are typical.

The overwhelming majority of chamber music composed before about 1900 consists of works that employ instruments in conventional ways. Tones are limited to the pitches in the chromatic scale (*i.e.,* a scale consisting of half steps, C, C sharp, D, D sharp, E, and so through all 12 tones), stringed instruments are used in the traditional manner, and the piano likewise. A few notable exceptions may be mentioned: in the *Piano Trio No. 1 in D Minor,* Opus 63, by Schumann the strings play a short passage *sul ponticello* ("against the bridge")—that is, play closer to the bridge of the instruments than usual in order to produce the higher overtones and give the pitches an ethereal or veiled quality; in the same composer's *Piano Quartet in E Flat Major,* Opus 47, the cello must retune its lowest string downward a whole step in order to supply a longheld tone beyond the normal range of the instrument. And, in a few works of the time, harmonics are called for: a string is touched lightly at its midpoint or at one of the other nodal positions at one-third or one-quarter of its length, and the harmonic (overtone) thus produced adds a distinctive quality to the music. Such effects, plus the traditional pizzicato (in which the string is plucked rather than set in motion by the bow) are virtually the only exceptions to normal writing.

In 20th-century chamber music, however, the number of purely instrumental effects has been increased; the Hungarian composer Béla Bartók in several of his quartets became the leading exponent of such devices. In his *String Quartet No. 4* (1928), for example, glissandi are required; in such cases the player slides his finger up or down the string to cover the span of an octave or more, and produces a wailing effect. Pizzicati are directed to be performed so that the string slaps back against the fingerboard, to add a percussive effect to the pitch. In works by other composers employing the clarinet, the performer is required to blow through the instrument with its mounthpiece removed while opening and closing the keys at random; this produces the effect of a high-pitched whistling wind along with a semblance of pitch changes. Or again, in the case of brass instruments, the composer's directives call for the player to tap his hand against the mouthpiece, to create a hollow percussive sound.

Pitches themselves are altered on occasion, for tones lying between those of the chromatic scale are sometimes employed; among early exponents of the quarter-tone practice, the contemporary composer Ernest Bloch may be mentioned. In his *Piano Quintet,* and elsewhere, the string performers are required to play certain tones a quarter step higher or lower than written, thereby departing from the scales that had served music for many centuries. Other composers carried the quarter-tone practice further and developed a kind of microtonal music that employs intervals even smaller than quarter-tones.

Use of quarter-tones

All such developments give evidence that 20th-century composers continue to seek new means of expression and expand their available resources—thus continuing a practice characteristic of composers in all periods. Two further aspects of that search remain to be considered: the development of new systems of tonal organization and the increasing use of instruments that embody the results of contemporary technology.

Early in the 20th century a number of composers led by Arnold Schoenberg experimented to reach beyond the confines of the tonal system. In a series of chamber music and other works, Schoenberg gradually arrived at a system

in which all 12 tones of the chromatic scale are used as independent entities; concepts of tonic and dominant, of major and minor, and of key centres themselves no longer apply in those works. The 12 tones are arranged in a self-determined series called a "tone row"; certain sections of that row, used vertically, form the chords that supply the harmonic material; the row may be manipulated in accord with self-imposed rules; and the row may be arranged differently for each composition. The system of composing with 12 tones, as Schoenberg referred to his invention, has been modified and enlarged by later composers, the relevant principles have been applied to other elements of music (notably the rhythmic factor); and under a new term, "serial composition," the system has become one of the most influential of the present day.

Electronic synthesizers

The other aspect concerns the use of various electronic sound-generating devices called "electronic synthesizers," and of magnetic tape recorders to transmit the results. The composer working with a synthesizer has virtually complete control over the shape and sound of the tones he wishes to produce. He can select tones with characteristics unlike those produced by conventional instruments, noises (that is, sounds with irregular vibration rates) to which a semblance of pitch has been given, or rapid changes in pitch, loudness, duration, and quality beyond the ability of any human mechanism. The new tonal materials, then, can be combined with voices and conventional instruments, or can be used alone. Devices such as the synthesizer have given the composer access to a new world of tonal resources; he still faces the problems of selection, combination, organization, and expressive purpose that have plagued composers since music began. Since his medium of performance is a tape recorder, since human participation in the performance may not be required, and since his composition may contain a few strands or a hundred strands of tone, it becomes impossible to make distinctions between chamber music, orchestral music, or any other genre. Electronic music is, thus, on the way to becoming a completely new type to which traditional classifications do not apply (see below *Electronic music*).

Audiences. For well over a century after its inception about 1600, chamber music was supported primarily by the nobility. Aristocratic establishments customarily employed groups of musicians who served as composers, conductors, and performers of a variety of operatic, orchestral, and chamber music; and traditionally the audiences were restricted to the patrons and their guests. Chamber-music concerts were instituted in London in 1672, and seem to have been exceptional for their time, for regularly established professional chamber-music groups did not emerge until about 1810, apparently first in Vienna.

Meanwhile, primarily at certain German university towns in the 1700s, the establishment of collegia musica (music societies) marked the beginning of a movement that brought nonprofessional participation in its wake. Eminent musicians directed those societies in many cases; the Collegium Musicum at Leipzig, for example, was founded by Georg Philipp Telemann and had Bach as its director for a decade after 1729. Audiences were at first restricted to university students; later the general public was admitted, and the rise of the modern chamber-music audience began.

Famous quartets

Since the mid-19th century, chamber-music concerts have been a staple of musical life. Many of the best known string quartets (for example, the Joachim Quartet from 1869 to 1907, the Kneisel from 1885 to 1917, the Flonzaley from 1902 to about 1928, the London from 1908 to 1935, the Budapest from 1918 to 1968, and the Juilliard, Paganini, Amadeus, and Fine Arts quartets of the present day) have travelled to countries around the world performing the standard and contemporary repertories of their day.

Parallel to this has been the continuing activity of informal, nonprofessional groups in virtually all musical centres of the Western world. An international association of amateur chamber-music players exists, whose members grade themselves (in a directory) according to technical ability and experience. The colleges and universities of the United States often stress ensemble activity in their music curricula, and many schools of music are centres of activity in the field.

The sheer amount of music being composed makes it virtually inevitable that chamber music will continue to receive the attention of major composers—especially in view of the economic factors that make performance of new orchestral works hazardous at best. One may hope that chamber music will play as vital and significant a role in the future as it has played in the last three and a half centuries. (H.U.)

FUGUE

Although the statement is debatable, it is often said that the fugue is the most complex and highly developed type of composition in Western music. The term fugue, derived from *fuga*, the Latin word for "flight," was first used about 1330 by Jacques de Liège, the author of *Speculum musicae*, an important medieval treatise. At that time it referred to a technique of musical writing based on strict imitation. Later, after its emergence as an independent musical form in the 17th century, the fugue became a composition in counterpoint based on a generating theme, in which different parts, or voices, enter successively in imitation, as if in pursuit of each other. The heir of all the compositional techniques that had developed earlier, it differs from its ancestors (the motet, the ricercare, the canzona) in having a more specifically tonal character, unity of form, and a greater economy.

The fugue is written in counterpoint, two or more lines that sound simultaneously. Counterpoint's laws and techniques have developed from the 10th century to the Renaissance, a period during which Western music was essentially polyphonic. One of the main problems was the harmonic aspect of the meeting of the voices, and the rules of counterpoint are always precise regarding the use of consonance and dissonance. Counterpoint deals also with movement between the parts. It includes various techniques of development, among which imitation is probably the most remarkable feature of polyphonic music. There are many kinds of imitations. The strictest is the canon, in which the melody stated by the first voice is later reproduced by the second voice. A good example is the song "Frère Jacques." Other common types of imitation include inversion of all the intervals, augmentation (in which the rhythmic values are doubled), diminution (in which they are reduced), or even retrograde imitation, in which the last note of one voice becomes the first note of the next. All these techniques are used in fugal composition, which is characterized more by its "language" than by its form.

Types of imitation

Elements of the fugue. The fugue is written for a certain number of voices, or instrumental parts. The most frequent are fugues for three or four voices, but there are also fugues for two, five, or more voices. Although the fugal form varies from composer to composer, there are certain common elements.

The subject is the theme of the fugue. It is stated alone by the first voice before being taken up by the others. In the course of the fugue, it will be stated in different keys, and it will be sometimes slightly modified or inverted. Some of its elements may be developed separately.

The second voice brings in the answer, generally stated in the key of the dominant (the fifth degree of the major or minor scale). If it reproduces the subject exactly, it is called a real answer. But in most cases, in order to preserve the tonal unity of the fugue, the answer has to undergo a "mutation" that alters some of its melodic intervals and makes the modulation to the dominant key smoother. This is called the tonal answer.

The countersubject accompanies the answer. If it is maintained throughout the fugue, it is called sustained or obbligato countersubject and will follow the subject like its shadow for each new statement. Subject and countersubject are the two principal "actors" of the fugue, and theoretically all the musical substance must be derived from them.

The first part of the fugue, which includes the successive entrance of the voices, in subject–answer alternation, is called exposition. This progressive enrichment of the

polyphonic web is one of the most striking traits of the fugue. In some fugues, after the exposition, the composer brings in the answer followed by the subject. This is called counterexposition.

An episode is any passage, developed or not, that links two statements of the subject. It is characteristically written in imitative style. Generally it uses a motive from the subject or the countersubject, but sometimes a new element is introduced. There is a great variety of episodes.

When the subject overlaps the answer (or the answer the subject), it is called a stretto. This device, whereby the entries are drawn more closely together, is often used at the end of the fugue, where it achieves spectacular effects.

Once past the exposition, the plan of the fugue depends on the will of the composer and the resources of its thematic elements. For instance, the Danish composer Dietrich Buxtehude often presents the subject and the answer only in the principal and dominant keys, in short expositions linked by small episodes. With J.S. Bach, the tonal plan becomes more elaborate and includes a journey to the principal neighbouring keys. Since the composer adapts his plan to the character and to the potential of his themes, the itinerary is always different. That is why in his hands the fugue becomes the most versatile of musical forms; each fugue of Bach brings a new solution to the problem of the relation between form and content.

Versatility of the fugue

Theorists created an ideal plan of the fugue and gradually perfected it, in the 19th century, as fewer and fewer real fugues were being written. They devised a tripartite form consisting of the exposition, the development, and the stretto.

Varieties of fugue. The simple fugue is monothematic, without a maintained countersubject (such as the *Fugue in D Major* of Bach's work *The Well-Tempered Clavier,* Book I, No. 5). More elaborate fugues use one or more countersubjects. In a counterfugue, the answer imitates the subject by inversion. There are beautiful examples of this technique in Bach's work *The Art of the Fugue,* numbers 5 to 7.

There are two ways of writing a double fugue; either the two subjects may be presented simultaneously, in which case the fugue is not very different from a fugue with countersubject (Bach, *Fugue in B Minor on a Theme of Corelli,* BWV 579), or else the second subject has a special exposition. The latter yields, in general, a tripartite scheme: exposition and development of the first subject, exposition and development of the second subject, and finally combination of the two elements, which are devised so that they can be superimposed. A splendid example is given by Bach's *Toccata and Fugue in F Major* for organ, BWV 540. The same principles apply to a triple or quadruple fugue.

The fughetta is a miniature fugue but strictly written, whereas the fugato starts like a fugue but gives up its discipline once past the exposition.

The choral fugue plays a considerable role in works for chorus and orchestra. Generally the chorus sings in strict counterpoint, while the instruments play an expressive or decorative accompaniment. The composition techniques of the fugue can also be used in forms as universal as the prelude, the aria, the chorus, the overture, the concerto, and others.

Literature of the fugue. Since vocal polyphony was based on a text that had to be sung by each of the parts (either simultaneously or, more frequently, in imitation), it was not very much concerned with the problem of form. That is why theorists and musicians concentrated on questions of texture.

At first the term *fuga* applied to strict imitations (which would now be called canons); the concept evolved in a more general sense when it was realized that a freer use of all kinds of imitations offered much more stimulating opportunities. Besides the purely vocal polyphony, the first independent forms of keyboard music (the ricercar, the canzona, the capriccio, the fantasia) testify to the remarkable development of what can be called the fugal style of the 16th and 17th centuries. In this evolution, the role of the Italian composer Andrea Gabrieli and of the English virginalists was preponderant. The two great precursors of the fugue proper were the Dutch composer J.P. Sweelinck and the Italian composer Girolamo Frescobaldi. Both greatly influenced the keyboard music of the 17th century, in particular through their students Samuel Scheidt and Johann Jakob Froberger. In Germany, a generation of musicians dominated by Buxtehude gave the fugue its modern form by putting it in a tonal perspective and abandoning the fragmentary style of their predecessors. Almost all the composers of the 17th century contributed to the history of the fugue.

The genius of J.S. Bach found particular expression in the fugue, perhaps because it allies the strictest economy of language to a relative freedom of form. Each of his fugues amazes by the freshness of its inspiration, the wonders of its writing, or by its gigantic proportions, all marvellously represented in the two volumes of *The Well-Tempered Clavier* (1722–44), two sets of 24 preludes and fugues going through the cycle of the 24 major and minor keys. Some of his organ fugues tend toward development, some toward symmetry, and some toward virtuosity; others take the form of double fugues.

His last work, *The Art of the Fugue,* is a collection of 14 fugues and four canons, all based on a theme in D minor and its inversion. All the resources and procedures of the fugue are demonstrated in what constitutes the most inspiring treatise on fugue, a treatise without words, in which music speaks alone. After being long slighted as a purely theoretical work, *The Art of the Fugue* has won a high place in the hearts of music lovers, who see it as Bach's musical testament. Bach's cantatas, passions, and oratorios abound in admirable fugues.

Bach's *Art of the Fugue*

Handel's fugues are less erudite than those of Bach and sometimes employ looser counterpoint, but they touch the listener by their vitality and their harmonious proportions. The great fugal sections of his oratorios are more important than his keyboard fugues.

After Bach the fugue lost much of its importance. With the appearance of the sonata, the musical taste changed, and composers tended to consider counterpoint as an archaic discipline. Nonetheless, the fugue retained a place in choral works, and fugal methods were kept in the sonata form, particularly in the development section.

A great passion for the music of Bach led Mozart to a more contrapuntal style. This influence is obvious in the *Fugue in C Minor,* for two pianos, K. 426, which, though pure Mozart, is nonetheless a homage to Bach. In ingenuity and mastery, Mozart rivalled the greatest contrapuntists in, for instance, the great choruses of the *Mass in C Minor,* K. 427, or in the final development of the *Jupiter Symphony.*

Beethoven resorted more and more to fugal technique in his last works. He confessed that he wrote his fugues with the greatest difficulty, and it is true that his counterpoint gives an impression of effort. Most of the fugal passages integrated into his last sonatas and quartets create a dramatic tension. Far from being a scholastic technique, the fugue was for Beethoven a means to reach the expressive limits of an idea. He used this language in particular circumstances. The strange and desolate atmosphere of the opening fugue of the *String Quartet in C Sharp Minor,* Opus 131, brings to mind the 20th-century fugue in the first section of the *Music for Strings, Percussion and Celesta* of Béla Bartók. The Promethean side of Beethoven asserts itself particularly in the *Great Fugue* from the *String Quartet in B Flat Major,* Opus 130, and the noble fugal section of the *Missa Solemnis.* Unlike Mozart's classical fugues, Beethoven's are rather irrational in form but are justified by their creative power alone.

Compared with the fugues of Beethoven, those of Felix Mendelssohn defer to traditional rules. Critics sense in them a nostalgia for Bach, sometimes weakened by a touch of sentimentalism. A more authentic romantic breath animates the fugues of Robert Schumann on B.A.C.H. (the German letters for the notes B♭–A–C–B♮), but the fugue is not his natural language. The genre is more suited to César Franck, as may be seen in his *Prélude, fugue et variation,* or in his *Prélude, chorale et fugue.* His harmonic sensitivity enriches a contrapuntal technique while not breaking with tradition. The fugues of Franz Liszt are

entirely different: once past the exposition, he cannot renounce symphonic developments. There is an original use of the fugato before the re-exposition in his *Piano Sonata in B Minor.* The fugal style was used to varying degree by the major composers of the 19th century, including Brahms in his *German Requiem,* Richard Wagner in his opera *Die Meistersinger,* and Verdi in his *Requiem* and at the end of his last opera, *Falstaff.*

Among the post-Romantics, who cultivated their own exaggerated form of counterpoint, mention must be made of Max Reger, whose admirers took him as the heir of J.S. Bach. Though that appears to be going too far, his counterpoint does possess vitality in works such as the *Variations and Fugue on a Theme by Mozart,* for orchestra, or the fugue on the chorale melody "Wachet auf, ruft uns die Stimme," for organ.

Bartók's use of fugue

As an autonomous form, the fugue played only a modest role in the first half of the 20th century. The most beautiful example is the already mentioned fugue of the *Music for Strings, Percussion and Celesta* of Béla Bartók, a born contrapuntist. This is a true model of fugal treatment in a post-tonal style. The methods of the fugue are also found in his *Sonata for Two Pianos and Percussion* and in his admirable quartets.

Stravinsky, though influenced by the composers of the 17th and 18th centuries, showed no particular interest in the fugue. Although the second part of his *Symphony of Psalms* can be considered a double fugue, it does not strike the listener as such.

In his collection of interludes and fugues, called *Ludus Tonalis,* Paul Hindemith seems to have drawn his inspiration from Bach's *Well-Tempered Clavier.* Although an interesting work, it did not herald a rebirth of the fugue. A new conception of counterpoint appeared in the works of Arnold Schoenberg and Anton von Webern. The serial techniques of composers like Pierre Boulez can, to a certain extent, claim some kind of kinship with fugal language, and a work such as the *Passion According to St. Luke* of Krzysztof Penderecki testifies to the permanence of a musical form the history of which is probably unfinished.

(L.A.R.)

SYMPHONY

The term symphony (literally, "sounding together"), though it has many meanings in musical literature, is commonly understood to refer to a lengthy composition for orchestra, often employing a sonata form (see below) in one or more large sections called "movements." Symphonies of this sort began to be composed during the so-called Classical era in European music history, *c.* 1740–1820 (the early part of this period and the decade immediately preceding it are sometimes called pre-Classical, as are the symphonies written before about 1750). During the 19th century, which included the Romantic era, symphonies grew longer, and composers concerned themselves with ways of unifying the movements; extramusical programs and new approaches toward tonality (the major–minor system of chord progressions) were among the solutions to the problems of large-scale symphonic form. Late in the century, symphonies—and orchestras—had grown to such an extent that reaction set in, culminating in the Neoclassical movement of the early 20th century, in which composers turned again toward principles of balance and formal discipline, using new techniques to achieve dynamic coherence. Economic considerations forced a reduction in the size of orchestras and amount of rehearsal time available to mid-20th-century composers, further justifying a return to less extravagant symphonic thinking. But throughout the 19th century a number of outstanding symphonists were able to reconcile the demands of fashion with strict musical logic: these composers represent the mainstream of symphonic activity, and their works remain models for much 20th-century activity in the genre. Throughout the following section two concerns predominate: a survey of the chief symphonic works and composers and consideration of the evolution of symphonic thought.

The concept of symphony before c. 1750. The word *symphōnia* was used by the Greeks in reference to notes sounding together in harmony and by extension meant an "ensemble" or "band" rather than a musical form. The word implies a pleasant concord of different notes and has been used in fields other than music to denote a pleasing combination of various elements. In the New Testament Gospel According to Luke (King James Version), *symphōnia* is translated as "musick," as distinct from *choroi,* "dancing." In the Middle Ages the name was given to several musical instruments, among them a double-headed drum, bowed stringed instruments, a large hurdy-gurdy, and bagpipes. Mention is made in 1582 of *eine Symphonie,* evidently a stringed keyboard instrument.

Vocal and instrumental works

From the mid-16th century, symphonia (and related spellings) is a term often found in titles in which it simply indicated ensemble music, whether for instruments with voices or either alone. A collection of madrigals published in Antwerp in 1585 is entitled *Symphonia angelica . . . raccolta per Huberto Waelrant.* Later notable examples are the *Sacrae symphoniae* of the Venetian composer Giovanni Gabrieli (Book I, 1597; Book II, 1615), collections of elaborate vocal and instrumental music, often for multiple choirs; and the *Symphoniae sacrae* of his celebrated German pupil, Heinrich Schütz (1629, 1647, 1650). Schütz's collection reveals his debt to the colourful and brilliantly orchestrated Italian style in works ranging from several voices to large polychoral compositions with solo parts and instruments. His countryman Samuel Scheidt's 70 *Symphonien auff Concerten-Manir* (1644) likewise combine instrumental and vocal ensembles to enrich the texture and heighten the drama of his music.

Symphonies for instruments alone during the early Baroque era (*c.* 1600–30) occur as independent pieces and as introductions or interludes in theatrical productions. The Italian Biagio Marini's Sinfonia *"La Orlandia"* (1617) is a duet for violin or cornetto (a wind instrument with finger holes and cup-shaped mouthpiece) and continuo in five brief contiguous sections, distinguished by contrasting metres and new melodic material in each section. (The continuo is a harmonic accompaniment improvised over the written bass line, usually played on a keyboard instrument and a bass viol or other bass melody instrument.) Early operas often include instrumental symphonies. Jacopo Peri's *Euridice* (first performed 1600) includes a sinfonia for three flutes; Claudio Monteverdi's lavish musical drama *Orfeo* (1607) is punctuated with five richly scored sinfonias, while a *sinfonia da guerra* ("sinfonia of war") accompanies a staged battle in his *Il ritorno d'Ulisse in patria* (*The Return of Ulysses to his Country*; 1641). Each act of Stefano Landi's opera *Il Sant' Alessio* (1632) opens with a sectional sinfonia. Many other opera and oratorio composers used short descriptive or introductory sinfonias, often of sectional form with contrasting metres and tempos.

Characteristics of Italian and French overtures

It remained for a Neapolitan, Alessandro Scarlatti (1660–1725), to formalize the overture to his operas as a fast–slow–fast *sinfonia avanti l'opera,* as in his opera *Dal male il bene* (*Good from Evil*; 1681). The so-called Italian overture of this and later works, scored for strings and continuo, has been widely considered to contain the germ of the later three-movement symphony. In contrast with the more contrapuntal French overture, which begins with a pompous slow movement and continues in a fugal section (involving imitation of a melody among several voices), the Italian style is immediately tuneful and predominantly homophonic (chordal) in texture. The first fast movement may be trivial; its symmetrical phrasing is unexpressive. The contrasting second movement may be more lyrical, perhaps anticipating tunes heard later in the opera. The last movement, sometimes a minuet, is an exuberant curtain raiser. This format spread quickly outside Italy, even to France. Jean-Philippe Rameau's *Zoroastre* (1749), for example, includes such a fast–slow–fast overture. Rameau, indeed, was considered an exponent of the Italian style, particularly in his lucid harmonic treatment. This late-Baroque concern with tonal clarity prefigured the attitudes of early Classical symphonists. Among the devices used to assure clarity are melodies constructed of arpeggiated ("harplike," or broken) chords and passages in unison or in parallel thirds or sixths (sequences of harmonies formed

by thirds, such as C–E or D–F, or sixths, such as C–A or D–B). These features are not common in Baroque music that is strictly contrapuntal (based on interwoven melodic lines) in texture.

While the opera overture settled into a form that eventually inspired early symphonists, the term sinfonia, or symphony, as yet had no formal definition. As late as 1771 *Encyclopædia Britannica,* reflecting ancient Greek usage, defined symphony merely as ". . . a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony." Sinfonia was used interchangeably with concerto, consort, overture, suite, and so on. Commonly a brief instrumental interlude, as in a song, was called a symphony, even into the 19th century. In the late Baroque era (*c.* 1700–50) the term was applied to such dissimilar pieces as J.S. Bach's didactic *Three-Part Inventions* for keyboard, called *Sinfonien* in the 1723 copy, and the orchestral "Pastoral Symphony," a quasi-descriptive interlude in Handel's *Messiah* (composed 1741), said to have been based on an Italian shepherd bagpipe tune and very much in the tradition of earlier descriptive symphonies in opera.

Bach's *Sinfonia VII in E minor* and *Sinfonia XI in G minor* are interesting in that in each piece the opening material recurs at the end. In *VII* this repetition is merely suggested, but in *XI* the last eight measures of the piece virtually duplicate the first eight. The whole intermediate body of these pieces develops the motivic material presented at the beginning, and the initial material is transformed contrapuntally and harmonically. In the closing bars the tension thus aroused resolves and the rhythmic drive reins in. This suggestion of an expository unit moving from the home key to a different key, followed by an extended development that explores still more remote keys and the motivic and contrapuntal implications of the beginning, concluding with a recapitulation in which the energy of the development is somewhat dissipated by a return to the opening material, prefigures the sonata form of the Classical symphonists. Bach uses this technique in some of his instrumental concerto movements; the concertos have other elements in common with early symphonies, especially in the mood of their lyric slow movements and fast duple-metre finales.

Exploitation of key relationships

The word sinfonia was applied to a trio sonata for flute, oboe, and continuo in Johann Joseph Fux's *Concentus Musico-instrumentalis* (1701), a collection of suites each comprising a number (as many as 15) of bipartite (two-section) dances and descriptive pieces. An intellectual and influential Viennese court composer, Fux departed in this sinfonia from the typical 17th-century suite, which is merely a collection of contrasting dances in the same key. The work falls into two major divisions, both comprising three short movements; the key scheme is F major, D minor, F major—F major, D minor, F major, and the last three movements have programmatic titles. Here is not merely a collection of various dances but a conscious attempt to relate movements tonally and thereby create larger hierarchic units. F major and D minor are closely related keys, and it would not be possible to omit a single movement without destroying the symmetry of the whole (not that either group of three, or even each dance, does not sound good by itself). By means of this simple, balanced harmonic structuring Fux advanced beyond the looser architecture of the typical suite; and by framing a minor-key movement between two movements in the same related major key he anticipated the overall form of many early symphonies.

Importance of tonal harmony

Both Fux and Bach were products of the evolution of tonal harmony, a system of key relations which brought with it the possibility of basing large-scale forms not only on melodic variation or counterpoint, as earlier, but on harmonic tension and modulation. (Modulation, unlike simple change of key, implies the establishment of a new tonic, or tonal centre, by means of progression through a number of related keys.) The wide-ranging modulations and affective harmonic progressions of German Baroque composers depended on equal temperament, a system that permits exploration of keys distant from the tonic without the necessity of retuning to accommodate the remote harmonies. Bach exploited this system to the utmost, as did many of his North German contemporaries; but their rich harmonic palette was foreign to the south, where many important symphonists arose. Concerned less with powerful emotions (*Affekten*) and more with clarity, the southerners avoided intricate counterpoint and convoluted harmonic progressions, preferring a restricted chord vocabulary and clear-cut symmetrical phrasing dominated by tuneful melody.

Besides the suite and opera overture, the short humorous intermezzo, which originated in Naples and flourished *c.* 1685–1750, strongly influenced pre-Classical symphonists. Neapolitan composers, headed by Alessandro Scarlatti, concerned themselves in the intermezzo with dramatic, comic interplay between two singers in two or three short acts made up of arias, recitatives, and duets. Because the texts demanded clear articulation and careful declamation, they influenced the melodic phrase structure, giving rise to repeated-note figures and brief rhythmic or melodic motives. These phrases normally fall into two-measure units. Counterpoint was abandoned, for it tended to obscure the text; and harmonies became simple and slow-moving. Intermezzo melodies abound in ornaments, sudden accents, syncopation (displaced accents), and playful leaps reflecting the text declamation and lack the broad, spunout arch and driving rhythm of typical Baroque melodies. Rather, they are made up of short motives joined one to another and give rise to frequently articulated phrase groups. This word-derived idiom furnished the melodic impulse of the early symphonies.

The symphony proper. *Early Classical period.* Chord-generated melodies (those arising from arpeggiated triads) abound in 18th-century symphonies, among which a number of stereotyped "theme families" can be distinguished. These furnished raw material for further development. In fact, a composer's originality found expression not so much in his original theme as in his realization of the implications of the theme later in the composition. Certain tunes are by nature not highly implicative; they are perfect closed units that cannot be easily developed and so are superficially inappropriate for symphonic use. Such, for example, are many folk tunes; and this explains why great symphonists rarely use folk tunes without at least distorting them so as to open them to development. On the other hand, motivic melodies, such as those in the intermezzi, coupled with slow harmonic motion, lend themselves well to fragmentation, recombination, extension, elision, reharmonization, and other developmental techniques. By the 1740s, Italian symphonists had learned to sustain interest by these means and to obtain contrast by dramatically apposing tunes of different character in different keys (usually the tonic, or home key, and the dominant, located five tones above the tonic, or related major or minor keys).

Early uses of sonata form

Among Italians influenced by these factors was Tomaso Albinoni (significantly, a composer of 48 operas). The third movement of his *Sinfonia in D Major,* fifth of the *Sei sinfonie a quattro* (1735), displays a simple sonata form (also known as "first movement form," though not so limited). Sonata form, crucial in the symphony's evolution, is based on the dramatic apposition and eventual reconciliation of contrasting keys. In essence it consists of an exposition in which one or more themes are presented, the first (often forceful in character) in the tonic key and the second (often lyric) in the dominant. Sometimes a third, closing theme follows in the dominant. The two key areas contrast not only harmonically and melodically but often in instrumentation, loudness, and texture. So-called monothematic sonata movements lack a contrasting second melody; indeed, it is not so much the character of the tunes but the dynamism of the opposed key areas that is essential to the dramatic structure. The transition between tonic and dominant areas was to become a focus of interest to later composers, but in early symphonies the transitions were brief and simple.

The exposition, often marked to be repeated, comes to a close on a key other than the tonic (usually the dominant) and is followed by a development section, beginning on the dominant, in which themes previously heard are re-

harmonized, fragmented, or otherwise reshaped. Again it is not melodies so much as harmonies that arouse tension in the development. The composer confronts the problem of returning to the tonic via more distant chords, and this is sometimes accomplished by modulations that bear no thematic relation to the exposition. In early symphonies this process is only tentatively exploited, and developments are brief, sometimes involving merely transposition of the original first theme to a new key. Later the development assumed the character of the meat in the sandwich, as it were.

Following the development comes a recapitulation of the exposition, this time all in the tonic key (before *c.* 1770 the recapitulation sometimes retained the key scheme of the exposition, except for the closing bars), resolving the harmonic tension of the development. The recapitulation may be simply a virtual repetition of the exposition, with appropriate key changes, or may be truncated, expanded, or otherwise varied so as to continue developmental processes. Many early symphonies take advantage of the implications of a varied recapitulation, literal repetition being abhorrent to imaginative composers. It will be observed that when both themes appear recapitulated in the tonic, the function of the transition between themes differs from that in the exposition, in which it leads from one key to another. After the 1750s, however, the first theme was often omitted in the recapitulation. Obviously, the recapitulation's tonal scheme allows extended treatment of the tonic, but sometimes a coda (tail) is added after the recapitulation to consolidate further the focal nature of the tonic.

It is important to understand that sonata form was subject to great variation and deviation from "textbook" norms throughout the symphony's history. Ideas of a "typical" sonata form did not evolve until *c.* 1830. Nevertheless, the vocabulary of exposition, development, recapitulation, transition, and so on is capable of wide application and will simplify the remainder of the present section.

Albinoni's *Sinfonia in D Major* as a whole is forward-looking. The orchestra lacks a continuo, harmonic orientation replaces counterpoint, and the movements are of larger scale than typical Baroque dance movements. The central minuet-and-trio movement, surprisingly modern-sounding, contrasts lightheartedly with the sonata form. Minuets and song-form movements relieve the dramatic tension of sonata movements; and from this time on minuets appeared frequently in symphonies. Gradually losing dance character, they moved from the last or middle position to penultimate place when, later, a fast fourth movement appeared as finale.

The symphonies of Sammartini

A leading early symphonist, the Italian Giovanni Battista Sammartini, is known from some 77 extant symphonies, some of them available in modern editions. A prolific composer of instrumental chamber music, his use of incipient sonata form, restricted harmonic vocabulary, and motivic, not highly ornamented melodies pointed to the future. Though dependent on Baroque models for inspiration during his first period of activity (to *c.* 1740), he had abandoned the continuo by about 1760, filling the harmony instead with horns or trumpets—which, however, were restricted in their ability to play in certain keys and therefore operated to constrict the available harmonic vocabulary. More than many contemporaries, Sammartini infused inner parts with contrapuntal life, especially in earlier works, although he rarely used extended imitation. His rhythmic energy was appreciated by operawriting contemporaries, from whom (especially the Italians Niccolò Jommelli and Rinaldo di Capua) he perhaps drew inspiration for the long, expressive cantabile (singing) phrases that, along with a firm grasp of modulation, characterize his later works. His slow movements are especially rich. Another late characteristic is the extended role of wind instruments, which are given independent, idiomatic parts. Sammartini wrote for oboes, flutes, and bassoons among the woodwinds (bassoons doubling the bass line); clarinets were also in use at this time, usually interchangeably with oboes. Significantly, Mozart heard Sammartini's music during a visit to Milan.

A third Italian, Padre Giovanni Battista Martini, renowned as a teacher and music historian, left 24 symphonies dating roughly between 1736 and 1777. There is remarkable consistency among this corpus. All but one are in the then-normal three movements (Sammartini wrote a number in four), and all have outer movements in a major key, whereas the middle slow movements are nearly always minor. Music of the Classical period greatly favours major keys; according to one investigator all but about 2 percent of 18th-century symphonies are major (excepting their expressive slow movements). Martini, although trained in counterpoint, avoided it in these works, favouring instead a treble-dominated texture over a simple, slow-moving bass. His chord vocabulary was restricted, his orchestration elementary. His melodies reflect a number of banal formulas in current use, but his manipulation and development of these formulas was skillful. Mozart visited Martini several times in Bologna in 1770.

In the hands of these and other Italian composers, symphonic style evolved considerably by 1740, and there was continued fruitful experimentation through the 1750s. That Italians influenced contemporary and later German and, especially, Austrian symphonists cannot be doubted; but the extent of indebtedness and mutual influence cannot now be fully determined because of the scarcity of available scores. Relatively few of the surviving early symphonies have appeared in reliable modern editions, and those known to survive in manuscript represent but a fraction of the thousands composed. The early history of the symphony remains, therefore, a matter of speculation and debate, despite the enormous progress in research and publication in the mid-20th century.

The Mannheim composers

Germany and Austria were important centres of symphonic composition after about 1740. In Mannheim, Germany, the Bohemian Johann Wenzel Stamitz developed a remarkably well-trained orchestra that by 1756 comprised (in addition to 30 strings) four horns, pairs of flutes, oboes, clarinets, bassoons, trumpets, and timpani. With this ensemble, independent wind writing and creative orchestration flourished. Stamitz—himself a violinist and composer of more than 70 symphonies, chiefly mature works—and his contemporary Ignaz Holzbauer evolved a bold style born of the confluence of Italian melody and German seriousness. Counterpoint is abandoned; expression arises from orchestral crescendos and diminuendos (anticipated by Jommelli), characteristic melodic effects such as sighing appoggiaturas (falling figures) and rocketing arpeggiated (broken) chords, and strong dynamic, thematic, and textural contrasts. This style degenerated into mannerism with Stamitz's son Karl (composer of about 80 symphonies) and Johann Christian Cannabich, who enlarged the Mannheim orchestra.

Mannheimers paid special attention to their development sections, which have been described as a "mosaic of fragments." They tended toward incomplete recapitulations, wrote tender slow movements, extended the number of movements to four: allegro (lively), andante (slow), minuet, and presto (rapid). Insisting on disciplined and precise performance, they wrote all parts out in full instead of leaving some to be realized by the players. With the rise of independent wind parts after *c.* 1770, the continuo became redundant and was abandoned; in outdoor music and in huge orchestras it had become inaudible anyway. Musical textures, which in early works were equally appropriate for string quartet or orchestra, became truly symphonic. Holzbauer occasionally features bassoon solos (as in the *Symphony in E Flat Major*, Opus 4, No. 3), liberating that instrument from simply doubling the bass. The elder Stamitz and Holzbauer were particularly highly regarded in Paris and strongly influenced symphonic activity there.

In Berlin and northern Germany another school arose, dominated by Carl Philipp Emanuel Bach (a son of J.S. Bach), Johann Gottlieb Graun, and other musicians reared in a tradition of rigorous counterpoint and formal conservatism. Retaining three-movement format and avoiding strongly contrasting themes, they maintained contrapuntal interplay in the prevailingly homophonic texture. Even more than the Mannheimers, they concerned themselves with melodic development and ornamentation and with emotional expressiveness—an aesthetic approach

they termed *Empfindsamkeit* (sensitivity). C.P.E. Bach's set of six symphonies commissioned by Baron Gottfried Bernhard van Swieten (completed 1773) aroused enthusiasm for their humour, technical challenge, and novelty of harmonic invention. Even more intensely passionate are the late *Orchestral Symphonies for Twelve Obbligato Parts* (1780), with their clever instrumentation and affective harmonies punctuated by unison passages. Reflecting the literary *Sturm und Drang* (storm and stress) movement, the Berliners powerfully influenced Haydn and Mozart and even Beethoven.

Another son of J.S. Bach, Johann Christian, the so-called London Bach, was perhaps yet more important for the future, influencing Mozart, who met him in London (1764) and again in Paris (1778). His 50 or so symphonies lack the passionate gestures of the Berliners' but are finely wrought and sophisticated in melody and orchestration. The *Sinfonias for Double Orchestra*, Opus 18, reflect in their *style galant* tunes the influence of his study with Martini in Italy, as well as French and Mannheim characteristics (*galant* was the 18th-century term for modern, light, elegant style). Numbers two and three of the set served as opera overtures. Simple in form, complex in texture, J.C. Bach's works are now considered to epitomize elegant, fashionable chamber music.

The Viennese school

The style most influential on Haydn, Mozart, and Beethoven was that of the Viennese school, headed by Georg Matthias Monn and Fux's pupil Georg Christoph Wagenseil. The Viennese experimented further with orchestration and tone colour, emphasized the violin's melodic role, and displayed popular influence in their playful minuets. Monn, though perfectly at ease with counterpoint, ignored it in his symphonies. His four-movement *Symphony in E Flat Major* for pairs of oboes and horns, strings, and continuo is noteworthy for its wide dynamic range and gracious melody so characteristic of Viennese music. The first movement's first theme recurs in the recapitulation transformed into a virtuoso horn duet, reflecting the skill of the players at his disposal and the liberation of horns from a mere harmony-filling role. Elsewhere in the movement are found the slow, repeated-note bass and inconsequential viola part common in early symphonies. As yet the development is quite short and thematically limited, and the movement's scale is small—only a little more than three minutes. But as is often the case, the first movement is the most extended of the four, first movements having gained importance beyond the first movements of opera overtures. In later works Monn dropped the continuo and extended the role of the winds. Together with Johann Stamitz he has been considered highly influential in establishing modern symphonic style, although perhaps Wagenseil, an experienced keyboard player and opera composer, was a more successful composer, especially notable for skillful thematic construction and manipulation, working ornamentation into structure. Also active in Vienna was Haydn's friend Karl Ditters von Dittersdorf, who contributed no fewer than 115 symphonies.

The Viennese style became widely disseminated in Europe. As many as 25 Viennese composers migrated to Paris; others moved to Dresden, Mannheim, and Munich and even as far as Dublin, St. Petersburg, and North America. Their style thus became truly international, and the innovations of these minor masters paved the way for the fully developed symphonic style of Haydn and Mozart. The music of the Viennese composers, mainly intended for elite entertainment, reflects the virtuosic attainments of many private orchestras and the cultured taste of aristocrats who commissioned a constant stream of symphonies and lighter chamber music.

The mature Classical period. Joseph Haydn, despite his isolation from urban musical centres for much of his life, was revered throughout Europe, beloved by Mozart and Beethoven, and widely published and copied—so much so that the authenticity of many works attributed to him remains in question. One hundred and eight symphonies are thought to have been written by him; one of these is lost. Few composers show such remarkable growth as Haydn: from his insignificant youthful pieces, entirely dominated by the style of his pre-Classical elders, to the towering achievement of his last works, his symphonies display an evolution in form and content that had tremendous effect on his followers.

Viennese in style, some of his early symphonies display originality in the use of nonstandard phrase lengths and in their monothematic tendencies. *Symphonies Nos. 1* and *2* are in three movements, lacking a minuet. These works require a continuo (the slow movement in *No. 2* consists only of a bass and treble part), and horns and oboes are as yet not independent. *Symphony No. 3* and others incorporate contrapuntal movements. The sonata recapitulations are subtly altered; but unlike Stamitz', they are generally complete. Melodically, Haydn drew on folk music for inspiration, especially in minuets but also on *galant* and operatic styles. His work reveals a gradual growth in appreciation of the idiomatic qualities of wind instruments, especially in trios of minuets (*e.g., Symphony No. 22, Symphony No. 40*); in *Symphony No. 5* he included winds in the slow movement, unusual at this time, and in *Nos. 6–8* he wrote independent wind solos, recalling the instrumental dialogue found in the Baroque concerto grosso. *Symphonies Nos. 6* and *11* begin with slow introductions, a characteristic which became common in Haydn's symphonies after *No. 84*.

With his appointment to the service of Prince Esterházy in 1761, Haydn's individuality began to emerge, partly because of his opportunity to experiment with the Esterházy orchestra. The bulk of his symphonic production dates from these years before 1771. Although humour and good nature pervade these works, stronger emotions and tension also begin to appear, as in the minor-key *Symphonies Nos. 26, 39,* and *49*. The *Farewell Symphony (No. 45)*, with its adagio (slow) coda, displays Haydn's wit and is one of the best of his symphonies from the decade before 1780. This transitional period shows him striking out into more remote keys, introducing new themes in development sections, and growing more confident in formal craftsmanship and orchestration. Powerful and concentrated, the symphonies of the so-called *Sturm und Drang* period recall the *Empfindsamkeit* of C.P.E. Bach. By turns rigorously contrapuntal and lucidly witty, the vitality evident in the forms reflects Haydn's overflowing adventurousness. Contredanse (country dance) melodies may have inspired some of his themes, for example in the finale of *Symphony No. 88*.

Haydn's later works

The late *London* and *Paris Symphonies* reflect the influence of Mozart and show Haydn at the height of his power. No two movements are alike; the "mosaic" of theme elements pervades even transition sections and codas; each instrument shares in the melodic development; minuets grow in fire or dignity while finales exploit varieties of rondo form (see below). His slow movements, often straightforward sets of variations, engage in artful modulations prefiguring the romantic aspect of Beethoven. *Symphony No. 103* is especially thematically economical, and its movements are related by thematic resemblances, foreshadowing the cyclic nature of many 19th-century symphonies.

Haydn, though by no means the "father of the symphony," contributed enormously to a definition of the harmonic basis of Classical form, the dramatic role of key relationships, and the expressive capabilities of the winds. Major–minor contrasts, wide-ranging modulations, and reconciliation between counterpoint and homophony underlie his unambiguous moods, so different from those of Mozart. An eclectic architect, he amalgamated all the styles of his time in uniquely free and expressive shapes.

Use of rondo-form movements

Rondo form (in which a recurrent theme alternates with other material, as A B A C A) had been found especially in Italian opera and French instrumental music before *c.* 1770; in the 1770s and '80s it became second only to sonata form in symphonic importance. Exploited already by C.P.E. Bach, Stamitz, and others, rondos became a favourite last-movement form with Haydn and Mozart after about 1773. Haydn wrote a number of slow movements as rondos (*Symphonies Nos. 73, 74, 76*) and employed rondos 12 times in his last 17 symphonies. Mozart avoided the rondo in his last symphonies, perhaps because

of the light nature of the form. Its vogue seems to have been brought about by the public's demand for structural simplicity and repetitive tunefulness. In the hands of Haydn and Mozart, however, the rondo increased in complexity, demonstrating in the so-called sonata-rondo the characteristics of sonata form, such as developments of earlier-stated material by means of fragmentation and modulation.

Wolfgang Amadeus Mozart raised the symphony to heights never surpassed. Of his 50-odd symphonies, produced between 1764 and 1788, the earliest ones are conventional but precocious, reflecting influences of J.C. Bach, Sammartini, and Haydn. An invigorating first movement predominates, followed by a light cantabile movement and a fast finale or minuet (minuets in his symphonies date mostly after 1767). The *Symphony in B Flat Major,* K. 22 (1765; Köchel numbers are the standard way of identifying Mozart's works) contains a lovely chromatic slow movement in the key of G minor.

Mozart's synthesis of Italian and German structures

Mozart's exposure to Europe's main musical currents led him to synthesize the playful Italian homophonic and operatic style with serious German polyphony. This is evident in the agitated *Symphony in G Minor,* K. 183 (1773)—a *Sturm und Drang* work and his first minor-key symphony—and in the cheerful *Symphony in A Major,* K. 201 (1774). In these works the balance of interest shifts to the last movement. The addition of codas ("tails," extended closing sections reaffirming the tonic), the increased length and scope of slow movements and minuets, and a growing orchestral sensitivity all point toward maturity. In contrast with those of Haydn, Mozart's slow movements lean toward the sonata form with its inherent drama.

Mozart, unlike Haydn, was not a formal experimenter; he re-used successful structural formulations in later works. It was his treatment of melody that set him apart. He preferred to ignore monothematic structure; and his first and second themes, neither folklike nor mosaic-like, contrast strongly. His harmonic range is narrow compared with Haydn's, but within his range he constantly transformed thematic material. Development sections expand with the introduction of new thematic material and modulations over a wider tonal field. His recapitulations tend to be straightforward. In this mature period, Mozart's symphonies became unified thematically and expressively, using fuller imitation, more singing figuration, freer instrumentation (the *Paris Symphony,* K. 297, in D major, introduces clarinets). Mozart rejected Mannheim gesture in favour of better integrated dynamics.

Mozart's last 10 years saw him further exposed to Haydn's influence and very aware of J.S. Bach's music. The monumental last six symphonies reflect his experience as an opera and chamber music composer. The *Symphony in C Major,* K. 425, has a rare, slow chromatic introduction, while K. 504 in D major (*Prague Symphony*) dispenses with the minuet, has all three movements in sonata form, and uses canonic development (development by means of exact imitation). The last three symphonies (K. 543, in E flat major; K. 550, in G minor; K. 551, in C major, or the *Jupiter Symphony*), summits of the Classical genre, are bold in their harmonies and counterpoint; the serious minuet of K. 550 foreshadows the scherzo of Beethoven's *Fifth Symphony.* (The scherzo is a rapid, rhythmic, minuet-derived form.)

Mozart was no revolutionary. Receptive to the influence of others, he rejected more than he assimilated, transforming all into a uniquely personal idiom. Several of his symphonies were used as opera overtures, but the best ones are so complete in themselves as to make their use as incidental music unthinkable to modern taste. Mozart's and Haydn's mature symphonies are comprehensive in mood and design. The various movements balance one another so well that those who are accustomed to hearing them would find it difficult to accept the substitution of other movements. This tendency toward intimate relation among the standard four movements reflects the urge of these composers to seek unity on the highest hierarchic level—a trend foreign to most of their lesser contemporaries but a basic factor in the symphony's evolution throughout the next two centuries.

With Ludwig van Beethoven the symphony became no longer entertainment music but an expression of monumental intellect and innermost feeling, as in Haydn's and Mozart's late works. The *Symphony No. 1 in C Major* (completed 1800) is Haydnesque, particularly in the opening theme of the finale (comparable to the finale of Haydn's *Symphony No. 88*), but full of originality. Its four classically structured movements reflect Beethoven's concern with expressive woodwind writing and dynamics. The third movement (Menuetto) is prophetic of Beethoven's later whirling scherzos. The slow introduction to the first movement is remarkable for its avoidance of the tonic, a technique used often in later works to arouse tension.

The *Symphony No. 2 in D Major* (1802) is transitional and, like the *Symphony No. 1,* somewhat diffuse. A long introduction announces a work of grand dimensions. The lyric slow movement is rich in themes that are organically unified. A dynamic scherzo, only slightly dancelike, and an expanded sonata finale (with an enormous coda introducing a new theme) point toward the revolutionary length and structure of the *Symphony No. 3 in E Flat Major* (*Eroica;* completed 1804), a work that many consider to herald the dawn of musical Romanticism. The *Eroica* (Beethoven's title) no longer aims at an elite audience. Its first movement employs a multitude of themes, again drawn together into a cohesive organism and developed in a context of great harmonic tension. The tonic, Eb, is avoided near the beginning for 14 measures. A pathetic funeral march, replacing the ordinary slow movement, is followed by a vigorous scherzo; this leads to a variation finale, based on a theme from his *Creatures of Prometheus* ballet and full of contrapuntal development. The symphony marked a new fusion of old formal structures with Beethoven's dynamic outlook.

The *Eroica* symphony

The cheerful *Symphony No. 4 in B Flat Major* (1806) and fateful *Symphony No. 5 in C Minor* (1808), so unalike in character, were composed side by side. The *Fifth,* like the *Third,* a visionary work, is unified by the famous four-note motive that permeates all four movements in one form or another. The scherzo and finale are joined, and an explosion of C major in the last movement is celerated with three trombones (possibly their first use in a symphony), piccolo, and contrabassoon. This grandiose edifice is constructed with relentless logic and rhythmic drive, hallmarks of Beethoven's mature style.

The *Symphony No. 6 in F Major* (1808), called the *Pastoral,* is in five movements, the first two and last in sonata form, each, according to Beethoven, expressing an aspect of rustic life. The whole has a unity of character that reflects a deeper rhythmic unity. A descriptive "Storm" movement links the scherzo ("Merrymaking of the Peasants") with a calm "Thanksgiving after the Storm" finale, which, incidentally, incorporates a Swiss yodel tune. The relaxed human and poetic qualities of the *Sixth* set it apart from the *Fifth* and from the demoniac *Symphony No. 7 in A Major* (1812), with its expanded scherzo and trio, blazing finale, and spirited first movement preceded by a long modulatory introduction.

The small scale of the first three movements of the *Symphony No. 8 in F Major* (1812) leaves one unprepared for its breathtaking finale. Its minuet is a subtle parody of the classical minuet of Mozart and Haydn.

The *Symphony No. 9 in D Minor (Choral)* found Beethoven deaf at its first performance in 1824. It marked a turning point in music history, not only for its novel inclusion of chorus and vocal soloists in the last movement and the extraordinarily variegated sonata form of that movement—incorporating a Turkish march, double exposition, double fugues, strophic (stanzaic) variations—but for the scope of the whole, a summary of Beethoven's ethical and symphonic achievements.

In his development of motifs and variation of entire themes Beethoven went unchallenged. He expanded the limits of Classical form, particularly in his finales, and increased the length of the symphonic process to more than four times the 15 or so minutes required for a pre-Classical symphony. Further, his orchestral sensitivity allowed all instruments a structural role while simultaneously making new demands on player and listener alike. Besides

widening the scope of the orchestra with extra winds and percussion, he made it more than ever a cohesive single instrument, bequeathing to the 19th century a standard against which composers measured the effectiveness of their own orchestrations. Finally, through the immense concentration of his symphonies he made it impossible for his followers to equal the sheer quantity of production of the Classical composers; far too much effort went into creating a symphony to allow pouring them out by dozens.

So overwhelming was the impact of Beethoven's symphonies, along with that of Mozart's and Haydn's mature ones, on later generations that they utterly obscure the productions of many other worthy symphonists. François Joseph Gossec, an early French symphonist, and Pierre van Maldere came to grips successfully with the dominating German–Italian idiom and were important among the Parisians influenced by Stamitz and his school. Van Maldere was eulogized for his imaginative thematic structures as well as for the unusually serious nature of his compositions, which strongly contrasted with the more lighthearted style characteristic of the Mannheimers.

An English composer, William Boyce, eclipsed by the London Bach, wrote eight sinfonias that betray in design the strong influence of theatre music. Basically merely overtures in French or Italian styles, they show none of the modern characteristics being formulated at the time in Germany; England, in general, was not quick to adopt the new symphonic style.

Revolutionary composers of Eastern Europe

Eastern Europe produced revolutionary composers of whom until recently little has been known. Stamitz, Bohemian by birth, overshadowed such competent composers as Jiří Benda. Benda's symphonies, dating mostly between 1750 and 1765, are generally brief, in three movements, and close to the Italian overture in form and feeling. The sonata form is not exploited, although characteristics such as contrasting themes and contrast within a single theme (a technique used also by Mozart) suggest a Mannheim influence or at least a revolt against Baroque conventions.

Luigi Boccherini, Giovanni Giuseppi Cambini, Michael Haydn (Joseph's brother), Leopold Mozart (father of Wolfgang), and many other important chamber music composers contributed numerous symphonies well worth performance. Later composers included the conservative Swede Franz Berwald and a brilliant but short-lived Spaniard, Juan Crisóstomo Arriaga, influential mostly in their own countries; and Muzio Clementi, Luigi Cherubini, Louis Spohr, and Carl Maria von Weber, who, although better known for work in other genres, were nevertheless popular symphonists. Spohr wrote a number of highly pictorial programmatic symphonies, going well beyond Beethoven's *Sixth*.

The Romantic era. Among 19th-century symphonists several trends can be distinguished. Concerned to some extent with self-conscious emotional expression, they often tended to use looser forms and slower paces than the Classical composers. Sometimes this led to lax discipline but not in the case of the finest composers, among them Schumann, Brahms, and Dvořák, who were all very conscious of their debt to Beethoven, Mozart, and Haydn. With later composers, such as Anton Bruckner, Peter Ilich Tchaikovsky, and Gustav Mahler, the normal balance of form was sometimes upset in favour of romantic license, but they too derived their basic goals from the Classical composers, with a more or less heavy admixture of the influence of Richard Wagner.

Schubert

Franz Schubert is known primarily as a songwriter. His nine symphonies stand in the shadow of Beethoven's but are revolutionary and Romantic in a way utterly different from Beethoven's. Whereas Beethoven wrestled with melodic problems, Schubert was a born melodist and consequently concerned himself more with the harmonic basis of form. He was likewise the more sensitive orchestrator, and in the last three symphonies he greatly expanded the role of the brasses.

His *Symphony No. 1 in D Major* (1813) and *Symphony No. 2 in B Flat Major* (1815) illustrate Schubert's departure from Classical models. Although the first movements are in sonata form, their pace is slower than the ordinary Classical allegro and is supported by long nonthematic passages that expand the harmonic arch. In the youthful sonata-form movements the second theme group is often set in an unexpected key before the music turns to the dominant at the end of the exposition. In recapitulations, too, Schubert shies away from harmonic simplicity and Classical expectation; his phrasing also is often irregular. Schubert's slow movements, scherzos, and minuets are not as strikingly original. Clear references to movements and themes of Beethoven occur in these early works, and in key scheme and major–minor contrast Schubert often betrayed his indebtedness to Beethoven. He was unembarrassed to borrow melodic material, which he transformed in an utterly personal way. This is particularly the case in the *Symphony No. 4 in C Minor* (the *Tragic*; 1816). The *Symphony No. 5 in B Flat Major* (1816), scored for a smaller orchestra, more strongly recalls Mozart and Haydn. The highly emotional *No. 6 in C Major* (1818) is of larger scale, based as usual more on rhythmic and harmonic impetus than melodic development. The incomplete draft of the *Symphony in E Minor-Major* (1821) has inspired attempts at completion. But it is the last two (the *Symphony in B Minor* or *Unfinished*, 1822, and *Symphony in C Major*, or *Great*, 1828) that raise Schubert to high rank among symphonists. Composed for large orchestras, they nevertheless reflect Schubert's experience in writing for voice and piano.

Schubert's *Unfinished* and *Great* symphonies

The *Unfinished* consists of two complete movements in $\frac{3}{4}$ and $\frac{3}{4}$ time and a sketch for a scherzo. The complete movements form a convincing unity; masterful in harmonic organization and orchestration, they are expressive without being diffuse, a criticism often levelled against passages in Schubert's earlier works. The *Great* is of Beethovenian scale, partly because of extensive repetition. The scherzo and related slow movement, no longer simply rustic pieces, are both sonatas. Irregular phrases, modulatory schemes, and rhythmic force give evidence of Schubert's concern with form based on slowed-down and far-reaching harmonic motion. His rhythmic manipulation was un-Classical, his themes personal and of more than Classical significance.

With the first group of symphonists born in the 19th century the Romantic style was fully fledged. The French composer Hector Berlioz and the Hungarian Franz Liszt contributed large symphonic works that to some extent departed in form from the Classical sonata-centred model. The literary program to Berlioz' *Symphonie fantastique: Épisode de la vie d'un artiste* (1830) was not written until the music was well along toward completion. The symphony was thoroughly planned out thematically and formally and stands as a musical unity without regard to the program, which Berlioz himself eventually withdrew. A very personal expression nevertheless, the *Fantastique* introduces a structural *idée fixe*, a theme (representing his mistress?) recurring throughout the five movements in various rhythmic forms, serving to unite the "scenes" musically as well as dramatically.

Harold en Italie (1834; after Byron's poem), like the *Fantastique*, makes use of preexistent material and is unified not only by a program but by a recurrent theme, a viola solo representing Harold. This theme is not subject to the kind of variation given the *idée fixe* in the *Fantastique*; yet from it springs much of the melodic inspiration of the whole work. Berlioz' third symphonic work, *Roméo et Juliette* (1839), rarely heard in its entirety, incorporates chorus and vocal soloists into its five large sections, which are programmatically derived from episodes of Shakespeare's drama. Not coincidentally, Berlioz was a great admirer of Beethoven. Beethoven's unity of moods, thematic development, and dramatic orchestration were models for Berlioz to extend, although he did so outside the formal confines of the sonata and with even more explicit passion.

Liszt owed much to Berlioz, both in his handling of enlarged orchestral forces and in thematic transformation (as opposed to development). The three movements of his *Faust Symphony* (1854) bear the names of Goethe's characters: Faust, Gretchen, and Mephistopheles; and the final movement parodies themes of the first two in a satisfyingly diabolical manner. Characters aside, the music is

highly effective and balanced; Liszt revised the score over several decades. The score is dedicated to Berlioz.

Liszt's other symphonic work, the *Symphony to Dante's Divina Commedia* (1856), depicts the Inferno, Purgatory, and Paradise. Liszt, at times a devout Catholic, portrayed Dante's scenes with great imagination and passion, cleverly suiting his melody—sometimes simple and tranquil, sometimes chromatic and writhing—and harmony to the special characters of the three levels. The symphony is dedicated to Wagner, who suggested the third-movement setting of the Magnificat for female chorus and orchestra. As do many operas of Wagner, Liszt's work uses the leitmotiv, an extension of Berlioz' *idée fixe*.

If Berlioz and Liszt represented a trend toward freedom and extramusical content in symphonic writing, Schumann and Mendelssohn were more conservative though not strictly comparable. All four were deeply concerned with formal discipline, but Schumann and Mendelssohn departed less widely from Classical norms and made less point of extramusical associations.

Mendelssohn's symphonic works

Felix Mendelssohn wrote 16 symphonies and a symphony-cantata. Twelve of the symphonies are immature works; but the remainder fairly exemplify his style: facile, full of light melody and brilliant orchestration, occasionally oversentimental, according to some critics. He is best known for his *Symphonies No. 3* (*Scottish*) and *No. 4* (*Italian*), both in A major–minor. The *Scottish* (also called *Scotch*), completed in 1842, although not programmatic, is expressive of Mendelssohn's poetic nature. Its beginning was sketched during a visit to Scotland in 1829. In structure the work consists of four movements played without pause, with a slow introduction. Its fairylike scherzo, which incorporates part of a Scottish folk song, exemplifies the delicate moods that Mendelssohn excelled in creating. The other movements are well developed, the many contrasting themes integrated contrapuntally and extended with interesting modulations. But although it is full of good music, the symphony is less powerful than its companion, the *Italian* (finished 1833). This happy work, inspired by visits to Rome and Naples, is particularly colourfully orchestrated. It ends with a dance movement incorporating three themes; the minor tonality does not detract from its vivacity. The first movement, too, has three themes, the third introduced in the development section. The second movement, recalling a religious procession, and the third, a quasi-minuet and trio, are picturesque without being descriptive and represent Mendelssohn at his finest—uncomplicated, lush, and vigorous.

Schumann's miniaturist style

Robert Schumann, like Mendelssohn and Mozart, wrote his symphonies at an age when most longer-lived composers are just beginning to mature and wrote only a few truly great ones. Like many first-generation Romantic composers Schumann was essentially a miniaturist, most at home in songs and short piano works. His orchestral style reflects these qualities; rhythmically restless, often repetitive, not sensitively scored, they have been praised more for their harmonic subtleties and wonderful lyric melodies than for development of these ideas.

The *Symphony No. 1 in B Flat Major* (*Spring*; 1841), based on a poem by Adolph Böttger, originally had titles given each movement; these were soon rejected by Schumann and indeed are irrelevant to the music. The first movement, opening with a slow introduction (a tradition since the days of Haydn), incorporates three contrasting themes (the third introduced toward the conclusion of the movement) as well as the opening dramatic figure of the introduction. The slow movement and unusual scherzo (it has two different trios, rather than one) are linked thematically and played without a pause between them. The impulsive progress of the finale is interrupted before the recapitulation by slower passages for flute and hunting horns, perhaps intended by Schumann to be descriptive.

The *Symphony No. 2 in C Major* (1846) is tightly organized and owes something in design to Beethoven. It has been overshadowed by more frequent performances of the last two symphonies, *No. 3 in E Flat Major* (*Rhenish*; 1850) and *No. 4 in D Minor* (1841, rev. 1851). The five-movement *Rhenish* is less "classical" than the *Symphony No. 2*. Inspired by a ceremony at Cologne Cathedral as well as by the appearance of the cathedral itself, the polyphonic grandeur and harmonic richness, especially of the fourth movement, are tempered by the relaxed pace and rustic character of the scherzo and following short, quiet slow movement. The outer movements are related both thematically and in mood, and the last two movements also share material, forming a large cohesive structure.

Even more cohesive is the plan of the *Fourth Symphony* in which all four movements are played, as in Mendelssohn's *Scottish Symphony*, without pause. A single theme recurs in various guises in all four movements; this thematic transformation is a hallmark of Schumann's style, as of Berlioz' and Liszt's. The last movement introduces new material but without destroying the cyclic nature of the whole work. Cyclic structure, which relates separate movements by means of re-use of thematic material, is a feature of much symphonic writing after Beethoven. As composers gradually departed from repetitive forms, cyclic construction became a chief mode of achieving unity over a large time span and greatly enlarged harmonic vocabulary. An advanced form of cyclic construction may be seen in the Belgian composer César Franck's influential single *Symphony in D Minor* (1888).

Traits of Bruckner's symphonic style

Although Johannes Brahms's four symphonies are popularly considered to be no less important than the greatest earlier symphonies, the contribution of his contemporary Anton Bruckner is controversial. Bruckner, a devout Catholic whose church music is among the finest of his generation, is noteworthy not only for the excessive length and heavy orchestration of many late movements but for his Wagnerian harmonies, large-scale repetitions, and (at its best) monumental conceptions of form. Bruckner gathered much from studying late Beethoven and Schubert. Yet his style evolved little in the course of nine symphonies (he was over 40 when he wrote his first symphonies; two other unnumbered early ones are never heard, and his last was incomplete at his death). Entirely personal in expression, his symphonies underwent frequent revision. They are in four movements and are basically unprogrammatic, even conservative. Despite his devotion to Wagner and Beethoven, Bruckner remained provincial; his technique was grounded on traditional studies, and his movement types seem to follow a set of typical formulas that derived from Classical patterns, especially the sonata. Within these formal types he develops themes powerful in their simplicity and monolithic in harmonic expanse. Chords reminiscent of German chorale (hymn melody harmonizations) and tremolo or pizzicato (plucked) accompaniments occur along with organ-like counterpoint and pedal tones (sustained notes against changing harmonies). Hardly imbued with youthful vigour, some scherzos still have roots in the fertile Austrian popular music that nourished Haydn and Beethoven. These movements, however, are not sufficient to lighten the overall impression of density. Unlike those of Brahms, Bruckner's symphonies are not immediately rewarding; yet connoisseurs, including Mahler, respect Bruckner's heroic finales, in which themes from earlier movements are sometimes combined. *Symphony No. 4 in E Flat Major* (1874, first performance of revision, 1881), with a Beethovenian andante and scherzo recalling the hunt, is noteworthy for the use of four themes in the first movement. *No. 7 in E Major* (1881–83, rev. 1885), well received at first hearing, is Wagnerian in orchestration (Wagner tubas play in the adagio) and makes use of contrapuntal techniques developed in the Renaissance. In the last two symphonies the adagio movements occur after the scherzos rather than before.

Individuality of Brahms's symphonies

The symphonies of Brahms, each highly individual, appealing on first hearing, and rewarding to rehear, could hardly be more different from Bruckner's. Yet Brahms, his technique grounded on thorough study of Classical and Baroque works, was no less essentially conservative. He retained the four-movement format and familiar methods of thematic development and rigorous contrapuntal craftsmanship, avoided programmatic content, and was always concerned with aural effect. These concerns are reflected in his orchestration, which is never merely flashy, never astonishing. His entire remarkable skill and attention to detail served the lyrical, spontaneous flow of his melody.

His tunes, Romantic as Schubert's, are developed with consistency, refinement, and a harmonic interest foreign to many lesser contemporaries (especially those seduced by Berlioz and Liszt but without understanding their talent). Brahms is a master of understatement. Finished in 1876, 20 years after it was begun, his *Symphony No. 1 in C Minor* was the fruit of a mature man's experience. It carried on where Beethoven left off, drawing inspiration especially from Beethoven's *Fifth*. The triumph of major over minor, epitomized in the finale, underlies the whole. The key scheme of the movements is cyclic, based on a succession of rising major thirds: C minor, E major, Ab (= G♯) major, C minor–major. The third movement, formally a scherzo with trio, slackens tension as though to prepare for the marvellously developed finale, which is preceded by a broad introduction (as is the first movement) that sets harmonic and thematic goals for the remainder.

Clear goal orientation also characterizes the *Symphony No. 2 in D Major* (1877). Unlike the *First* in mood, it is pervaded in all movements by optimistic calm. The first and last share a three-note motive that is joined by other serene themes in the first movement, which includes a long horn solo near the end. The second movement begins in B major, a third lower than the first, and the fast third movement begins a lower third still, in G major; the finale returns to D. This third-based tonal scheme, like that of the *First*, marks Brahms as a true Romantic, as do the tempo changes within movements, the sensuous modulations that circumscribe harmonic goals, and the intense major–minor conflicts.

Modal tension—major versus minor—characterizes the cyclic *Symphony No. 3 in F Major* (1883), the movements of which are related by material derived from Brahms's "motto" motive, FAF, *frei aber froh* ("free but joyful"). Winds are prominently featured, particularly clarinet and horn, as elsewhere in these symphonies. Brahms retained Classical outlines as usual; but, as in the *First*, the scherzo with trio serves to throw the vigorous, stormy finale into relief. The first movement plunges to the heart of things from the opening chords, harmonizing the motto; there is no introduction, no coyness in exposing the main themes. Chromatic harmony and contrapuntal development are fully exploited.

Brahms's architectural skill is nowhere more in evidence than in the finale of the *Symphony No. 4 in E Minor* (1884–85), an extended chaconne, or set of variations over an (eight-bar) repeated bass melody. This movement is almost Baroque; and elsewhere in the work Brahms employs Baroque contrapuntal techniques, chromatic labyrinths, and modal melody that hovers between major and minor but is neither. In this work particularly, but throughout the symphonies, Brahms epitomized the tendency of the later Romantics to seek a balance between the expressive forms of the early 19th century and older traditional technique, to apply to the wealth of available harmonic and orchestral colour constructive methods consciously founded upon study of Beethoven (particularly *Symphonies No. 4, No. 7,* and *No. 8*), Handel, and other models. These disciplined composers (including Schumann and Mendelssohn) reacted partly against what they felt to be the extramusical emphasis and compositional excesses of Berlioz, Liszt, and lesser figures, who took as their point of departure the less conventional Beethoven of *Symphonies No. 5, No. 6,* and *No. 9*.

Dvořák and Tchaikovsky

Both trends found reflection in the symphonies of Dvořák and Tchaikovsky, composers who were products of growing nationalistic tendencies in music. Antonin Dvořák continued a distinguished line of Bohemian symphonists stretching back to Stamitz. Conscious of his musical heritage, Dvořák infused his music with folk-derived elements, particularly dances; his last symphony, *No. 9 in E Minor* (*From the New World*, 1893), even incorporates American tunes; but these are almost incidental to the strong Slavonic character of the work. An early devotee of Wagnerian sonorities, Dvořák in his later symphonies returned to the more conservative models and orchestrations of Beethoven and Brahms. It is these later works, through which Dvořák is known today, that have led detractors to call him a "second-rate Brahms." In fact, Dvořák's melodic invention, often based on irregular folk-like scale forms, and his captivating irregularity of phrase length, surprising variety of orchestration, and impetuous rhythms are entirely personal.

Peter Ilich Tchaikovsky, on the other hand, was not comfortable working with preestablished formal models but was at his best in ballets and tone poems in which his somewhat extravagant nature found fuller scope for expression. Of his eight symphonies, only *No. 4 in F Minor* (1877), *No. 5 in E Minor* (1888), and *No. 6 in B minor* (*Pathétique*, 1893), actually fourth, sixth, and eighth in order of composition, are well-known. These are controversial works, partly because their novel structures are not easily analyzed (or heard) in standard formal ways. Some feel that Tchaikovsky's freedom and tendency to musical autobiography were inimical to purely abstract musical expression and that understanding of his music depends on knowledge of his state of mind at various times or upon some extramusical imagery or program. This attitude conflicts with an essential determinant of symphonic idiom, which is that the establishment and working-out of tensions in the piece are primarily occasioned by purely musical, formal means; and that extramusical data, interesting though they may be, are not directly relevant to apprehension and appreciation of the symphonic process. If Tchaikovsky's symphonies are to be considered successful as symphonies, they must make purely musical sense—and the three mentioned fulfill this condition.

Tchaikovsky's kind of musical logic, however, is quite different from that exemplified by the main-line German symphonists. Isolated in his formative years from the influence of Brahms and Wagner, he learned instead by hearing Mozart and Italian opera, characteristics of which he fused with elements of non-European melody, harmony, rhythm, and colour; in this he followed Aleksandr Borodin and other Russians. He strongly favoured the minor mode, no doubt partly because of its inherent instability. This unique confluence of stylistic sources produced a new model for later symphonists, particularly in regard to orchestration and a reevaluation of sonata form based on a fresh conception of tonal harmony.

Mahler as the culmination of the Viennese tradition

With Gustav Mahler, the central path, if not the culmination, of Viennese symphony was regained. In importance Mahler's nine completed symphonies (a 10th was left unfinished at his death) stand equal to any corpus since Beethoven's. That this has been so recently recognized may have something to do with historical perspective but is more probably a matter of relevance of his music to the mood of the mid-20th century. Nowhere else in music is found such explicit cynicism, such deliberate distortion of the familiar; by the same token no symphonist exceeds him in desire for reconciliation. Mahler's melodies and harmonies are strongly goal oriented; that his goals are so frequently frustrated or beset with obstacles reflects a truly contemporary outlook.

Mahler's symphonies, like those of Tchaikovsky and Berlioz, suffer from being too often considered solely in the light of extramusical associations. Mahler himself suppressed the programs of his early symphonies and subjected their music to frequent revision. Structurally, the symphonies are entirely logical, even simple, beneath the multitude of themes and wealth of colouristic detail. Mahler was a fastidious and brilliant orchestrator. The seeming superfluity of orchestral resource he called for, especially in the later symphonies, is handled with restraint and sensitivity—Mahler was a conductor as well as a composer and knew well the capabilities of the instruments.

Enormous in time scale, Mahler's symphonies contain sufficient variety and contrast to maintain interest. Underlying this stylistic multiplicity—including parodies of folk song, waltzes, fanfares, marches, text painting (four symphonies include voices), chorales, borrowings from other composers as well as his own songs—was a leaning toward cyclic structure, with themes or motives shared among movements, as in his song cycles and those of Schubert and Schumann. Mahler also experimented with tonal structure to the extent of combining movements in unrelated keys, so that the ear never tires of a single tonal area. *Symphonies No. 5, No. 6,* and *No. 7,* themselves a

huge cycle, show him coming to grips with Classical sonata form, greatly expanded though it is. Unity on a lower level is achieved through extensive counterpoint. These later works show an economy of structure that is foreign to Bruckner, from whom Mahler nevertheless learned much.

Nielsen and Sibelius

The 20th century. Important symphonists of the early 20th century include many non-Germans. Carl Nielsen and Jean Sibelius, the former Danish, the latter Finnish, both owe much to the Viennese symphonists but acquired individual styles that resulted in new conceptions of symphonic form. Nielsen's six symphonies display a kind of unity based on "progressive" or "emergent" harmony, one key moving on to the next in such fashion that the gamut of harmonies in a single symphony (or movement) does not totally relate to a single tonic. His harmonies sometimes fluctuate between two or more goals and incorporate chromatic and modal features. This untraditional harmonic tension is an aspect of the breakdown of normal Classical ways of establishing tonality, for which the 19th century (and Wagner in particular) is largely responsible. (Nielsen, however, was an anti-Wagnerian.) This "destructive" impulse, elements of which may already be heard in Haydn, led to constant re-evaluation of the basis of sonata form and hence of the symphony as a whole. As the traditional harmonic foundation weakened—partly because the enlarged time scale makes long-term harmonic relationships hard to hear—symphonists sought new unifying techniques, among them cyclic forms, extramusical plots, progressive harmony, etc. None of these is incompatible with dramatic sonata form, taken in its broadest sense. Nielsen retained and emphasized key conflict as a dynamic force and experimented with counterpoint and conflicting rhythms (*e.g., Symphony No. 4, The Inextinguishable,* 1916; and *Symphony No. 5,* 1922), joined movements, and the rest.

Sibelius wrote his seven symphonies between 1899 and 1925. Like Nielsen's, they departed from Classical models (notably Beethoven's *Fifth*) and reflected especially the advances of Brahms and Bruckner. Sibelius was a restrained orchestrator, a non-Wagnerian. Although nationalistic, he used no folk songs and incorporated no programs. He had little immediate influence, isolated as he was after World War I, but is highly regarded presently in his native country, and in England and the United States. Sibelius, like Nielsen, is not tied to Classical tonic-dominant opposition. He sometimes introduces modal scales and polar harmonic goals between which the music oscillates. A chief unifying device is a repeated bass line or sustained pedal tone. His themes are often groups of melodic fragments, meaningless when out of context, that are capable of being combined in various ways. The gradual integration of these motifs is an important means of development. In this Sibelius resembles Borodin; the effect is quite unlike that of Mahler's long melodies. Structurally Sibelius is terse and simple. He eliminated transitions and introductions, avoided simple recapitulation, and kept harmonies static or ambiguous over long stretches. Rarely was he merely playful. He was fond of low, dark sounds. Sibelius is hardly unemotional but certainly is not effusively romantic. His symphonies represent a great contrast with Mahler's, and he strikes a new path away from the sonata.

Elsewhere in the early 20th century important symphonic contributions were being made by the Frenchman Albert Roussel, whose four symphonies are elegant and classical in form; the American Charles Ives, who quotes well-known tunes in his highly dissonant four symphonies; and the Englishmen Sir Edward Elgar and Ralph Vaughan Williams. Their works are not often heard outside their native countries, and the extent of their influence on the growth of symphonic thinking remains to be determined. A more important innovator, the Viennese Arnold Schoenberg, considered his *Chamber Symphony,* Opus 9 (1906), "the climax of my first period." Basically still sonata-oriented and tonal, this work departed from the gargantuan orchestrations of Mahler and Richard Strauss and is scored for 15 soloists, 10 of whom play winds. The idiom is highly dissonant and motivic, straining at the limits of traditional tonality and pointing to Schoenberg's formulation of dodecaphony, or 12-tone serialism (deriving melody and harmony from the composer's ordering of the 12 tones of the chromatic scale).

Stravinsky's imaginative force

Igor Stravinsky likewise inherited a living tradition and transformed it with great imaginative force. Like Schoenberg, he was not primarily a symphonist; his early *Symphony in E Flat Major* (1905–07) is no more original than anything of other Russians such as Borodin or Aleksandr Glazunov. But the *Symphony in C* (1940) and *Symphony in Three Movements* (1942–45) are unique. The former, a Neoclassical work, reinterprets in Stravinsky's language the thematic construction and sonata form of the Classical era. The result, far from a simple parody of Classical style (such as in Sergey Prokofiev's *Symphony No. 1 in D Major* or *Classical Symphony* of 1917), was an altogether fresh and revealing insight into the implications of Haydn's work. The *Symphony in Three Movements,* inspired by wartime impressions, is independent of models, yet in outward form the movements appear traditional. Two other of Stravinsky's works deserve mention here: the *Symphonies of Wind Instruments* (1920, rev. 1947) and the *Symphony of Psalms* (1930), which includes chorus. These works are symphonies only in the 17th-century sense of ensemble pieces: in both form and structure they are dissimilar from the other symphonies.

Chief among other Russians are, besides Prokofiev (seven symphonies), Nicolay Myaskovsky (also seven) and Dmitry Shostakovich (15). Shostakovich's large corpus marks him as one of the most important and prolific modern symphonists. His works are uneven in quality. A number are programmatic, dealing with Russian political and social upheavals. Shostakovich at times concerns himself with incorporating popular and folk tunes, giving expression to national feelings, and, more basically, with problems of achieving cyclic unity by such means as leitmotivs and thematic recurrences and joining movements without pause.

The mainstream of American symphonic production resides with Roy Harris, Walter Piston, William Schuman, and Roger Sessions. Important as teachers, these men have influenced younger symphonists such as Easley Blackwood and helped create a distinctive style of composition that resulted in the first important symphonic output in the Western Hemisphere. Although many younger composers on both sides of the Atlantic are turning to avant-garde techniques, including experiments in formlessness, and to small instrumental and vocal ensembles as well as to electronic sources, the future of the symphony seems secure. Extremely large orchestrations are not widely favoured, partly because of the difficulty and expense of mounting a performance; yet Blackwood has written one symphony for an orchestra larger than Mahler's as well as one for chamber orchestra. Audiences tend to favour works in familiar forms. Prizes and commissions assure a steady output of symphonies and many have been written for college and university orchestras. Flourishing amateur orchestras also furnish outlets for the young composer. As regards the masters of the 18th and 19th centuries, there seems no possibility that their symphonies will become museum pieces in the foreseeable future. On the contrary, the recording and broadcasting industry has brought about renewed interest in even the lesser known symphonists. Scholars and public alike have now almost unlimited access to the treasures of three centuries of symphonic production. (La.L.)

SONATA

Deriving from the past participle of the Italian verb *sonare,* "to sound," the term sonata originally denoted a composition played on instruments, as opposed to one that was *cantata,* or "sung," by voices. Its first such use was in 1561, when it was applied to a suite of dances for lute. The term has since acquired other meanings that can easily cause confusion. It can mean a composition in two or more movements, or separate sections, played by a small group of instruments, having no more than three independent parts. Most frequently it refers to such a piece for one or two instruments. By extension, sonata can also refer to a composition for a larger instrumental group having more than two or three parts, such as a string quartet or

an orchestra, provided that the composition is based on principles of musical form that from the mid-18th century were used in sonatas for small instrumental groups. The term has been more loosely applied to 20th-century works, whether or not they rely on 18th-century principles.

Sonata and sonata form

Quite distinct from all of the preceding, however, is the use of the term in "sonata form." This denotes a particular form or method of musical organization normally used within instrumental sonatas, string quartets, and other chamber music, and symphonies written since the beginning of the Classical period (the period of Mozart, Haydn, and Beethoven) in the mid-18th century.

The first concern of this section will be to establish the principles of musical form often associated with sonatas for small and large groups of instruments. They will be approached through an examination of the principle of musical structure called "sonata form." A historical account of the origins and development both of the instrumental sonata and of sonata form will then endeavour to throw light on other meanings of the term. In conclusion, some estimate will be offered of the present and possible future roles of the sonata in musical life.

Structure of the Classical sonata. Sonata form denotes a particularly fertile manner of organizing the musical structure of a single movement. It commonly occurs within the larger context of a multimovement scheme. Maturing in the second half of the 18th century, it provided the instrumental vehicle for much of the most profound musical thought until about the middle of the 19th century, and has continued to figure largely in the methods of composers down to the present day.

The basic elements of sonata form are three: exposition, development, and recapitulation, in which the musical subject matter is stated, explored or expanded, and restated. There may also be an introduction, usually in slow tempo, and a coda, or tailpiece, but these optional sections do not affect the basic structure. Although sonata form is sometimes called first-movement form, the first movements of multimovement works are not always in sonata form, nor does the form occur only in first movements. Likewise, another name for it, sonata-allegro form, is misleading, for it need not be in a quick tempo such as allegro.

At first glance sonata form may appear to be a species of three-part, or ternary, form. The three parts of ternary form are a first section (A), followed by a contrasting section (B), followed by a repetition of the first section (that is, A B A). The parts are interrelated not in terms of basic structure but by purely lyrical or character contrast. Actually, the three parts of sonata form developed out of the binary, or two-part, form prominent in the music of the 17th and early 18th centuries. In binary form the structure depends on the interrelationship not only of themes but also of tonalities, or keys, the particular sets of notes and chords used in each part. Thus, the initial part, which is repeated, leads directly into the second part by ending in the new key in which the second part begins. The second, also repeated, moves from the new key back to the original key, in which it ends. The second part thus completes the first.

Binary form

In sonata form the exposition corresponds to the first part of binary form, the development and recapitulation to the second. The exposition moves from the original key to a new key; the development passes through several keys and the recapitulation returns to the original key. This echoes the motion, in binary form, away from and back to the original key. In relation to binary form, sonata form is complex. It offers, in the exposition, contrasting musical statements. In the development these are treated dialectically; that is, they are combined, broken up, recombined, and otherwise brought into change and conflict. In the recapitulation they are restated in a new light. This organic relationship between parts marks the sonata form as a higher, more complex, type than the ternary form. The occasional designation of sonata form as compound binary form is useful in that it stresses its origins in the earlier form, but notes its added complexity.

The emphasis on contrast, even conflict, is the element that distinguishes the exposition of a sonata-form movement from the first section of an earlier binary form. The first section of a binary movement in a Baroque suite or instrumental sonata, for example, might contain two clearly differentiated themes, but the stress is on continuity and on uniformity of musical texture rather than on contrast. In sonata form the emphasis is more dynamic; there is a stronger sense of contrast within the movement. The terms usually given the contrasting areas are "first subject/second subject" or "principal group/subsidiary group." These are misleading terms, for they imply a simple contrast of themes.

In reality it is contrast of key, or tonal contrast, that characterizes the sonata exposition. Usually the opening of the exposition is firmly rooted in the tonic, or "home," key of the work. The later segments of the exposition move decisively to a closely related but distinct key. The second key chosen is almost invariably one of the two keys most closely related to the home key. If the home key was a major key, the dominant key is chosen; if the home key was minor, the relative major is chosen. (The dominant key is the one whose keynote is five tones above that of the tonic, as C–G; the relative major has a keynote three tones above the relative minor, as A minor–C major.) The exposition thus creates an opposition of tonalities or key areas that the rest of the movement—the development and recapitulation—will strive to reconcile. Compared with the contrast of keys, the question of how many themes the movement possesses is of minor structural significance. Very often, a movement in sonata form has two clearly defined main themes, for example the first movement of Mozart's *Symphony No. 41 in C Major*. It may also have only one, like the first movement of Haydn's *Symphony No. 85 in B Flat Major*. Or it may have more than a half dozen strongly characterized themes, as does the first movement of Brahms's *Fourth Symphony*.

Thematic and tonal contrast

The thematic organization of a movement in sonata form may affect the character of the exposition, and thus of the whole movement, in two specific respects. When two themes or groups of themes are clearly differentiated, their distribution may help the listener to assimilate the cardinal points of the tonal design (that is, the arrangement of keys) of the movement. When, on the other hand, such differentiation between themes is obscured or set at variance with the organization of tonalities, the very tension between thematic design and tonal scheme may greatly enhance the subtlety and interest of the form. Such tension may produce not merely an interplay of melody and key within the movement but an interplay between two interplays. One fairly simple way of achieving this is shown in the first movement of Haydn's *Symphony No. 99 in E Flat Major*. Here, as in *No. 85*, the first theme is restated in the dominant key. This restatement could appear at first to be the second subject. But later it is followed by another distinct motive that, in terms of themes, is the real second subject. At the same time the neat, almost epigrammatic character of the second subject makes it similar to a codetta theme, which is often used to round off the exposition after both main subjects have been stated.

In the first movement of Mozart's *Symphony No. 35 in D Major (Haffner)* this interplay of interplays reaches a higher level of subtlety. The second theme, against which the first persists as a counterpoint, is stated "on" rather than "in" the dominant; that is, its harmonies suggest the dominant key, but remain part of the home, or tonic, key. The second theme is thus heard as a new perspective on the tonic. Later, when the dominant key is firmly established in its own right, Mozart introduces a new subject whose tune is closely related to the first theme. In this richly ambiguous structure, the newly introduced motive would be regarded by the criterion of key, as the second subject; in purely thematic terms, it might almost be said to constitute the beginning of the codetta, or concluding section.

The functions of the other two main sections follow naturally from what has been established in the exposition. Their purpose is to discuss and resolve the conflicts of tonality and theme that the exposition has raised. The development is an area of tonal flux—it usually modulates, or changes key, frequently, and any keys it settles

Modulation and thematic alteration

in are likely to be only distantly related to the keys found in the exposition. It frequently proceeds by breaking the principal themes down into smaller elements and bringing these elements into new tonal or contrapuntal relations with each other. That is, themes or fragments of themes may appear in new keys; they may be combined to form apparently new melodies; they may be played against each other as counterpoint, or countermelody. One of the finest illustrations of the methods of development used in the Classical period occurs in the first movement of Mozart's *Symphony No. 38 in D Major (Prague).* Another resource of development is to seize on an apparently minor feature of the exposition and, by developing it extensively, to demonstrate its hidden importance. Another is to introduce entirely new material. This may provide a moment of relief in the course of a rigorous argument (as in the last movement of Mozart's *Piano Sonata in C Major,* K. 330); or it may allow the composer to expand the scope of a large-scale movement (as in the first movement of Beethoven's *Symphony No. 3 in E Flat Major,* the *Eroica*).

Sometimes such a theme may only *seem* to be new. In the first movement of Beethoven's *Symphony No. 4 in B Flat Major,* for instance, the theme in the development that is usually described as "new" is really a decorated version of a motive already heard in the exposition.

One common tactic in the Classical development is to begin the section with the codetta theme that ended the exposition. The first movement of Beethoven's *Cello Sonata No. 2 in G Minor,* Opus 5, No. 2, is an example.

The impact of this device, and of the development section as a whole, is often obscured by the common tendency among modern performers to ignore the composer's instruction, present in almost all sonata form movements of the Classical period, to repeat the entire exposition. When this repetition is omitted, the thematic balance of the movement is upset and the dramatic effect of the development's sudden departure from an established regularity can be ruined. Music is an art to which the controlled use of time is basic. The temporal structure of a movement cannot be altered without seriously changing the proportions of the whole.

Tension and recapitulation

Like the beginning of the development section, the point at which development passes into recapitulation is one of the most important psychological moments in the entire sonata structure. It marks the end of the main argument and the beginning of the final synthesis for which that argument has prepared the listener's mind. The Classical masters differ in their handling of this juncture. All usually prepare for it with a long passage of gathering tension. In Mozart the return of the tonic key and subject is managed with understated punctuality, the actual moment of recapitulation gliding in almost unnoticed. Haydn and Beethoven tend to celebrate its advent with panoply.

The recapitulation presents the principal subject matter of the movement in a new state of equilibrium. The main subjects of the exposition are heard almost always in the same order as before, but now both subjects are typically in the tonic key, whereas in the exposition the first was in the tonic, the second in the dominant key. As a result of the musical events in the development, the listener perceives the subjects in a new relationship—rather like a traveller who glimpses the constituent parts of a valley separately as he climbs a hill and then, when he reaches the summit, sees the entire landscape for the first time as a whole. The recapitulation can vary greatly in the literalness with which it repeats the elements of the exposition. Sometimes, as in the first movement of Mozart's *Sonata in B Flat Major,* K. 570, a tiny modification in the transition that originally led from the tonic to the dominant key is enough to effect the necessary change of key perspective and keep the second subject in the tonic key. In other cases (the first movement of Beethoven's *Eroica Symphony,* for instance, and many of Haydn's symphonic movements) far-reaching modifications and reshufflings of the original material are made in the recapitulation. As in any living manifestation of a principle of musical form, the methods differ vastly from work to work; but the effect is always to bring about the reconciliation of opposites that is essential to sonata form.

A large-scale sonata movement often creates conflicts of key and theme that cannot be completely settled even by the full process of recapitulation. In this case, the movement may be rounded off with a coda, or concluding section. Beethoven often extends the coda so greatly that it becomes almost a second development section, as in his *Appassionata* piano sonata. But this is no more an essential element of sonata form than the introduction that may precede the main movement.

The form described above is that exemplified in most first movements of sonatas, and of sonata-style compositions, in the Classical period. There are usually two, three, or four movements in the entire work. Two-movement and, more particularly, three-movement schemes are most common in sonatas for one or two instruments. Symphonies and string quartets almost always have four movements, and Beethoven, particularly in his earlier period, sometimes expanded the scheme of the instrumental sonata to four movements too.

The first movement in all of these patterns is usually fast; the second commonly provides the contrast of a slower tempo; and the last in most cases is again fast. When there are four movements, a simpler, dance-style movement of the type also found in the suite is included. This is usually placed between the slow second movement and the finale; in some cases it stands second and the slow movement third.

The forms of these other movements vary much more than that of the first, which in Classical examples is almost invariably the weightiest. Since their function is to complement the experience of the first movement through a new but related range of contrasts, their scope and manner depend on the point to which the issues of the work have already been taken. Simple ternary (A B A) form and variation form (*i.e.,* theme and variations) are among the most common patterns for the slow movement, but rondo and sonata forms are also used. In rondo form a recurring theme is contrasted with a number of intervening themes, as A B A C A. When sonata form is used in slow tempos, the demands of overall proportion frequently cause the omission of the development section. Sonata form, rondo, and, less often, variation form are also used for the final movement. In final movements, also, the simple rondo pattern (A B A C A) is often expanded into A B A-development-B A, with B in the dominant key at its first appearance and in the tonic key at its second. The result is a hybrid form known as sonata-rondo.

The dance movement

In the first part of the Classical period, the dance movement, when it appeared, usually consisted of a minuet in fairly simple binary form (the two-part form from which sonata form evolved). This was followed by a second minuet known as the trio, which tended in orchestral works to be more lightly scored. The first minuet was then repeated, normally without its own internal repeats. The minuet-trio-minuet structure forms an overall ternary pattern. Haydn frequently, and Beethoven still more often, chose to speed the traditional minuet up to the point at which it lost its dance character and became a scherzo, a quick, light movement usually related to the minuet in form. In some extreme cases, such as the ninth symphonies of both Beethoven and Schubert, the binary structures of both scherzo and trio were expanded into small but complete sonata-form structures. In this way, as with the sonata-rondo, the principles of thematic development and key contrast spread during the Classical period as the sonata form began to influence other movements.

Such are the outlines of the most fertile form in Western instrumental music since 1750. Before discussing its origins, growth, and later modification, there should be a warning against phrases like "true sonata form." If sonata form as described is considered the sole "true sonata form," the implication is that instrumental sonatas written in forms other than sonata form are not genuine.

Actually, the principle exemplified in sonata form represents one way of organizing the passage of sound through time. Its scope is enormous; it was the basis for some of the greatest works of Western music; and it still contains the seeds of potential further development. But it is only one episode in a complex chronicle of styles and princi-

ples of musical organization. In contrast to earlier forms, it emphasizes conflict instead of continuity and derives its impact from the explosive power of tonal organization instead of the smoother influence of melody.

History of the sonata. The sonata in all its manifestations has roots that go back long before the first uses of the actual name. Its ultimate sources are in the choral polyphony of the late Renaissance (music having several equal melodic lines, or voices). This in turn drew at times on both liturgical and secular sources—on the ancient system of tones or modes of Gregorian chant, and on medieval European folk music. These two lines were constantly interweaving. Popular tunes, for example, were used as the starting point for masses and other religious compositions from the 15th to the early 17th centuries. Sacred and secular elements influenced the development of both the sonata and the partita (or suite) of the Baroque period.

Earliest origins

The specific musical procedures that were eventually to be characteristic of the sonata began to emerge clearly in works by the Venetian composers of the late 16th century, notably Andrea Gabrieli (*c.* 1520–86) and Giovanni Gabrieli (1556–1612). These composers built instrumental pieces in short sections of contrasted tempo, a scheme that represents in embryo the division into movements of the later sonata. This approach is found not only in works entitled "sonata," such as Giovanni Gabrieli's *Sonata pian' e forte* (*Soft and Loud Sonata*) of 1597, which was one of the first works to specify instrumentation in detail; the instrumental fantasia and the canzone, an instrumental form derived from the chanson or secular French part-song, display a similar sectional structure. Like early sonatas, they were often contrapuntal (*i.e.*, built by counterpoint, or the interweaving of melodic lines in the different voices, or parts). At this stage sonatas, fantasias, and canzoni were often indistinguishable from each other, and from the fuguelike ricercare, though this form is generally more serious in character and more strictly contrapuntal in technique.

In the 17th century stringed instruments eclipsed the winds, which had played an at least equally important role in the sonatas and canzoni composed by the Gabrielis for the spacious galleries of St. Mark's Cathedral, Venice. Claudio Monteverdi (1567–1643) devoted more of his energies to vocal than to instrumental composition. The development of instrumental writing—and of instrumental musical forms—was carried on more and more by virtuoso violinists. One of these was Carlo Farina (flourished *c.* 1630), who spent part of his life in the service of the court of Dresden, and there published a set of sonatas in 1626. But the crowning figure in this early school of violinist-composers was Arcangelo Corelli (1653–1713), whose published sonatas, beginning in 1681, sum up Italian work in the field to this date.

Apart from their influence on the development of violin technique, reflected in the works of such later violinist-composers as Giuseppe Torelli (1658–1709), Antonio Vivaldi (1678–1741), Francesco Maria Veracini (1690–*c.* 1750), Giuseppe Tartini (1692–1770), and Pietro Locatelli (1695–1764), Corelli's sonatas are important for the way they clarify and help to define the two directions the sonata was to take. At this point the *sonata da chiesa*, or church sonata, and the *sonata da camera*, or chamber sonata, emerged as complementary but distinct lines of development.

Church and chamber sonatas

The *sonata da chiesa* usually consists of four movements, in the order slow–fast–slow–fast. The first fast movement tends to be loosely fugal in style (*i.e.*, using contrapuntal melodic imitation), and thus reflects, most clearly of the four, the sonata's roots in the fantasia and canzone. The last movement, by contrast, is simpler and lighter, often differing from the dance style typical of the *sonata da camera* only in that its sections are not repeated. The *sonata da camera* is altogether less serious and less contrapuntal than the *sonata da chiesa*, and it tends to consist of a larger number of shorter movements in dance style. If the *sonata da chiesa* was the source from which the Classical sonata was to develop, its courtly cousin was the direct ancestor of the suite, or partita, a succession of short dance pieces; and in the 18th century, the terms suite and partita were practically synonymous with *sonata da camera*. The two streams represented by church and chamber sonatas are the manifestation, in early Baroque terms, of the liturgical and secular sources found in Renaissance music. The Baroque style flourished in music from about 1600 to about 1750. Down to the middle of the 18th century the two influences maintained a high degree of independence; yet the injection of dance movements into the lighter examples of the *sonata da chiesa* and the penetration of counterpoint into the more serious suites and *sonate da camera* show that there was always some cross-fertilization.

Another characteristic of the Baroque sonata that Corelli's work helped to stabilize was its instrumentation. Around 1600 the musical revolution that began in Italy had shifted emphasis from the equal-voiced polyphony of the Renaissance and placed it instead on the concept of monody, or solo lines with subordinate accompaniments. The comparatively static influence of the old church modes was superseded by the more dramatic organizing principle of the major–minor key system with its use of contrast of keys. Although counterpoint continued to play a central role in musical structure for another hundred years and more, it became a counterpoint that took careful account of the implications of harmony and of chords within the framework of the major and minor keys.

The continuo part

In this context the continuo, or thorough bass, assumed primary importance. The composer that used a continuo part wrote out in full only the parts of the upper melody instruments. The accompaniment, which was the continuo part, was given in the form of a bass line, sometimes supplemented with numbers, or figures, to indicate main details of harmony, whence the term "figured bass." The continuo was "realized," or given its performed form, by a low melody instrument (viola da gamba, violone, or later cello or bassoon) in collaboration with an organ, harpsichord, or lute. The collaborating instrument improvised the harmonies indicated by the figures or implied by the other parts and so filled the gap between the treble and bass lines.

In Corelli's work, "solo" sonatas, for one violin with continuo, are found alongside others for two violins and continuo described as sonatas *a tre* (*i.e.*, for three), early examples of the trio sonata that was the principal chamber-music form until about 1750. The use of "trio" for sonatas played by four instruments is only superficially paradoxical: although trio sonatas were played by four instruments, they were considered to be in three parts—two violins and continuo. Moreover, specific instrumentation at this period was largely a matter of choice and circumstance. Flutes or oboes might play the violin parts, and if either harpsichord or cello or their substitutes were unavailable, the piece could be played with only one of them representing the continuo. But a complete continuo was preferred.

Corelli's importance is as much historical as musical. Perhaps because a vigorous line of Italian composers of violin music followed him, he is commonly accorded the main credit for late 17th-century developments in sonata style. But his undeniably vital contribution should not distract attention from equally important work that was done around the same time outside Italy.

Early development outside Italy

In France Jean-Baptiste Lully's lucrative monopoly of music at the royal court and the immense popularity of spectacular ballets used as courtly entertainments naturally led, through François Couperin (1668–1733), to a concentration on the smaller dance forms found in the ballet and courtly social dance. This concentration gave the French school its preeminence as producer and influencer of the 18th-century dance suite. The French, thus occupied with dance music, had little effect on the growth of the *sonata da chiesa*. But in Germany, where in 1619 Michael Praetorius (1571–1621) published some of the earliest sonatas, the sonata developed from an originally close relation to the suite into a more ambitious blend. As it evolved it combined the suitelike multisectional structure of the *sonata da camera* with the contrapuntal workmanship and emotional intensity of the Italian *sonata da chiesa* form.

One of the first contributors to this development of

the Italian influence was the Austrian composer Johann Heinrich Schmelzer (*c.* 1623–80). In Nürnberg in 1659 he published a set of trio sonatas for strings, following it in 1662 with a set for mixed strings and wind instruments, and in 1664 with what may have been the first set of sonatas for unaccompanied violin. The German composer Johann Rosenmüller (*c.* 1620–84) spent several years in Italy; his *Sonate da camera cioè sinfonie* (*i.e.,* suites or symphonies), published in Venice in 1667, are essentially dance compositions. But 12 years later, in Nürnberg, he issued a set of sonatas in two, three, four, and five parts that vividly illustrate the German trend toward more abstract musical structure and expressive counterpoint. During this period even pieces with dance titles began to lose their danceable character and became compositions meant only for listening.

Meanwhile, the greatest member of this school, Heinrich Ignaz Franz von Biber (1644–1704), published several sets of sonatas—some for violin and continuo, others in three, four, and five parts. In these, from 1676 onward, he took a penchant for expressiveness to extremes of sometimes bizarre but often gripping profundity that contrast sharply with the bland, polished style of Corelli. The titles of some of Biber's sets of sonatas specifically indicate his aim of reconciling church and chamber styles. The 1676 publication, for instance, is entitled *Sonatae tam aris quam aulis servientes* (*Sonatas for the Altar as Well as the Hall*). And being himself, like Corelli, a violinist of extraordinary powers, Biber made a valuable contribution to the development of instrumental technique in a set of sonatas for unaccompanied violin in which the practice of *scordatura* (adjustment of tuning to secure special effects) is ingeniously exploited.

The English composers were achieving a comparable intensification of expression during the 17th century, though in their case the technical starting point was different. In accordance with the characteristic time-lag of the English in the adoption of new European musical methods, the English continued to work with polyphony in the Renaissance manner, while the Italians were perfecting monody and the Germans fruitfully uniting monody with their own contrapuntal tradition. English polyphony in the 17th century attained a remarkable level of technical finish and emotional grandeur. Thomas Tomkins (1572–1656), Orlando Gibbons (1583–1625), John Jenkins (1592–1678), and William Lawes (1602–45) were the chief agents of this refining process. They and their predecessors, notably John Coperario (*c.* 1575–1626), made a gradual transition from the string fantasia bequeathed by William Byrd and other composers during the reign of Elizabeth I (1558–1603) and approached the new kind of musical form associated with the Baroque sonata; but they always stayed closer than their continental colleagues to the spirit of polyphony.

Contribution of English polyphony

When Henry Purcell (*c.* 1659–95), in his three-part and four-part sonatas, submitted this rich English tradition to the belated impact of French and Italian influence, he produced a fusion of styles that was the highest point of musical inspiration yet reached by the emergent sonata form.

The Baroque era. The years from the end of the 17th century to the middle of the 18th represent a moment of equilibrium in the interaction of counterpoint and monody that had created the Baroque sonata. The continuo device, as long as it endured, was a sign that the balance still held—and it did endure as long as the trio sonata kept its central position as a chamber-music medium. During the first half of the 18th century the later Italian violinists, most notably Vivaldi, were prolific creators of trio sonatas. Sometimes they leaned to a three-movement pattern (fast–slow–fast), influenced by the direction the Italian operatic sinfonia, or overture, was taking. More often the old four-movement pattern was preserved. In this well-tested shape, too, Georg Philipp Telemann (1681–1767) produced hundreds of examples that maintained a remarkably consistent standard of musical interest. George Frideric Handel (1685–1759), working for most of his life in England, composed some trio sonatas, and also some valuable sonatas for solo instrument with continuo. In France, Joseph Bodin de Boismortier (1691–1755) and the violinist Jean-Marie Leclair the elder (1697–1764) cultivated both solo and trio genres with charm although with less profundity.

Yet even while the sonata with continuo flourished, the forces of tonality, or organization in terms of keys, developed intensely toward a use of key contrast that would eventually drive the trio sonata from the scene. The continuo itself was being undermined by the growth of interest in instrumental colour, and the figured bass could not long survive the tendency toward scoring for specific instruments and exhaustive detailed musical notation.

Rise of tonal consciousness

Beginning in 1695 Johann Kuhnau (1660–1722) had published the first sonatas for keyboard instrument alone, some of them programmatic pieces on biblical subjects. J.S. Bach (1685–1750), the greatest composer of Baroque sonatas, continued the move away from the treatment of the keyboard in the subordinate, "filling-in" capacity that was its role in the continuo. He wrote a small number of trio sonatas after the traditional scheme, and also a few violin and flute sonatas with continuo; but at the same time he produced the first violin sonatas with obbligato harpsichord parts (that is, obligatory and fully written out, rather than improvised), others for flute or viola da gamba with obbligato harpsichord, and three sonatas (along with three partitas) for unaccompanied violin.

In these works, as in some of Telemann's later sonatas, the power of key or tonality to articulate sections of musical structure, and its ability to provide a harmonically derived eventfulness—a sense of expectation succeeded by fulfillment—began to make itself felt. These powers of key are the seed from which the Classical sonata form originated. But at this point the dualism engendered by tonal and thematic contrast had not yet supplanted the more continuous, unitary processes at work in a composition based on counterpoint. Nor was the consciousness of tonality any more advanced in the otherwise forward-looking work of Domenico Scarlatti (1685–1757). His harpsichord sonatas—555 movements survive, many designed to be played in pairs or in groups of three—are often original to the point of idiosyncrasy in expression. They introduced a valuable new flexibility in the treatment of binary form, and they had a powerful effect on the development of keyboard writing. But in formal terms they still belong in the old world of unity—even their strongest contrasts have an air of being suspended in time, quite unlike the far-ranging effects of conflict through time that are the basis of the Classical sonata.

A later generation of composers completed the transition from Baroque to Classical sonata. One of J.S. Bach's sons, Carl Philipp Emmanuel Bach (1714–88), plunged enthusiastically into the new resource of dramatic contrast. In about 70 harpsichord sonatas, and in other works for chamber ensembles and for orchestra, he placed a new stress on key contrast not only between but, more important, within movements. Correspondingly, he emphasized the art of transition.

Transition from Baroque to Classical

In the development of sonata form in orchestral music, particular value attaches to the work of the Austrians Georg Matthias Monn (1717–50) and Georg Christoph Wagenseil (1715–77) and of the Italian Giovanni Battista Sammartini (1701–75). All three played vital roles in shaping the symphony, which assumed an importance equal to that of the solo or small-ensemble sonata. Their symphonies further stressed the individual characterization of themes and, in particular, the use of the second subject to shape form. Another of Bach's sons, Wilhelm Friedemann Bach (1710–84), made sporadic but interesting contributions to this development, and a third, Johann Christian Bach (1732–82), who settled in London, exploited a vein of melodic charm that influenced Mozart.

The Classical era and later. By about 1770 most of the specific changes that dictated the shift from Baroque sonata to Classical sonata were firmly established. Through the work of the Neapolitan school of opera led by Domenico Scarlatti's father Alessandro (1660–1725), the operatic sinfonia, or overture, had streamlined the traditional *sonata da chiesa.* It omitted the opening slow movement and abandoned the fugal manner that was

the first allegro's link with the past. In the new three-movement pattern, a minuet sometimes replaced the fast, abstract finale. In other cases, the inclusion of both minuet and finale brought the number of movements back to four. The south German Mannheim school of composers —most notably Johann Wenzel Stamitz (1717–57) and his son Karl (1745–1801)—developed the technique of the orchestra, whose resources now provided an ideal laboratory for experimentation with the dramatic effects of tonal contrast.

By this time the Classical sonata proper (*i.e.*, with at least one movement in sonata form), whether in the medium of sonata, trio, quartet, quintet, or symphony, could provide a vehicle for consolidating the process begun nearly two centuries earlier by the revolution from equal-voiced polyphony to monody, with its emphasis on melody and harmony. The Rococo style of the mid-18th century, generally known as *style galant*, had attained a halfway stage in which counterpoint had been virtually dropped and tunes had occupied the forefront of interest. But now, in the mature Classical style of Haydn and Mozart, superficial melodic interest was in turn subordinated. In this style the value of tunes lay in their role as functions of tonality. Key by this time had had assumed a central role as the fundamental articulator of form. As a corollary, musical themes were often, though not always, reduced to the status of mere motives, or tags. The theme's harmonic implications, which contribute to the feeling of key, took precedence over its attractiveness as melody.

Subordination of melody to tonality

The new musical principle—that of contrast of key—reached full expression in Haydn and Mozart through their use of sonata form as a principle of musical organization. Haydn's most valuable work in the sonata form is found in his series of over 80 string quartets, over 100 symphonies, 52 keyboard sonatas, and 31 trios for piano, violin, and cello. Unlike Haydn, Mozart was at his greatest in the fields of opera and of the solo concerto. (The latter, though it shared with sonata form such elements as the central principle of key contrast, was a medium that evolved, through the Baroque concerto grosso, from the fundamentally different source of the solo vocal aria and the vocal-instrumental concerto.) But in the last six symphonies, the last 10 string quartets, about a dozen keyboard sonatas, and several trios, quartets, quintets, and serenades, Mozart achieved outstanding examples of sonata structures. The formerly prominent sonata for violin plays a relatively minor part in both men's output: the violin had been eclipsed by the rise of interest in keyboard instruments. It was reintroduced almost surreptitiously as a distinctly subordinate partner and regained a leading role only toward the end of the 18th century in Mozart's later violin sonatas and then in Beethoven's.

The strikingly individual details in Haydn's and Mozart's handling of sonata form are all features consonant with the general outlines of the form. Examples of different approaches include Haydn's taste for combining dualistic key schemes with monistic thematic material (that is, the use of the same basic theme in both keys). He also frequently set slow movements in keys only distantly related to the key of the first movement. Mozart preferred strongly differentiated themes, and he often reshaped his second subjects drastically when they reappeared in the recapitulation. Beethoven, in his sonata compositions (preeminently, the 32 piano sonatas, the 16 string quartets, the trios, the 9 symphonies, and the sonatas for violin and for cello), retained the basic sonata form. But he vastly extended its scale; *e.g.*, by increasing the importance of the coda, or concluding section, and by using unusual keys in the exposition, which was greatly increased in length. He also introduced extramusical implications of a profound philosophical nature. In his later sonatas and quartets he began to move away from the dualistic sonata principle and back to the monistic approach exemplified in variation form and fugue.

The case of Franz Schubert (1797–1828) is quite different. The first movement of the *Symphony No. 5 in B Flat Major* (written when he was 19) is one among several places that illustrates a changing attitude to sonata principles. In the recapitulation of this movement, the first theme is given in the subdominant key (the key whose keynote is five tones below that of the tonic, or home key, as F–C, just as the tonic's keynote is five tones below that of the dominant key, as C–G). This device enables Schubert to place the second theme in the tonic key (the goal of the recapitulation) without altering the transition between the two themes; for the same passage that, in the exposition, took the music from the tonic to the dominant serves, in the recapitulation, to take it from the subdominant to the tonic. This essentially labour-saving procedure is evidence of a certain lack of patience with the workings of sonata form as hitherto practiced. Up to this time, sonata form, first treated as a textbook study after Schubert's death, was not a set of rules codified by theorists and followed by composers. Rather, it was a principle of composition that grew out of earlier forms and that can be generalized from an examination of the actual work of Haydn, Mozart, Beethoven, and their contemporaries.

19th-century trends

Schubert's interests lay in new directions, and the first steps in two such directions are to be found in the greatest of his instrumental works. His later sonata-form compositions in all media—when they follow the rough traditional scheme of exposition, development, and recapitulation—modify it substantially. He frequently expanded the number of tonal centres (central keys) in the exposition, and sometimes also the number of basic themes, from two to three. This tendency to expansion affects the whole subsequent course of the Austro-German symphonic tradition. It is the direct ancestor of the expositions of Anton Bruckner (1824–96), with their three distinct thematic groups, and of the vastly extended sonata structures of Gustav Mahler (1860–1911). At the same time, Schubert's *Fantasy in C Major (Wanderer)* for piano (1822) exemplifies an opposite 19th-century trend toward contraction, through the fusion of the sonata's formerly separate movements in one closely integrated whole: the four movements of the fantasy are based on transformed versions of a single theme. Similarly, in France, Hector Berlioz (1803–69) in his *Symphonie fantastique* transformed the theme representing the artist's beloved (the *idée fixe*, or fixed idea) so that it took different forms in each movement. In this case the transformation was affected by the program or "plot" of the symphony. This was a departure from the abstract, or plotless, character of the Classical sonata. The tendency to fusion—that is, to thematic unity between movements—was the source of the thematic transformations used in symphonic poems, such as those of Franz Liszt (1811–86), as a basic principle of musical structure. But in these works the program rather than any abstract musical form suggests the particular course of the transformation of the themes. For this reason their specific form does not depend, as did that of the Classical sonata, on the exposition–development–recapitulation principle of contrast, conflict, and reconciliation of keys. A corresponding evolution away from the Classical form of the sonata for one instrument occurs in Liszt's one-movement *Piano Sonata in B Minor* (1853). In this work he used a single extended movement with subdivisions analogous to the sections of sonata form. But the specific use of his four themes, which are transformed and combined in free fashion, departs from the usual order of the classical Sonata.

The influence of program music

Robert Schumann (1810–56) likewise experimented fruitfully, especially in his *Symphony No. 4 in D Minor*, with the Schubertian idea of fusing movements together. The tendency to use thematic transformation in a manner that moved away from the Classical sonata form was complemented by César Franck, who adhered to the basic form but from 1841 utilized a "cyclic" approach; that is, one of fusion, or thematic relationships between movements. Brahms, on the other hand, carried the more familiar Classical sonata form to its highest point of complexity. In addition to making valuable innovations in rhythmic structure, he gave the role of counterpoint a new lease of vigour and interest and used the concept of thematic relationships between movements in a particularly subtle way. Chopin's three piano sonatas are concerned more with lyrical expression than with innovative formal methods. Similarly, the sonata compositions of Carl Maria von Weber (1786–1826) and Felix Mendelssohn (1809–47),

which generally followed the patterns of their Classical predecessors and were highly regarded in their day, contributed little to the evolution of sonata form away from its Classical state. This evolution, illustrated by the works of Berlioz and Liszt, was carried forward by Mahler. In his symphonies expansion, through inclusion of more than two tonal centres and groups of themes, and fusion, or the creation of unity between movements, are combined. This gives rise to expansive compositions held together by complex interrelationships between themes. Arnold Schoenberg (1874–1951), in such works as his *First String Quartet* (1904), carried the idea of fusion of movements to its logical conclusion: this is a one-movement work with contrasting sections in which all the themes used are derived from a few basic motives.

Weakening of the Classical sonata form

Two important 19th-century developments tended to weaken the effectiveness of the Classical sonata form as an organizing principle. One, exemplified by Richard Wagner (1813–83), was an increasing use of chromaticism; that is, of notes and chords foreign to the key in which a passage of music is written. Chromaticism, when used extensively, broke down key feeling. Instead of being heard as a contrast to, or special modification of, the key, it became so prominent that the key itself was not heard strongly enough to establish itself in the listener's mind. Secondly, Liszt and his followers weakened the sonata form by using in their symphonic poems musical organizations based on program rather than on contrast of keys. But although the effectiveness of key as a basis for musical organization was weakened by the late 19th century, Mahler and Carl Nielsen (1865–1931) provided a modification of the sonata form that made use of tonality in a new way. This innovation, progressive tonality, used the home key as a goal to be worked toward from more or less distant key regions, so that a work ends in a different key from the one in which it began. Mahler and Nielsen arrived at the same notion independently at the same time. Nielsen's *First Symphony* and Mahler's *Second Symphony* (both 1894) are the first to use progressive tonality, and both composers forged highly individual new forms from it.

Most compositions written in sonata form after Wagner's era, however, lack a certain sense of vitality. Frequently, because the effectiveness of key or tonality has been weakened, such compositions centre on melody without the strong contrast of tonality that underlay the Classical sonata. Some composers made stylistic compromises. Schoenberg's *Fourth String Quartet* used his 12-tone (dodecaphonic) approach to composition, an approach that began with a "row," or series, of the 12 tones of the chromatic scale, chosen by the composer to serve as the melodic and harmonic basis for the composition. In this work he fits the 12-tone style into the outlines of sonata form. The result is based on contrasting themes, rather than on the Classical sonata principle of key contrast, because 12-tone music, being atonal, deliberately avoids the creation of a sense of key. In a comparable way, though in the context of a different style, some of the sonatas of Sergey Prokofiev (1891–1953) use the outward formal divisions of the classical sonata form but stress the interest of melody as such, leaving tonality—still present in this case—to play a decorative rather than a structural role.

New principles

Other modern composers developed new principles of musical form. Although these principles appear in genres traditionally associated with the sonata, such as instrumental sonatas, string quartets, and orchestral works, they vary in the degree to which they are or are not related to the Classical sonata form.

One of the more useful of such principles has been the technique of constructing large-scale compositions from transformations and developments of a single germinal motive, often merely two or three notes. Like Schoenberg's approach, in which a 12-tone row is transformed, this is actually the application at a more radical and consistent level of the 19th-century principle of thematic transformation. The symphonies of Jean Sibelius (1865–1957) are based on this method. So are those of Ralph Vaughan Williams (1872–1958), who also used some of the features of sonata form but imaginatively reshaped them and transformed their proportions to suit his purpose. In the nonsonata works of Schoenberg and his pupils Alban Berg (1885–1935) and Anton Webern (1883–1945), the 12-tone method produced legitimate new forms of the highest historical importance; but when forced into an uncomfortable liaison with earlier schemes of organization such as the sonata, its effectiveness diminished. In the works of Béla Bartók (1881–1945), passages built on folk music scales, rather than on the major and minor scales of 18th- and 19th-century keys or tonalities, are used alongside atonal passages. His musical structure frequently takes the form of a combination of elements of sonata form with a simple "archlike" structure such as A B C B A. Paul Hindemith (1895–1963) contributed copiously to the sonata medium with works for almost every known instrument, but as far as the form was concerned his innovations were of minor significance. Sir Michael Tippett in his *Second Symphony* and sonatas (*e.g.*, for piano; for four horns) uses tonality in a fresh and valid way, and he has effected a stimulating rapprochement of the sonata form with the equal-voice polyphony characteristic of the English fantasia and madrigal (a genre of part-song) of Elizabethan and Jacobean times. The *Second Symphony* of Wilfred Josephs shows yet another potentially valuable reinterpretation of the fused-movement approach to the sonata: its long first movement serves the function of exposition, three intermediate movements act on one level as development and on another level as a combination of slow movement and scherzo, and a brief finale serves as a kind of recapitulation.

Other musical approaches use metre and instrumental tone colour to mark important musical points much as traditional sonata form used contrast of keys. Elliott Carter has combined a use of germinal motifs with a new rhythmic technique known as "metric modulation," a controlled change of metre foreshadowed in Brahms by such passages as the end of the *Second Piano Concerto*. Carter's *Sonata for Cello and Piano* is an example of this use of metre. Carter also uses the idea of sharply differentiating the musical subject matter given to the individual instruments of an ensemble—a resource found earlier in the *Second String Quartet* of Charles Ives (1874–1954). Some of the many styles of Igor Stravinsky (1882–1971), particularly after his late adoption of the 12-tone approach, make ingenious use of germinal motifs; but his music really bases its structure on the juxtaposition of large blocks of distinct musical character, rather than on "development" in the sense traditionally associated with the sonata.

Music in the latter half of the 20th century is too various in form, medium, esthetic attitude, and social function to allow any confident predictions. But all of these examples suggest that the sonata, and its special manifestation, the sonata form, can still provide composers with fertile areas of activity. As in the time of Haydn, Mozart, and Beethoven, success will continue to reward those who develop musical forms that grow naturally from the specific principles of composition used in their works, much as the sonata form grew out of the principle of contrast, conflict, and resolution of tonalities that characterized the sonatas, symphonies, and chamber music of the 18th and 19th centuries. (B.Ja.)

CONCERTO

Since about 1750 the term concerto has been applied primarily to the solo concerto; *i.e.*, a musical composition for instruments alone in which an orchestra and a soloist interrelate by alternating, competing, or combining on a more or less equal footing. In this sense the concerto, like the symphony or the string quartet, may be seen as a special case of the generic musical form embraced by the term sonata. Like the sonata and symphony, the concerto is typically a cycle of several contrasting movements integrated tonally and often thematically. The individual movements are usually based on certain recognized designs, including sonata form, A B A (the letters refer to large distinct musical sections), variations, and rondo (such as A B A C A).

But the concerto tends to differ from the sonata, too, in certain ways that set it apart. Thus, in the sonata form

of the concerto's first movement, the exposition often remains in the tonic key while played by the entire orchestra the first time through. The expected departure to a nearly related key and the introduction of the soloist are reserved to a characteristically more elaborate repetition of the exposition. Moreover, to meet a felt need for a more brilliant ending in the same movement, the concerto provides or at least invites an improvised cadenza near the end of the movement—an extended, free flourish that may go on for as long as several minutes. A shorter cadenza may also occur at a strategic point in one or more of the other movements. In addition, the concerto has followed much more consistently than the sonata the plan of three movements, in the order fast–slow–fast. The second movement leads, often without pause, into the finale, or last movement, and the finale has shown a more consistent preference for the rondo design. But, importantly, all of these distinctions of musical form are secondary to the dialogue inherent in the concerto's interrelationship of soloist and orchestra. This dialogue influences the very nature of the solo part by almost forcing the soloist into a virtuoso's role so that he can compete on an equal footing with his adversary, the orchestra. The dialogue, furthermore, influences not only the construction of individual musical phrases but also the musical textures chosen. In addition, it affects the ways of developing musical material (*e.g.*, themes, rhythms) according to the logic of musical form, and even the broader blocking off of sections within forms, as in the concerto's repeated exposition, with its sections for full orchestra (tutti) and soloist.

Dialogue between soloist and orchestra

The literature of the concerto since 1750 is extensive in all categories, although the standard repertoire is limited to scarcely more than a few works for each main solo instrument. Being a prime ingredient of popular concert fare, the concerto is subject, much as is opera, to the exigencies of the box office. The film and phonograph industries have helped further to give disproportionate promience to a few highly successful and undeniably effective examples like those for piano by the Norwegian Edvard Grieg (in A minor) and the Russians Peter Ilich Tchaikovsky (in B flat minor) and Sergey Rachmaninoff (in C minor).

Taking music's commonly accepted eras for its framework, this examination of the concerto starts in the late Renaissance (16th century), with the origins and first uses of the term. It proceeds to the Baroque era (about 1580 to 1750), which was the first main era of the concerto, including the vocal-instrumental concerto in the late 16th and 17th centuries and, especially, the concerto grosso in the late 17th and early 18th centuries. The discussion progresses next to the Classical era (about 1730 to 1830) and the Romantic era (about 1790 to 1915), which mark successive though dissimilar heydays of the solo concerto partially discussed above. Lastly it reaches the modern era (from about 1890), which has witnessed further vitality in the solo concerto and a renaissance of the older concerto grosso principle of contrasting instrumental groups. Within each era examined, the prime considerations of the discussion are the meanings of "concerto" as then current; the concerto's place in the social life of the time: its scoring, or particular use of musical instruments and voices; its means of achieving opposition and contrast (if any); its musical structure; and its output by chief regions and masters.

Origins of the concerto. The word concerto has given trouble to music historians concerned with word origins because within a century after its first known applications to music, in the early 1500s, it had acquired two meanings that would seem to be mutually exclusive. One meaning still current in Italian is that of "agreement," or, as in English, of being "in concert." The other is that of "competing" or "contesting," from the Latin *concerto, -are, -atus* ("to contend"). Probably derived from the same Latin word are such related terms as the Italian *conserto, concertato,* and *concertante;* the Spanish *concierto;* the French *concert* and *concertant;* and the English consort. Yet it is this dual meaning itself that offers the most tangible thread of unity throughout the four-century history of the concerto in its various forms. In other words, the concerto, in whatever guise it assumes, reveals a continuing need to resolve the antithetical ideas of concord and contest. The balance between contest and concord is the concerto's particular solution to the problem of variety within unity that must be resolved in all dynamic art forms.

Original dual meaning of concerto

In the 16th century the word concerto embodied several meanings. As early as 1519 in Rome it referred simply to a vocal or instrumental group (*un concerto di voci in musica*). By 1551 it was used with implications of musical texture, specifically of the contrast of soprano voice with bass and alto ("soprano in concerto col basso & alto"). By 1565 the cognate word concertato was being used in reference to both voices and instruments. And by 1584 a Venetian title, *Musica . . . per cantar e sonar in concerti,* brought forth the meaning of group presentations or concerts.

Although in 1578 "concerti" was used to mean the music itself, for both voices and instruments (rather than performers or concerts), the first formal musical title of this sort appeared in 1587. This was the *Concerti . . . a 6–16 voci* (*Concertos . . . in 6 to 16 Parts*), a collection of vocal and instrumental music by the Venetian composer Andrea Gabrieli and his nephew Giovanni Gabrieli. No formal title concerto is known to be given to strictly instrumental music before 1621, and then the word means both "concerted" or "playing together" and "technically [or even 'virtuosically'] elaborated." This title, with significant implications of a new style—that of the virtuoso soloist—is the *Sonate concertate in stilo moderno* (*Concerted Sonatas in the Modern Style*), by an Italian, Dario Castello, a collection for a violin and for a bassoon that elaborates on the basso continuo part. (The basso continuo, a constant device of Baroque music, calls for a low, sustained-tone instrument—*e.g.*, cello, viola da gamba, bassoon—playing the bass line, plus one or more chordal instruments—*e.g.*, harpsichord, organ, lute—that improvise harmonies above the bass line. Small numbers, or figures, are often placed above the bass line music as a guide to the harmonies, hence the term figured bass.)

Means of contrast

In these early, loosely titled collections by the Gabrielis and by Castello, there can be found at least five of the means of contention or opposition that later became closely identified with the *stile concertato* or concerto. Listed in their approximate order of evolution, they include opposition between voices and instruments; between one choir and another (whether of voices or instruments); between the essential basso continuo and its melodic elaboration; between simple, straightforward parts and more decorative, virtuoso parts; and between two or more voices or instrumental parts engaged in imitative or motivic interplay.

Within the span of a century and a half the Baroque era saw the word concerto change from a broad general term applied on several musical levels to a fairly specific term whose meaning had two senses: that of an instrumental group and that of a musical structure or process. Thus in the Gabrielis' early Baroque "Concerti" the title referred to a collection consisting of church motets (Latin choral compositions) and madrigals (similar Italian compositions) for six to 12 voices in one or two choruses, without and with instruments; a piece for eight voices imitating a battle; and a "Ricercar per sonar" for eight instruments (a ricercar is a piece often based on melodic imitation; *sonar* means to play instrumentally). By contrast the more than 460 late-Baroque "Concerti" composed by the Italian Antonio Vivaldi from the first half of the 18th century are purely instrumental works, mostly three-movement cycles (fast–slow–fast) for one to four soloists and strings with or without other orchestral instruments.

Sonata, symphony, and concerto

The same century and a half saw a similar narrowing of definition in two closely allied terms: sonata and sinfonia. Before sonata, sinfonia, and concerto became clearly defined and attained a degree of mutual exclusion, they often overlapped and were sometimes even equated in meaning. The full title on one musical manuscript by the Italian Alessandro Stradella, for example, reads, *Sonata di viole, cioé per concerto grosso di viole, concertino di due violino e leuto* (*Sonata for Viols, that is, for Full Complement [concerto grosso] of Viols, and Small Group [concertino] of Two: Violin and Lute*). Another reads, *Sinfonia per violini*

e bassi a due concertini distinti (*Sinfonia for Violins and Basses in Two Distinct Groups*). Many so-called trumpet sonatas of the same period, especially those by Domenico Gabrielli and Giuseppe Jacchini, simply equate the three terms without distinction. When Tommaso Antonio Vitali entitled his Opus 4 *Concerto di sonate* . . . (published 1701), he evidently meant no more than "A Collection of Sonatas," for there was only a violin part, a basso continuo part, and the *concertate* cello part that so often elaborated on the basso continuo. But later, when "Concerto" was crossed off a harpsichord solo by the German composer Johann David Heinichen, copied posthumously in 1731, and "Sonata" was entered in its place, the intention was probably to choose a title more identified with the performing instrument, although the work may well have been transcribed from a concerto.

It is no wonder, then, that even the traits most basically identified with the concerto can be found in works of other titles. G. Gabrieli wrote works for as many as five opposed choirs of instruments under the title of "Sonata." The "sonatas" of the German composers Johann Joseph Fux and Georg Muffat have passages actually marked "T." and "S." for tutti and soli (soloists) groupings, and, indeed, the tutti–soli principle of contrast still operates strongly in the classical symphonies of Haydn and Mozart. These cross-influences are important reminders that any full history of the concerto idea must take into account not only the concerti in the literature but many works with other titles. Yet in a more concise, encyclopaedic summary it is necessary to stay close to the evolution of the term concerto itself, and there is a real significance in observing how the word acquired definition. The evolution of the word in effect reveals the composers' own developing concepts of it. Concerto was the last of the three terms (sonata, sinfonia, concerto) to attain clear definition. In part this was because the word first had to grow free of its original association with music for both voices and instruments.

Cross-influences

The Baroque vocal-instrumental concerto (c. 1585–1650). As already suggested, the first category of music to be associated significantly with the term concerto was that of the vocal-instrumental concerto. If this category is sometimes incorporated only incidentally into overall accounts of the concerto, the reasons lie, first, in its lack of clear identification with any one type of musical form and, second, in the longer, more vivid association of all later categories of the concerto with music exclusively for instruments.

Both the early association of the word with vocal-instrumental combinations and the lack of a clear, identifiable musical form are apparent in the important discussion of the concerto in 1619 by the German composer and theorist Michael Praetorius in his *Syntagma Musicum* ("Writings on Music"). Praetorius classified the concerto, along with the motet and the *falsobordone* (or simple harmonization of a liturgical reciting tone), among vocal pieces that have a sacred or serious secular text. He recognized the two general, and related, types that were to prevail in the vocal-instrumental concerto. The multivoice type was in more than four parts and typically subdivided into opposing choirs, especially low versus high choirs. The few-voice type was for one to four parts; often solo parts, and basso continuo; according to Praetorius, this type, which permitted the text to be understood better, was then replacing the madrigal in Italy. Aside from implications of modernism and greater appeal in the concerto and conservatism and greater weightiness in the motet, Praetorius found no distinction between *concert, concertos ecclesiasticos, sacras cantiones, sacros concentus,* and *motettas.*

Praetorius found that the concerto was performed especially in the church and, particularly the few-voiced type, in the monastery. Today one surmises from titles and prefaces to published concerti, from contemporary paintings, and even from the kinds of instruments specified, that the main social breeding ground for the vocal-instrumental concerto was the chapel, above all the court chapel, and the chapel's resources of musicians and instruments were in fact largely those called for by the concerti of the time.

The distinction that Praetorius drew between the multi-voice, polychoir concerto and the few-voice, soloistic concerto proved to be the most significant distinction throughout the course of the vocal-instrumental concerto. Yet the two types were not independent of each other but were interrelated in their common derivation from the late-Renaissance, polyphonic madrigal and motet. Moreover, they were interdependent. On the one hand, the few-voiced concerto thrived not only on the desire to make the text more understandable and hence more appealing but also on a practical need, in the smaller, less fortunate chapels, to reduce the larger vocal and instrumental groupings to such resources as were available locally (as, for example, during the economizations in Germany brought on by the Thirty Years' War, 1618–48). On the other hand, the polychoir and other larger groupings thrived not only on the desire for more massive, imposing sound but on the opportunity that larger, better staffed chapels provided to expand compositions written for the smaller groupings, whether by adopting alternative scorings that the composer might provide or by improvising other dispositions to suit the immediate place and occasion.

Freedom in use of singers and instruments

There is a clear instance of expanding the scoring in one Gabriele Fattorini's . . . *Sacri concerti a due voci* . . . (. . . *Sacred Concerts for Two Voices* . . .). This work appeared originally in 1600 merely "with a basso continuo for the greater convenience of organists" and only two years later was republished "with a new addition of some four-part ripieni [or *tutti* groupings] to sing in two [opposed] choirs." A good hint of the improvisatory practices is offered in the *Vezzo di perle musicali* (1610; *Necklace of Musical Pearls*), by Adriano Banchieri. Banchieri explains that his pieces are arranged so that "the same concerto can be altered in six ways over the *basso seguente* [a composite bass line taken from the lowest notes in whatever parts], with one or more parts, whether vocal or instrumental."

The natural consequence of this much interdependence and interrelationship of the two types, multivoice and few-voice, was their fusion in vocal-instrumental concerti that provided the massive oppositions of the larger groups, the subjective intensity of the soloists, and the opposition between group and soloist. This fusion, especially in Protestant Germany, often with the incorporation of a Protestant chorale, or hymn, substantially influenced the subsequent development of the German cantata, which was frequently based on a chorale and, like the vocal-instrumental concerto, included vocal soloists, choir, and instruments.

A more specific idea of the Baroque vocal-instrumental concerto might best be given by a brief description of the scoring and nature of six successive, representative examples, running from shortly after the pioneer collection by the Gabrielis in 1587 to a late collection (1650) by the German composer Heinrich Schütz. Banchieri's *Concerti ecclesiastici,* published in Venice in 1595, consists entirely of eight-part motets for double chorus, with a "score" added for organ. This "score" for this double-chorus collection consisted of the soprano and partially figured bass parts of the first chorus only—a partial score enabling the keyboard player to orient himself. Unlike the Gabrieli collection of concerti, Banchieri's is composed exclusively of sacred texts. By contrast, Lodovico da Viadana's popular and influential *Cento concerti ecclesiastici a 1, a 2, a 3, e a 4 voci, con il basso continuo per sonar nell'organo* (*100 Ecclesiastical Concertos* [*i.e.,* motets] *for One, Two, Three, and Four Voices, with the Basso Continuo to be Played on the Organ;* Venice, 1602) exploits the new style, simpler and more intimate, yet florid and expressive, and including actual monody (solo vocal melody accompanied by expressive harmonies, a type of music new with the Baroque Era). These "concerti" achieve opposition mainly through the polarity of upper part(s) and bass, including such dispositions as two tenors and bass, tenor and two trombones, or two sopranos and two basses. In an important preface, especially treating of the organ part, Viadana argued that the reduction from the multivoice type of motet to these new few-voice "concerti" was made possible by the device of the basso continuo and its realization (*i.e.,* the improvised harmonies), which serve as a filler in lieu of the missing parts. Similar oppositions of high and

Influences of the Protestant chorale

low parts, but with secular texts and still greater variety, appeared in the *Concerto, Settimo libro de madrigali a 1, 2, 3, 4, & 6 voci, con altri generi de canti* (*Concerto* [*i.e.*, ensemble or concert consisting of the], *Seventh Book of Madrigals in 1, 2, 3, 4, & 6 Voices* [plus basso continuo], *with Other Kinds of Songs;* Venice, 1619), by the celebrated composer Claudio Monteverdi. Along with two pieces in homophonic, or chordal, style, labelled "Sinfonia," for five unnamed instruments, the book contains both compositions for smaller groups with virtuosic tendencies in the vocal parts and large pieces employing melodic imitation and suggesting Renaissance polyphony, with its independent melodic lines. An example of the larger type is *Con che soavità* [*With What Gentleness*], *concertato a una voce e 9 instrumenti* (making up three choirs of instruments specified for the viola family and a corpus of bass and filler instruments).

German developments

In the same year (1619), in Wolfenbüttel, Germany, there appeared one of several pertinent collections by Praetorius, *Polyhymnia caduceatrix & panegyrica* (named after the muse Polyhymnia), "containing 40 concertos of solemn peace and joy" for one to 21 or "more voices, arranged in" two to six choirs, "to be performed and used with all sorts of instruments and human voices, also trumpets and kettledrums." As Praetorius made clear in his detailed, prefatory instructions and in broader remarks about his concerti in his *Syntagma Musicum,* his concerti comprise a virtual compendium of the vocal-instrumental concerto in all its uses of voices and instruments and styles of opposition and in all its applications of the Protestant chorale, as well. The German composer Johann Hermann Schein acknowledged the influence of Viadana's more intimate concerti in the first set of his "sacred concertos," *Opella nova I* (1618; *Little New Opus*). But in his second set (Leipzig, 1626), he turned more to the larger scale styles of Praetorius for three to six voices and basso continuo. Representative is No. 12, *Hosianna dem Sohne David* (*Hosannah to the Son of David*), for two sopranos, two tenors, two basses, three *bombardi* (bass shawms), and basso continuo, with alternating sections of instrumental episodes, tutti in chordal style, and melodic imitation. In addition there are passages for three instrumental or vocal soloists, a combination often already encountered in the popular Baroque trio setting of two high parts over a low part. The last main landmarks of the vocal-instrumental concerto were the three sets of Schütz's *Symphoniae sacrae,* or *Sacred Symphonies* (Venice, 1629; Dresden, 1647 and 1650), works that reveal all the variety of treatment to be found in Schein's sacred concerti, except for Schein's interest in the chorale. The first two of Schütz's sets consisted of few-voice settings, mostly one to three voices with one or two obbligato (required solo) instruments and basso continuo. The third set extended to as many as eight parts (some of them optional) and basso continuo; in style it showed a considerable return to the concept of oppositions between choirs, chiefly between vocal and instrumental choirs.

The composers cited here were the main exponents and the Italian and German chapels were the main centres of the early-Baroque, vocal-instrumental concerto. After giving birth to the genre, Italy soon turned to opera, oratorio, and more independent instrumental forms. The Germans, whose derivation from the Italians was direct and unequivocal, developed the idea further and longer before it largely gave way to the Protestant cantata around the mid-17th century. Yet echoes of the vocal-instrumental concerto are still strong in the cantatas of J.S. Bach and his predecessor Dietrich Buxtehude.

The Baroque concerto grosso (c. 1675–1750). Late in the 17th century, within a generation after the vocal-instrumental concerto had last flourished in Germany, the concerto grosso began to assume a clear identity of its own in Italy and soon after in Germany and beyond. Its main ingredients have been noted earlier—the opposition of choirs or choir and soloists, the exchanges of melodic imitation, the trio setting of soloists, and even the use of "concertate" in a title of a purely instrumental work (by Castello). Other purely instrumental precedents of the mature concerto grosso exist in the considerable literature of music for opposing instrumental choirs in numerous "sonatas," "sinfonias," and "canzone" (instrumental pieces in several sections), starting with the works of Giovanni Gabrieli. Such anticipations, including the *Sinfonia à 8* (*i.e.*, in eight parts; 1618) of one Francesco Usper—a fortuitous, miniature concerto grosso in all but the name—accumulated during the 17th century. Good examples are the orchestral "trumpet sonatas" written in Bologna, Italy, during the second half. But not until the 1670s did the term concerto grosso itself come into general use. It indicated the larger of two contrasting instrumental groups within a composition, and in this sense the term was opposed to concertino (the smaller group), and signified the relation of full orchestra to one or more soloists. By 1698 it appeared as an actual title itself, in the published *Concerti grossi . . .* , by an Italian, Lorenzo Gregori. That this title did indicate a composite concept (*i.e.*, of opposing instrumental groups) is evidenced by frequent distinctions in prefaces and tables of contents between it (or its shorter equivalent, "Concerti") and the sinfonia or sonata. As one example, the *Sinfonie a tre e concerti a quattro* (*Sinfonias in Three Parts and Concertos in Four Parts,* Opus 5; 1692), by the Italian violinist and composer Giuseppe Torelli makes a distinction not only in the number of parts but in the style: between a dense, polyphonic, older style in the sinfonias, often performed with only one player to a part, and a newer, more open style in the concerti, suitable to multiple (orchestral) performance of the parts. As another example, whereas the German Georg Muffat had already called attention to the tuttisoli dispositions in his five orchestral "Sonate" of 1682, when he republished these in 1701 with revisions he changed the title of each to "Concerto."

Place in society

The social function of the concerto grosso was explicitly stated in 1701 by Muffat, who was as articulate about the secular concerto grosso and its performance as Praetorius had been about the sacred vocal-instrumental concerto:

> These concertos [in his *Ausserlesene . . . Instrumental-Music* or, *Selected . . . Instrumental Music*], suited neither to the church (because of the ballet airs and airs of other sorts which they include) nor for dancing (because of other interwoven conceits, now slow and serious, now gay and nimble, and composed only for the express refreshment of the ear), may be performed most appropriately in connection with entertainments given by great princes and lords, for receptions of distinguished guests, and at state banquets, serenades, and assemblies of musical amateurs and virtuosi. (As translated in Oliver Strunk's *Source Readings in Music History,* W.W. Norton and Company, Inc., New York, 1950, p. 449.)

The breeding ground of the concerto, therefore, was no longer the chapel but the court. From the standpoint of the local court administrator the concerto grosso offered certain economic as well as functional advantages, advantages that might even help to account for its predominance in Baroque instrumental music. The opposition of a full orchestra, playing relatively simple parts, to a few soli, playing more difficult, even virtuosic parts, made it possible to entrust the full-orchestra parts to relative novices in the court entourage, often to servants who could play in addition to their other duties. Thus, only a few solo parts had to be played by experts hired primarily as professional musicians. This practical advantage can be argued only while the distinction between simple and difficult parts prevailed. The distinction became less clear as the concerto matured, at least in works with one or more soloists.

Fundamental not only to the scoring but to the style, and even the musical structure of the Baroque concerto, was the opposition between the full orchestra, or *concerto grosso* (also called tutti, or *ripieno*), and the *concertino* (also called soli, or *principale*). A full complement of strings, usually two to four on a part, often sufficed for the "full orchestra," in addition to the one to three instruments needed to play and realize the basso continuo. Usually at least a low melody instrument, bowed or blown, and a chordal instrument, plucked or keyed, were used for the basso continuo. The same trio setting that had been popular from the start of the century, typically two violins and a cello, often served as the concertino. When the concertino was not playing soli passages it figured as part of the *concerto grosso.* Illustrative of these typical settings is the celebrated *Christmas Concerto* (Opus 6, No. 8; 1714),

Early examples of concerti grossi

by the Italian violinist and composer Arcangelo Corelli. The basso continuo sometimes rested while the concertino played (a frequent procedure in Vivaldi's concerti). One significant consequence of the tutti–soli relationship and its opposition of weighty and light masses of sound was a tendency to sharpen the contrast with the popular Baroque device of "terrace dynamics," or blocks of contrasting loud and soft sound. This occurred especially in the echo effect of a soli passage played piano after a tutti passage played forte. To this dynamic contrast might be added the rhythmic contrast between steady, solid beats in the tutti and more intricate, quicker figures in the soli, growing out of that same tendency toward simplicity, on the one hand, and virtuosity, on the other. Furthermore, not only all of the melodic ornamentation but also most of the passagework were ordinarily given to the soli rather than the tutti. When the tutti strings were augmented by wind instruments and the concertino was reduced to two players or only one (resulting in the first solo concerti), all these oppositions became that much more pronounced. Attention may be called, too, to the artful highlighting of the contrasts through different spacing—that is, through varied alternations of the two groups, now frequent, now less frequent after longer passages.

Opposition and contrast

These several means of contrast provided by motive interplay hardly exhaust the sources of variety to be found in the Baroque concerto grosso. Much variety is achieved in another of its basic kinds of opposition or competition. This is the motivic (or imitative) interplay between parts that is so characteristic of the *stile concertato,* or concerted style.

Such interplay may occur either between tutti and soli choirs or entirely within a succession of single instrumental parts in the full orchestra. In fact, there are numerous Baroque "concerti" that thrive primarily on the latter style of continuity, without any tutti–soli designations at all (for example, Bach's *Brandenburg Concerto No. 3*). The employment of motivic interplay offers certain inherent contrasts of its own. These include shifts from one high or low range to another within a texture of interwoven melodies: rhythmic conflicts based on patterns that do not necessarily coincide with the regular musical metre; and an almost continuous change of key. The last is achieved by rapid successions of modulations (bridges from key to key) and drives to the cadence; *i.e.,* building up of tension in the harmonies used, culminating and relaxing in the cadence, or stopping point. In fast movements, when the propelling force is not such motivic interplay, it is likely to be a force achieved by outright statements of musical figures based on chords and scales. Or it may be an unfolding succession of figures together with the harmonic drive to the cadence. In slow movements it is likely to be compelling progressions of chords, enhanced by melodic ornamentation and enlivened by continual suspensions, dissonances, and resolutions (*i.e.,* by suspending single notes while the harmony around them changes; this creates dissonance, the tension of harmonies that seem to clash; the tension is "resolved" when the harmonies change again).

In spite of all this variety there are consistencies of style in the scoring and musical textures just described. In addition, certain additional rhythmic and melodic traits help further to bring a sense of overall unity to the concerto grosso. With regard to rhythmic traits, a steady motoric pulse is likely to prevail throughout the fast movements. Also, true to the nature of the ever-present basso continuo, a steady running bass line is likely to underlie both the slow and the fast movements. With regard to melodic traits, one cannot ordinarily speak of "main and contrasting themes" as in the classical and later concerto. One reason is the lack of individuality in the main thematic ideas. Corelli's and Vivaldi's themes, vigorous as they may be rhythmically, hardly stand out melodically from the remaining music. Like the musical context in which they occur, the themes themselves are likely to consist of chord notes, scales, or simple repeated notes. Frequently they are announced in unison (all parts playing the same notes) and thus lack a strong initial association with the harmonies of an accompaniment. Bach is exceptional for the individuality of his themes, especially in the finales, where they are usually out-and-out tunes, memorable and fetching (as in his *Violin Concerto No. 2 in E Major,* BWV 1042). The less a melodic idea stands out, the less it functions as a true "theme" or unifier when it recurs and the less it can contrast with any of the other melodic ideas.

Concerto grosso themes

Such relatively neutral themes and motives, which unfold more as supplements than as contrasts, seem to have satisfied most Baroque, especially North German, tastes, including the express preference for limiting any one piece or movement to but one "Affekt" (or characteristic emotion). In addition, and more important for musical continuity, the themes, such as they are, do tend to recur, not only at the more local level of melodic imitation and motivic interplay but also at certain strategic points in the musical structure. Their recurrence, most often at the three or four main tonal landmarks, imparts at least a vague overall outline of formal musical structure. In fact, these strategic recurrences, plus the melodic imitations, the passagework, and the adjunct musical themes that separate them, produce in a loose way the most prevalent structural principle of the fast movements. This is the rondo principle, which is based on the alternation of a refrain, or "ritornello," with contrasting musical passages. In the more tuneful finales, or final movements, the sense of a rondo "ritornello" is most distinct (as in Handel's Opus 6, No. 11). Generally, the alternations of refrains and intervening episodes tally with alternations of the tutti and soli groups, respectively.

Recurring melodic ideas account for two other of the most frequent principles of musical structure in the concerto grosso, those of fugue and of variation. A fugue is based on the polyphonic treatment (through extensive melodic imitation) of a recurring subject, or theme. In fugal sections of a concerto grosso, tutti and soli unite as one group or alternate in expositions (statements of the subject) and episodes (passages in which the subject appears only fragmentarily, if at all). The fugal style occurs largely in fast movements and varies from loose applications, especially among the Italians, to strict ones, especially among the Germans. The variation process depends on continual variation of a constant factor, such as a theme or a group of harmonies. In the concerto grosso it occurs largely in slow movements; its constant factor is a simple, freely recurring bass line, or ostinato (a short, repeated motive or melody). The ostinato often sounds alone in the tutti and may be played in unison at the beginning and end of the movement. It serves as a foil for the soli parts, which sometimes enter successively on long tones and gradually unfold into decorative, expressive passages (as in Bach's *Violin Concerto No. 2.*) When the ostinato's recurrences are free enough and the bass line and treble melody of the tutti stand out enough, the effect is that of an expressive aria (solo song, as in an opera) with a firm prelude and postlude (as in Vivaldi's Opus 3, No. 8), providing one of the many hints of operatic influences in the concerto grosso. To these structural types—rondo, fugue, and variation—may be added especially the binary design, with each half repeated, that prevails in Baroque dances. In binary form, the music of the first half moves from the tonic key to a closely related key. The second half begins in the new key and progresses back to the original key. Dances abound in concerti grossi, not only in those that are primarily orchestral suites or groups of related dance pieces (as are many by Handel) but in others as well. For instance, the finale of Corelli's Opus 6, No. 3, although headed only "Allegro," is a fine example of a binary gigue (a courtly dance ultimately derived from the jig).

Fugue and variation

The number of movements in the concerto grosso varies more than in the later solo concerto or in the sinfonia, symphony, and sonata at any time after the concerto grosso's emergence. But the average may be put at from three to five. Corelli and other Italian pioneers had led off with more movements (insofar as separate movements can be distinguished from mere sectional changes in their concerti). Vivaldi reduced the number, mostly by omitting an initial slow movement that his predecessors had probably derived from the French overture. Instead, Vivaldi largely settled on and, in fact, standardized the cycle at three movements in fast–slow–fast order. He may have been in-

fluenced by the same cycle in the Italian opera sinfonia (or overture). The Germans seem to have varied the number more, with the most movements likely to be made up of relatively short dances. Bach's six *Brandenburg Concertos* do follow the fast–slow–fast plan except that Number 1 adds two dances and No. 3 leaves out the slow movement, simply substituting in its place two slow chords that create a feeling of suspension. Handel's *Twelve Grand Concertos* in Opus 6 contain four to six movements that vary considerably in order and type.

Unity among movements

As usual in tonal music (music based on the system of major and minor keys), additional variety within unity is achieved in the cycle of concerto grosso movements through departure from and return to the home key. Much more often than in the suite, a slow inner movement is placed in a nearly related key. In the shortest, freest slow movements the tonality, or key orientation, sometimes remains uncertain and in flux, giving the sense of a bridge from the previous to the following movement (as in Vivaldi's Opus 3, No. 10). Unlike the Baroque suite and sonata, in the concerto the use of interrelated musical themes is not a frequent means of linking the movements. But the concerto grosso is like these other cycles in its dynamic tendency to progress from the more serious to the lighter movements. Infrequently a "program"—a story or nonmusical image—lends further unity to the cycle, as it does in the four concerti of Vivaldi's Opus 8 that are known collectively as *The Four Seasons.* Each of these concerti is tied closely to a sonnet describing one of the seasons. More often a special unity results from some unusual trait of musical style or use of an instrument. An example is the brilliant solo part given, exceptionally, to the "cembalo concertato" (*i.e.,* a harpsichord that participates with the other instruments in the melodic discourse rather than, as is normal, confining itself to the realization of the basso continuo) in Bach's *Brandenburg Concerto No. 5.*

Like the vocal-instrumental concerto before it, the concerto grosso originated and reached a first peak in Italy, then attained a further peak in Germany. French and English centres responded more than they contributed to it. Again, some of the main landmarks may be briefly noted. The 12 concerti grossi in Opus 6 by Corelli were not first published until 1714, the year after he died. Although they were preceded in print by other pioneer examples, like those of Torelli (from 1698), Tomaso Albinoni (from 1700), and even Vivaldi (from 1712), some of them may have been among the "several concertos" by Corelli that Muffat had already heard in Rome by 1682. Corelli still made the loose distinction, best known in the 17th-century sonata, between *da chiesa* and *da camera*—that is, church and court-style, or serious and light. The first eight of his concerti grossi are *da chiesa* (church-style), in four to seven movements, the last four *da camera* (court-style), in five movements. A trio setting of two violins and cello is specified for the *concertino,* and two violins, viola, and bass for the *concerto grosso,* "which may be doubled as desired." Between the two groups the opposition is not an antiphony of musical ideas but only a change of musical texture and sonority in the continuous unfolding of the short, tasteful, well-proportioned movements.

Vivaldi's more than 460 "Concerti" (written from about 1710 to 1740) bring the Italian contribution to full maturity, and they rank Vivaldi with his contemporaries Bach and Handel among the greatest masters of the concerto grosso. The maturity is marked by larger forms and broader musical architecture, including tighter organization of the rondo principle, and by more distinctive, energetic musical themes, at least rhythmically if not melodically. There is also greater brilliance and exploitation of idiomatic instrumental techniques, including *bariolage* (quick shifts from string to string) and broken chords for the solo violin. Another characteristic is the standardization, as noted earlier, of the three-movement cycle, fast–slow–fast. But if the cycle becomes standardized, with only infrequent exceptions, very little else is predictable about Vivaldi's imaginative, resourceful concerti. Least predictable of all is the scoring, which makes highly varied combinations of string and wind instruments—for example, a tutti of strings with cello and bassoon as the soli; or two oboes, two horns, bassoon, and violin as the soli; or viola d'amore (a violin-like instrument) and lute as the soli.

Starting with Muffat's concerti done under Corelli's immediate guidance, the spread of the instrumental concerto from Italy to Germany was as direct and wide as that of the vocal-instrumental concerto had been. French influences in Germany were considerable, too, especially where the suite touched the concerto. This was often true in the large, resourceful, and highly varied output of the German Georg Philipp Telemann. In Bach's approximately 25 concerti (about 1720–35) Italian influences are especially evident, quite apart from his unusual setting for harpsichord alone specifically entitled *Concerto in the Italian Style.* Again, Italian influence is reflected in the many concerti by Vivaldi and others that Bach transcribed and reworked for harpsichord or for organ. A rare opportunity to learn what mattered most to Bach in concerto structure is provided by a study of his changes in the Vivaldi models. Such changes include themes sharpened melodically and musical textures enriched by the addition of new melodic entries to contrapuntal passages or by more intensive interplay of musical motives. The designs of the musical forms themselves are pointed up by insertions of new musical material, deletions, and altered timing of phrases and entries. Bach summed up the Baroque concerto as he did the cantata, fugue, and other Baroque genres. Besides the transcriptions and the magnificent six *Brandenburg Concertos,* with all their own varieties of scoring, he left concerti in which the solo requirements are one violin; two violins; flute, violin, and harpsichord; violin and oboe; one harpsichord; two harpsichords; three harpsichords; and four harpsichords. The majority of the harpsichord concerti are further transcriptions and reworkings, some not yet tracked to their sources. For example, two of seven solo harpsichord concerti come from Bach's own solo violin concerti, and the concerto for four harpsichords comes from Vivaldi's Opus 3, No. 10, for four violins. These concerti, like the *Brandenburg Concerto No. 5* already noted, emphasize Bach's priority in giving the harpsichord prominence as a concerto solo instrument.

Bach's concerti grossi

Handel left around 35 concerti in all (about 1715–50), including three sets of organ concerti with oboe and strings; one set for strings and winds (Opus 3); one set in the tutti–soli setting for strings alone (Opus 6) that Corelli had used; and several concerti not in sets. Among the last are two works more properly classified in his day as trio sonatas (works usually for two violins and basso continuo but sometimes for orchestra). Transcriptions and reworkings figure in many of Handel's concerti, as in Bach's. Handel's concerto style, like that of his chief contemporary in England, the Italian violinist-composer Francesco Geminiani, is more progressive than Bach's in its frequent French dance influences and in its more open, less complex musical textures. Although imposing fugues can be found, the prevailing atmosphere in Handel's concerti is more often that of light, wide-spaced chamber music. Thanks to his unmatched skill, imagination, good timing, and almost childlike enthusiasm, there is also a feeling of extraordinary vitality, robustness, and breadth in the concerti, especially in the finest of the sets, the *Twelve Grand Concertos* (that is, concerti grossi as translated then), Opus 6. The exploitation of the tutti–soli opposition is less in Opus 3, although the instrumental scoring is more restricted in Opus 6. But in both sets the variety of instrumental combinations is exceptional, even from movement to movement. In Opus 3, No. 2, for example, the soli change from two oboes and two violins to solo oboe, then to two oboes doubling two violins and a viola, further to two oboes and two violins not doubled, and finally to two oboes and cello. Much as Bach had transcribed concerti for organ alone to serve as introductions to cantatas, so Handel played his own original and transcribed concerti for organ and orchestra as introductions and entr'actes in his oratorios. These organ concerti were widely copied by minor followers of Handel in England. Nothing in France close to Handel's level can be pointed to until near the end of the era, when a violinist and composer, Jean-Marie Leclair, produced his solo concerti.

Handel's concerto style

In the opening of this section "concerto" was defined as

it is thought of first today—that is, in the sense that has prevailed since about 1750. Essential to that definition is the interrelation of orchestra and soloist, not soli. Whereas a *concertino* of soli had been the norm before 1750, with a single soloist being a variant or reduction of the concertino idea, the single soloist became the norm after 1750. As a result two or more soloists became the exception in what has since become known as "double concerto," "triple concerto," and so on. Because the concerto since 1750 has been likened to the sonata (again, as in the opening definition), it is often distinguished as the "sonata concerto," although the same could have been done with at least as much justification, especially because of the confusions of terms noted earlier, for the concerto before 1750. More justified, in spite of all the exceptions, might be the designations "solo concerto" for the later type and "orchestral concerto" (or concerto grosso) for the earlier type. The concerto grosso may be said to have dissolved into the solo concerto and the sinfonia concertante. The second term was Mozart's designation for certain concerti with more than one soloist, but it has also been used for symphonies that still reveal the imitative interplay of the concerto grosso or that employ the tutti–soli rondo principle. There are differences between the earlier solo part, which was a minimal concertino, and the later solo part, which was a self-sufficient adversary to the orchestra. There is also a difference in scoring between the two types of concerto, for at the time that the concerto grosso was being replaced by the solo concerto the basso continuo was falling into disuse. In addition there is a difference of degree, with a sharp increase of independence and virtuosity in the soloist's part in the later form of the concerto.

The Classical concerto (c. 1750–1830). Since 1750 the concerto has found its chief place in society not in church or at court but in the concert hall. Some of the excitement it could arouse in classical musical life is recaptured in the Mozart family letters. Mozart's introduction of a new piano concerto (K. 456?) in a Vienna theatre concert was reported by his father on February 16, 1785:

The solo concerto

> . . . your brother played a glorious concerto, . . . I was sitting [close] . . . and had the great pleasure of hearing so clearly all the interplay of the instruments that for sheer delight tears came into my eyes. When your brother left the platform the Emperor waved his hat and called out "Bravo, Mozart!" And when he came on to play there was a great deal of clapping. (As translated by Emily Anderson, *The Letters of Mozart and His Family,* 2d. ed. The Macmillan Co., New York, 1966.)

The solo concerto was the main concert vehicle for composer-performers such as Mozart and for itinerant virtuosos like the Italian violinist Antonio Lolli, whose incessant crisscrossing of all Europe scarcely can be reconciled with the incredibly bad travel conditions that still prevailed. A secondary place for the solo concerto has been in the realm of musical instruction. Although the category of "student concerto" to which certain works have been relegated seems largely to associate with the 19th century, a good many classical concerti evidently served that purpose too. Thus, Mozart, who wrote his latest, finest, and most difficult concerti for his own concert appearances, earlier wrote easier ones to be used mainly in teaching. The concerto also had an occasional place in the theatre, as evidenced by the fact that the Italian composer Francesco Maria Veracini played concerto movements as entr'actes during operatic performances.

The strings remained the nucleus, though less often the whole, of the tutti in the solo concerto. But now the more equivoice setting of the string quartet gradually superseded the polarity of the basso continuo and the melody or concertante parts. Moreover, the tutti was no longer reinforced by the solo instrument in the tutti passages, as it had been in the concerto grosso, for the solo became exclusively a solo part. Though optional instrumentation disappeared insofar as the choice of instruments for the old basso continuo was concerned, the free use of what instruments were available still applied to the wind parts of the usual concerto tutti throughout most of the 18th century. The instrumental colour of solo concerti, up to Mozart's mature works, was therefore relatively neutral, without particular refinement or individuality caused by specifically exploiting the tone colours of the instruments. On the other hand, the solo part became increasingly individualized in the solo concerto as a result of the further exploitation of spectacular playing techniques. Accordingly, the music of the solo part became highly idiomatic for the chosen instrument; that is, it was calculated to take most advantage of the characteristic sound and techniques particular to that instrument. Solo violin parts in particular had already reached heights of virtuosity during the overlap between the Baroque and Classical eras. Such works were scarcely surpassed before the most brilliant writing of the violin virtuoso Niccolò Paganini and his successors in the Romantic era. Examples may be found in abundance in the solo violin concerti of Leclair and the Italians Pietro Locatelli, Veracini, and Giuseppe Tartini. Most of these works, especially Tartini's, have real musical distinction, rooted as they are in an important heritage from Torelli, Albinoni, and Vivaldi in Italy and Johann Georg Pisendel, Telemann, and Bach in Germany.

The rise of the piano

Yet, from the 1780s and the peak of the Classical era, and despite a continuing if limited output of concerti for the cello, flute, oboe, clarinet, bassoon, and horn, it was no longer the violin or any of these instruments that ranked first among solo instruments of the concerto. Rather it was the newly emerging piano, which was rapidly superseding the harpsichord and clavichord. Mozart, who with the London-centred, Italian-born Muzio Clementi was one of the first great pianists, wrote not only some of the first but some of the greatest concerti the instrument has yet known. Two generations earlier, Bach's more limited exploitation of the keyboard in his harpsichord concerti had already shown what a stalwart adversary a keyboard instrument could be in the concerto contest. Now, with the greater independence of the solo part and the greater self-sufficiency of a keyboard part, both the drama and the variety of the tutti–solo opposition could be increased considerably. As for the variety, either orchestra or soloist might perform alone, either might carry the theme while the other accompanied, or the two might share in the theme by doubling, by antiphony (alternating with each other in playing phrases of the theme), or by more rapid interchange and alternation. Thus, Mozart's popular *Concerto in A Major,* K. 488, begins with an extended orchestral tutti without soloist, after which the solo piano enters on a restatement of the main theme, lightly and intermittently accompanied by the strings alone. Another tutti, this time short, leads into a modulatory (key-changing) bridge consisting of rapid piano scales that elaborate on harmonies given in simpler notes in the tutti. The piano now enters alone on a second theme, then decorates snatches of the theme as the orchestra restates it an octave higher. So the work unfolds in a kaleidoscope of ingenious, fresh settings.

Movement cycles and forms

The standard cycle of three movements, fast–slow–fast, became even more standardized in the Classical era. It occurred without notable exception in the concerti of that era's three greatest masters, Haydn, Mozart, and Beethoven. Furthermore, the outer movements are generally predictable, too, at least in their overall plans. "Sonata form" is approximated in the opening movements. In the finales, apart from an occasional minuet (a dance form) in Haydn's concerti, the prevalent forms are rondo and sonata-rondo (which combines the recurrent refrain of the rondo with the exposition-development principle of the sonata). The middle movements are only a little less predictable, with A B A design being far in the majority (as in Mozart's *Concerto in D Minor,* K. 466). Forms such as the dialogue-like fantasy in Beethoven's *Piano Concerto No. 4 in G Major,* Opus 58, or the free variations in his *Violin Concerto* are late-Classical or pre-Romantic exceptions. But, of course, these masterworks are no stereotypes. They find their variety and distinctions in the details and working out of the forms. At most, "sonata form" in the Classical era was not yet the conscious concept or crystallized design that later textbooks have made it out to be. Its thematic organization in particular was still fluid and certainly not bound to any fixed number of themes or any fixed dualism of "masculine" and "feminine" themes. Textbook discussions of the solo concerto say that the tutti

plays the exposition first, all in the tonic key, after which the soloist joins to repeat it, this time more elaborately and with the contrasting theme in a nearly related key. But that concept of the strict "double exposition" is honoured as much in the breach as the observance.

Actually, the application of "sonata form" was likely to be freer, even looser, in the concerto than in the symphony or string quartet. In part this was because of the extensive passagework that is inherent in the virtuosity and idiomatic treatment of the solo instrument. This passagework and the loose treatment of the musical form reach their extreme in a terminal cadenza of the first movement, more so than in the shorter cadenzas likely to be found at one or more focal points in the other movements. The cadenza had already been introduced in late-Baroque violin concerti, undoubtedly influenced by singers' florid, improvised embellishments of arias in current opera, although early instrumental precedents exist, too. The concerto's cadenza was generally improvised by the performer until Beethoven insisted on the use of his own short cadenzas as supplied in *Piano Concerto No. 5 in E Flat Major,* Opus 73. Many later performers have found too little opportunity for technical display in other cadenzas that the masters previously had left for optional performance in some of their own concerti. The dissatisfied performers often substituted more brilliant cadenzas in such cases. But the structural looseness of the cadenza becomes less tolerable when the virtuoso performer goes to later sources or composes new cadenzas that are anachronistic in their technical and harmonic style, out of proportion in length, and inadequately related to the musical themes of the movement.

Improvised and written cadenzas

As with both the vocal and the instrumental concerto of the Baroque era, the starting point for the solo concerto in the Classical era lies in Italian music. But this time more weight must be attached to the evolution of the concerto in Germany and Austria. In these countries, there lies the more significant development, that of the piano concerto, as cultivated by the chief Classical masters.

The transition to the lighter texture and more fragmented musical thoughts of the pre-Classical "gallant style" may be credited in part to the Italian string concerti, notably those of Tartini, Giovanni Battista Sammartini, Luigi Boccherini, and Giovanni Battista Viotti. But the one piano concerto that Boccherini may have left about 1768, along with several cello concerti, and the very few concerti that Clementi in England supposedly converted to solo piano sonatas hardly make any niche for Italian composers in the history of the piano concerto. The full exploitation of the piano in the concerto and the creation of more substantial, consequential concerti for it must be credited primarily to two of J.S. Bach's sons and to the high-Classical Viennese triumvirate of Haydn, Mozart, and Beethoven. Whereas Wilhelm Friedemann Bach had largely followed his father in his half dozen concerti for harpsichord, strings, and basso continuo, Carl Philipp Emanuel Bach opened new paths in about 50 keyboard concerti, as well as some violin concerti and flute concerti. This is especially true of his later concerti intended for the piano (1772) rather than the harpsichord. Original instrumentation, dialogue between piano and orchestra, bold flights and expressive recitatives, are among the characteristics of Emanuel's concerti. So also are final movements that resemble in character the lively musical and dramatic development at the end of an act of opera buffa (Italian comic opera).

By contrast, Johann Christian Bach's 37 harpsichord or piano concerti from the same period are lighter, more fluent, easier works aimed at amateur skills and tastes. Most of them, like his sonatas but unlike most of his 31 sinfonie concertante, have only two movements, the finale often being a minuet or set of variations. The anticipations of Mozart's style are unmistakable.

Haydn left 36 concerti that can be verified, spanning the years from about 1755 to 1796; for violin (four); cello (five); bass; horn (four); hurdy-gurdy, or wheel fiddle (five); trumpet; flute; oboe; baryton, a cello-like instrument (three); and keyboard (11, whether for organ, harpsichord, or piano). In 1792 he also wrote a sinfonia concertante for violin, oboe, cello, bassoon, and full orchestra that returns to the tutti–soli relationships of the concerto grosso. The keyboard concerti bear witness in their unenterprising, sometimes pedestrian handling of the solo part that Haydn was no distinguished keyboardist. Even the best known of them, the *Piano Concerto in D Major* (1784), is heard today more in education than in concert circles, in spite of its musical strengths, especially in the "Rondo all'Ungherese" ("Rondo in the Hungarian style"). The one concerto by Haydn that is widely performed in today's concert world is an admirable, sonorous work for cello, in D major (1783, once attributed to the German cellist Anton Kraft). Cast in the usual three movements, with clear thematic ties between them and accompanied only by the usual orchestra in eight parts (four strings, two oboes, two horns), this work is variously songful, brilliant to a taxing degree, and dancelike. Another important contribution by Haydn was his last concerto (1796), a resourceful and difficult work in E-flat major that exploited the new keyed trumpet, which unlike earlier trumpets was capable of playing diatonic (seven-note) and chromatic (12-note) scales.

Haydn's concerti

During his short career, Mozart left about 45 verifiable concerti dating from 1773 to his last year, 1791. These do not include five early piano concerti arranged from concerto or sonata movements written by Emanuel and Christian Bach and two lesser composers. Out of the total, there are 21 for piano, six for violin, five for horn, two for flute, and one each for oboe, clarinet, bassoon, flute, and harp, two pianos, three pianos, and two violins (called *Concertone*). Two further examples, entitled "Sinfonia concertante," are for violin and viola, and for a concertino of oboe, clarinet, horn, and bassoon. Best known and most played are five of the last eight solo piano concerti (K. 466, 467, 488, 491, and 595), which rank among the finest of his works and the best of the genre. Highly valued and often played, too, are the *Sinfonia concertante in E Flat Major for Violin, Viola and Orchestra,* K. 364, E. 320d, and the *Concerto for Two Pianos,* K. 365, E. 316a. Two of the violin concerti are well-known (K. 218 in D major and K. 219 in A major), although more so to students than to concertgoers. Among those five solo piano concerti, that in D minor (K. 466) reveals a new urgency and compactness in Mozart's writing, reflecting the atmosphere of the *Sturm und Drang* ("Storm and Stress") period in German art, except in the naïvely charming "Romance" that is the middle movement. One among many instances of the striking tutti–solo contrasts in this work is the reservation of certain material, including the soloist's initial theme, for the soloist alone. The *Concerto in C Major,* K. 467, is a more cheerful work, broad and stately in its opening ideas, bubbling with intriguing melodic figuration, and capped by one of Mozart's most delectable rondos. The *Concerto in A Major,* K. 488, is rich in wistful songlike melodies. The spun-out line of the middle movement, in the rhythm of the siciliano (an Italian dance), makes an ideal foil for the gay, tuneful "Presto" that follows. Like the D-minor concerto, that in C minor (K. 491) is an intense work, more extended but even more driving. Mozart's last concerto for solo piano, that in B-flat major (K. 595), is another masterpiece, ever fresh in its ideas, yet with an air of sweet resignation in its almost neoclassical simplicity.

The concerti of Mozart

The much smaller output of concerti by Beethoven, anticipating the still smaller outputs by his 19th-century successors, is not surprising in view of the wider range of expression, further exploration of instrumental resources, and greater size of his concerti. There are nine complete works in all. These include seven with piano—the so-called standard five (1795–1809) plus one more from his boyhood and another, using chorus as well as orchestra, that is seldom performed, oddly constructed, and almost unclassifiable (*Choral Fantasia,* Opus 80, first performed 1808). Further, there is the *Violin Concerto in D major* (1806) and a worthy, but much less successful, *Triple Concerto in C Major for Piano, Violin, and Cello,* Opus 56 (1804). One could hardly find a wider range of expression than that between the third, fourth, and fifth (*Emperor*) piano concerti. Reduced to capsule, subjective terms, the third, in C minor, must be characterized as compelling drama, hushed serenity, and feverish drive in its respective

Beethoven's concerti

movements; the fourth as joyous lyricism, stark tragedy, and scintillating gaiety; and the fifth as heroic grandeur, noble dignity, and victorious rejoicing. The opening tutti sections may be taken as samples of the wide variety of musical structure in these same three concerti. In the third, the tutti extends the exposition of the themes by developing or discussing each after it is first stated. The solo enters almost at once, with only a short flourish, on the main theme. In the fourth concerto, the piano begins alone with a short, refreshingly simple pronouncement of the main theme, followed immediately by a surprising, tangential entrance of the orchestra. There unfolds a full exposition that discusses each theme even more than in the third concerto. This time the solo enters for the repeated exposition only after a more extended flourish, lasting 15 measures. In the last concerto, the soloist begins by embellishing each of the three primary harmonies in the orchestra with a separate cadenza. Only after this opening does there begin a complete tutti exposition that, in its discussion of the themes, is still more developed than in the fourth concerto. Not until the orchestral exposition is ended does the solo enter again to begin its highly virtuosic elaboration in a repeated exposition. It is such development throughout all parts of the musical forms, and not only in the "development sections," that accounts for the great lengths of *Piano Concerto No. 5* and the *Violin Concerto.* Notable are the exceptional technical difficulties in these two peerless masterpieces, which grow as much out of their musical complexities as out of the composer's evident desire to reveal new ways to utilize his solo instruments (especially the rapidly advancing piano, with its wider range, heavier action, and bigger tone).

The Romantic era (c. 1790–1915). Between the Romantic and the Classical concerto there occurred no such marked, relatively abrupt changes in form or style as were observed earlier here between the Classical and the Baroque concerto. The onset of the Romantic era was not signalled by any shift in the concerto's musical structure. Thus there was no stylistic change equivalent to the shift from the polyphonic interplay of short motives in the concerto grosso to the solo concerto's grouping of longer musical phrases in homophonic style (based on chords). Nor was there any shift in instrumental texture equivalent to that from the polarity of basso continuo and melody parts to a more equal distribution of voices or parts. Nor again was there any shift from the piano to another instrument as the preferred solo vehicle.

Gradual evolution of the genre

As with much other Romantic music, the Romantic concerto was marked by an extension or expansion of those same Classical trends in all directions. This development led eventually to their exaggeration and ultimately to their extremes or breaking points. The concerto as a genre became more than ever the ideal showpiece at public concerts, doing much for the composer's profit, the performer's triumph, and the listener's delectation. Indeed, Franz Liszt, the dominant composer-pianist of his time, distinguished between the concerto and the sonata, calling the first a public showpiece and the second a private, personal expression (in 1838, while questioning a publisher's title, *Concerto Without Orchestra,* for the Opus 14 of Robert Schumann, a title changed to *Piano Sonata No. 3 in F Minor*). Over the century, several 19th-century concerti won more popularity than was accorded to any earlier concerti. Time has influenced that preference but little, to judge from a listing, in order of popularity, of the 15 piano concerti most played in major U.S. concerts in the late 1960s: Beethoven No. 5, Tchaikovsky No. 1, Brahms No. 2, Beethoven No. 3, (Prokofiev No. 3, Modern era), Schumann, Rachmaninoff No. 2, Mozart K. 595, Grieg, Beethoven No. 4, Camille Saint-Saëns No. 2, Brahms No. 1, Chopin No. 2, Beethoven No. 1, and Liszt No. 1 (from statistics compiled by Broadcast Music Industries).

Concerto orchestration

Another expansion of Classical trends is seen in the concerto orchestra, with the larger number, greater variety, and more discriminating use of its instruments. It is true that only the thinnest possible "support" for the soloist sufficed for composer-performers such as the pianist Chopin, the violinist Paganini, and others whose musical thinking ranged but little beyond the spheres of their own instruments. But the orchestra developed the status of a genuine if not superior adversary of the soloist in newly resourceful orchestrations by composers of wider instrumental perspective. Examples of this exploitation of the orchestra include *Harold en Italie* (1834), a symphony with solo viola, by the French composer Hector Berlioz; *Piano Concerto No. 1 in E Flat Major* (published 1857), by Liszt; and *Burleske* (completed 1885) for piano and orchestra, by the German Richard Strauss. At the same time, the piano, as the ideal Romantic instrument, secured ever more firmly its Classical preeminence as the preferred solo vehicle of the concerto. Although the total output of violin concerti in particular was very great, there was a decided preponderance of piano concerti among all concerti that appeared on printed public concert programs. In turn, the use of the piano in concerti was one main incentive for further advances in piano construction. By the mid-19th century the instrument reached a peak very close to the sonorous, seven-octave, triple-strung, cast-iron framed behemoth that is the modern "concert grand." With its perfection came also the extension of keyboard technique to the last reaches of athletic dexterity. Evidence of such technical development includes the unreasonably difficult requirements of the three etudes ("studies") that comprise the huge unaccompanied *Concerto,* Opus 39, Nos. 8–10, by the French pianist-composer Alkan (Charles-Henri Morhange). It is also apparent in the more reasonable but no less difficult requirements in Rachmaninoff's *Piano Concerto No. 3 in D Minor,* Opus 30 (1909). The wind instruments used in concerto solos underwent mechanical advances, too, and both they and the stringed instruments enjoyed analogous exploitations of their technical possibilities in this century of virtuosos—not only of Liszt (and so many more) on the piano but of others such as Paganini on the violin, Alfredo Piatti on the cello, and Domenico Dragonetti on the double bass.

Romantic innovations

The most significant extension or expansion of the concerto principle in the Romantic era might in one sense be called a contraction, for it concerns a continuing effort to consolidate, interrelate, and fuse the over-all cycle, both within and between the movements. Certain composers, mostly forgotten perfunctories, yet including as important and successful a figure as Chopin, were satisfied to pour new wine into old bottles. Thus many concerti accepted without question the movement forms and cycle that by then had become self-conscious stereotypes, especially "sonata form" in the first movement. Brahms largely preferred to accept the traditional cycle and forms, too, but with the masterful individuality, flexibility, and logic that were needed to revitalize them. On the other hand, most of the Romantics whose concerti are still played sought to modernize and advance the traditional structural principles. These changes may be summed up in six categories.

First, there is the elimination, in the opening movement, of the long initial tutti section. This innovation corresponded to the elimination in the sonata of the previously customary repeat of the exposition, a change that had begun in Beethoven's late sonatas and had soon become general. Such is the pattern in Schumann's *Piano Concerto in A Minor,* Opus 54 (1845), in which the soloist enters at the outset and proceeds promptly to an almost constant interrelationship with the orchestra as the exposition unfolds but once.

Second, there is the interlocking of the movements, achieved by leading not only from one movement to the next without appreciable pause in time or sound but also without either a definitive cadence (stopping point made clear by the harmonies) or full break in the continuity of harmonies or tonality. Thus in the *Violin Concerto in E Minor,* Opus 64 (1844), of Felix Mendelssohn, a lone bassoon suspends one note of the final chord of the first movement. Preventing a pause in time or sound, it leads directly into the middle movement. Again, between the middle and final movements a brief interlude, midway in tempo, mood, and intensity, supplies the continuity and avoids any full break.

A third Romantic innovation is the effort to bind the cycle more positively through the use of related themes and motives in the successive movements. Such themes and

motives can be only melodic nuclei, as in the so-called basic motive employed by Brahms. Or they may be more extended melodic thoughts, such as are subjected to "thematic metamorphosis" by Liszt or "cyclical" treatment by the Belgian César Franck. (Both terms refer to the practice of transforming a theme melodically and rhythmically in various ways throughout the cycle of movements.) Among well-known examples is the tight thematic organization, with its final retrospective summary, in the four interconnected movements of Liszt's *Piano Concerto No. 1* (*Triangle Concerto,* published 1857), a work Liszt himself claimed to be innovational on this account.

Fourth, there are certain other, more incidental, yet effective means of unifying the cycle. These include the sense of culminating joy or triumph in those many concerti that change from a minor home key to its tonic major (for example, from A minor to A major) for the finale; or the consistency of musical textures caused by making all the movements similar in weight and style; or the stronger sense of return achieved by a finale that follows a middle movement characterized by a marked sense of departure or contrast.

"Program" concerti and fusion of movements

The remaining two categories of changes concern Romantic developments that go somewhat beyond expansions (or contractions) of Classical concerto traditions. As a fifth category, there is the extramusical unification of the cycle by means of a program—that is, a story or image. Unlike the Romantic sonata, the Romantic concerto abounds in examples. One of the earliest such examples is the image that the German composer Carl Maria von Weber identified with his *Konzertstück* (*Concert Piece*) for piano and orchestra (1821). Its four interconnected movements are said to describe a medieval lady's longing for her absent knight, her agonized fears for his safety, the excitement of his impending return, and the joys of reunion and love.

Sixth and last, there are numerous efforts to contract or consolidate the concerto cycle still more drastically, by fusion of movements. Four different solutions may be cited as representative. Tchaikovsky's *Piano Concerto No. 1 in B Flat Minor* (1875) follows a number of symphonies and sonatas of the period by integrating the slow movement with the scherzo (a lively movement that had become a rather frequent additional item in the cycle). Liszt's *Piano Concerto No. 2 in A Major* (published 1863) is a pioneer among the several concerti that reduce the separate movements to sharply contrasting sections within a single movement. Franck's *Variations symphoniques* for piano and orchestra (first performed 1885) substitute for the cycle a single movement based on a single principle of musical structure (in contrast to the distinct structures of distinct movements). And the Russian Nikolay Medtner's *Piano Concerto in G Minor* is a single, experimental variation of "sonata form." It consists, as he himself explains,

> of an exposition, [a short, transitional cadenza,] a series of [nine] variations on the two chief themes, constituting the development [section], and then the recapitulation.

Still other changes from the Classical to the Romantic concerto are concerned less with overall plans than with language and idiom: the characteristic harmonies, melodic styles, and manner of musical development. But such changes were not limited to the concerto. They touched all of Romantic music. Among them are fuller, more varied textures, greater use of the high and low extremes of instruments' ranges, and more sonorous, widespread spacing of sounds. Indicative of the third development was the significant change in piano writing from the Alberti bass in close position to the "um-pah-pah" bass and free arpeggiations in open position.

Romantic harmonies and nationalistic colour

In addition there was a marked new preference for minor keys as being almost indispensable to the intensity of Romantic feeling. There was also an increased use of chromatic harmonies (chords whose notes do not all belong to the key of the composition and that frequently seem to have a more expressive character). Similarly characteristic of the era were brief, temporary modulations whose functions were more colouristic than structural (*i.e.,* they were introduced more for the harmonic colour they embody rather than strictly as a means of changing keys). Another new development was the late-Romantic turn to nationalistic colours, introducing folk melodies or allowing folk music to influence melodies, harmonies, and rhythms. An example is the *Symphonie espagnole* for violin and orchestra (1875), by the French composer Édouard Lalo.

From beginning to end in the Romantic era, Germany reigned supreme in the concerto, both as leader and producer, as with all the major instrumental forms. The majority of the non-Germans whose concerti were more or less successful in their day were at least trained in Germany. Here, in one loose chronology, may be mentioned the most important of the Romantics from both in and out of Germany, along with their most important concerti, which generally are those with the best chance still of being heard today. The once successful piano concerti of the Czech Jan Ladislav Dussek and the Germans Johann Nepomuk Hummel and Ignaz Moscheles—all renowned virtuoso pianists—have given way to other early Romantic works. These include the *Konzertstücke* of Weber, two concerti by Mendelssohn, and, especially, two by Chopin and the one by Schumann. Mendelssohn's two piano concerti are rapidly slipping into the status of "student concerti" today, but his *Violin Concerto in E Minor* continues to hold top position in its class, along with the violin concerti of Beethoven, Brahms, and Tchaikovsky. These works followed and eclipsed the successes of Viotti, Paganini, the German Ludwig Spohr, and other violinist composers. Schumann left one of the era's few most played cello concerti, two others being the later ones by Saint-Saëns and the Czech Antonín Dvořák. As noted, Liszt was a pathbreaker with his two piano concerti. His other, more programmatic works for piano and orchestra are less played today, but they also exercised a variety of influences on such different late-Romantics as Grieg, Franck, the American Edward MacDowell, Rachmaninoff, Richard Strauss, and the Hungarian Ernő Dohnányi. Brahms's concerti, every one a highly popular masterpiece today, mark a peak for the era on the conservative side. They include besides the two piano concerti in D minor and B-flat major, the *Violin Concerto in D Major* and the *Double Concerto in A Minor* (with violin and cello as the solo instruments). Among later romantic concerti, though those onetime favourites for violin by Henri Vieuxtemps, Henryk Wieniawski, Max Bruch, Karl Goldmark, Aleksandr Glazunov, and Sir Edward Elgar have recently lost much ground in the concert hall, those of Dvořák, Saint-Saëns, the Finnish composer Jean Sibelius, and, especially, Tchaikovsky still hold strong. Similarly, while the piano concerti of the famed piano virtuoso Anton Rubinstein are all but forgotten, two (in G minor and C minor) out of the five by Saint-Saëns and the *Concerto No. 2 in D Minor* by MacDowell get occasional hearings, and those already mentioned by Tchaikovsky and Rachmaninoff remain among the most successful. Certain concerti are less likely to be heard at least partly because they are written for less usual solo instruments. These include works for bassoon by Weber; for clarinet by Spohr, Weber, and Ferruccio Busoni; and for horn by Weber and Richard Strauss.

The modern era (from about 1915). By and large, and up to about 1950, the concerto of the modern era has kept pace with the language and idiom of modern music. There has been little introduction of new principles, or new trends, or even further extensions of the structural changes that have been noted here in the Romantic era. If anything, it has turned back on itself. It has sloughed off the advances, if such they be, of the Romantic era and has reverted to styles and forms of the Baroque and Classical concerto. In so doing it has provided some of the most telling examples of the neo-Baroque and Neoclassical trends in modern music.

More explicitly, the modern concerto has kept pace with the breakdown in traditional tonality and various efforts to revitalize, bypass, or replace that comfortably secure system. It has shared in the modern erosion of the contrast between chords traditionally considered consonant (*i.e.,* bearing musical repose) and dissonant (*i.e.,* bearing musical tension), thus contributing to the release of endless new chord forms and progressions. And it has joined in perhaps the most basic trend; *i.e.,* the return from the

Changes in the soloist's role

Romantic and Classical tendency of groups of melodic phrases in predominantly homophonic textures to the Baroque ideal of interplay of melodic motives in predominantly polyphonic textures. But at the same time, the modern concerto has abandoned the gigantic orchestra, the massive technical requirements and extreme opposition of the solo part, and the decided preference for the piano as the ideal solo instrument. Similarly, it has abandoned the intensive effort to interconnect, consolidate, and contract the musical forms and has turned away from the frequent concern with extramusical programmatic content. The downgrading of virtuosity for its own sake has caused the soloist to become more a part of the orchestra again. Some modern works, such as *Piano Concerto No. 3 in C Major*, Opus 26 (1921), by Prokofiev, do continue to offer some of the formidable difficulties, glittering passagework, and soaring lyricism of the late Romantic concerto in the solo part. But even in these, the nature of the modern musical language permits the soloist generally to blend with the orchestra rather than to "do battle" with it, as has been said regarding Tchaikovsky's *Piano Concerto No. 1* and similar concert favourites of the Romantic era.

From the present limited perspective, no one country appears yet to have dominated the cultivation of the modern concerto. The total output has continued to be high, with nearly every composer of renown having contributed to it. Among representative German works that have won widest public endorsement—which, in the very nature of the solo concerto, must continue to be a main criterion—may be cited numerous concerti (mostly called "Chamber Music") that Paul Hindemith seems systematically to have written for almost every standard instrument as a solo, and for a variety of combinations. Both the Austrians Arnold Schoenberg and his disciple Alban Berg left 12-tone concerti for violin and Schoenberg left one for piano. (Twelve-tone music is based on a series or "row" of the 12 notes of the chromatic scale, chosen by the composer to serve as the melodic and harmonic basis for the composition.)

From France may be cited works by Claude Debussy for piano (*Fantaisie*) and for saxophone (*Rapsodie*); by Maurice Ravel for piano (two, of which one is for left hand alone) and for violin; and by Darius Milhaud for various instruments, even mouth organ, and various instrumental combinations, including percussion. From England there is a double concerto for violin and cello by Frederick Delius and there are various works by Sir Arnold Bax, Sir Arthur Bliss, Ralph Vaughan Williams, Sir William Walton, and Benjamin Britten. Among examples from the United States are successful concerti by George Gershwin, including *Rhapsody in Blue* for piano and jazz orchestra, and by Aaron Copland, whose *Piano Concerto* (1926) also exploits jazz. Of major importance have been solo or duo concerti by Prokofiev (five for piano, two for violin, and one for cello), the Russian-born Igor Stravinsky (two for horn, one for violin, one for oboe, and one for clarinet and bassoon), and the Hungarian Béla Bartók (four for piano and three for violin). Attention also should be called to the neo-Baroque *Harpsichord Concerto* (1926), by the Spaniard Manuel de Falla.

A special indication of neo-Baroque interest may be seen in the return on the part of a number of composers to the tutti–soli grouping, the motoric pulse, and the interplay of motives of the concerto grosso. Notable examples have been left by Bartók, Stravinsky, the German Max Reger, the Swiss-born Ernest Bloch, and the Austrian-born Ernst Krenek.

The present discussion of the modern era has concerned developments largely ending by about 1950, although occasional returns to what might already be called the "traditional (solo) concerto" have occurred since, as by John Cage, Leon Kirchner, and Elliott Carter in the United States; by the Argentine Alberto Ginastera; the French composer Olivier Messiaen; the Greek Yannis Xenakis; and the Russian Dmitry Shostakovich. In the main, from 1950 on, the pronounced swing of the avant-garde to electronic, computerized, and aleatoric, or chance music, has tended to do away with everything traditionally identified with "concerto," including the title itself. The only identifiable characteristic to remain is the basic idea of the group–solo relationship, as in several works by Karlheinz Stockhausen and Lukas Foss. That basic idea is essential not only to the concerto but to much other music. Whether it alone will survive in a way that still can be related to the venerable career of the concerto remains to be seen. (W.S.N.)

ELECTRONIC MUSIC

Definition and nature of electronic music

Although any music produced or modified by electrical, electromechanical, or electronic means can be called electronic music, it is more precise to say that for a piece of music to be electronic its composer must anticipate the electronic processing subsequently applied to his musical concept, so that the final product reflects in some way his interaction with the medium. This is no different from saying that a composer should have in mind an orchestra when he composes a symphony and a piano when he composes a piano sonata. A conventional piece of popular music does not become electronic music by being played on an electronically amplified guitar, nor does a Bach fugue become electronic music if played on an electronic organ instead of a pipe organ. Some experimental compositions, often containing chance elements and perhaps of indeterminate scoring, permit but do not necessarily demand electronic realization, but this is a specialized situation.

Electronic music is produced from a wide variety of sound resources—from sounds picked up by microphones to those produced by electronic oscillators (generating basic acoustical wave forms such as sine waves, square waves, and sawtooth waves), complex computer installations, and microprocessors—that are recorded on tape and then edited into a permanent form. Generally, except for one type of performed music that has come to be called "live electronic music" (see below), electronic music is played back through loudspeakers either alone or in combination with ordinary musical instruments.

This section covers both early experimentation with electronic sound-producing devices and composers' subsequent exploitation of electronic equipment as a technique of composition. Throughout the discussion it should be clear that electronic music is not a style but rather a technique yielding diverse results in the hands of different composers.

Historically, electronic music is one aspect of the larger development of 20th-century music strongly characterized by a search for new technical resources and modes of expression. Before 1945 composers sought to liberate themselves from the main Classical–Romantic tradition of tonal thinking and to reconstruct their thinking along new lines, for the most part either Neoclassical or atonal and 12-tone, in which a composition is built up entirely from a tone row consisting of all 12 notes of the ordinary chromatic scale.

This pre-World War II period was accompanied by substantial experimentation with electrical and electronic devices. The most important outcome for the composer was the development of a number of electronic musical instruments (such as the Hammond organ and the theremin) that provided new timbres and that laid the technical foundations for the future development of electronic music proper from about 1948 onward. The rapid development of computer technology has had its effect in music, too, so much so that the term computer music is replacing electronic music as the more accurate description of the most significant interaction between the composer and the electronic medium.

Electronic music is represented not only by a wide variety of 20th-century works, and not only by serious concert pieces, but also by a substantial literature of theatre, film, and television scores and by multimedia works that use all types of audiovisual techniques. Electronic music for theatre and films seems an especially appropriate replacement for a disembodied, nonexistent orchestra heard from a tape or a sound track. Electronic popular music has also won adherents. This mostly has consisted of arrangements of standard popular music for electronic synthesizers, the tentative use of electronic alterations by some of the more ambitious and experimental rock groups, and the preparation of recordings by innovative studio techniques.

History and stylistic development. *Beginnings.* During the 19th century attempts were made to produce and record sounds mechanically or electromechanically. For example, the German scientist Hermann von Helmholtz traced wave forms of regular sounds to check results of his acoustical researches. An important event was the invention of the phonograph by Thomas Edison and Emile Berliner, independently, in the 1870s and 1880s. This invention not only marked the beginning of the recording industry but also showed that all the acoustical content of musical sounds could be captured (in principle, if not in actuality at that time) and be faithfully retained for future use.

Cahill's pioneer work

The first major effort to generate musical sounds electrically was carried out over many years by an American, Thaddeus Cahill, who built a formidable assembly of rotary generators and telephone receivers to convert electrical signals into sound. Cahill called his remarkable invention the telharmonium, which he started to build about 1895 and continued to improve for years thereafter. The instrument failed because it was complex, impractical, and could not produce sounds of any magnitude since amplifiers and loudspeakers had not yet been invented. Nevertheless, Cahill's concepts were basically sound. He was a visionary who lived ahead of his time, and his instrument was the ancestor of present-day electronic music synthesizers.

The Italian Futurist painter Luigi Russolo was another early exponent of synthesized music. As early as 1913 Russolo proposed that all music be destroyed and that new instruments reflecting current technology be built to perform a music expressive of industrialized society. Russolo subsequently did build a number of mechanically activated *intonarumori* (noise instruments) that grated, hissed, scratched, rumbled, and shrieked. Russolo's instruments and most of his music apparently vanished during World War II.

Between World War I and World War II developments occurred that led more directly to modern electronic music, although most of them were technically, rather than musically, important. First was the development of audio-frequency technology. By the early 1920s basic circuits for sine-, square-, and sawtooth-wave generators had been invented, as had amplifiers, filter circuits, and, most importantly, loudspeakers. (Sine waves are signals consisting of "pure tones"—*i.e.*, without overtones; sawtooth waves comprise fundamental tones and all related overtones; square waves consist only of the odd-numbered partials, or component tones, of the natural harmonic series.) Also, mechanical acoustical recording was replaced by electrical recording in the late 1920s.

Invention of the electronic organ

Second was the development of electromechanical and electronic musical instruments designed to replace existing musical instruments—specifically, the invention of electronic organs. This was a remarkable achievement and one that absorbed the attention of many ingenious inventors and circuit designers. It should be stressed, however, that it was the objective of these organ builders to simulate and replace pipe organs and harmoniums, not to provide novel instruments that would stimulate the imaginations of avant-garde composers.

Most electromechanical and electronic organs employ subtractive synthesis, as do pipe organs. Signals rich in harmonic partials (such as sawtooth waves) are selected by the performer at the keyboard and combined and shaped acoustically by filter circuits that simulate the formant, or resonant-frequency, spectra—*i.e.*, the acoustical components—of conventional organ stops. The formant depends on the filter circuit and does not relate to the frequency of a tone being produced. A low tone shaped by a given formant (a given stop) is normally rich in harmonics, while a high tone normally is poor in them. Psychologically, one expects this from all musical instruments, not only organs but also orchestral instruments.

Some electronic organs operate on the opposing principle of additive synthesis, whereby individually generated sine waves are added together in varying proportions to yield a complex wave form. The most successful of these is the Hammond organ, patented by Laurens Hammond in 1934. The Hammond organ has odd qualities because the richness of its harmonic content does not diminish as the player goes up the keyboard. The German composer Karlheinz Stockhausen (in *Momente*, 1961–62), the Norwegian composer Arne Nordheim (in *Colorazione*, 1968), and a few others have scored specifically for this instrument.

New instruments in the 1920s

Third was the development of novel electronic musical instruments designed to supply timbres not provided by ordinary musical instruments. During the 1920s there was a burst of interest in building an extraordinary variety of such instruments, ranging from practical to absurd. The most successful of these were relatively few in number, were monophonic (*i.e.*, could play only one melodic line at a time), and survive chiefly because some important music has been scored for them. These are the theremin, invented in 1920 by a Russian scientist, Leon Theremin; the Ondes Martenot, first built in 1928 by a French musician and scientist, Maurice Martenot; and the trautonium, designed by a German, Friedrich Trautwein, in 1930.

The theremin is a beat-frequency audio oscillator (sine-wave generator) that has two condensers placed not inside the circuit chassis but, rather, outside, as antennas. Because these antennas respond to the presence of nearby objects, the pitch and amplitude of the output signal of the theremin can be controlled by the manner in which a performer moves his hands in its vicinity. A skilled performer can produce all sorts of effects, including scales, glissandi, and flutters. A number of compositions have been written for this instrument since the 1920s.

The Ondes Martenot consists of a touch-sensitive keyboard and a slide-wire glissando generator that are both controlled by the performer's right hand, as well as some stops controlled by the left hand. These, in turn, activate a sawtooth-wave generator that delivers a signal to one or more output transducers. The instrument has been used extensively by several French composers, including Olivier Messiaen and Pierre Boulez, and by the French-American composer Edgard Varèse.

The trautonium, like the Ondes Martenot, uses a sawtooth-wave generator as its signal source and a keyboard of novel design that permits not just ordinary tuning but unusual scales as well. Most of the music composed for this instrument is of German origin, an example being the *Concertino for Trautonium and Strings* (1931) by Paul Hindemith. In about 1950 a polyphonic version (capable of playing several voices, or parts, simultaneously) of this instrument was built by Oskar Sala, a former student of Trautwein and Hindemith, for preparing sound tracks in a Berlin film studio. These instruments have become virtually obsolete, however, because all the sounds they produce can easily be duplicated by electronic music synthesizers.

Tape music. With tape music the history of electronic music in the narrower sense begins. This history seems split into three main periods: an early (by now classical) period lasting from the commercial introduction of the tape recorder immediately following World War II until about 1960; a second period that featured the introduction of electronic music synthesizers and the acceptance of the electronic medium as a legitimate compositional activity; and the third period, in which computer technology is rapidly becoming both the dominant resource and the dominant concern.

Invention of the tape recorder

The invention of the tape recorder gave composers of the 1950s an exciting new musical instrument to use for new musical experiences. Fascination with the thing itself was the dominant motivation for composing electronic tape music. Musically, the 1950s, in contrast to the 1960s, were relatively introverted years: in all kinds of music, the focus of interest was technique and style, especially with the avant-garde. In time, the medium became fairly well understood, the techniques for handling it became increasingly standardized, and a repertory of characteristic and historically important compositions came into being. The burning issues were whether tape would replace live musicians; whether the composer was at last freed from the humiliations so often endured to get his music into the concert hall; and whether a new medium of expression had been created, quite different from and independent of instrumental music, analogous, say, to photography as opposed to traditional painting.

It became increasingly evident, however, that there was no reason to think that the electronic tape medium would eliminate instrumental performance by live musicians. Tape was increasingly regarded as something that could be—but did not need to be—treated as a unique medium. Thus the notion that the tape recorder could function as one instrument in an ensemble grew more and more popular. This conception obviated the visual monotony of an evening in an auditorium with nothing to look at but a loudspeaker. To this has been added a further stage of evolution, namely, live electronic music, in which the tape recorder and its tape is eliminated or greatly restricted in function, and transformations of the sounds of musical instruments are effected at the concert with electronic equipment. Not infrequently, this kind of performance environment also involves scores in which aleatory (chance, or random), improvisatory, or quasi-improvisatory musical guidelines for the manipulation of such equipment are supplied by a composer who prefers to let what happens just happen. Actually, it is open to question whether live electronic music is really an advance or a reversion to a more primitive state of the art, in the sense that it is the enhancement of the timbres of familiar instruments, rather than music conceived totally in terms of electronic media per se.

The first period of development was certainly one into which Europeans put the most consistent work. Tape music quickly gained recognition and financial support, and, before long, a number of well-equipped electronic music studios were established, primarily in government-supported broadcast facilities. Some important work was also done in the United States, but this was much more fragmentary, and not until after 1958 did Americans begin to catch up, either technically or artistically.

Establishment of electronic studios

In 1948 two French composers, Pierre Schaeffer and Pierre Henry, and their associates at Radiodiffusion et Télévision Française in Paris began to produce tape collages (analogous to collages in the visual arts), which they called *musique concrète.* All the materials they processed on tape were recorded sounds—sound effects, musical fragments, vocalizings, and other sounds and noises produced by man, his environment, and his artifacts. Such sounds were considered "concrete," hence the term *musique concrète.* To this Paris group certainly belongs the credit both for originating the concept of tape music as such and for demonstrating how effective certain types of tape manipulation can be in transforming sounds. These transformations included speed alteration, variable speed control, playing tapes backward, and signal feedback loops. Schaeffer however, opposed the use of electronic oscillators as sound sources, claiming that these were not "concrete" sound sources, not "real," and hence artificial and anti-humanistic.

Two of the most successful and best known *musique concrète* compositions of this early period are Schaeffer and Henry's *Symphonie pour un homme seul* (1950; *Symphony for One Man Only*) and Henry's *Orphée* (1953), a ballet score written for the Belgian dancer Maurice Béjart. These and similar works created a sensation when first presented to the public. *Symphonie pour un homme seul,* a descriptive suite about man and his activities, is an extended composition in 11 movements. *Orphée* is concerned with the descent of Orpheus into Hades.

The second event of significance was the formation of an electronic music studio in Cologne by Herbert Eimert, a composer working for Nordwestdeutscher Rundfunk (now Westdeutscher Rundfunk), who was advised in turn by Werner Meyer-Eppler, an acoustician from the University of Bonn. Eimert was soon joined by Karlheinz Stockhausen, who composed the first really important tape composition from this studio, the now-famous *Gesang der Jünglinge* (1956; *Song of Youth*). The Cologne studio soon became a focal point of the reemergence of Germany as a dominant force in new music.

At Cologne emphasis was immediately placed on electronically generated sounds rather than concrete sounds and on electronic sound modifications such as filtering and modulating rather than tape manipulation. Eimert and Stockhausen also published a journal, *Die Reihe* ("The Row"), in which appeared articles emphasizing the "purity" of electronic sounds and the necessity of coupling electronic music to serial composing (using ordered groups of pitches, rhythms, and other musical elements as compositional bases), which made no more sense than the Paris group's insistence on using only nonelectronic, nonserial material. This activity was part of the campaign of the 1950s that brought about the collapse of Neoclassicism (a style that drew equally on 20th-century musical idioms and earlier, formal types); the emergence of the Austrian composer Anton von Webern as the father figure of the new music; the development of total serialism, pointillism (a style making use of individual tones placed in a very sparse texture), and intellectualism; and an emphasis on technique. The examples set by these two studios were soon widely imitated in Europe. This trend continued in the 1960s, with many more studios, from modest to elaborate, being set up in almost every major urban centre in Europe. As time passed, the techniques and equipment in the newer studios became more standardized and reliable, and the rather peculiar issue of concrete versus electronic sounds ceased to concern anyone.

Stockhausen's first tape composition

In the United States the production of electronic music, until 1958, was much more sporadic. The only continuing effort of this sort was the project undertaken by two composers at Columbia University, Otto Luening and Vladimir Ussachevsky, to create a professional tape studio and to compose music illustrating the musical possibilities of the tape medium. Luening and Ussachevsky often collaborated on joint compositions. They gained particular attention for the composition of several concerto-like works for tape recorder and orchestra. In 1959 Luening and Ussachevsky joined with another U.S. composer, Milton Babbitt, to organize, on a much larger scale, the Columbia–Princeton Electronic Music Center, in which an impressive number of composers of professional repute have worked.

Other tape compositions in the early 1950s in the United States were largely those of individual composers working as best they could under improvised circumstances. One major composer who did so was Varèse, who completed *Déserts,* for tape and instrumental ensemble, in 1954, and *Poème électronique,* for the Philips Pavilion at the 1958 Brussels World's Fair. Another was John Cage, who completed *Williams Mix* in 1952 and *Fontana Mix* in 1958. Both Varèse and Cage had anticipated the electronic medium; Cage's *Imaginary Landscape No. 1* (1939) for RCA test records and percussion can well be regarded as a forerunner of current live electronic music.

Varèse's *Déserts*

With the establishment of the Experimental Music Studio at the University of Illinois in 1958 by Lejaren Hiller and the University of Toronto studio in 1959 by Myron Schaeffer, the formation of facilities for both production and teaching began to move forward. The number of studios in university music departments grew rapidly, and they soon became established as essential in teaching as well as composing.

The individual components may vary in a well-designed "classic" studio, but basically the equipment may be divided into five categories: sound sources (sine-wave, square-wave, sawtooth-wave, and white-noise generators; and microphones for picking up concrete sounds); routing and control circuitry (patch panels, switching boards, and mixers for coupling components together; amplifiers; and output connections); signal modifiers (modulators, frequency shifters, artificial reverberators, filters, variable-speed tape recorders, and time compression–expansion devices); monitors and quality-control equipment (frequency counter, spectrum analyzer, VU metres that monitor recording levels, oscilloscope, power amplifiers with loudspeakers and headsets, and workshop facilities); and recording and playback equipment, including high-quality tape recorders.

With this equipment the composer records sounds, both electronic and microphoned; modifies them singly or in montages by operations such as modulation, reverberation, and filtering; and finally re-records them in increasingly complex patterns. Inevitably, a major part of the composer's effort is tape editing, unless he is satisfied

with the crudest string of effects merely linked together in sequence. As in any other kind of music, the aesthetic merit of an electronic music composition seems to depend not only on musical ideas as such but also on the way in which they relate to one another and how they are used to build up a musical structure.

Integration of live instruments and recorder with performance ensembles

The integration of the tape has become a rather popular form of chamber music, if not of symphonic music. Varèse's *Déserts* is an early example of this. It is scored for a group of 15 musicians and a two-channel tape and consists of four instrumental episodes interrupted by three tape interludes. In other works the tape recorder is "performed" together with the remaining instruments rather than merely in contrast to them. The problems of coordination, however, can become overriding, for it is difficult for a group of performers to follow a tape exactly. Obviously, the tape dominates the situation, remorselessly moving along no matter what happens in the rest of the group.

Thousands of electronic tape compositions were in existence by the early 1970s, many of ephemeral interest. It is relatively rare for a composer to have established a reputation solely as a composer of tape music. Pierre Henry perhaps is an example, but in general the important names in instrumental music of the 1950s and 1960s are the significant contributors in electronic music, too.

Stockhausen remained in the forefront of electronic music composers with several important pieces following *Gesang der Jünglinge.* These included *Kontakte* (1959–60; *Contacts*), for tape, piano, and percussion, and *Telemusik* (1966), for tape alone. Luciano Berio and Bruno Maderna, both Italians, worked for a while at the Radio Audizioni Italia (now Radiotelevisione Italiana) studio in Milan. Besides *Différences* (1958–60), a composition for tape and chamber group, Berio's tape pieces include *Thema-Omaggio a Joyce* (1958; *Homage to Joyce*) and *Visage* (1961), which exploited the unusual voice of the American singer Cathy Berberian.

In the United States the Columbia–Princeton Electronic Music Center has had the greatest output, a long list of composers besides Luening and Ussachevsky having used its facilities. Tape music from the University of Illinois studio includes Salvatore Martirano's *L's GA* (1967), a savage political satire for tape, films, helium bomb, and gas-masked politico. The University of Toronto studio, in spite of its technical excellence, has not been well represented on discs. One Canadian piece that is very amusing, however, is Hugh LeCaine's *Dripsody* (1955), all the sounds of which are derived from the splash of a single drop of water.

Music synthesizers. Composing tape music by the classic method was neither easy nor free of technical pitfalls. A complex piece had to be assembled from hundreds or even thousands of fragments of tape. Splicing these sounds together consumed a vast amount of time and could also lead to an accumulation of errors and deterioration of the sound. Consequently, substantial efforts were expended to reduce this work load and at the same time improve quality. Music synthesizers were the first product of these efforts. They cannot, however, be regarded as more than an intermediate technological development because of later computer technology (see below).

In contrast to Cahill's period, by the 1950s the means finally existed to construct full-scale music synthesizers, starting with the RCA Electronic Music Synthesizers, designed by Harry Olson and Herbert Belar, research scientists working at the RCA Laboratories at Princeton, New Jersey. The first machine was introduced in 1955; a second, improved model was turned over to the Columbia–Princeton Electronic Music Center in 1959.

The basic advance of the RCA synthesizer was an information input mechanism, a device for punching sets of instructions into a wide roll of punched paper tape. The composer could at any time during the programming process interrupt this activity to listen to what had been punched, to make corrections, and to edit the material before making a final paper tape that then constituted the "master score" of the composition.

The composer whose name became particularly associated with the RCA synthesizer was Milton Babbitt. He had developed a precisely defined compositional technique involving total serialization (*i.e.,* of every musical element). When he became aware of the synthesizer, he was anxious to use it, because it gave him the opportunity to realize his music more precisely than had hitherto been the case. Among Babbitt's compositions created with this machine were *Composition for Synthesizer* (1961), *Vision and Prayer* (1961), *Ensembles for Synthesizer* (1963), *Philomel* (1964), and *Phonemena* (1974).

In about 1960 a new circuit, the voltage-controlled oscillator (VCO), attracted the attention of engineers interested in electronic music because the frequency of its output signal is proportional to an independently generated input voltage rather than being internally set. The response is immediate because no mechanical couplings or controls are required. Robert Moog was the first to design several types of compact synthesizers of moderate price that supplied an extended range of possibilities for sound manipulation. In addition to VCO's, which produce sine, square, sawtooth, and triangular waves, the Moog synthesizer contained white-noise generators, attack and decay generators (controlling a sound's onset and fading), voltage-controlled amplifiers, and band-pass filters and sequencers.

One major advance in sound manipulation provided by VCO's is frequency modulation; if the input is a periodic function, the output frequency will vary periodically to provide tremolos, trills, and warble tones. Moog's synthesizer soon had to compete with several other synthesizers of essentially the same design, the Buchla Electronic Music Box, the ARP, and the later, more sophisticated Prophet 10.

Design of the Moog synthesizer

These popular synthesizers eliminate much of the drudgery of tape splicing, but at a price. The range of timbres and processes is more limited because they operate by subtractive synthesis and impose transients that affect all partials (component vibrations) of a complex wave identically. An advantage of a harmonic tone generator built in 1962 by James Beauchamp at the University of Illinois, also from VCO's, was that it used additive synthesis—*i.e.,* it created sound by combining signals for pure tones (sine waves)—instead of removing partials from a complex signal. It was designed so that each partial of a sound could have its own entry point, its own rise time, and its own decay time. The improvement in tone quality was enormous, because the ear normally expects nuances such as higher partials that decay faster than lower ones. Salvatore Martirano's *Underworld* (1965) is a good example of music in which the tape was made largely by additive synthesis.

A composer closely associated with synthesizers is Morton Subotnik, who has produced a series of extended electronic music compositions, starting with *Silver Apples of the Moon* (1967). These pieces were created on the Buchla synthesizer, and any one of them demonstrates in relatively unmodified form the types of sounds one may obtain with these instruments.

The success of *Switched-on Bach*

A word should be said about realizations of instrumental music through synthesizers, notably an early, commercially successful album called *Switched-on Bach* (1968), arrangements made by Walter (later Wendy) Carlos on a Moog synthesizer. The record displayed technical excellence in the sounds created and made the electronic synthesis of music more intelligible to the general listening public. This is useful so long as it is realized that the materials on the record are arrangements of familiar music, not original compositions. (Carlos later created an original electronic score for the science fiction film *Tron.*)

Computer music. Perhaps the most important development in electronic music is the use of digital computers. The kinds of computers employed range from large mainframe, general-purpose machines to special-purpose digital circuits expressly designed for musical uses. Musical applications of digital computers can be grouped into five basic categories: data processing and information retrieval, including library applications and abstracting; processing of music notation and music printing; acoustical, theoretical, and musicological research; music composition; and sound synthesis. In all these fields considerable research and ex-

perimentation is being carried out, with sound synthesis perhaps being the most widespread and advanced activity. Dramatic illustrations of the growth of this work include the appearance of the periodical *Computer Music Journal,* the formation of the Computer Music Association, made up of hundreds of members, and the holding each year of the International Computer Music Conference. The 1982 conference dominated the Venice Biennale—one of the major festivals of contemporary music.

Computer composition. Composition and sound synthesis are complementary processes because the first may lead to the second. A composer may elect to use a set of compositional programs to produce a composition. He may then stop using a computer and print his results for transcription to instrumental performance. Alternatively, he may transfer his results directly into electronic sounds by means of a second set of programs for sound synthesis. Finally, he may desire only to convert an already composed score into sound. When he does this, he translates his score into a form that can be entered into a computer and uses the computer essentially as a data translator.

The first point to understand about computer composition is that, like electronic music, it is not a style but a technique. In principle, any kind of music, from traditional to completely novel, can be written by these machines. For a composer, however, the main appeal consists not in duplicating known styles of music, but, rather, in seeking new modes of musical expression that are uniquely the result of interaction between man and this new type of instrument.

At present, composers above all need a compiling language comprised of musical or quasi-musical statements and a comprehensive library of basic compositional operations written as closed subroutines—in effect, a user's system analogous to computer languages (such as Fortran) used by mathematicians. Two major obstacles stand in the way of building up an effective musical computer language. The first is the obvious one of allocation of sufficient time, money, and other resources. The second is defining what goes into the subroutine library; *i.e.,* of stating with precision the smallest units of activity or decision making that enter into the process of musical composition. Unlike mathematics, in which traditional modes of thinking prepared the way for such a definition of subroutines, in music the defining of "modules" of composition leaves even sophisticated thinkers much more at sea.

Earliest example of computer-composed music

The earliest example of computer-composed music is the *Illiac Suite for String Quartet* (1957) by two Americans, the composer Lejaren Hiller and the mathematician Leonard Isaacson. It was a set of four experiments in which the computer was programmed to generate random integers representing various musical elements, such as pitches, rhythms, and dynamics, which were subsequently screened through programmed rules of composition.

Two very different compositions, *ST/10-1,080262* (1962), by Yannis Xenakis, and *HPSCHD* (1968), by John Cage and Hiller, are illustrative of two later approaches to computer composition. *ST/10-1,080262* is one of a number of works realized by Xenakis from a Fortran program he wrote in 1961 for an IBM 7090 computer. Several years earlier, Xenakis had composed a work called *Achorripsis* by employing statistical calculations and a Poisson distribution to assign pitches, durations, and playing instructions to the various instruments in his score. He redid the work with the computer, retitled it, and at the same time produced a number of other, similar compositions. *HPSCHD,* by contrast, is a multimedia work of indeterminate length scored for one to seven harpsichords and one to 51 tape recorders. For *HPSCHD* the composers wrote three sets of computer programs. The first, for the harpsichord solos, solved Mozart's *Musical Dice Game* (K. 294d), an early chance composition in which successive bars of the music are selected by rolling dice, and modified it with other compositions chosen with a program based on the Chinese oracle *I Ching* (*Book of Changes*). The second set of programs generated the 51 sound tracks on tape. These contained monophonic lines in microtone tunings based upon speculations by the composers regarding Mozart's melodic writing. The third program generated sheets of instructions to the purchasers of a record of the composition.

Hiller has continued to develop compositional programming techniques in order to complete a two-hour cycle of works entitled *Algorithms I, Algorithms II, and Algorithms III.* Otherwise, interest in computer composition gradually has continued to grow. For example, Gottfried Michael Koenig, director of the Instituut voor Sonologie of the University of Utrecht in The Netherlands, has after a lapse of several years written new computer music such as *Segmente 99-105* (1982) for violin and piano. Related to Koenig's work is an extensive literature on theoretical models for music composition developed by the American composer Otto Laske. Charles Ames, another American, has written several works for piano or small ensemble that are less statistical and more deterministic in approach than most of the above. Clarence Barlow has written a prize-winning composition, *Çoğluatobüsîşletmesî* (1978), that exists in two versions—for piano or for solo tape. A different, but nevertheless important, example of computer music composition is Larry Austin's *Phantasmagoria: Fantasies on Ives' Universe Symphony* (1977). This is a realization, heavily dependent on computer processing, of Charles Ives's last and most ambitious major composition, which he left in a diverse assortment of some 45 sketch pages and fragments.

The borderline between composition and sound synthesis is becoming increasingly blurred as sound synthesis becomes more sophisticated and as composers begin to experiment with compositional structures that are less related to traditional musical syntax. An example of this is *Androgeny,* written for tape in 1978 by the Canadian composer Barry Truax.

Computer sound synthesis. The production of electronic sounds by digital techniques is rapidly replacing the use of oscillators, synthesizers, and other audio components (now commonly called analogue hardware) that have been the standard resources of the composer of electronic music. Not only is digital circuitry and digital programming much more versatile and accurate, but it is also much cheaper. The advantages of digital processing are manifest even to the commercial recording industry, where digital recording is replacing long-established audio technology.

Basic techniques for producing sounds with a computer

The three basic techniques for producing sounds with a computer are sign-bit extraction, digital-to-analogue conversion, and the use of hybrid digital–analogue systems. Of these, however, only the second process is of more than historical interest. Sign-bit extraction was occasionally used for compositions of serious musical intent—for example, in *Computer Cantata* (1963), by Hiller and Robert Baker, and in *Sonoriferous Loops* (1965), by Herbert Brün. Some interest persists in building hybrid digital-analogue facilities, perhaps because some types of signal processing, such as reverberation and filtering, are time-consuming even in the fastest of computers.

Digital-to-analogue conversion has become the standard technique for computer sound synthesis. This process was originally developed in the United States by Max Mathews and his colleagues at Bell Telephone Laboratories in the early 1960s. The best known version of the programming that activated the process was called Music 5.

Digital-to-analogue conversion (and the reverse process, analogue-to-digital conversion, which is used to put sounds into a computer rather than getting them out) depends on the sampling theorem. This states that a wave form should be sampled at a rate twice the bandwidth of the system if the samples are to be free of quantizing noise (a high-pitched whine to the ear). Because the auditory bandwidth is 20–20,000 hertz (Hz), this specifies a sampling rate of 40,000 samples per second though, practically, 30,000 is sufficient, because tape recorders seldom record anything significant above 15,000 Hz. Also, instantaneous amplitudes must be specified to at least 12 bits so that the jumps from one amplitude to the next are low enough for the signal-to-noise ratio to exceed commercial standards (55 to 70 decibels).

Music 5 was more than simply a software system, because it embodied an "orchestration" program that simulated many of the processes employed in the classical electronic music studio. It specified unit generators for the standard

wave forms, adders, modulators, filters, reverberators, and so on. It was sufficiently generalized that a user could freely define his own generators. Music 5 became the software prototype for installations the world over.

One of the best of these was designed by Barry Vercoe at the Massachusetts Institute of Technology during the 1970s. This program, called Music 11, runs on a PDP-11 computer and is a tightly designed system that incorporates many new features, including graphic score input and output. Vercoe's instructional program has trained virtually a whole generation of young composers in computer sound manipulation. Another important advance, discovered by John Chowning of Stanford University in 1973, was the use of digital FM (frequency modulation) as a source of musical timbre. The use of graphical input and output, even of musical notation, has been considerably developed, notably by Mathews at Bell Telephone Laboratories, by Leland Smith at Stanford University, and by William Buxton at the University of Toronto.

There are also other approaches to digital sound manipulation. For example, there is a growing interest in analogue-to-digital conversion as a compositional tool. This technique allows concrete and recorded sounds to be subjected to digital processing, and this, of course, includes the human voice. Charles Dodge, a composer at Brooklyn College, has composed a number of scores that incorporate vocal sounds, including *Cascando* (1978), based on the radio play of Samuel Beckett, and *Any Resemblance Is Purely Coincidental* (1980), for computer-altered voice and tape. The classic *musique concrète* studio founded by Pierre Schaeffer has become a digital installation, under François Bayle. Its main emphasis is still on the manipulation of concrete sounds. Mention also should be made of an entirely different model for sound synthesis first investigated in 1971 by Hiller and Pierre Ruiz; they programmed differential equations that define vibrating objects such as strings, plates, membranes, and tubes. This technique, though forbidding mathematically and time-consuming in the computer, nevertheless is potentially attractive because it depends neither upon concepts reminiscent of analogue hardware nor upon acoustical research data.

Another important development is the production of specialized digital machines for use in live performance. All such instruments depend on newer types of microprocessors and often on some specialized circuitry. Because these instruments require real-time computation and conversion, however, they are restricted in versatility and variety of timbres. Without question, though, these instruments will be rapidly improved because there is a commercial market for them, including popular music and music education, that far exceeds the small world of avant-garde composers.

Some of these performance instruments are specialized in design to meet the needs of a particular composer—an example being Salvatore Martirano's *Sal-Mar Construction* (1970). Most of them, however, are intended to replace analogue synthesizers and therefore are equipped with conventional keyboards. One of the earliest of such instruments was the "Egg" synthesizer built by Michael Manthey at the University of Århus in Denmark. The Synclavier later was put on the market as a commercially produced instrument that uses digital hardware and logic. It represents for the 1980s the digital equivalent of the Moog synthesizer of the 1960s.

The most advanced digital sound synthesis, however, is still done in large institutional installations. Most of these are in U.S. universities, but European facilities are being built in increasing numbers. The Instituut voor Sonologie in Utrecht and LIMB (Laboratorio Permanente per l'Informatica Musicale) at the University of Padua in Italy resemble U.S. facilities because of their academic affiliation. Rather different, however, is IRCAM (Institut de Recherche et de Coordination Acoustique/Musique), part of the Centre Georges Pompidou in Paris. IRCAM, headed by Pierre Boulez, is an elaborate facility for research in and the performance of music. Increasingly, attention there has been given to all aspects of computer processing of music, including composition, sound analysis and synthesis, graphics, and the design of new electronic instruments for performance and pedagogy. It is a spectacular demonstration that electronic and computer music has come of age and has entered the mainstream of music history.

In conclusion, science has brought about a tremendous expansion of musical resources by making available to the composer a spectrum of sounds ranging from pure tones at one extreme to random noise at the other. It has made possible the rhythmic organization of music to a degree of subtlety and complexity hitherto unattainable. It has brought about the acceptance of the definition of music as "organized sound." It has permitted the composer, if he chooses, to have complete control over his own work. It permits him, if he desires, to eliminate the performer as an intermediary between himself and his audience. It has placed the critic in a problematic situation, because his analysis of what he hears must frequently be carried out solely by ear, unaided by any written score. (L.Hi.)

Vocal music

Music for voices encompasses a broad variety of genres for solo voice and voices in combination, with or without instrumental accompaniment. It includes monophonic music (having a single line of melody) and polyphonic music (consisting of more than one simultaneous melody). This section deals with Western art music preserved in staff notation, either for a single solo voice or for voices in unison, and briefly discusses the differences between Western and non-Western traditions. It excludes the complex forms of opera, oratorio, cantata, mass, and requiem, in which solo singing is frequently combined with choral music. The earliest written examples date from the 10th century, prior to which music was transmitted principally by oral tradition.

GENRES OF VOCAL MUSIC

Medieval and Renaissance periods. The chant most important for Western music is the so-called Gregorian repertory, earliest preserved in French manuscripts beginning from *c.* 900. Music for other major early medieval Latin repertories either has not survived (old Frankish, or Gallican, chant), is indecipherable (Mozarabic chant from Spain), or did not serve as the basis for later musical development (Ambrosian chant from Milan).

French development of Gregorian chant

From *c.* 750 to 850, music and musicians moved freely between the north and south with the intention of transferring Roman chant to France, but the methods and the extent of the process cannot be documented. The French greatly expanded their repertory until *c.* 1150 through the addition of both melodies and texts. Particularly important for future developments in vocal music were the new hymns, sequences, and other poetic settings, which were organized into regular stanzas with rhymes and metrical patterns. Gregorian chants not only served a liturgical function but also provided source material for much of the polyphonic music of the Middle Ages and Renaissance.

The degree of elaboration in a particular chant melody generally relates to its function within the liturgy. In chants that serve for recitations, such as psalms, lessons, or prayers, the music is secondary to a clear projection of the text; these settings are predominately syllabic (*i.e.*, only one note per syllable) and use relatively few pitches. Somewhat more ornate are melodies that accompany a liturgical action (such as processionals or communions in the mass), while chants completely independent of these functions, such as mass graduals and alleluias, tend to become the most elaborate. In these last two types, settings vary from neumatic (two to five notes per syllable) to highly melismatic (many notes per syllable).

Unlike the Gregorian repertory, the medieval chants of the major Eastern churches no longer continue as living traditions. The Byzantine liturgy, codified by the 11th century, has been subject to continual change since the fall of Constantinople in 1453. The early chants, preserved in manuscripts from the 11th to the 15th centuries, show fascinating parallels with the Gregorian repertory, suggesting close relationships or common origins between the two liturgies. Other Eastern churches developed independent chant repertories: Coptic (Egyptian), Abyssinian, and

Armenian; but written sources for these chants are either nonexistent or presently indecipherable. Russian (*znamenny*) chant evolved from the Byzantine liturgy imported in the 10th century and reached a classical stage in the 15th–17th centuries; but the only legible manuscripts date from the end of this period.

Latin songs by wandering scholars as early as the 7th century survive in a musical notation now unreadable. But the largest repertories of monophonic songs come from the troubadours in southern France (late 11th to early 13th centuries), the trouvères in northern France (mid-12th through 13th centuries), and the German minnesingers (mid-12th to late 15th centuries). These musicians and poets from all classes of society composed and performed for the nobility until well into the 13th century, after which patronage gradually shifted to the bourgeoisie and prosperous clergy. Their texts most frequently treat the ideals of chivalry and courtly love, using polished and often obscure language; at times similar poems offer praise to the Blessed Virgin. Service songs, called *sirventes* in southern France (*Spruch* in German), deal with didactic, political, or personal matters, perhaps in a satirical fashion. Other texts record events of the court, such as marriages, deaths, or participation in crusades. Among the more traditional songs from northern France are the *chansons de geste,* extended narratives glorifying earlier heroes or saints.

Poetic form and music

The poetic texts inherited strophic (stanzaic) design, rhyming, and metrical schemes from earlier medieval Latin. To these devices the trouvères added the idea of a refrain, varying in length from a single word to several poetic lines and placed at any position within the stanza. Eventually certain arrangements became fixed forms: the *ballade* or German *Bar* form (a a B), the *rondeau* (A B a A a b A B), and the *virelai* (A b b a A). In the diagrams, identical letters indicate same rhymes, and capitals show the refrain; as a rule, two sections of music are repeated according to the design of the poem. Shown here in their simplest structures, the forms were regularly expanded or varied in detail. Less standard designs were the *lai* in northern France (*Leich* in German), with irregular groupings of couplets, and the lengthy *chansons de geste,* probably repeating a simple melodic formula for each text line.

Many monophonic songs resemble Gregorian chant, although without lengthy melismas. Others present a more modern sound through the use of the major scale and organization in short symmetrical phrases. Most of the earlier songs (before 1200) have no written indications of metre. Recent scholarship suggests a free rendition for songs with irregular phrasing and embellishments but more regulated rhythms for the simple dancelike tunes. Improvised accompaniments are often appropriate, although not indicated in the original manuscripts.

Vernacular songs spread to the courts of England, Spain, and Italy, although the surviving examples from these regions are primarily religious. The monophonic art eventually declined during the 14th century for three principal reasons: the rise of interest in polyphonic composition, the loss of aristocratic patronage, and the substitution of theoretical rules for creative instinct. The last phenomenon is best illustrated in the works of the German middle class meistersingers from the 15th and 16th centuries.

Polyphonic settings of fixed-form songs

The most characteristic and persistent type of early polyphonic song is the French chanson, in the form of a *rondeau, ballade,* or *virelai.* Chanson composers included the most outstanding musicians of the 14th and 15th centuries, among them Guillaume de Machaut, Guillaume Dufay, Gilles Binchois, Antoine Busnois, and Jean d'Okeghem. Their activities centred in the courts of France and Burgundy, although many travelled to other areas, particularly Italy and northern Spain. Indigenous forms developed in the 14th century in Italy (*madrigal, ballata,* and *caccia*), and in the 15th century in Spain (*villancico* and *romance*), England (carol), and German (*Bar*); but these types shared many features of the Franco-Burgundian compositions. The chanson consists of two principal sections of music, with no text repetition except as required by the poetic structure. Three contrasting voices are standard: cantus, tenor, and contratenor. The cantus typically moves in a high tenor or alto range, in counterpoint with the lower tenor. To this two-part framework is added the contratenor, at times following the style and range of the cantus but at other times that of the tenor. Although most performances undoubtedly combined the voice(s) with instruments, it is by no means certain how the parts were distributed. Evidence suggests that performances were quite flexible, depending upon the singers or instruments available and upon the style of the individual song.

During the later 15th century new ideals for vocal composition arose that were incompatible with the earlier fixed-form songs. The different voice parts, now at least four in number, tended toward more equalization in style. All voices were underlain with a text, or were potentially singable; they either imitated the same melody or had similar rhythmic and melodic characteristics. Poetic structure was now obscured by a continuous overlapping of sections, and the words of the text were often blurred by the activity of the various voices. Native Italian partsongs (*frottole,* carnival songs, and *villanelle*) generally presented texts with clearer declamation, but, as the century advanced, even these simpler types gave way to the more complex Renaissance madrigal, with frequent use of melodic imitation. Musicians regularly arranged these polyphonic works for solo performance with instrumental accompaniment. But no significant part of this artistic repertory, with the possible exception of Spanish *vihuela* songs, was designed exclusively for the solo singer.

Transition to a new style

The advent of the modern art song depended upon a rejection of two prevailing attitudes found in mid-16th-century polyphony: the principle that a piece of vocal music was performable in any conceivable medium (for solo, for ensemble of voices, or even for instruments alone) and the idea that the text needed only be the servant of the music. An increasing concern for textual interpretation and declamation began to appear in late 16th-century polyphonic compositions. Texts were often delivered in a speechlike recitation; emotionally charged words were emphasized through special rhythms, unexpected harmonic progressions, chromaticism (use of notes foreign to the song's mode), and coloratura (florid ornamentation); and simultaneous rhythms in the different voices made possible a clearer projection of the words. Of more temporary influence were the French experiments with quantitative metre in poetry and music (*musique mesurée*). But the final step in the transfer of these various techniques from part music to genuine solo music came at the end of the century, notably in Italian monody (expressive melody with chordal accompaniment) and English lute songs.

The 17th–20th centuries. The art song of the 17th through 20th centuries always reflects the mutual influences of music and literature, and most enduring masterpieces show an extraordinary sensitivity of the composer to the individual words, to the prosody, or simply to the overall character of his text. The poet Goethe felt that the simpler the musical setting, the more likely it was to reflect the original nature of the poem; any extensive musical elaborations often reinterpreted the message or character of the poem and were therefore undesirable. But the more imaginative composers, particularly those of the 19th and 20th centuries, used the full resources of their art to embellish the text or even to realize potentials that were not explicit in the original.

Ages producing great poetry have often prompted a flourishing of important song writing, as Elizabethan England, 19th-century Germany and Austria, and late 19th- through early 20th-century France. Since the early 19th century, composers have frequently selected a group of poems by a particular author or on a single topic by different authors to produce a collection of related songs. Some of these cycles are undoubtedly designed to be performed as integrated compositions. As examples, Beethoven's *An die ferne Geliebte* (*To the Distant Beloved*) musically relates the opening with the closing of the cycle and joins each song to the next without interruption; individual songs in Schumann's *Frauenliebe und Leben* (*Woman's Love and Life*) and Brahms's *Magelone* present lyrical moments within a continuous narrative.

Song cycles

Three methods are possible for setting strophic poetry.

Methods for strophic setting

Simple-strophic setting consists of a single piece of music to be repeated for all stanzas. Modified-strophic setting retains the same musical framework for each stanza but with changing details in the voice and accompaniment to suit the progressing text. Through-composed setting proceeds to a different musical plan for each new stanza. The simple-strophic approach is effective if the entire poem suggests a central mood that can be captured in the music or if the composer creates a neutral setting that avoids detailed text illustration. Prosody and syntax must follow a regular pattern in each stanza if the result is to be satisfactory. Thus in Franz Schubert's "Das Wandern" ("Wandering) from the cycle *Die schöne Müllerin* (*The Miller's Beautiful Daughter*), the accompaniment suggests the continual flow of the millstream, while the energetic vocal melody reflects the enthusiasm of the young traveller. The singer's rhythm is easily adaptable to each stanza of text.

Either the modified-strophic or the through-composed method is more likely to be successful for poems that contain widely differing moods in each stanza, progress to a dramatic climax, or follow irregular prosodic patterns. In the modified-strophic setting of "Der Lindenbaum" ("The Linden Tree"), from the cycle *Winterreise* (*Winter Journey*), Schubert changes from major to minor for the stanza suggesting bitter recollections, gives a more dramatic interpretation to both the voice and piano for references to the chilling winter wind, and, finally, repeats the music for the opening stanza but with modifications in the piano when the thoughts return to pleasant memories. The through-composed approach does not necessarily require new musical ideas for all parts of the song; the crucial distinction is the lack of any structural correspondence between the stanzas of text and the sections of music. Although the vocal lines in each stanza of Claude Debussy's "C'est l'extase langoureuse" ("This Is Langorous Ecstasy") are entirely different, the piano unifies the setting by frequently returning to its opening motive. The art song since the late 19th century and simple strophic works from earlier periods normally provide a straightforward setting that avoids any word repetitions. The frequent text repetitions in many art songs from the 17th through mid-19th centuries generally indicate a predominance of musical over textual considerations, a feature also important in the operatic or concert aria.

Speech rhythms and prosody

In setting a text to a vocal melody, the composer may choose to present his interpretation of the natural speech patterns in the poem; in his solution, the rhythmic complexity, the melodic range of tones, and variations in volume will depend ultimately upon his own musical language. Also open to the composer's interpretation is the versification of the poem. The music may reflect whatever prosodic principles are present in the language: poetic feet, qualitative or quantitative accent, or mere count of syllables. Although some vocal settings show a complete preoccupation with speech inflections (strict recitatives of the 17th century) or with prosody (*musique mesurée* experiments in the late 16th and early 17th centuries), most successful songs incorporate either or both of these considerations into a melodic line that is satisfying because of musical qualities as well. Hugo Wolf's "Kennst du das Land" ("Do You Know the Land") faithfully reflects the iambic feet (⏑′) of Goethe's poem, but this prosodic awareness is combined with a sensitivity to the important words in the text. Furthermore, the melody progresses to a musical climax, as Wolf prepares for his setting of the high point of the poem. Even in works in which the text is obviously the servant of the music, a neutral treatment of rhythm and pitch usually avoids glaring distortions of the words. In the final portion of Arnold Schoenberg's "Sommermüd ("Weary of Summer") Opus 48, the pitches in the vocal melody are entirely determined by the 12-tone row (composer's ordering of the 12 notes of the chromatic scale) chosen for the whole song; yet the rhythm generally follows that of the poem.

Continuo accompaniment

The nature and role of the accompaniment has undergone many changes since the earliest art songs. In the repertory of the 17th and 18th centuries, the singer is the prime interpreter of the text. As a rule, the accompanying part of these songs consists only of a figured bass (the basso continuo), in which the notation for the bass melody also indicates the harmonies to be improvised on the harpsichord, lute, or some other chord instrument. Except for an occasional imitation or anticipation of the voice or for interludes between the stanzas, the continuo accompaniment provides little commentary on the poem. Even when these early songs call for additional instruments, such as a flute or violin, or when the harmony is fully written out, as in 17th-century lute songs, the accompaniment only supports or imitates the voice. Complete piano parts regularly appear first in the late 18th century, replacing the abbreviated continuo. Although some piano accompaniments continue a subservient relationship to the voice, the trend in the 19th and 20th centuries has been toward greater participation in the interpretation. The piano may reinforce the emotional states of the poem; *e.g.,* underlying anxiety in Wolf's "In der Frühe" ("In the Early Morning"); represent external details in the setting, as the spinning wheel in Schubert's "Gretchen am Spinnrade" ("Gretchen at the Spinning Wheel"); or assist in building dramatic climaxes, as in Wolf's "Kennst du das Land." It may provide extensive preludes, as in Richard Strauss's "Morgen" ("Morning"), interludes or postludes, as in Schumann's "Alten, bösen Lieder" ("Old, Evil Songs") from *Dichterliebe* (*Poet's Love*), or complete the phrasing in the voice; *e.g.,* Schumann's "Nussbaum" ("Nut Tree"). In the present century, the piano frequently follows its independent ideas, freeing the voice for more expressive declamation, as in Maurice Ravel's *Histoires naturelles,* in which the instrument effectively portrays the various animals in the texts. Many songs from the 19th and 20th centuries, particularly the period *c.* 1880–1920, have either alternative or original accompaniments for orchestra (*e.g.,* by Gustav Mahler, Strauss, Schoenberg, Alban Berg, Anton Webern, Ravel, and many others). Such settings enrich the texture and make possible a much greater range of colouristic effects. Other 20th-century songs require small chamber ensembles. The instruments may provide interpretative details, as in Ravel's *Chansons madécasses* (*Madagascan Songs*) or simply complement the musical ideas of the voice, as in Webern's chamber songs for various combinations.

Role of the piano

The concert aria, primarily an 18th-century composition with orchestral accompaniment, was originally intended either as an independent showpiece, as a substitute aria for an operatic production, or as a special number, called *licenza,* to follow a performance. Usually composed for a specific singer, the aria was generally more concerned with displaying vocal qualities than with interpreting the literary details of the text. Consequently, the poems are concise, with each verse typically repeated many times throughout a setting. The structure follows the same designs of the operatic aria. Most characteristic is the *da capo* plan, consisting of two contrasting sections of music: after the second section, the performers repeat the first, this time with more elaborate embellishments improvised by the singer. Another plan, popular in the later 18th century, is the composite design, consisting of several different sections with contrasting moods, usually with a brilliant conclusion. In both the *da capo* and composite forms, the composer represents a minimum of stereotyped emotional states, generally one for each section of music. A single tempo and metre are maintained for each section. If the aria is preceded by a recitative, the entire composition becomes a dramatic scene (*scena*).

The concert aria's influence

The concert aria was so influential a form that many continuo songs followed its structure and style. Henry Purcell's "Ye Gentle Spirits of the Air, Appear" (published posthumously in 1702) is in *da capo* structure, with textual repetitions and difficult coloratura, but it is also an objective musical portrayal of the words "repeat" and "trembling." Such text painting, characteristic of the earlier madrigal genre and sometimes found in arias, is exceptional in the general literature of the art song.

The solo voice has at times been used within works that are primarily instrumental, as an imposing climax to a symphonic composition (the finales of Beethoven, *Symphony No. 9;* Mahler, *Symphonies Nos. 2* and *3;* and Franz Liszt, *Faust Symphony*—each example using a chorus as

well); as an incidental commentary to introduce completely instrumental movements (Hector Berlioz, *Roméo et Juliette*); as the primary participant in a song movement with a symphonic or chamber work (Mahler, *Symphonies Nos. 2–4*; Schoenberg, *Quartet No. 2* and *Serenade*, Opus 24); and as an inconspicuous member of an otherwise instrumental ensemble, as in the finale of Pierre Boulez's *Marteau sans maître* (*The Hammer Without a Master*), where the voice generally has a humming part. Two other of Mahler's symphonic compositions have more extensive vocal participation: *Das Lied von der Erde* (*The Song of the Earth*), labelled "A Symphony for Tenor, Contralto (or Baritone), and Orchestra," where one or the other soloist is heard in each movement, and *Symphony No. 8*, employing voices (solo or choral) throughout; the finale of the latter work has the spirit of an oratorio.

Vocal compositions with no articulated text are called vocalises (*vocalizzi* in Italian). Although such works have been traditionally used as exercises, many 20th-century composers have written concert vocalises as well, among them Ravel, Sergey Rachmaninoff, and Igor Stravinsky. Vocalises are particularly suitable for chamber compositions, since the voice without text is easily adapted to the level of the other instruments.

THE REPERTORY SINCE 1600

Continuo Lieder and concert arias

Art songs in German, French, and English. The most important German songs (Lieder) of the 17th century were continuo Lieder used for informal entertainment, notable composers being Heinrich Albert and Adam Krieger. With the rising prestige of opera in the later 17th century, these simple Lieder declined in favour of extended virtuoso songs and concert arias, such as Handel's nine *Deutsche Arien* (*German Arias*) of *c.* 1729. The concert aria eventually reached a peak in the late 18th-century works of Mozart and Haydn. At the same time, three counterdevelopments pointed toward the future for the German Lied: a reaction against the superficialities of the operatic aria, the availability of a new repertory of lyric poetry, and an increasing use of the keyboard (eventually the piano) as an expressive accompaniment. First to reflect these directions were north German composers (Carl Philipp Emmanuel Bach, Johann Friedrich Reichardt, Karl Friedrich Zelter, and Johann Rudolf Zumsteeg), particularly in their settings of devotional poetry by Christian Gellert, Julius Sturm, and Friedrich Klopstock. The keyboard part was often fully written out, yet generally subordinate to the voice. Beethoven eventually expanded the role of the accompaniment in his finest songs, including settings of Goethe and Gellert, and the cycle *An die ferne Geliebte*.

At the head of distinguished 19th-century Lied composers stands Schubert, whose masterpieces combine a natural feeling for musical design with an extraordinary sensitivity to the essentials of the text. More than 600 in number, his Lieder encompass a wide range of poets, forms, and moods. Schumann's approximately 250 songs draw from outstanding German lyricists: Heinrich Heine, Goethe, Friedrich Rückert, Joseph Eichendorff, Justinus Kerner, and Adelbert von Chamisso. His accompaniments are closely linked with the voice through doubling, imitation, or completion of musical ideas. Brahms, more like Schubert than Schumann, assigned prime importance to the voice but at times sacrificed text declamation for balance in musical phrasing. Among his approximately 300 solo works are numerous harmonizations of folk tunes (many altered according to his musical taste), a cycle of 15 romances from Ludwig Tieck's *Magelone*, and the extensive *Vier ernste Gesänge* (*Four Serious Songs*) of his last years. Wolf, in sharp contrast to Brahms, gave scrupulous attention to literary details, frequently requiring changes of pace and vocal styles within a single song. The best songs of Richard Strauss, like Wolf's, combine an expressive vocal line with a rich accompaniment, often in alternative versions for piano or orchestra.

The 20th century

Early 20th-century Lieder either develop further the possibilities of the orchestral song (Mahler, Schoenberg, Berg, Webern), explore revolutionary techniques in works using chamber ensemble or piano (Schoenberg, Webern), or merely continue late 19th-century traditions (Max Reger, Joseph Marx). Mahler's songs—*e.g.*, *Lieder eines fahrenden Gesellen* (*Songs of a Wayfarer*), settings from *Des Knaben Wunderhorn* (*The Youth's Magic Horn*), *Kindertotenlieder* (*Songs on the Death of Children*), *Das Lied von der Erde*—deal with the sorrows and aspirations of man, the consoling powers of nature, and childlike visions of heaven; the vocal lines range from folklike simplicity to soaring lyricism. Of central importance in their composers' careers are Schoenberg's *Buch der hängenden Gärten* (*Book of the Hanging Gardens*) and his 12-tone *Drei Lieder*, Opus 48; Webern's aphoristic yet highly contrapuntal chamber songs (Opuses 13–19) and later settings of Hildegard Jone; and Berg's more lyrical *Altenberg Lieder* and concert aria *Der Wein* (*Wine*). Continuing later into the century, Paul Hindemith's skillful songs in German, French, and English incorporate various accompaniments and styles.

Airs de cour

French publishers issued numerous books of *airs de cour*, or "courtly airs," during the early 17th century. Some airs treat serious secular topics. Others, called *voix de ville*, have jovial texts, which are often set to dance rhythms. *Récits* concentrate on textual declamation, since they usually originated as commentaries within the *ballets de cour*, or "courtly ballets"; but they have little of the passion found in Italian recitatives of the same time. Still other airs are settings from the Huguenot psalter. France was nevertheless slow in developing compositions designed only for the solo singer. Aside from the *récits* and psalm settings, the airs were either arrangements of polyphonic chansons or were easily singable as part-songs. In the late 17th and 18th centuries, most vocal writing was for the large forms of opera, cantata, and motet. But a demand for songs returned with the "back to nature" movement in the mid-18th century and with the French Revolution, giving rise to *romances*, or simple, rustic tunes with folkish texts, and to patriotic songs, including "La Marseillaise."

Many 19th-century composers continued writing *romances*, some of more extended scope. But the most important type of song was the new *mélodie*, which concentrated on subtle nuances of the text and provided a substantial accompaniment, as in Hector Berlioz' cycle *Les Nuits d'été* (*Summer Nights*; to poems by Théophile Gautier), with accompaniment for orchestra or piano. The *mélodie* flourished with the rich developments in French poetry during the later 19th century. Gabriel Fauré, in his cycle *La Bonne Chanson* (*The Good Song*), set nine love poems of Paul Verlaine; the lyrical voice soars above continuous figurations in the piano. Henri Duparc's *mélodies*, only 14 in number, have long been considered masterful settings of Charles Baudelaire, Charles Leconte de Lisle, Armand Silvestre, and others. Debussy's 57 published songs use poems of his contemporaries (especially Verlaine) but also three by the 15th-century François Villon. His vocal lines freely mix a declamatory style with more lyricism at points of climax. The piano emphasizes contours of the poem and imparts unity through recurring motives. Among the most colourful song composers of the early 20th century is Ravel. His *Shéhérazade* has orchestral accompaniment, while *Trois Poèmes de Stéphane Mallarmé* and the *Chansons Madécasses* use chamber ensembles. Originally for voice and piano (although some are also orchestrated) are his folk-tune harmonizations; *Don Quichotte à Dulcinée*, dance-inspired songs intended as movie music; and the *Histories naturelles*.

Darius Milhaud treated both humorous and serious poems from all periods, while Francis Poulenc's most characteristic texts are by the Surrealists. Among the more recent French composers, Olivier Messiaen, André Jolivet, and Boulez employed advanced vocal techniques with various instrumental combinations.

Lute ayres

England's first art songs are the lute ayres published in large numbers from 1597 to 1622; the principal composers are John Dowland, John Daniel, and Thomas Campion. Of high literary quality, the strophic texts are generally anonymous, except those by the composers themselves. Many ayres resemble dance music, using standard rhythms and symmetrical phrasing. The finest songs place the voice and lute in full partnership. The ayres of the early 17th century gradually gave way to declamatory songs, usually

through-composed, many of which were originally written for masques or the theatre. In the simplified accompaniment, the complete lute part was eventually replaced by a single basso-continuo line. Late 17th-century continuo songs reached a high point in the works of Purcell. His earliest songs emphasize textual prosody, but his more representative works become brilliant concert pieces.

In the 18th and 19th centuries, many songs continued to reflect the influence of opera and operetta. But more characteristic of the two centuries are less pretentious strophic works, many originating in popular concerts in the London Gardens. In the late 18th century, the turn toward simplicity resulted in collections of Scottish, Irish, and Welsh folk music; the Scottish publisher George Thomson commissioned folk-song arrangements from Haydn, Beethoven, and others.

Since the late 19th century, England has revived interest in the art song. Texts are often from the best contemporary poets, as well as from earlier classics. Musical styles have drawn on folk-music tradition as well as on advanced 20th-century musical idioms. Although the piano remains the principal accompanying instrument, orchestral or chamber-ensemble accompaniments are also prominent. Among the more significant song composers have been Sir Hubert Parry and Sir Charles Villiers Stanford; Frederick Delius, largely influenced by continental and Scandinavian music; Gustav Holst and Ralph Vaughan Williams, both with a strong interest in folk music; Peter Warlock (real name, Philip Heseltine); John Ireland; Benjamin Britten; and Sir Michael Tippett.

In the United States, songs composed before the mid-19th century were primarily by amateur musicians, and intended for singing instruction, devotion, or entertainment. Minstrel shows of the early 19th century provided the source for the stage songs of Daniel Decatur Emmett, Stephen Foster, and others. Songs of late 19th-century composers such as George Chadwick, George Foote, Horatio Parker, and Edward MacDowell were influenced by conservative trends in European Romanticism. Early 20th-century songs show the effects of French Impressionism (John Alden Carpenter, Charles Loeffler, Charles Griffes) or follow more individual directions. Sidney Homer's songs focus on a smooth vocal melody, while those of Charles Ives often vigorously represent textual details. After a lull during the 1930s and early 1940s, composers returned to the art song, often setting contemporary American literature. Some of the better known are Theodore Ward Chanler, Virgil Thomson, Samuel Barber, David Diamond, Aaron Copland, Ben Weber, Miriam Gideon, and Milton Babbitt.

Art songs in other countries. The Russian art song dates primarily from the 19th and 20th centuries, although the period of Catherine the Great (reigned 1762–96) supplies a substantial background in its imitations of French *romances* (either in French or Russian), editions of Russian folk tunes (or pseudo-folk tunes), ballads, and pseudo-Oriental songs. The chief pioneers of the 19th-century song were Mikhail Glinka and Aleksandr Dargomyzhsky, the latter brilliant for his depiction of realistic peasant scenes. The "Russian Five" (César Cui, Mily Balakirev, Aleksandr Borodin, Modest Mussorgsky, and Nikolay Rimsky-Korsakov) contributed the most significant repertory in the second half of the 19th century. Their songs present a remarkable variety of moods and styles, perhaps best illustrated in the works of Borodin and Mussorgsky. In contrast to "The Five," the conservatory musicians (chiefly Anton Rubinstein and Peter Ilich Tchaikovsky) were governed more by Western influences than by native styles. Among other pre-Revolutionary song composers, Aleksandr Grechaninov, Sergey Rachmaninoff, and Nikolay Medtner provided polished masterpieces, but no significant technical advances; more forward-looking are the early songs of Stravinsky and Sergey Prokofiev. Soviet composers have avoided the radical musical developments elsewhere. As a rule, songs since the Revolution are objective settings of Soviet poetry or traditional Russian literature (especially works by the poet Pushkin).

The art songs of Italy begin with the numerous books of monodies (continuo songs) from the first third of the 17th century by such composers as Giulio Caccini, Jacopo Peri, and Sigismondo d'India (a more significant composer). Although originally labelled with various titles, the songs fall into two general types: madrigals and strophic arias. Some madrigals are strict recitatives, although the vocal style is more frequently a smooth-flowing arioso (*i.e.*, freely expressive and lyrical). Arias tend toward symmetrical phrasing and standard rhythmical patterns, sometimes dancelike, but at times approach madrigalesque style. Many arias repeat the same music for each stanza, but others have a through-composed vocal line over the same bass (strophic-bass arias). As a rule, the accompaniments are entirely subordinated to the voice, which in the more expressive songs introduces ornaments for emphasizing important words or punctuating poetic lines. The early monodies eventually expanded into longer, more musically oriented compositions called cantatas.

Early Baroque monody

Opera was so dominant in the 18th and 19th centuries that song composition became a lost art. A return to song writing in the early 20th century, for composers such as Ottorino Respighi, Alfredo Casella, and Gian Francsco Malipiero, was inspired by the ideals and accomplishments of Italy's past, especially the Middle Ages and Renaissance. Other outstanding recent song composers are Mario Castelnuovo-Tedesco (settings of all Shakespeare's songs), Luigi Dallapiccola (using 12-tone techniques), Ildebrando Pizzetti, and Goffredo Petrassi.

Spanish songs from the 17th through 19th centuries are primarily related to theatrical productions: either the older and more enduring *zarzuelas* or the lighter *tonadillas* (*c.* 1750–1810). The vocal style is simple, often with rhythmic and ornamental clichés; the accompaniment frequently consists only of the composer's sketches to be filled out in performance. In the repertory of serious modern art songs the way was led by Felipe Pedrell, who composed folk-inspired melodies and published works of older Spanish masters. Among his better known successors are Enrique Granados, Manuel de Falla, Joaquín Turina, and Federico Mompou.

Spanish and Latin American songs

Latin America has produced a rich and varied repertory of art songs, but mostly during the present century. A great number of these compositions depict regional colour through their texts, melodies, and rhythms. Other works eschew native influences in favour of an international style. Among 20th-century Latin-American composers, the Brazilian Heitor Villa-Lobos and the Argentine Alberto Ginastera achieved worldwide fame.

The most outstanding Norwegian song composer was Edvard Grieg, whose song style blends folklike simplicity with imaginative musical ideas. As is usual with Scandinavian composers, the texts are drawn from several languages (German, Danish, Norwegian), but his finest works are in his native Norwegian. The Finn Jean Sibelius concentrated primarily on Swedish literature, interpreting a wide range of moods in a highly distinctive musical language.

Hungary's principal contributions come from Béla Bartók and Zoltán Kodály, whose songs reflect their lifelong interest in collecting native peasant tunes. For both composers folk-song arrangement became a refined art. Many songs faithfully set a traditional tune to a simple accompaniment, while more elaborate works blend native elements with advanced contemporary idioms.

In Czechoslovakia, strong ties with German culture long prevented the development of native art songs. Nineteenth-century nationalism inspired some composers to turn to Czech texts, although part of their output continued in German: Jaroslav Tomášek, Bedřich Smetana, Anton Dvořák, and the younger Leos Janáček. Poland shows a similar pattern: during the 19th century many composers turned to their native literature (especially the poetry of Adam Mickiewicz), the most important being Joseph Elsner, Frédéric Chopin, Stanislaw Moniuszko, and Karol Szymanowski. Belgium, the Netherlands, and Switzerland have also produced sizable repertories of art songs, particularly in the 19th and 20th centuries.

WESTERN AND NON-WESTERN CONCEPTIONS

In the relationship between poet, composer, and performer—and especially in the importance assigned to the

composer—Western vocal music has arrived at a stage during the past few centuries that is basically unlike that of any other world culture. By the 19th century composers were recording in musical notation virtually all the essentials in their interpretations of the text: pitch, rhythm, and tempo, as well as indications for dynamics and articulation. Although the performers must bring the composer's notation to life, particularly through subtle nuances and appropriate vocal sounds, this process is primarily one of reinterpreting a previously established work of art. Comparative research in the present century has revealed certain general parallels in the vocal art of other civilizations, but no culture other than Western has placed such a premium on individual compositions from the past, and consequently nowhere else is there preserved such an extensive history of vocal literature. Aside from certain types of ritualistic music, where the slightest change in tradition is viewed as a desecration, the non-Westerner has relied primarily upon the creative role of the performer. Although the singer at times begins with a preexistent "work" notated with some pitches, rhythms, or even other indications for performance, this notation merely functions as a suggested framework. The performer contributes new details for the voice and the accompaniment, so that the composition is actually re-created rather than reinterpreted. Because of this process of creative performance, most non-Western vocal art before the advent of 20th-century recordings has been irretrievably lost.

Performer's role

During the present century, Western concepts of art song have strongly influenced the vocal music in non-Western cultures, unfortunately threatening the continued existence of many indigenous practices. The influence has at times gone in the other direction: recent examples of Western avant-gardism give the singer many improvisatory options within broader limits prescribed by the composer. It can be expected that future vocal music will continue to show intercultural exchanges of ideas and techniques without requiring the complete sacrifice of any heritage.

(W.V.P.)

CHORAL MUSIC

Music sung by a choir, known as choral music, ranks as one of several musical genres subject to misunderstanding because of false historical perspectives or misinterpretation caused by the confusion engendered by unsolved semantic problems. Choral, chorale, choir, and chorus stand in obvious relationship to one another and are in some respects used interchangeably when a body of singers, for example, is referred to as a choir, a chorus (Latin noun derived from the Greek word *choros*), or a chorale, which properly is a Lutheran hymn tune. The adjective choral may therefore be applied in a general way (choral music, choral technique) or in a specific way (such as Beethoven's *Choral Symphony* and *Choral Fantasia*). The nouns chorale, choir, and chorus are frequently used as adjectives in such expressions as chorale prelude ("choral prelude" is incorrect), choir organ, or chorus part.

The definition of choral music has by circumstance and usage been forced to comprise a far wider area than a comparable definition of an instrumental genre. It is unusual, to say the least, to perform a symphony with only a single instrument to each part, even though the opposite has occasionally happened when a string quartet movement is played by the massed strings of an orchestra. Much music now performed by choirs, however, was originally intended for soloists; and, while the lack of historical authenticity may here be deplored, it is evident that a choral performance of a madrigal (equivalent to an orchestral performance of a string quartet movement) permits many amateur musicians to enjoy, as members of a team, music that might otherwise escape their knowledge.

If a choral performance of genres for several solo voices, such as the madrigal, ballett, villanella, and part-song, results in a more neutral sound and a less personal intensity of expression, it is nevertheless true that the reverse sometimes offers unsuspected advantages, as when a work written for choir alone is performed by a group of soloists. In certain cases the work may take on a new and enhanced aspect because each strand of melody within the texture carries a personal rather than a group expression.

In defining choral music, some attention should also be paid to the enormous variation in the size of choirs. A chamber choir need contain only a dozen voices, certainly not more than 20; whereas a choir assembled for the Handel Festivals in the 19th century or for the Berlioz *concerts monstres* in Paris during the same epoch, might have numbered thousands. Modern traces of such massive choral effects may be found in the *Symphony No. 8 in E Flat Major* (sometimes called *Symphony of a Thousand*) of the Austrian composer Gustav Mahler. This work calls for a large double choir and a separate boys' choir, in addition to a large orchestra and eight soloists. On the other hand, numerous modern choral works, because of their difficulty and complexity, seem to have been composed with a chamber choir in mind, as in the case of *Cinq rechants* (1949) by the French composer Olivier Messiaen.

Variation in size of choirs

If there is more than one voice to each part—*i.e.*, to each line of polyphony (music of several voice parts) or strand of melody—the performance is choral, even though the actual sonority may not seem choral in the accepted sense until there are more than five or six voices to a part. Both types of singing may also coexist, since a choir may contain several capable soloists who may at certain points sing as a group without the choir or with the choir as a background. This feature is the choral equivalent of the orchestral concerto grosso, in which a small group of solo instruments alternate or combine with the main body of players. Examples of this may be found in choral music of all types and ages. The medieval rondeau was usually performed by a soloist who sang the verses, with a small choir for the refrain. When the mass became a vehicle for choral performance in the 15th century, the Christe Eleison, certain parts of the Gloria and the Credo, the Benedictus, and the Agnus Dei were frequently assigned to a group of soloists within the choir. *The Eton Choirbook* motets demand similar treatment since red and black text is used to differentiate between those sections intended for soloists and those for full choir. Comparable effects may be found in music written for special occasions, oratorios, verse anthems, and settings of the Passion.

Although choirs existed throughout Europe in the Middle Ages, their role was restricted to unison singing of plainchant. Polyphony was the exclusive preserve of soloists. This state of affairs was gradually modified for several reasons. Early forms of musical notation were not precise enough to allow choral performance of even the simplest two-part polyphony. As time went on, improved accuracy in notating pitch and time values permitted some degree of experiment in choral performance.

Emergence of the choral tradition

Knowledge of the subtleties of mensural (precisely measured) music was at first the prerogative of a small number of initiates. The ordinary member of the plainchant choir, or schola, was not expected to understand the notation or to perform music using it. But the teaching of musical theory spread rapidly in the 14th century, and singers became better equipped and educated than they had been at any previous time. The ever-growing wealth of the church also acted to encourage choral performance, since abbeys, cathedrals, parish and collegiate churches, and court chapels vied with each other in the opulence and perfection of their choral establishments. Laws were passed enabling royal chapels to impress (that is, to seek out and enroll) eligible provincial choirboys for the great central establishments, and in consequence every boy was a soloist in his own right, just as were the countertenors, tenors, and basses. Finally, the rapidity with which composers took advantage of this situation, evolving new techniques and adapting old ones, created a tremendous surge of choral activity and composition, which the new art of music printing was to aid even further in the early years of the 16th century. From that time until the present, there has been no abatement of interest in choral music, which is performed at amateur and professional levels throughout the entire world.

Sacred music. *The mass.* The ordinary of the mass (consisting of the Kyrie, Gloria, Credo, Sanctus and Benedictus, Agnus Dei, and in some medieval masses also the

"Ite, missa est") has been a focal point of choral music for more than 600 years. The earliest masses, such as the four-part setting by the 14th-century French composer Guillaume de Machaut, were intended for soloists; remarkable both in musical texture and structure, they are often performed chorally today. In the 15th century this tradition, in which architectonic considerations still held sway, was carried on in the masses of the English composer John Dunstable and his Burgundian contemporary, Guillaume Dufay. The use of a plainchant cantus firmus, or dominating tenor theme, knit together the movements even though they were separated during the liturgy. Modern concert performances and recordings obscure this feature, sometimes to the disadvantage of even the greatest masterpieces, which, with all movements in immediate sequence may sound too concentrated. The Renaissance saw the highest development of the cantus firmus mass, using as the central melodic support not only plainchant but even secular songs, as Josquin's *L'Homme armé* (printed in 1502) or folk songs, as John Taverner's mass, *The Western Wynde* (*c.* 1520).

Hundreds of composers wrote settings of the ordinary of the mass at this time; some, like the Italian composer Giovanni da Palestrina, wrote more than 100 masses. The Spaniards Cristóbal de Morales and Tomás Luis de Victoria and the Englishmen William Byrd and Thomas Tallis all avoided secular melodies, even though these would have been largely obscured by the texture of the voices. On the other hand, the Netherlanders Orlando di Lasso and Philippe de Monte did not hesitate to draw upon themes of diverse origins. Byrd and his Flemish contemporary Heinrich Isaac also set a considerable amount of the proper of the mass (that part of the liturgy liable to change according to the feast), but such settings remained comparatively rare.

The parody mass found many advocates, since it was possible by this means to base a long work on all voice parts of a shorter one, such as a motet or a hymn, and by beginning with familiar and recognizable material, to progress gradually into inventive independence. This particular technique may have owed as much to convenience as to a desire to pay homage to another composer.

Addition of instruments

The 16th- and 17th-century Venetian school, especially Giovanni Gabrieli and Claudio Monteverdi, added an instrumental element to the basically choral foundation of the mass. They also occasionally employed two or more choirs to create massive antiphonal effects. Further development of the orchestral mass occurred in the 17th century in the works of the Italian composers Francesco Cavalli and Alessandro Scarlatti and the French composer Marc-Antoine Charpentier, while the polychoral element was brought to a colossal and almost unmanageable pitch by Orazio Benevoli in his mass for the dedication of the Salzburg cathedral (1628) in 53 parts.

In the 18th century, Haydn's early masses, notably the *Missa Sanctae Caeciliae,* lean toward Italian models. His choral writing is robust and sonorous, even though four-part writing is the norm. His later masses emphasize soloists and orchestra but without diminishing the interest of the choral writing. Mozart's early masses tend to be brief (because of the taste and dictates of his archbishop patron), yet the fugal choruses sometimes dispel this impression by their very excellence, as in the *Mass in C Major,* K. 317 (1779; *Coronation Mass*). The unfinished *Mass in C Minor,* K. 427, abounds in magnificent choral music.

Remote in style and function from the Classical Viennese works, J.S. Bach's *Mass in B Minor* (1733–38) was a monument of the preceding Baroque era. It was never intended to be performed as a whole within the liturgy, and its various movements date from different periods of Bach's life. Five-part choral writing is most in evidence, the two soprano lines adding brilliance and edge to a richly contrapuntal (interwoven melody) texture. In the "Sanctus," Bach branches into six-part polyphony, and in the "Osanna" he calls for an eight-voice double choir apt for antiphonal writing.

Beethoven's *Mass in C Major,* Opus 86 (1807), and *Missa Solemnis,* Opus 123 (1823), written in the maturity of the Classical era, are not liturgical, yet they stem from an inner need to carry on a great tradition and to set to music a text of central importance. The role of the choir is central to the work. The composer uses it to produce effects ranging from breathtaking mystery to the utterly grandiose. The masses of the 19th-century Austrian composers Franz Schubert and Anton Bruckner worthily continue the same tradition in their individual ways. The *Petite Messe solennelle* (*Little Solemn Mass;* 1864) of Italian composer Gioacchino Rossini was originally written for soloists, chorus, and an accompaniment of two pianos and harmonium, but it was later scored for full orchestra.

Outstanding among 20th-century masses are those of the English composer Ralph Vaughan Williams, the Czech composer Leoš Janáček (*Glagolitic Mass,* setting an Orthodox text in Old Slavonic), and the Russo-American composer Igor Stravinsky, who is said to have derived his inspiration from Mozart, although some of the effects created by the mixed chorus and wind instruments are more reminiscent of medieval music.

The Missa pro Defunctis ("Mass for the Dead"), or Requiem Mass (often simply called Requiem) also stimulated numerous choral masterpieces, beginning with Jean d'Ockeghem in the late 15th century and continuing through Victoria, Felice Anerio, Scarlatti, Mozart, Luigi Cherubini, Hector Berlioz, Giuseppe Verdi, and Gabriel Fauré to the present century. Johannes Brahms' *Ein deutsches Requiem* (*German Requiem,* 1857–68) is based on the composer's own selection of Biblical texts. The *Requiem* (1914–16) of the early 20th-century British composer Frederick Delius derives its libretto from the 19th-century German philosopher and poet Friedrich Nietzsche. The *War Requiem,* Opus 66 (first performed, 1962), of the British composer Benjamin Britten makes skillful and impressive use of liturgical texts but also contains secular poetry by Wilfred Owen, killed in World War I. The work as a whole is thus linked with the senseless suffering of war and the idea of sacrifice induced by false patriotism. The choral effects are rich in novelty, originality, and forcefulness. One of the most successful of 20th-century masses for unaccompanied chorus is the *Mass in G Major* (1937) by Francis Poulenc.

Vespers and Anglican services

In the Middle Ages, the service of greatest musical importance, after the mass, was Vespers. Its component antiphons, psalms, hymn, and Magnificat have given rise to much noble choral music, from the time of the Flemish composer Adriaan Willaert in the 16th century, through Monteverdi, Scarlatti, and Mozart. In the Anglican Church, service settings embrace Holy Communion and Morning and Evening Prayer and have been continuously written since the time of Byrd and Tallis. These early services for choir and organ were followed by "verse services," in which solo voices played an important part, combining or alternating with the choir. By the time of the 17th-century British composer Henry Purcell, instruments were accepted as a means to fuller accompaniment, notably in the Chapel Royal, London. But modern composers, except in works for ceremonial use, tend to return to scoring their services for choir and organ.

Motets. Choral music has been enriched for centuries by the composition of motets, which were originally settings of liturgical or biblical texts. Responsories (liturgical texts originally performed responsively) were of major importance until the great monastic institutions lost their influence in the early years of the 16th century. Subsequently, the choral motet was mainly cultivated in royal and collegiate chapels. Settings of votive antiphons (verses preceding psalms and canticles), frequently, though not exclusively, texts in honour of the Virgin Mary, were popular in the late 15th and early 16th centuries. Many of these compositions demanded a high degree of skill and virtuosity from the choir and its soloists; a noble example is the British composer John Browne's *Stabat Mater,* from *The Eton Choirbook.* An Italian contemporary, Giovanni Spataro, displays a more simple and restrained style in his four-part *Virgo prudentissima,* which nevertheless belongs to the same category of motet.

During the 16th and 17th centuries, the term motet was used in looser connotation, sometimes linked with a few

verses of a psalm, sometimes a complete psalm including Gloria Patri (lesser doxology). Many of these longer settings, by 16th-century composers such as Josquin, Willaert, and Lasso, attain the level of symphonic choral writing through their high degree of formal organization and their imaginative vocal scoring. The concertato motet (using contrasting groups of singers and instruments), as developed and perfected in the 17th century by Gabrieli, Monteverdi, Heinrich Schütz, and Scarlatti, added the vivid colours of the orchestral palette to the already highly malleable vocal textures. Pergolesi's *Stabat Mater,* although sometimes performed as a choral work, was originally written with solo voices in mind. Bach's motets, of which *Jesu meine Freude (Jesus My Joy, c.* 1723) is a typical and splendid example, return to the a cappella manner of performance. Contrary to one popular conception, this often included instrumental doubling of the voice parts and the use of an organ continuo, an improvised part. Subsequently little used in the Protestant Church, the motet continued to be cultivated by the Catholic composers of Europe and the Americas. Especially worthy of note are the motets and psalm settings of Anton Bruckner, whose *Te Deum* (composed 1881, revised 1883–84) is one of his choral masterpieces. Conservative tastes in much religious music somewhat discouraged the greatest talents from contributing fully to this genre. Stravinsky's *Threni* (on the Lamentations of Jeremiah), for instance, is more frequently heard in the concert hall than in church, as are also Poulenc's *Stabat Mater* (1951) and other liturgical motets of his.

Anthems. The use of the vernacular after the Reformation in England made it necessary for composers to forge a new style of choral music. The elaborate melodic tracery of Robert Fayrfax and John Taverner gave way to a completely unelaborate kind of choral counterpoint designed to allow the English words to be clearly heard. Both Thomas Tallis and William Byrd made outstanding contributions to the development of the anthem. Tallis perfected a style of contrapuntally animated homophony that ensured clarity of declamation, while Byrd experimented with more elaborate textures both in full anthems (for choir alone) and in verse anthems, in which the choir was supported by the organ and sometimes other instruments, allowing solo voices to detach themselves from the main body of singers. Among Byrd's finest verse anthems are *Christ rising again* (for Easter) and *O God that guides the cheerful sun.* Orlando Gibbons carried to a further stage the use of a consort of viols, which accompanies with a rich but discreet body of sound the countertenor and bass soloists in *Glorious and powerful god.* One of the most effective of his full anthems is the seven-part *Hosanna to the Son of David* for Palm Sunday. Thomas Tomkins displays a mastery of 12-part polyphony in his full anthem *O praise the Lord, all ye heathen,* but for quiet expressive intimacy of thought there is little to surpass *When David heard that Absalom was slain.* Among a considerable number of verse anthems by Tomkins, two of the most inspiring are *My Shepherd is the living Lord* and *Thou art my King, O God,* both of which can be accompanied by organ alone or by organ and string ensemble.

When the monarchy was restored in 1660, Matthew Locke contributed a number of fine anthems to the repertory of the revived Chapel Royal, among them the double-choir setting of *Not unto us, O Lord* and the grandiose, almost Venetian *The king shall rejoice,* scored for three four-part choirs and orchestra. Another eminent musician of the time was Pelham Humfrey, whose verse anthem *By the waters of Babylon* is one of the best examples of its kind. For chromatically expressive music Michael Wise provides an admirable pattern in his *The ways of Sion do mourn,* as does Daniel Roseingrave in his *Lord, thou art become gracious.*

The verse anthem with instruments reached its zenith in the late 17th century in the music of Henry Purcell and John Blow. Much of their music was performed in the Chapel Royal, the choir and consorts of which had improved markedly. Among the most memorable of Purcell's full anthems are the eight-part *Hear my prayer, O Lord* and the five-part *Remember not, Lord, our offences.* His most successful verse anthems frequently make use of short, impressive passages for choir alone, as in the evocation of the turtle's voice in *My beloved spake* and the moving harmonies of "O worship the Lord" toward the end of *O sing unto the Lord.* Blow excels in the antiphony of verse soloists and full choir in *I beheld, and lo, a great multitude.* In his full anthems, such as *God is our hope and strength* and *O Lord God of my salvation,* he sometimes almost equals Purcell in the richness and resource of his eight-part writing.

Of the succeeding generation of composers, William Croft seems most at ease in his full anthems, notably *Put me not to rebuke* and *O Lord, rebuke me not,* two distinct and different works in spite of the similarity of text. Maurice Greene excelled in this style in works such as *God is our hope and strength* and *Acquaint thyself with God.* William Boyce carried on the tradition of sensitive word setting in such works as *I have surely built thee an house* and *O where shall wisdom be found?*

Although the late 18th and early 19th centuries did not exactly overflow with masterpieces, a trio of composers proved themselves competent craftsmen. *O Lord, look down from heaven* will assure Jonathan Battishill a place in the history of the genre, while the Epiphany anthem *O God, who by the leading of a star* speaks eloquently for Thomas Attwood. Although Samuel Wesley, converted to Catholicism, chose Latin for the greater number of his church compositions, one of these is sometimes sung to its English text, *Sing aloud with gladness.*

Samuel Sebastian Wesley attempted, often with considerable success, to raise up the anthem to a new level of artistry and accomplishment, extending it so as to form a kind of cantata giving freer rein to soloists than was customary in the older type of verse anthem. His finest contributions are perhaps *The Wilderness; Ascribe unto The Lord;* and *O Lord, Thou art my God.* Also noteworthy from this epoch are Sir John Goss's setting of *The Wilderness,* Thomas Attwood Walmisley's *O give thanks,* and the double-choir anthem *O Saviour of the world* by Sir Frederick Gore Ouseley.

Sir Joseph Barnby, Sir John Stainer, and Sir Arthur Sullivan wrote anthems of fair quality, but not until Sir Hubert Parry demonstrated the need for a return to conscientious word setting did new spirit begin to pervade English church music in works such as Parry's double-choir anthem *Lord let me know mine end.* Sir Charles Stanford's similarly scored *Jesus Christ is risen today,* and Charles Wood's *O thou the central orb.* In the 20th century, T.T. Noble's *The souls of the righteous* and John Ireland's *Greater love hath no man* are typical of the earlier period, while *O pray for the peace of Jerusalem* by Herbert Howells and Benjamin Britten's *Hymn to St. Peter* successfully continue a long tradition.

Cantata and oratorio. The cantata, as developed in northern Germany in the 17th century, often relied only upon soloists and a small group of instruments, although the role of the chorus gradually became more important. In more than 200 church cantatas written by J.S. Bach, the chorus often occupies a prominent place and is given music of challenging complexity—frequently on a par with the music of the accompanying instrumental forces. The cantatas use the chorus again in the closing chorale, which is usually a special setting of a hymn tune with orchestral doubling or accompaniment.

Bach's 200 church cantatas

In Italy, the oratorio achieved what was beyond the motet's capabilities by projecting through verse and music a story of Biblical origin that the public could enjoy while learning. Giacomo Carissimi, whose *Jephtha* is still an established classic, led the way to the oratorios of Antonio Vivaldi (*Juditha triumphans,* first performed 1716), Handel (a long series of oratorios written for London, all dramatic in form except for *Israel in Egypt* of 1739 and the *Messiah* of 1741), and Haydn, whose greatest oratorio is *Die Schöpfung* (1798; *The Creation*). The choral contribution to 19th-century oratorios remained at a remarkably high level, enhancing such works as Beethoven's *Christus Am Ölberg* (1803; *Christ on the Mount of Olives*), the perennially popular *Elijah* (1846) of Mendelssohn, Franz Liszt's *Die Legende von der heiligen Elisabeth* (*The Leg-*

end of St. Elizabeth), Berlioz's *L'Enfance du Christ,* Opus 25 (1854), and a series of compositions by the British composer Edward Elgar, culminating in *The Dream of Gerontius* (1900). The oratorio tradition, because of its links with choral bodies, has shown constant renewal and growth in the 20th century. Among outstanding 20th-century oratorios are Frank Martin's *Golgotha* (1949), Arthur Honegger's *Le Roi David* (*King David;* 1921), Sir William Walton's *Belshazzar's Feast* (1931), and Bernard Rogers' *The Passion* (1944). A work in oratorio style, though in a class of its own, is Ernest Bloch's *Avodath Hakodesh* (*Sacred Service*) composed 1930–33 and scored for baritone solo, chorus, and orchestra.

Occasional music. In addition to sacred and secular works, a very considerable number of compositions, many of them choral, were written for great occasions of state. These include motets and cantatas based on special texts, suitable for performance in a palace, outdoors on a platform or rampart, in a private chapel, or wherever the occasion demanded. The signing of a peace treaty, a royal marriage, ducal obsequies, consecration, election of a doge—all these and many similar events called for music written to order; since composers have always been happy to receive a commission, the number of occasional works is virtually incalculable.

Soon after St. Mark's, Venice, inaugurated in 1403 a choir of boys from the city, their master Antonio Romano was invited to compose a festive work in honour of the doge. When Francesco Foscari was elected doge in 1423, Christoforo de Monte introduced the choral parts of his motet with brass fanfares. Dufay, asked to produce a stirring work for the consecration of a new cathedral at Patras (now Pátrai) in Greece, scored his *Apostolo glorioso-Cum tua doctrina-Andreas* (1426) for wind ensemble and mixed chorus; but, although the work was undoubtedly performed in the cathedral, the use of an Italian rather than a Latin text places it firmly in the category of occasional music. An equally impressive work by the same composer, *Supremum est mortalibus bonum pax* (*The Supreme Gift for Mortals Is Peace*), was written expressly for the signing of the Treaty of Viterbo in 1433, when Pope Eugenius IV and King Sigismund of Bohemia were both present at the ceremony. Toward the end of the motet, the choir sings, in successive block chords, the names of Pope and King, syllable by syllable. Another peace treaty celebrated in music is that of Bagnolo, Italy, when the Franco-Flemish composer Loyset Compère was commissioned to write the motet *Quis numerare queat* (1484). Imaginative use is made of the chorus throughout this work, even to the extent of the composer's choice of tessitura (high or low part of the voice range): when the chorus sings of the lamentations of the people over the terrors of war, the words are sung by the dark-hued combination of tenors, baritones, and basses in their middle or lower register. A further example of choral writing so disposed as to represent a state of mind is the "Amen" of Isaac's *Optime pastor* (written in 1513 in honour of the newly elected Pope Leo X), where the opulent six-part polyphony suggests the wealth and substance of the Emperor Maximilian I and his desire to impress listeners with a show of temporal power at least the equivalent of the Pope's spiritual power.

Occasional music is sometimes considered of less value than sacred or secular music, even when it stems from a composer of high reputation. Since the work could by definition receive only one formal performance and since it might have been written in a hurry, the theory is that the music must be inferior. There are, however, examples of such works whose music was used for more than one occasion, thanks to the simple but effective process of stripping away the original text and substituting another, or even substituting one name for another. A study of the text of Taverner's motet *Christe Jesu pastor bone* (*Jesus Christ, Good Shepherd*) shows that it must have been intended first as a votive antiphon for St. William of York, then as a paraliturgical prayer for Cardinal Wolsey (Taverner being at one time organist and master of the choristers at Cardinal's College, now Christ Church, at Oxford), and finally as a prayer for Henry VIII. Similarly, the anthem *O Lord, make thy servant Elizabeth our Queen,* written by William Byrd for Queen Elizabeth I, remained in the repertoire of the Chapel Royal for several decades, the name being changed first to James and then to Charles.

Repetition of occasional works

Most events of importance were planned months in advance, and the composer could usually count on being given adequate warning of a new commission. The meeting of Louis XII of France and Ferdinand V the Catholic of Castile at Savona in 1507, for which the French composer Antoine de Févin wrote a superb choral work, *Gaude Francorum regia corona,* was certainly not decided upon at short notice. Nor was the visit of Cardinal Ippolito de' Medici to Venice the result of a sudden decision, for Willaert had ample time to pen his solemn and sonorous motet *Adriacos numero* just as he did in the case of *Haud aliter pugnans,* in honour of King Ferdinand.

A later Ferdinand, who became Holy Roman Emperor Ferdinand III in 1637, commissioned two outstanding choral works by Monteverdi, both of which were published in his *Madrigali guerrieri et amorosi* (*Madrigals of War and Love,* 1638). *Altri canti d'amor* (*Let Others Sing of Love*) is a choral cantata for six voices, bass solo, and instrumental ensemble. The Emperor's military prowess is recounted in considerable detail, with choral imitations of swords clashing and guns firing. His qualities as a leader are also referred to in the ballet *Movete al mio bel suon* (*Move to my Beautiful Sound*), which extols him also as a just and equitable monarch in time of peace—although the Thirty Years' War did not in fact come to an end for several years. The text used by Monteverdi was a reworking of a poem which his friend the Italian poet Ottavio Rinuccini had originally written for Henry IV of France.

Purcell's odes

Purcell, a composer of occasional music who was also a brilliant choral writer, enriched the history of music with a series of odes and welcome songs beginning in 1680 (*Welcome, vicegerent of the mighty King*) and extending until the year of his death, 1695, which saw the production of the ode for the Duke of Gloucester's birthday, *Who can from joy refrain?* Among the finest of the series, and especially notable for the noble vigour of the choruses, are the odes for Queen Mary's birthday and for the St. Cecilia's Day celebration, 1692.

In France scores of comparable proportions were being written for such occasions as the baptism of the Dauphin (1688), for which Jean-Baptiste Lully set Pierre Perrin's *Plaude laetare* for double chorus and orchestra. Numerous court ceremonies or rejoicings called for large-scale performances of the Te Deum, Marc-Antoine Charpentier and Michel-Richard de Lalande, as well as Lully, providing music of the requisite pomp and proportions. Handel wrote two festive settings of the Te Deum for the Treaty of Utrecht (1713) and the British victory at Dettingen (1743). His royal odes worthily continue the Purcellian tradition, especially in the *Ode for the Queen's Birthday* (1713) for Queen Anne and in two wedding anthems, *This is the Day* (1734) for Princess Anne and *Sing unto God* (1736) for the Prince of Wales.

Although J.S. Bach did not disdain to write occasional music, he followed Handel's practice in the *Occasional Oratorio* (a patriotic piece given in 1746) without ever knowing Handel, by reworking this kind of music to a new text. One of the cantatas Bach supplied for the election of the Leipzig town councillors was deftly changed into a cantata for the 12th Sunday after Trinity; another, destined for the same annual event, *Preise, Jerusalem, den Herrn* (*Praise the Lord, O Jerusalem*), BWV 119 (1723), has been reedited in modern times with a new text, in imitation of the composer's own practice.

Haydn, in spite of his considerable duties as court conductor and composer, found time to write occasional works of considerable proportions, such as the two-hour birthday cantata, *Applausus* (1768), intended for the Abbot of Zwettl Stadt, Austria. His masses, even though they are liturgical, sometimes border also on the occasional because of their close ties with contemporary events, such as the *Missa St. Bernardi de Offida* (1796) written to celebrate the recent canonization of a Capuchin monk from Offida in Italy. An occasional choral composition of Beethoven's is his *Kantate auf den Tod Kaiser Josephs*

II (1790; *Cantata on the Death of the Emperor Joseph II*).

Berlioz, who had toyed with the idea of a large-scale choral and orchestral work to honour Napoleon, eventually had to abandon it but salvaged certain movements and incorporated them into his *Te Deum* (1849). His contemporary, Liszt, was more deliberately productive in this area, enjoying consistently enthusiastic receptions for his choral works of an occasional nature, such as the St. Cecilia antiphon *Cantantibus organis* (for a Palestrina festival in Rome in 1880), the *Missa solennis zur Einweihung der Basilika in Gran* (1855; *Mass for the Dedication of the Basilica at Gran*); the *Hungarian Coronation Mass* for Emperor Francis Joseph I (1867), and a unique composition for male chorus and organ accompaniment, *Slavimo Slavno Slaveni!*, written in 1863 for the millenary of SS. Cyril and Methodius. Also noteworthy are his two cantatas in honour of Beethoven.

The Czech composer Josef Förster achieved widespread recognition in his own country as a master of choral style, and a telling example of this may be heard in the cantata *Mortuis fratribus*, written as a kind of requiem after the end of World War I. In Hungary, Zoltán Kodály went to texts of a 16th-century Hungarian poet, Michael Veg, for his *Psalmus Hungaricus* (first performed, 1923) celebrating the 50th anniversary of the union of the cities Buda and Pest. For the Paris Exhibition of 1937, the French composer Florent Schmitt composed one of his finest choral works, the *Fête de la lumière* (*Festival of Light*).

Modern English occasional music

In 20th-century England the royal odes appeared less frequently than in the time of Purcell and Handel, yet there are a few choral works worthy of mention—Charles Stanford's *Welcome Song* for the opening of the Franco-British Exhibition (1908), and Sir Arthur Bliss's *Song of Welcome* (1954) for the homecoming of Queen Elizabeth II. Britten's cantata *St. Nicolas*, for tenor solo, mixed chorus, strings, piano, organ, and percussion, was written for the centenary of Lancing College in 1948, and 12 years later he supplied a *Cantata Academica* for the quincentenary of the University of Basel. The score of this work has parts where alternative words may be used for celebrations at other institutions of learning.

Secular music. Since the vast majority of secular vocal works of the Middle Ages and the Renaissance were written with soloists in mind rather than a chorus, this repertory will be dealt with in a later section of this article. A truly secular choral tradition does not really emerge until the 17th century, apart from dramatic works, which are mainly dealt with in the section on opera. Choruses were, however, supplied by way of incidental music to plays in the late 16th century; outstanding examples include the music written in 1585 by Andrea Gabrieli for the *Oedipus Tyrannus* of Sophocles and that of Giovanni Giacomo Gastoldi for Battista Guarini's play *Il pastor fido* (1590; *The Faithful Shepherd*). Choruses appear in 17th-century drama from time to time, as well as in masques and comparable extravaganzas. In the age of Lully, Marc-Antoine Charpentier, Purcell, and Matthew Locke, their position is clearly established. Secular cantatas tended for the most part to rely on solo voices, and when the chorus does make its appearance it sometimes consists only of three-part writing, as in Purcell's setting of Abraham Cowley's poem "If ever I more riches did desire."

The majority of Bach's secular cantatas call for solo voices only, in addition to the orchestra. Among those that do make full use of the chorus are *Phoebus und Pan* (*Geschwinde, geschwinde, ihr wirbelnden Winde*, BWV 201; 1731), the *Birthday Cantata* (*Schleicht, spielende Wellen*, BWV 206; 1733), and the *Hunt Cantata* (*Was mir behagt, ist nur die muntre Jagd*, BWV 208; 1716). The choral writing in Handel's secular cantatas and odes tends to be as massive and dignified as in the best of his oratorios, yet they are on the whole less frequently performed in the 20th century; as a group they do not fit easily into any single category. *Athalia* (1733) draws its inspiration and plot from the drama by the 17th-century French playwright Jean Racine; *Il trionfo del tempo e del disinganno* (1708; *The Triumph of Time and Truth*) is an allegory deriving from two of the composer's youthful Italianate compositions; *Alexander's Feast* (1736) and the *Ode for St. Cecilia's Day* (1739) both have texts by the 17th-century English poet Dryden; and the trilogy *L'allegro, Il penseroso, ed il moderato* (1740) is based on the poetry of another Englishman, John Milton.

Those powerful and opposite poles, church and opera, monopolized choral writing for many years, and apart from isolated works of an occasional nature there is little in the truly secular field until Beethoven's *Choral Fantasia* (1808), an unusual work in nine movements, the first seven of which are a set of variations for piano and orchestra. Voices are introduced only in the eighth movement—solo voices at first, singing verses in praise of music by a minor German poet of the early 19th century named Christoph Kuffner, then the choir, so that the previously dominant instrumental texture is gradually and effectively modified to include richly deployed vocal sonorities that assist the work to a climax in the same way as in the later *Choral Symphony*.

Beethoven's "Choral" symphony

This gigantic work, the ninth and last symphony by Beethoven, is planned in such a way that the choral finale is the only proper and logical way for it to end, although performances have been given where the finale has been omitted (using the scherzo as ending). The choral finale of the *Ninth Symphony* grows from the fertile soil of its predecessors and becomes a structural, thematic, and aesthetic necessity. It is notoriously difficult to perform, as Beethoven often seems to treat the singers like instruments.

The influence of his *Ninth Symphony* on later symphonic literature was considerable. Beethoven's bravura choral writing sent its echoes to the outer limits of the Romantic era, and there were many subsequent essays in the integration of choral and orchestral forces. In *La Damnation de Faust*, Opus 24 (1846), Berlioz uses the weight of massed voices in an imaginative and dramatic way; in contrast, in his *Roméo et Juliette* symphony the voices tend to serve as an extra dash of colour to the orchestral palette. Brahms made skillful use of the chorus in his *Rhapsodie* (1869) and *Schicksalslied* (*Song of Destiny*; 1871), and Schumann relied upon it throughout his *Das Paradies und die Peri* (*Paradise and the Peri*; 1843), a kind of secular oratorio based on the long poem *Lalla Rookh* (1817) by the Irish poet Thomas Moore. The best of both composers, chorally speaking, is to be found in their many settings of contemporaneous poems for mixed voices, male voice choir, or female choir. Much of this remains little known outside Germany, to the detriment of choral programs that would gain interest from one of Schumann's finely constructed double-choir compositions or from one of Brahm's sensitive settings of the poetry of Ludwig Uhland or Goethe.

The technical demands of the choral sections in Antonín Dvořák's *Svatební košile* (*The Spectre's Bride*), a cantata written for the Birmingham Festival of 1885, are within the capabilities of the amateur choral societies for which it was intended, and in general his treatment of voices shows consideration as well as ingenuity. The macabre plot of this work is a narrative poem by a learned countryman of the composer's, the Czech poet Karel Erben, who achieved fame as a collector of folklore. Czech folk songs and tales exercised a powerful attraction for Dvořák throughout his life, and some of his best choral music consists of settings such as *V přírodě* (*Amid Nature*, 1882) and *Tři sbory* (*Three Slovak Folksongs*, 1877). Czech poetry gave rise to many remarkable compositions among the choral works of Janáček, perhaps the most memorable being the three male-voice choruses written between 1906 and 1909 that were based on poems by Petr Bezruč: *Kantor Halfar* (*Teacher Halfar*), *Maryčka Magdanova*, and *Sedmdesát tisíc* (*The Seventy Thousand*).

In modern Germany and Austria, the most far-reaching attempt to bring together choral and orchestral forces in symphonic literature was that of Gustav Mahler. Unable for three years to find the solution to the problem of a finale for his second symphony, Mahler heard at the funeral of the eminent conductor-pianist Hans von Bülow the *Resurrection* Ode by the 18th-century German poet Friedrich Gottlieb Klopstock. He decided to use this poem as a basis for a choral finale in the *Symphony No. 2 in C*

Minor (1894). The use of massed voices for unaccompanied passages, such as the beginning of the ode, and later on with orchestral accompaniment and the collaboration of soprano and contralto soloists, affords ample evidence of Mahler's deep understanding of choral effects and techniques. The role of the choir is considerably less in his *Symphony No. 3 in D Minor* (1896), but it is nonetheless highly artistic and imaginative in the setting of the old popular verses *Es sungen drei Engel* ("Three angels were singing"). The *Eighth Symphony* (1906–07) marks the high point of symphonic choral music not only in Mahler's own output but in the entire history of the symphony as an art form. Instead of saving the chorus for climactic effects in the finale, as in his *Second Symphony* (and as in Beethoven's *Ninth*), Mahler integrates it from the very beginning into the complex and many-hued vocal and instrumental colours—eight soloists, a boys' choir, two large choirs of mixed voices able to project powerful antiphonal effects with orchestra and organ. This *Symphony of a Thousand,* as it is generally called, presents two texts of a complementary and opposing nature: the hymn *Veni creator spiritus* and the closing scene of Goethe's *Faust.* Mahler's inspired use of his colossal forces to enhance, explain, and endow with added meaning the divine and human aspects of the two texts is without parallel. His achievement has not since been matched for sheer virtuosity and impact.

The importance of Mahler

It is true that Arnold Schoenberg's *Gurrelieder* (1900–11) calls for even larger orchestral forces than Mahler's *Eighth Symphony,* although it has never enjoyed as much success. Choirs have preferred other early works of Schoenberg or those of Anton von Webern.

At the opposite end of the scale are the robust, tonal, and extrovert compositions of Paul Hindemith and also of Carl Orff, whose particular genius for setting classical and medieval texts may be seen in his *Catulli Carmina* (1943) and *Carmina Burana* (1937). Modern American choral music has been much enlivened by the contributions of Charles Ives (*An Election* composed in 1920), Randall Thompson, Roger Sessions, and many other eminent composers. Igor Stravinsky, who spent the latter part of his life in the United States, retained his interest in choral writing and constantly sought new ways of presenting the sonorities of a massed group of voices. To his earlier *Les Noces* (1923; *The Wedding*), and *Symphony of Psalms* (1930) for chorus and orchestra, he added the *Cantata on Old English Texts* (1952) on anonymous English poems of the 15th and 16th centuries and *A Sermon, A Narrative, and a Prayer* (1961) which is not a liturgical work, though its text is taken from the New Testament.

Twentieth-century English choral music for secular use finds one of its best advocates in Ralph Vaughan Williams, whose early setting of *Toward the Unknown Region* (first performed 1907) by the 19th-century American poet Walt Whitman was followed by *A Sea Symphony* (1910) based on material by the same poet. Frederick Delius also drew upon Whitman for his *Sea Drift* (1903) and upon the poems of the contemporary British poet Arthur Symons for his *Songs of Sunset* (1907). Britten's genius for word setting is evident in his *Hymn to St. Cecilia* (1942) and *A Ceremony of Carols* (1942) and in the handling of the boys' choir and mixed chorus in his *Spring Symphony* (1949), which ends with a choral waltz combining syllabic effects and the Old English lyric *Sumer is icumen in.* Outstanding among contemporary Polish choral works are three compositions by Krzysztof Penderecki: *Dimensions of Time and Silence* for chorus and chamber orchestra (published 1961); *Stabat Mater* for three choirs (1962); and *Psalms of David* for choir and percussion (1958).

Madrigals and related forms. A considerable amount of music sung by choirs in the 20th century is not really choral music at all, since it was conceived for performance by small groups of soloists and attains its fullest expression only through the individually projected personality of the solo voice. Assignment of these solo lines to a body of singers tends to neutralize this effect of personality, producing instead a weight of tone and an impression of superimposed dynamics and expression which, however carefully cultivated and disciplined, cannot surpass the kind of performance originally envisaged by the composer; yet a reasonable multiplication of voices does no harm to the texture as such, since the harmonies, the interweaving of parts, and the vocal spacing all remain constant. It is also true that a madrigal sung by 50 instead of by only five musicians will be more readily and rapidly understood by those directly involved because a massed performance of a five-part madrigal with 10 singers on each line is a more practical proposition than forming 10 separate consorts of five soloists. Individual voices, especially in amateur groups, may not possess the technique, the stamina, or the confidence to sustain a part on their own, but if they sing as a member of a group the likelihood is that they will achieve good results.

Choral performance of madrigals

Madrigals were originally published for professional singers and for amateur singers of high standard. They were issued not in score, as is the 20th-century custom, but in the form of part books, each one of which contained only the music necessary for one line—soprano, alto, tenor, bass, or any intermediate voice. The quantity printed of each edition was generally modest, with the result that prices were high, and choral performance was ruled out for economic reasons as well as artistic ones. The development of modern methods of engraving and printing music, allied to the creation of a worldwide market for choral works, has brought about a situation directly opposed to that of the Middle Ages and the Renaissance, whereby each singer now has a full score (or vocal score) that is less expensive than the part books printed in earlier times. In consequence, the choral performance of madrigals and related forms has become an economic possibility.

One of the most important predecessors of the madrigal proper was the frottola, which flourished in Italy between 1490 and 1520. In its early stages, the frottola was a song with instrumental accompaniment, with the main melody and text in the uppermost part (usually in the soprano or alto range) and supporting harmonies below. These harmonies were so simple and functional that an entire line could be dispensed with when intabulations for voice and lute were made. Four-part harmony was thus reduced to three, though without any serious loss since the polyphonic element tended to be of minimal importance. In later collections of frottolas, however, a different technique appears: instead of the upper line alone being supplied with text, all four parts join in. These completely texted frottolas were certainly intended to be sung by four singers, possibly, though not necessarily, doubled by instruments; and they could even have been sung by a small chorus.

Contemporary with the frottola were cognate forms such as the German lied, the French chanson, the Spanish villancico, and the English songs for voice and viols. All these began as accompanied songs, and all eventually followed the Italian fashion by dropping the instruments and substituting voices. This process was at first an obvious makeshift and can be detected as such because of the characteristically instrumental nature of the lower three parts, with numerous unvocal skips and contours. Words can be added to lines such as these, but they are often uncomfortable to sing because of the lack of conjunct movement and the paucity of breathing spaces. Occasionally, the added words appear only in one source, often a manuscript copy rather than a printed edition, the earlier sources on the other hand retaining the instrumental nature and function of the alto, tenor, and bass. The songs of Isaac provide clear examples of this gradual change, by which *Tenorlieder* (songs with the tune in the tenor) were transformed into part-songs by the addition of text to the instrumental lines. Some German composers, however, favoured the purely vocal or choral type of performance and made certain that all parts were texted.

Similar tendencies can be seen in France, in Spain, and in England, where many of the court songs written during Henry VIII's reign have text in all voice parts. One of the best known of these, *Passetyme with good cumpanye,* is a part-song for three male voices, written in all probability by the monarch himself. As the century progressed, amateurs began to take an interest in the part-song, which was generally for four voices, and several composers helped

Henry VIII's part-song

to lay the foundation for the English madrigal school. It is worthy of note that Byrd, in his *Psalmes, Sonets, & songs of Sadnes and pietie* (published, 1588), underlaid text to every part but mentioned in his preface that the songs were "originally made for Instruments to expresse the harmonie, and one voyce to pronounce the dittie."

The early development of the Italian madrigal was fostered as much by foreigners as by natives, and the considerable contributions made by the 16th-century Flemish composers Jacques Arcadelt, Philippe Verdelot, and Adriaan Willaert should not be underestimated. Although Willaert's settings of the works of the 14th-century Italian poet Petrarch and other serious Renaissance poets maintain an invariably high contrapuntal interest and are frequently suitable for choral performance, his compositions in the lighter, more homophonic vein, are well worth acquaintance.

Cipriano de Rore, another Netherlander adopted by Italy, felt Willaert's influence strongly yet contrived to set new standards in the interpretation of poetry through music and also to encourage an artistic fusion of the contrapuntal and homophonic styles, using them alternately in one and the same composition according to the dictates of the poem. Even his early madrigals show a deep concern for intensity of expression, as in the Petrarch setting for five voices *Hor che'l ciel e la terra.* One of his finest four-part madrigals, *Ancor che col partire,* sets off pairs of voices one against the other. New heights of expression are reached in his descriptive madrigal *Quando lieta sperai* (text by the woman poet Emilia Anguissola), in which a sudden and disappointing change in the weather is perfectly mirrored in the music. The four-part *Datemi pace,* based on a Petrarch sonnet, favours homophony and looks eagerly forward to the bold chromaticism of Pomponio Nenna and Don Carlo Gesualdo. In his maturity, Rore produced a number of remarkably intense madrigals for the court of Parma. One of the finest is his setting of *Dalle belle contrade,* full of powerful contrasts of mood and colour underlining the interplay of direct and indirect speech.

Further experiments in chromaticism were carried out by Nicola Vicentino, whose dramatic setting of *O messaggi del cor,* by the Renaissance poet Ludovico Ariosto, makes highly effective use of a mounting modulatory scheme (changes of key) to enhance the insistent repetition of the opening exclamations. His early madrigals exploit a more classical vein, without ignoring illustrative possibilities. His most typical and fascinating work is nevertheless to be found in such madrigals as *Poichè il mio largo pianto* or *L'aura che il verde lauro* in which Petrarch's verbal puns are suitably matched by Vicentino's harmonic ambiguities. Even more extreme is the Neapolitan composer Pomponio Nenna, whose striking and original harmonies must have made an indelible impression on his pupil Gesualdo. But whereas Gesualdo's chromaticism is often wayward and illogical, that of Nenna tends toward reason and reality. Several of the master's madrigals can be usefully compared with those of his noble pupil that were set to identical texts. *Mercè, grido piangendo,* for example, is treated by Nenna with an enviable intensity of expression heightened by tremendous contrasts of timbre and dynamic; and, although this pattern is followed in Gesualdo's setting (*Book V,* 1611), perhaps with even greater violence, the most favourable musical impression comes from Nenna. His four-part madrigal *La mia doglia s'avvanza* is startling by any standards, for the opening four bars move rapidly from G minor to F-sharp major, D minor, and C-sharp major.

Gesualdo's extraordinary range

Gesualdo's preoccupation with poems containing diametrically opposed ideas and concepts finds its outlet in his last two books of madrigals (V and VI, both 1611). *Itene, O miei sospiri* not only looks forward in its manneristic treatment of vocal texture and harmony; it looks backward to classical procedures such as the interpolation of rests at the word *sospiri* (sighs), invented much earlier when the quarter-note rest was called *suspirium.* It would be wrong, however, to classify Gesualdo as an extremist on every occasion, for he could often write melting phrases of unforgettable beauty. He can even be witty at times, as in the madrigal about a venturesome mosquito (*Ardita zanzaretta*), which is somewhat in the vein of a vocal scherzo.

Luca Marenzio, one of the most prolific among late 16th-century Italian madrigalists, achieved his high reputation not through experiment but rather through his remarkable sensitivity to words, both as single entities and as the basic elements of a poetic phrase. His balance between the two opposing claims of general mood and particular effect is always perfect, and the mastery of his vocal spacing is probably unrivalled, no matter whether four, five, or six parts are involved.

At the court of Mantua (now Mantova, Italy), two important composers were active toward the very end of the 16th century—Giaches de Wert and Giovanni Giacomo Gastoldi. Each of them, in his own particular way, helped to renew and transform madrigal techniques even though the countless admirers of Marenzio felt that the pinnacles of perfection had already been reached. De Wert's contribution to the new madrigal was in some ways unusual and unexpected, for he approached the dramatic madrigal-poetry in a way that combined realism with clarity. He returned, in fact, to homophonic writing when it was necessary to emphasize a point, allowing the highest voice part to project the melody in what was essentially a kind of "choral recitative." His pupil Monteverdi published nine books of madrigals. From the sixth book onward continuo support becomes obligatory, and in consequence solo voices emerge from a choral background with tremendous dramatic effect, especially in the later works. The ballet *Tirsi e Clori* is rich in five-part choral writing of considerable elegance and resource, and the same is true (though in six-part texture) of *Altri canti di Marte. Vago augelletto* contrasts solo and choral writing until the last tutti, when all singers combine in a sonorous statement. Perhaps the greatest Monteverdi work of all is *Hor che'l ciel e la terra,* a six-part madrigal in two sections, with many solos and choral sections accompanied by violins and continuo. Monteverdi rarely surpassed the heights of emotional expressiveness found in this product of his maturity.

Monteverdi's mastery of the madrigal

At the time of the Italian madrigal's fullest flowering, German composers derived much inspiration from the south while still contriving to retain something of their earlier heritage. The result was often a kind of international style, greatly influenced by Orlando di Lasso, who was as much at home writing Italian madrigals as he was with French chanson and German lieder. His pupils, the Austrian Leonhard Lechner and the German Johann Eccard, developed this style still further, as may be seen in the former's setting of *Wohl kommt der Mai* (*Welcome May*), a lively and optimistic May song full of expressive harmonic colour. The setting by Lasso of the same text is calmer, more homophonic; yet its apparent simplicity and unostentatiousness hides a subtle and skillful mastery of vocal art.

In his five-part lieder, Lasso makes the most of contrasting duets and trios very frequently, as in *Es jagt ein Jäger* a hunting song which serves as an excuse for lightly concealed amatory dalliance. Hans Leo Hassler was obviously fired by Lasso's lead in the sheer variety and latent possibilities of secular vocal style, and much of his best work was done in the dialogue form. A peak of brilliance and energy is reached in his eight-part dialogue for two opposing choral bodies, *Mein Lieb will mit mir kriegen* (*My Love Wants to Wage a War*), which might be described as a musically stylized battle of the sexes, with blows given and taken freely until the two groups combine to sing of final reconciliation and contentment.

Dialogues in this vein were also cultivated successfully by Christoph Demantius, whose anthology of 1609 contains examples of memorable beauty and charm. In his *Jungfrew, ich het ein' Bitt' an euch* (*Maiden, I have a Request for You*), Demantius allows one four-part choir to represent the girl and the other the boy in a conversation full of innocent affection and honest courtship, the two groups joining at the end to sing goodnight. In his five-part lieder, Demantius sometimes displays a learned touch in his imitative counterpoint, although the general impression is one of Italianate elegance rather than of studious endeavour. It is worthy of note that many of his lieder are

strophically conceived, and in consequence he printed the verses complete in each voice part, a feature which has been unfortunately obscured in the modern edition of his works. One of the finest of his lieder is *Lieblich ich hörte singen*, which tells of the Sirens' song and reproduces its allegedly hypnotic effect by means of flowing melismata in the upper voices.

The dialogue, considered as an art form of the Renaissance and Baroque eras, contains many choral elements. In its earliest form, as exemplified by the dialogues of Willaert, seven voices is the norm, and the texture is not yet clearly separated into two groups. Instead there is a kaleidoscopic impression caused by the skillful deployment of varied groupings. By the time of Andrea Gabrieli, a dialogue such as the popular and erotic *Tirsi morir volea* calls for a trio of high voices representing the girl and a quartet of deeper voices for the man. The amorous interchanges are carefully allocated to the individual groups, and there is no attempt to join them together until the very end. But in a typical dialogue by the younger Gabrieli, *Dormiva dolcemente*, there is no relationship between direct and indirect speech as far as the music is concerned. The setting is in this sense abstract, and the beauty of the dialogue lies in its purely musical architecture and expression.

The dialogues of Lasso

One of the greatest masters of the French dialogue was Orlando di Lasso, who set two poems of the 16th-century French poet Pierre de Ronsard in eight-part, double-choir compositions of exceptional quality. *Que dis-tu, que fais-tu?* (1576; *What Are You Saying, What Are You Doing?*) plays off one group against another in a series of sympathetic exchanges culminating in a final chorus praising the constancy of the lovebirds. Another masterpiece of this kind is *O doux parler* (1571), in which the interlocutors are human and the approach of both poet and composer more intensely passionate.

The French chanson, one of the most popular secular vocal genres in the 16th century, is essentially in miniature form. Unlike the Italian madrigals, which were sometimes composed in sequences of three, four, or more sections, French chansons tend to remain individual in the sense that they are self-contained, epigrammatic, and brief. It is partly for this reason that they have been less explored by 20th-century choral groups, although the language factor must also be taken into consideration.

English madrigals, because of their relatively innocuous texts and their moderate degree of difficulty, have always been a staple diet of choral societies and to an even greater extent of chamber choruses. The 16th- and 17th-century madrigals of William Byrd, Thomas Weelkes, John Wilbye, Thomas Morley, and their contemporaries and successors are too well-known to need elaborate description and too numerous to permit individual discussion. It is nevertheless true that although this repertory may today be considered as generally choral, certain madrigals are better reserved for performance by soloists. The criterion for making such a choice lies often with the text rather than with the music, for a certain degree of personal intensity in the words demands a corresponding projection of individual lines and their message. On the other hand, others are eminently suitable for choral performance.

After the vogue of the madrigal had disappeared, that of the glee eventually took its place, flourishing from the early 18th century to the middle of the 19th. Like the madrigal, the glee was originally intended for solo voices, but choral performances were by no means infrequent. The word glee, derived from the Anglo-Saxon word for music (*gligge*) does not necessarily imply a composition of a cheerful nature, and many of the best glees in fact express solemn or poetic themes. Samuel Webbe's *Glorious Apollo* and R.J.S. Stevens's *Ye spotted snakes* provide very different, though typical, examples of this vocal genre. Tonality is for the most part simple and unaffected, harmony is robust, and the span of musical thought necessarily brief. (D.W.S.)

Theatre music

Music as an art of the theatre has its roots in primitive ritual and ceremony and its branches in every modern means of theatrical presentation. Its functions are as varied as the forms require and range from being the primary reason for performance, as in opera, to mere noise, filling a vacuum in imagination for some screen and stage presentations. The more significant and universal aspects of theatrical music are considered in this section; opera is the subject of a separate section.

Theatre music is all music composed to govern, enhance, or support a theatrical conception. Music composed for theatrical purposes obeys different laws than does the music for concert performance or conventional opera. Whereas in opera the music dictates the form in which the dramatic visual imagery is presented and governs its development, in other kinds of theatre the music is, at best, an equal partner among its principal elements. In concert, of course, the music is the sole factor that determines the experience.

In the West, the concept of music as an intellectual experience for its own sake emerged only in the second half of the 18th century. Theatrical music is variously related to something other than itself, whether as an enrichment of words (as in operetta), a factor in structure and mood (ballet), or an intensification of situation and feeling (as in incidental music for plays and films).

In some instances music is dominant, in some it is subservient, and in operetta or stage musical the emphasis alternates between speech, song, and dance. In opera and spoken drama, in which words are wholly sung or spoken, a convention once set is consistently sustained and thereby creates its own kind of reality. The constant change of focus in operetta and musical, from music to speech and back again, emphasizes the artificiality of the illusion they seek to create.

The classical mainstream of theatre music in the West extends from the mid-17th century to the 1930s, and the instances of drama and music meeting on an equal level of imagination are relatively few. More frequently great music was lavished on weak or corrupt theatre, or great drama was embellished with indifferent music. From the early 20th century new dramatic developments were seldom directly matched in music. A German-Italian composer, Ferruccio Busoni, wrote in 1906:

> The greater part of modern theatre music suffers from the mistake of seeking to repeat the scenes passing on the stage, instead of fulfilling its own proper mission of interpreting the attitudes of the persons represented.

The German composer Kurt Weill's score for *Der Silbersee* (1933; *The Silver Sea*) was the last major musical contribution to a serious play requiring a full orchestra and chorus. Thereafter, for economic reasons, the dramatic theatre had to equip itself with small-group music or prerecorded tapes. The orchestra and chorus became the prerogative of stage musicals and films. The more these were commercially debased the more they came to rely heavily on the clichés of 19th-century music, to the exclusion of newer musical developments.

Producers of stage musicals, the choreographers of dance, and the directors of drama need to be wary of the properties of music. It is more demanding of attention than is often thought, and its use should ideally be confined to circumstances where it can provide something that none of the other theatrical elements can offer. The more its qualities are understood and respected, the better it can be guided to an effective theatrical purpose.

MUSIC FOR BALLET

The partnership of choreography and music

During the 20th century the element of music in all forms of ballet has changed and developed its significance to an unprecedented extent. It has acquired the status of an equal partner with the choreography, where once it was entirely the servant of the ballet master. In the 19th century he asked little more than that the music should decorate his ballets prettily and give rhythmic support to the movements of the dancers. His modern successors have been made aware that the highest level of balletic achievement now requires the music and choreography to become extensions of each other, to be heard and seen on equal levels of perception.

The finest modern choreographers are not content simply

to ride the surface of their chosen music, whether it is specially written, borrowed, or adapted. They seek to exploit the relationship of eye and ear, recognizing that the effect of any danced step can be changed by the stress of the musical rhythm, the degree of loud or soft in its dynamics, the nature of its harmonic character, and the expressive quality of its instrumental timbre. All these factors can make a positive contribution to the balletic image, and they give coherence to the sequence of movement as they merge into its continuous momentum.

Until the end of the 19th century, each new ballet customarily had music specially composed for it, but it was rare for any composer of distinction to write ballet music, unless it was part of an opera. There were exceptions—such as Beethoven's score for *Die Geschöpfe des Prometheus* (1801; *The Creatures of Prometheus*), originally a ballet by an Italian choreographer, Salvatore Viganò—but the great era of Romantic ballet from about 1830 was seldom enhanced by music of intrinsic worth. When ballet gained a musical interest, the difference was soon apparent; it has been well said that Léo Delibes gave ballet music a heart, Peter Tchaikovsky gave it a soul, and Igor Stravinsky made an honest woman of it.

Stravinsky's influence on music for ballet

Stravinsky was the dominating figure for nearly half a century (beginning in 1910) in composing music for ballet. He gained international acclaim with the first products of his collaboration with the Ballets Russes of the Russian impresario Sergey Diaghilev: *The Firebird* (1910), *Petrushka* (1911), and *The Rite of Spring* (1913). The first two continue to be performed in their original choreography by Michel Fokine, also a Russian, each with a narrative basis illustrated in music notable for its expressive colour and harmonic innovations. *The Rite of Spring* provoked one of the most notorious scandals in theatre history when Vaslav Nijinsky's original ballet reduced its first Paris audience to verbal insult and physical assault; its rhythmic audacity has since remained a recurring challenge to other choreographers.

Largely as a result of the standard set by Diaghilev's flair and artistic success, most leading composers in the 20th century have contributed something to the art of dance. Diaghilev directly commissioned two outstanding examples in the French composer Maurice Ravel's *Daphnis et Chloé* (1912), which the composer defined as a "poème chorégraphique," and *The Three-cornered Hat* (1919) by the Spanish composer Manuel de Falla. Distinctive original scores for ballet continued usually to be the outcome of specific commissions. Composers do not yet normally think in terms of dance (as they do in terms of song), although in Great Britain the composer Peter Maxwell Davies incorporated an integral role for solo dancer in his otherwise instrumental work, *Vesalii icones* (1969).

Contrary to what is still sometimes thought by musicians and a section of the public, music for ballet is not necessarily written to be "interpreted" in dance. Stravinsky has emphasized:

> Choreography must realise its own form, one independent of the musical form though measured to the musical unit. Its construction will be based on whatever correspondences the choreographer may invent, but it must not seek merely to duplicate the line and beat of the music.

Stravinsky's collaboration with Balanchine

The composer was writing from the experience of a long collaboration with a Russian-born choreographer, George Balanchine, mainly for what is now the New York City Ballet. Their partnership began in 1928 with *Apollo*, reached a peak in 1957 with *Agon*, and was to the 20th century what the collaboration of Tchaikovsky with choreographers Marius Petipa from France and Lev Ivanov from Russia was to the 19th.

In the former Soviet Union and present-day Russia, a post-Revolutionary equivalent to the classical three-act narrative ballet has continued to be in demand. This form has been furnished by many composers of ballets that have not been performed outside of Russian cultural circles, but it has been chiefly distinguished by the work of Sergey Prokofiev. His full-length scores for *Romeo and Juliet* (1940), *Cinderella* (1948), and *The Stone Flower* (posthumously staged in 1954) have variously succeeded in reconciling an older classical form to new expressive demands. Its offshoots in western Europe have included, in Great Britain, Benjamin Britten's music for *The Prince of the Pagodas* (staged by the Royal Ballet, 1957) and Hans Werner Henze's music for *Ondine* (Royal Ballet, 1958).

The stronger emphasis in western Europe and the United States in the late 20th century was on one-act ballets, varying from about 15 minutes' to more than one hour's duration. Composers continue to show some reluctance to write music specifically for dancing, partly because they are seldom closely involved with the art and also because they have relatively less control over the finished performance than in opera and in most other forms of musical theatre. Apart from works already mentioned, however, the ballet repertory has been enriched by such scores as the French composer Erik Satie's *Parade* for Diaghilev in 1917; the British composer Vaughan Williams' *Job* (1931) and the English composer Sir Arthur Bliss's *Checkmate* (1937) for the British choreographer Ninette de Valois, in Britain; and the American composer Aaron Copland's *Appalachian Spring* (1944) and the American composer Samuel Barber's *The Serpent Heart* (1946; later revised as *Cave of the Heart*, 1947) for the choreographer Martha Graham, in the United States.

Creation of modern ballets to existing scores

Nevertheless, the greater proportion of new ballets in the West during the last half-century have been created to preexisting music, and it is evident that choreographers have felt a greater freedom to experiment visually in the use of such music. The practice dates principally from the first orchestration (by the Russian composer Aleksandr Glazunov, 1894) of an arbitrary suite of piano music by Frédéric Chopin to which Fokine created *Chopiniana* (1908)—a title retained by Soviet ballet companies for what Diaghilev renamed *Les Sylphides* (1909). More than 60 years later, another arbitrary suite by Chopin, although retained in its piano form, proved to be no less fruitful for the American choreographer Jerome Robbins in *Dances at a Gathering* (1969).

Almost every category of music—from medieval music to advanced electronics and from symphonic compositions to the simplest pop tunes—has now been used for choreographic purposes. The function of music in a dance context has varied almost as much—staining the ballet's surroundings as a kind of aural decor at one extreme, as with the soundscapes of John Cage for Merce Cunningham's dance works in the United States, to the mutual absorption of music and choreography phrase by phrase in such works as the British choreographer Sir Frederick Ashton's *Symphonic Variations* to the music of César Franck (Royal Ballet, 1946), as well as the Balanchine-Stravinsky *Agon* (1957) and *Movements* (New York City Ballet, 1963).

Sometimes the same music has been used for several different ballets within a short time by various choreographers. An outstanding example is the *Sinfonia* by an Italian composer, Luciano Berio, written originally in 1968 as a concert work. By the end of 1971 it had been taken over for at least eight separate ballets in almost as many countries in western Europe alone.

Ballet concerned with musical associations

Another trend in ballet in the second half of the 20th century has been to make ballets apparently more concerned with musical associations than with human personality. Instances include Balanchine's *Agon* and *Movements*, already mentioned, and the British choreographer Kenneth (later Sir Kenneth) MacMillan's *The Song of the Earth* (1965) to the song-symphony by the Austrian composer Gustav Mahler. The dancers seem required to assume the "personality," or expressive character, of the musical instruments they parallel, as if the choreographers were moving toward a form of "ideal" dance once postulated by a French poet, Stéphane Mallarmé, who envisaged music and dance not only as equals but also equally devoid of human personality.

In the view of most ballet critics, the antidote lies in the continuing appeal of narrative dance-dramas with their illustrative music, although the success or otherwise of any ballets that engage preexisting music is basically governed by a single crucial principle: the level of choreographic imagination should never be less than that of the music. A ballet can be better than its music, but it can never

afford to be worse. There will always be ballets dependent on music for no more than expressive colour and supporting rhythm, but the "perfect analogous concord between what we see and what we hear," recommended as the ideal nearly 150 years ago by Carlo Blasis, a great Italian teacher, still remains the most desirable aspiration for every kind of ballet music.

STAGE MUSICALS

When, in the 1930s and '40s, dancing became an integral element in a genre governed chiefly by song—instead of being merely a diversion—the "musical" established itself as the legitimate theatrical heir to "musical comedy" and a form of popular theatre art that dominated the latter half of the 20th century. It has been challenged by the newer "rock musical," using a variation of the common musical vernacular and techniques related more to the recording studio than to the theatre, the effect of which is not yet determined. Meanwhile, what originally started as a democratic counterpart to aristocratic opera reached its fruition as the theatrical association of sentiment with illusion.

The sentiment is usually dispensed by the narrative; the illusion is created by the music. The most potent narratives in stage musicals have often been adaptations of classical drama and literature—for example, *Romeo and Juliet* transformed into *West Side Story: The Taming of the Shrew* into *Kiss Me, Kate; Don Quixote* into *Man of La Mancha;* and *Oliver Twist* into *Oliver*—or the many variations on the *Cinderella-Pygmalion* legend by which rags are transformed into riches (from *The Shop Girl* in 1894 to *My Fair Lady* in 1956). A distinction was at one time drawn between the frivolous musical comedy and the "musical play," denoting a dramatically serious or even tragic narrative, but both are now equally defined as musicals.

Their specifically musical character is born from a marriage of convenience between first- and second-generation descendants of European operetta and music-hall variety, on the one hand, and American jazz and American music hall, on the other—plus the romantic balladry of both continents. An English musicologist, Wilfred Mellers, asserts that, although most successful stage songs contain subtleties unappreciated by the nonmusical listener, they all reflect "an illusion that we can live on the surface of our emotions" and that "the world of musical comedy never gets beyond, or wants to get beyond, this illusion."

First musical comedy

The first musical comedy to be called so was *A Gaiety Girl,* staged in 1893 by George Edwardes at the Gaiety Theatre, London. A romantic farce adorned by the songs of Sidney Jones, it was successfully exported to New York in the same year. John Hollingshead (Edwardes' predecessor at the Gaiety Theatre) wrote in 1903:

> The invention or discovery of musical comedy was a happy inspiration of Mr. George Edwardes's. It provided a new form of entertainment for playgoers who go to a theatre for amusement and recreation, which was more elastic in plot or story than the old burlesque . . . [It] exhibited a little of the old burletta and vaudeville, most of the best elements of farce, a dash of the French revue . . . and much that would not have been out of place in Parisian *opéra-bouffe.*

Some 50 years of development in musical theatre are reflected in the contrast between the foregoing remarks and the following comment in 1952 by Jack Burton, American theatre historian, on *Oklahoma!* (1943), an epoch-making musical by Richard Rodgers and Oscar Hammerstein:

> This phenomenal production set a new pattern in which every line, every song, every dance routine is an indispensable part of a closely-knit whole. It was a show that had dramatic substance and never ran off the plot track, and so real, so simple, so engrossing was its story that its narrative could be safely entrusted to other than big-name stars.

The years embraced by these comments set up a dominant axis of theatrical exchange between New York and London. Success in this field is governed more by economic than artistic considerations, with longer and longer runs of each production becoming necessary to recover increasingly heavy expenditures before profits can be made. The primary requirements for the composer are, therefore, quick assimilation combined with durability. His music should also be easily adaptable to other media such as motion pictures and phonograph or tape reproduction, whereby it becomes a commonplace of experience to a mass audience far beyond the reach of the original theatrical context.

Although musical theatre of this kind has developed toward a closer integration of music and story, its primary feature has remained the individual song. Lehman Engel, a leading conductor of stage musicals in the United States, has defined five types of song basic to the stage musical: ballad—usually but not exclusively romantic in feeling; rhythm song—varied in emotional character but primarily propelled by a prominent musical beat; comedy song—enhancing verbal humour and divided into "short joke" and "long joke"; charm song—generally delicate, optimistic, and lightly rhythmic; and musical scene—in which a song may form part of a continuous dramatic episode. Engel further asserts that the successful impact of any song in the first instance is generally governed by the following considerations: the tempo, the mood of the scene, the song's position in relation to the whole production, the inherent value of the song itself, and the relative importance of the character who delivers it. It will be noted that integral musical quality is subordinate on this scale, although it is specifically the musical appeal that establishes success in the first place, disseminates that success through other media, and may later lead to revival in the country of origin and to reproduction in other countries.

Success of *My Fair Lady*

One of the most successful specimens is *My Fair Lady,* with music by Frederick Loewe, a Viennese-born American composer. This musical had first runs of 2,717 performances in New York (from 1956) and 2,281 in London (from 1958), and it has since been staged in translation in most European countries. It is rare for the English-language dominance of the musical-comedy genre to be breached by other countries, as France did with *Irma la Douce* (1956) or pre-Nazi Germany did with *Die Dreigroschenoper* (*Threepenny Opera,* 1928) and *Im weissen Rossl* (1930; *White Horse Inn*); but in most European countries except Britain the line between musical and operetta (see below) is less distinctly marked.

In Italy such lighter forms of musical theatre are submerged in an already popular taste for the broadest range of opera, while in Spain they manifest themselves in the category of zarzuela (discussed below in conjunction with operetta). Differences of idiom are often more the outcome of theatrical or other conditions in their respective countries than of theatrical or musical distinctions in the work itself. In the erstwhile Soviet Union, the musicologist Andrey Olkhovsky once noted that

> the numerous attempts which have been made to create a Soviet repertory have led to no results. At best the plots of comedies are based on episodes from Soviet life, but musically they are still imitations of the pre-Revolution operettas.

Stage musical comedies in the Western sense have produced their own original talents among composers—notably Jerome Kern, Irving Berlin, George Gershwin, Cole Porter, and Richard Rodgers in the United States and Noel Coward, Vivian Ellis, Ivor Novello, Lionel Bart, and Sandy Wilson in Great Britain. They have also had occasional recourse to adaptations from classical composers, including Franz Schubert and Edvard Grieg, who are dramatically characterized respectively in *Lilac Time* (originally *Das Dreimäderlhaus;* 1916) and *The Song of Norway* (1944); Georges Bizet, whose music became the basis of *Carmen Jones* (1943); and Aleksandr Borodin, for *Kismet* (1953).

Musicals ought to be adaptable to varied instrumentation, because theatre orchestras can vary considerably in size and composition from place to place. Paradoxically, the looser form of the rock musical is propelled by a much more rigid instrumentation derived from the ensemble used in pop-music recording, itself determined by studio techniques. In *Jesus Christ Superstar* (1971) the covering of the orchestra pit, the permanent amplification of instruments, and the use of voices entirely dependent on microphones amounts to a replacement of the illusion of theatre in any traditional sense

The rock musical

with the actuality of a modern recording studio made visible.

MUSIC FOR MOTION PICTURES

Many successful stage musicals have become additionally popular through the medium of motion pictures, but music as a basic element in filmmaking has gained recognition only since midcentury as something more than a means to heighten local colour or intensify emotional expression. In the early silent films, all kinds of music were recorded, classified, and adapted to fit different moods (Beethoven overtures for cowboy-Indian chases, for instance). Several talented hacks also wrote short descriptive pieces. A few bigger films, such as *The Birth of a Nation,* had special scores fitted to them. Since the 1960s it has turned a full circle of the wheel back to extensive musical quotation from classical resources for similar ends but in different ways.

Russian filmmakers first gave serious consideration to the contribution music could make. V.I. Pudovkin, a Russian musicologist, defined a theory and practice of film music in the early 1930s, advocating a close and contrapuntal relationship between sound and sight. The Russian film director Sergey Eisenstein described his careful collaboration with Prokofiev in making *Alexander Nevsky* (1938). His perceptive observations on the potential link between cinematic rhythm and musical rhythm suggested a technique that has influenced others, such as the British composer Sir William Walton in his score for *Hamlet.*

Hanns Eisler's theories of film music

Hanns Eisler, a German-born composer, formed his own theories of film music, based on empirical experience composing in this medium. His published findings recommended short musical forms in a film context, the composer's conscious awareness of the film's realistic sound element (the "where" and "when" of its location), and music that could suggest an objective, universal character for the film's emotions, rather than being introspective on its own account. Eisler also supported Pudovkin in maintaining that film music should create its own sense of line independently of, although related to, the film narrative.

Film music has travelled through five broad phases: an initial borrowing from existing conventional sources; the use of musical-cliché catalogs, which enabled any musician of modest ability to assemble an emotional or dramatic sequence and which served as the basis for most later background music in films; the active interest of major composers in writing original scores; a subsequent reaction of either near silence or advanced techniques of electronic sound generation and transformation; and the borrowing from classical sources for new purposes.

In France, in particular, the regular participation of leading composers in film music has been the rule rather than the exception. The opposite holds true in the United States and Great Britain, although most composers of distinction in both countries between the mid-1930s and the mid-1950s made some original contributions to the motion-picture medium. In the United States these included Aaron Copland, Marc Blitzstein, and Virgil Thomson, who received the first Pulitzer Prize awarded to film music—for *Louisiana Story* (1948); in Great Britain, Ralph Vaughan Williams, Benjamin Britten, Sir William Walton, Alan Rawsthorne, and Richard Rodney Bennett.

Isolated experiments to marry films to specific classical music have been made from time to time. These include the Austrian director Max Reinhardt's film of Shakespeare's *A Midsummer Night's Dream* (1935), which varied the cinematic structure to incorporate the complete suite of Mendelssohn's incidental music originally written for the play. The American filmmaker Walt Disney's celebrated *Fantasia* (1940) adapted the technique of the animated cartoon to illustrate a sequence of musical classics, outraging some people because the visual relationships were held to be irrelevant to the music but continuing to the present to entertain audiences, especially young ones, on an international scale.

When the making of motion pictures became an industry more than a craft, a situation developed in which music was recognized as desirable by the manufacturers, who nevertheless made no claim to "understand" music in the way they would be expected to understand motion-picture techniques. A parallel attitude among musicians unfortunately came to regard the skilled provision of a score tailored to the demands of script and camera as a spiritually impoverished relation of aspiring symphonic or operatic works.

Renewed use of concert music

In the late 1960s original film composition tended to decline in favour of renewed and often extensive borrowing from existing concert music. The slow movement from a Mozart piano concerto served to express the passage of time as well as for emotional mood in *Elvira Madigan.* The American film director Stanley Kubrick's *2001: A Space Odyssey* (1968) led an audience's imagination outward into space by a transition from the diatonic (using the natural scale of five tones and two semitones) C major of the introduction to Richard Strauss's tone-poem *Also sprach Zarathustra* to the polytonal Kyrie from the *Requiem* by the contemporary Hungarian-born composer György Ligeti. In the Italian film director Luchino Visconti's *Death in Venice,* four repetitions of a long passage from the Adagietto movement of Gustav Mahler's *Symphony No. 5* achieved a different expressive purpose in association with the visual scene each time it was heard.

Examples like these achieved an even greater impact than many original scores because they formed an organic part of the filmmaker's conception. Conversely, even scores distinguished by their own merits—such as Copland's for *Of Mice and Men* (1939) or Walton's for *Henry V* (1944)—were added only after the film itself was more or less finished. The major hope for the future of this medium lies in what Vaughan Williams urged: the composition of original scores but prepared in conjunction with the director from the film's inception. Film music might then be turned to more constructive instead of merely decorative purposes, without the dramatic license of the British film director Ken Russell's treatment of extensive passages from Tchaikovsky's music in his film *The Music Lovers* (1971).

MUSIC FOR TELEVISION

The screen medium's first law, that the visual element must come first, has been intensified by television. On the home screen, the experience of music performed for its own sake customarily operates under a double disadvantage. First, it runs the risk of being swamped by its visual presentation, which may range in character from the matching of nonmusical images in varying degrees of relevance to the technique of using close-ups of musicians in action. Secondly, it suffers the continuing handicap of inadequate reproduction by the average television receiver.

Limited repertory of television music

Apart from rare exceptions—such as an occasional "television opera," a dance-film, or Stravinsky's mixed media *The Flood* (1962)—original music to television is chiefly confined to the provision of theme passages or supporting music hopefully intended to enhance verbal or dramatic presentation. Like the cinema pianist who played for silent films, television music has a limited repertory of conventional gestures. Even when these are given a more contemporary harmonic or instrumental garb, they remain basically governed by the 19th-century mode of musical thought, to which it is assumed that mass audiences will most easily react.

Programs about, rather than of, music have obtained a modicum of television success. While the occasional theme quotation has perhaps introduced a famous musical classic to millions who would not otherwise havehead it, the "workshop" program, showing how music and musicians go about their business, has broken down barriers of technique and exposed the raw materials of music in a way that has probably helped to foster a wider interest in the finished product. Television cannot otherwise be accepted as a musical medium, until sets have a higher standard of musical reproduction.

INCIDENTAL MUSIC FOR THE THEATRE

Incidental music in the theatre, whatever its idiom or degree of stylistic emancipation, justifies itself through its exclusive concern with a specific play or theatrical presentation. Its three main uses involve songs, intensi-

fied dramatic effect, and interlude filling, and these have been clearly defined in Western theatre since Renaissance drama freed itself from the church in the 16th century.

A major modification of its character since the 1920s has been brought about largely by the wider use of mechanical techniques of amplification and recorded music. This has encouraged short musical fragments rather than fully composed pieces, except where the latter are specifically called for. Examples of this technique were heard in modern times in the musical productions of the National Theatre and the Royal Shakespeare Company in Great Britain. Such carefully planned but more informal use of incidental music has replaced the elaborate suites customary in the 19th and early 20th centuries, which presupposed the complete performance of each piece and required the stage drama to be produced so that the music could be accommodated in it (a characteristic example is Mendelssohn's music for *A Midsummer Night's Dream* at Potsdam, Germany, in 1843).

Informal incidental music

Economic conditions are now the principal factor governing the provision of incidental music. Theatres not concerned with opera or ballet can no longer afford to hire musicians for a pit band. Trade-union restrictions in the musical profession also limit the public use of recorded music in many countries. The trend is consequently for spoken drama either to dispense with music, to restrict it to one or two musicians with a singer, or to make increasingly fruitful use of electronic sounds on prerecorded tape.

Some famous 19th-century suites of incidental music were brought into being by conditions that favoured resident musicians at court theatres in Germany or lavish orchestral resources in Tsarist Russia. The music has since acquired independent status on its own merits and has become part of the classical concert repertory, such as the Mendelssohn just mentioned and Beethoven's music for Goethe's *Egmont* (1810); Schubert's for the German playwright Helmina von Chézy's *Rosamunde* (1823); Schumann's for Lord Byron's *Manfred* (1852); and Grieg's for Henrik Ibsen's *Peer Gynt* (1876).

Earlier theatre music was often, for long periods of time, governed by measures of censorship and legal restrictions that varied greatly from one country to another. In England, for instance, the monopoly of spoken drama was vested by King Charles II in the Theatres Royal in the 17th century, and this continued until 1843. Other theatres that opened during this time—including those catering to a new working class—were licensed only on condition that plays included five musical items in each act or a "musical accompaniment." The latter condition was sometimes held to be satisfied by no more than a chord struck at intervals on a piano during the performance. Such conditions inevitably brought about a profusion of inferior music, which in turn gave rise to the traditions of music hall and burlesque.

The renaissance of secular theatre, from the 17th century onward, led in Italy to the evolution of the predominantly musical forms of opera and oratorio, in France to the court ballet, and in England and Spain to the cultivation of spoken plays with incidental music. The unparalleled achievements of secular drama in the latter two countries are the roots of present-day musical theatre and help to explain why opera failed to flourish in competition. The drama in England expanded into the allied form of masque and involved the participation of such composers of distinction as Henry Purcell.

The masque in relation to its own period might well have been defined as "mixed media." This term has now come to stand for theatre presentations in a line of descent from Stravinsky's *Histoire du Soldat* (1918; *The Soldier's Tale*), which combines speech, song, mime, dance, and instrumental music with pictorial design. These elements have since been supplemented by the mechanical techniques of film or photographic projection, and of electronic sounds, in almost infinite permutations, together with a free form of expression no longer necessarily shaped by a narrative content.

The masque

Most of these manifestations incorporated two different kinds of musical contribution. One has been defined by a 20th-century German composer, Bernd Alois Zimmermann:

> All elements of the theatre of movement, including film, sound, speech, electronic music, must be mobilized into one great time-space structure, whose arrangement will be constituted by music as the most general form of temporal order.

Zimmermann's ideas were embodied in his opera, *Die Soldaten* (The Soldiers). The alternative is described by another composer, John Cage, as "Single sounds or groups of sounds which are not supported by harmonies but resound within a space of silence" and are added more or less at random to the other elements. It remains to be discovered whether the future of theatre music in drama or mixed media lies primarily with the highly organized patterns of interaction postulated by Zimmermann or with Cage's arbitrary combination of simple, disparate activities into a complex whole.

OPERETTA AND ALLIED FORMS

It seems unlikely that any future exists for operetta except as part of a "museum" repertory, because the contemporary musical has taken its place in musical theatre. Operetta in the usual sense of a work of lesser musical pretensions than opera, with spoken dialogue linking the musical episodes, was a direct descendant of comic opera, overlapping this category, on one hand, and early musical comedy, on the other. It was born as a democratic expression of popular wit and social satire, flourished for almost exactly a century (*c.* 1840–1940), and died from a surfeit of sentiment.

Offenbach. The satirical, romantic operetta emerged primarily in Paris in the mid-19th century with the French composer Jacques Offenbach; two of his works are still widely staged: *Orphée aux enfers* (1858; *Orpheus in the Underworld*) and *La Belle Hélène* (1864; *Beautiful Helen*). The character of Offenbach's operettas established several musical precedents, including the burlesque of Italian opera, the romantic ballad in $\frac{3}{8}$ or $\frac{6}{8}$ metre, and the drinking song and the *ensemble de perplexité* ("ensemble of confusion"). In England, Arthur Sullivan followed in Offenbach's wake with his fruitful partnership with the author W.S. Gilbert, bequeathing a commentary on aspects of Victorian society through music of popular and enduring, if somewhat relentless, charm.

Viennese operetta. Charm is the main ingredient of the more sentimental Viennese operetta, and it usually submerges the rarer shaft of social comment. The younger Johann Strauss made operetta an international entertainment by an expert blend of charm and craft, and his *Die Fledermaus* (1874; *The Bat*) remains a classic of its kind. A second generation in this tradition was chiefly distinguished by Franz Lehár, whose *Die lustige Witwe* (1905; *The Merry Widow*) represents the genre at its peak of romantic elegance, demonstrating a style and craftsmanship that seems in serious danger of being lost altogether.

Johann Strauss's contribution to operetta

Such operettas remain current in today's musical theatre mainly as an indulgence of musical and emotional nostalgia. Their popular style enabled them to take root and flourish far from their native territories, including transplantation to the United States. The indigenous tradition of the U.S. stage musical, already mentioned, first had to compete with European-style operetta. That the latter keeps a tenacious hold on popular affections is demonstrated by figures listing Rudolf Friml's *Rose Marie* (1924) and Sigmund Romberg's *The Desert Song* (1926) as the most frequently performed works in U.S. musical theatre, in terms of both amateur and professional performances.

Zarzuela. Spain was a prominent exception to the wide dissemination of operetta, preferring instead the flourishing native variety of zarzuela. This form customarily incorporates regional songs and dances, sometimes with traditional rather than original music. It continues to some extent as a staple fare in Spanish musical theatre, although the general contemporary trend toward a more universal style of musical expression has meant that the younger Spanish composer has shown much less interest in the zarzuela form as an outlet for his musical imagination.

The Romantic zarzuela has little resemblance to the aristocratic and courtly character of its 17th-century namesake and emerged with French and Viennese operetta during the 19th century. It divided into two forms—the *zarzuela*

grande in three acts, equivalent to romantic operetta, and the *género chico* in one act, invariably comic, usually satirical, employing the broadest musical vernacular, and verging on revue. In the former category, the names of Francisco Barbieri, Amadeo Vives, and Federico Moreno Torroba are probably the most significant representatives of their respective generations.

The Spanish character and language of the Romantic zarzuelas made them exportable to Central and South America, where they became a model for the limited indigenous musical theatre. The South American centres are otherwise dominated by imports or imitations of the Italian opera tradition or used as transit bases for the latest North American stage musical on its theatrical circumnavigation. Certain examples of the Spanish zarzuela, such as Moreno Torroba's *Luisa Fernanda* (1932), have achieved popular success in Latin American countries, where local contributions to the genre have notably been made by Juan Bautista Massa in Argentina, Andrés Martínez Montoya in Colombia, Luis Delgadillo in Nicaragua, and Teodoro Valcárcel in Peru.

ORIENTAL MUSICAL THEATRE

Theatre music generally serves different purposes in non-Western idioms—usually adding dimension and perspective to song and dance, indicating symbolic associations, suggesting mood, and even inducing a desired response in an audience. Most Oriental streams of music divide between popular music of a folk character and a more sophisticated style for a cultured elite. The distinction is often less clearly defined than in Western music and is now not so firmly maintained in the wake of recent political and social changes.

China. The classical Peking opera (*ching-hsi*) in China is a form of musical theatre in which music is one among several elements rather than a governing factor, as in Western opera. The vocal writing alternates between styles broadly equivalent to recitative and song, distinguished by a forced high falsetto tone required from the male singers. A less stylized variety is the all-female *yüeh ch'ü*, in which natural singing voices perform musical plays in realistic and decorative scenery, and the Manchurian *P'ing Hsi*, which has developed into an operetta-like equivalent, with traditions and subjects derived from strolling players and folk legends.

Since 1964 the performance of classical Peking opera in Communist China has been mainly restricted to festival occasions (although state-sponsored schools continue to train performers especially for it). More emphasis has been put on entertainments closer to Western musicals, involving contemporary dialogue, everyday dress, and less stylized music. As a popular form of musical theatre it has been turned to political and social advantage with a new and adapted repertory of dramatic ballets and musical plays, bearing such titles as *Taking Tiger Mountain by Strategy* and *The Red Detachment of Women.*

Political overtones of modern Chinese opera

Japan. Music is as much a regular part of theatre performance in Japan as it is in China. The highly formal tradition of Japanese Nō drama incorporates music as an integral feature, usually performed by flute, a variety of stringed instrument called the samisen, drums, and singers. The music varies in content and character with the subject of the play and obeys detailed melodic rules—especially in the central dance episode designed to reveal the spirit of the play's principal character. A less formal counterpart, the Kabuki theatre, has almost as impressive an ancestry as the Nō and continues to be widely performed, with music used to indicate period, place, time, or mood and often functioning by phrase association like the principle of leading motives in Richard Wagner.

India. Japanese theatre also incorporates music dramas of Indian origin, and the Indian theatre tradition is a full combination of poetry, music, dance, and symbolism. The music is often interpolated rather than specially composed and is likely to be drawn from the repertory of widely known songs without aiming at a high classical standard. The close association of music with drama in Indian culture has been carried over into Indian film, which cannot hope to enjoy wide success among its modern audiences unless it is liberally embellished with songs and other forms of music.

THE HISTORY OF THEATRICAL MUSIC

Formative period. What is thought to be the oldest document of musical history depicts a man wearing an animal mask, manipulating what is possibly a form of musical bow, and dancing in the wake of a herd of reindeer. This is a prehistoric cave painting dating from the Stone Age, discovered at Ariège in France. Masks are tangible signs of that transfer of personality on which every form of theatre is based and in which song and dance have participated since the dawn of communication and animated ritual. Music in dramatic entertainment reached early peaks of development in European and Oriental cultures in, respectively, the ancient Greece of Homer and, some centuries later, the Chinese classical drama.

Descriptive evidence of the earliest Greek theatre indicates that music, mostly sung by a chorus, was essential but not continuous. At drama festivals the poet wrote his own music (as well as being actor, producer, and choreographer), probably based on some kind of traditional repeated formula. Later Greek theatre, after the fall of Athens (404 BC), initiated both the repertory system and a category of musicians trained more highly than the populace. Amateur and professional became separated for the first time, and increasing sophistication brought about its counterpart in popular pantomime expressed in song and dance, often satirical or bawdy in character.

Early Greek and Roman theatrical music

The Roman musical theatre derived directly from the Greek, ousting a short-lived native form with Etruscan actors who also danced to pipe music. Latin versions of the Greek theatre with music were supplemented by a Roman variant of the pantomime as a dramatic solo dance with chorus and orchestra. It implied some prior knowledge on the audience's part of the subject and the dance vocabulary. Amphitheatre shows of gladiatorial contests were regularly accompanied by music, sometimes involving up to 100 horn blowers and 200 pipers, as well as such extra devices as water organs.

About the time the Roman theatre flourished, an Oriental equivalent emerged in China from ritual ceremonies that came to be repeated for their entertainment value. The puppet theatre was a significant intermediate stage in this process, and the forms evolved into different styles of entertainment for courtier and commoner. Strings, flute, and handbells accompanied the songs and dances in upper-class entertainments; a form of mouth organ replaced the bells in shows for the common people. By the time of the Sung dynasty (AD 960–1279), from which the earliest written music survives, a type of musical variety theatre, the *tzarjiuh,* was widely popular.

The Chinese classical opera tradition has already been mentioned as a modern form of musical theatre. It first developed during the Yüan dynasty (1206–1368) and reached its peak of style and classical form in the Ming period (1368–1644). Its evolution was accompanied by a less formal counterpart based on the dramatization of folk songs linked by a thin narrative plot (*Chueichang*). The full-scale opera and its regional variants remained the most significant form of Oriental musical theatre until the modern post-revolutionary times, but throughout the Far East the indigenous forms of music have always played a prominent part in theatrical presentations.

In Europe the vestiges of Greco-Roman culture were submerged by the early Christian Church. By the 6th century the church had suppressed drama and adapted pagan rituals to its own liturgical puposes. A small flame of musical theatre was left burning only in the form of religious ceremonial (for example, in the mass). Festive religious celebrations eventually expanded into the liturgical music drama that slowly developed from about the 10th century. This brought in its wake the equally religious "mysteries" and miracle plays of the Middle Ages in Europe, which were performed in the vernacular instead of in Latin, had a strong musical element, and, in due course, developed a secular counterpart.

Musical elements of the miracle plays

In a pattern that was to repeat itself after the birth of opera 200 years later, the secular theatre in the Middle

Ages established itself either as lighthearted interludes in serious moralities or as deliberate parody tolerated by the church as a safety valve to consistent piety. The annual Feast of Fools in 15th-century Paris, for instance, incorporated an obscene parody of the mass performed in song and dance within the church. By the year 1400 numerous comedies and farces had appeared, usually performed on festive occasions in aristocratic houses or on open stages in municipal squares.

These plays often employed musical forces comparable to those of the religious plays and used them for similar purposes. Choirboys from the church sometimes took part, but surviving texts suggest that there was little choral music as such. The individual actors incorporated parts of songs chanted monophonically to embellish or heighten the dramatic effect, and dancing to specific instrumental music also had a regular place in the entertainment. Professional musicians might be hired and might also be required to act; the constituent parts of the entertainment varied widely from place to place.

The fact that, except for songs, documents of the period contain almost no music directly linked with the theatre is thought to indicate that very little original instrumental music was written for theatrical purposes at this time. Whatever was suitable for weddings, banquets, and other feasts perhaps served a theatrical purpose just as well. Musicians probably had little or no acquaintance with musical notation and played pieces from their regular repertory. These seem to have included arrangements of vocal melodies as well as dance tunes, among which the play texts most frequently identify *basses-dances* and branles.

The Renaissance and Baroque periods. When Catherine de Médicis married King Henry II of France in 1533, she brought from Italy a taste for entertainments in which dancing was prominent. Her encouragement established the court ballet (*ballet de cour*) as the foundation of classical ballet, the source of a new theatrical identity for music and a precursor of French opera. As a unified blend of poetry, music, and movement, the court ballet dates from the performance of the *Ballet comique de la reine* at a court wedding in 1581. The form comprised an optional number of scenes in mime and dance, prefaced by explanatory verses that were either spoken or sung; the scenes were accompanied by solo and choral songs with lute, and instrumental ensemble pieces for strings.

The French court ballet

In about 1605 a more mannered style of singing had become customary, and by 1620 the court ballet was more a vehicle for display than drama. Unified dramatic plots were restored by the poet Isaac de Benserade in midcentury, and Jean-Baptiste Lully, who entered the service of King Louis XIV in 1652, endowed the music with fresh distinction. He favoured dramatic musical expression with the use of larger choral and orchestral forms and formulated such dances as the minuet, first danced by Louis as "Le Roi soleil" (the sun king), the gavotte, rigaudon, bourrée, passepied, and loure—each with its particular rhythmic metre.

Lully collaborated with the playwright Molière in a famous succession of comedy-ballets, of which *Le Bourgeois Gentilhomme* (1670) is probably the best known. Thereafter the character of Lully's work became essentially operatic, and music in the French theatre was left to function in a more subsidiary role. The dramatist Pierre Corneille, for instance, wrote "I have employed music only to satisfy the ear while the eyes are occupied with looking at the machines." In another category, the pastoral comedies derived from Italian models were liberally embellished with songs loosely strung together and alternating with spoken verses.

The French court ballet exerted an influence on the English masque, which took its name and some of its early character from the medieval Italian *mascherate* (masquerades) in carnival entertainment. At a time of distinctive English literary achievement, the masque reached a high artistic level, performed mainly as an aristocratic entertainment. It combined instrumental and vocal music, mixed with dancing and acting, in the representation of mythological and allegorical subjects. At the same time, the first public theatres in London came into being. They

The English masque

date from 1576 (61 years before the first public Venetian opera house); the earliest public plays are known to have incorporated some form of music.

Cues for music recur throughout Shakespeare's plays, usually for simple songs or dances. Music between the acts of public plays was customary by 1600, with the audience often calling for the tunes they wanted played. Instrumental music was employed for supernatural effects and to heighten dramatic tension; it was usually performed behind, at the side of, or even under the stage. After the suppression of playhouses during the Civil War, the restoration of the English monarchy with King Charles II brought an even richer flowering of theatre music, led by Henry Purcell.

Besides those works of Purcell that are nearer to masque than drama, such as the Shakespeare adaptations for *The Fairy Queen* (1692) and *The Tempest* (1695), he composed suites of incidental music for more than 40 plays. These generally comprised overtures, "act-tunes" (interludes), dances, and songs. Rather than growing out of the verbal drama, however, they are often so arbitrarily interpolated into it that only the quality of the music can justify most of them. After Purcell's death, English theatrical music ceased to contribute significantly to the theatre, but Thomas Arne, who wrote numerous masques and ballad operas such as *Love in a Village* (1762), was very popular in the mid-18th century, and his simplicity of expression has a certain direct appeal.

The flourishing tradition of Spanish Renaissance drama precluded much opera from taking root in Spain, but the music for plays had generally less distinction than the English equivalent. The early zarzuela (not to be confused with the later Romantic version already mentioned) originated in the 17th century as a court entertainment. It was the Spanish counterpart to the court ballet and acquired a strong Italian influence on its musical character. Spanish music and musicians travelled to the Western Hemisphere with the early explorers, and by the late 17th century the Peruvian capital of Lima had become musically important. The composer José Diaz worked there and wrote much incidental music to the plays of Calderón de la Barca.

Renaissance theatre in Italy bred the *intermedio*, which consisted of songs and instrumental music added before or after the acts of a play. The words of the songs were generally relevant to the action of the drama, and this development—together with more extended musical settings in pastoral plays—became the direct precursor of Italian opera. As a new form of "drama in music" which rapidly acquired serious artistic pretensions, the opera inevitably brought in its train a less aristocratic variety of musical theatre variously termed opera buffa (comic opera), vaudeville, ballad opera, singspiel (literally, song-play), or *tonadilla*, always performed in the vernacular of its audience and often in dialect.

The Italian *intermedio*

These depicted current events instead of historical or mythological subjects, involved elements of parody and social satire, and usually depended on modest musical resources for economic reasons. They began as interludes performed between the acts of serious opera and comprise an essential link in the history of musical theatre. By about 1700 the scenes (usually two) had acquired a linked plot, and by 1740 they were performed apart from the opera as a genuinely popular entertainment. Eventually they responded to the demands of the rising middle classes by raising their own standards into the category of comic opera.

Classical developments. The Italian commedia dell'arte entertainment of strolling players in mainly improvised comedy had left its mark on French fairground theatre, although the performers were expelled from France in 1697 for having ventured their satire too close to court topics. Ten years later French satirical comedies were also banned, whereupon the resourceful performers found a new way round by employing monologue, mime, and music. They thereby developed a new form of popular entertainment to contrast with the aristocratic *opéra-ballets*, which were soon to be dominated by the spectacular productions with Jean-Philippe Rameau as composer, and in 1713 two theatrical managements in

Paris were given license to perform "Le nouvel Opéra-comique."

Opéra-comique was a contraction of *opéra rendu comique* ("opera made comic"), signifying parody and satire at the expense primarily of serious opera. The entertainment soon came to veer either toward *comédie vaudeville,* mostly made up of bawdy satire or simply songs of disparaging social comment, or to the alternative *comédie à ariette,* involving a generally more decorous musical parody at the expense of Italian styles. The *Guerre des Bouffons* ("war of the comedians") between partisans of French and Italian theatrical styles was eventually resolved by the emergence of the opéra bouffe (literally, "comic opera")—the French variety of operetta. It is usually dated to the Paris production in 1753 of *Les Troqueurs* ("The Barterers"), based on a fable by Jean de La Fontaine and having original music by a court violinist, Antoine Dauvergne.

Ballet was declining about this time from courtly heroics to simple diversion unrelated to any dramatic point. Apart from the *opéra-ballets* of Rameau, little significant music was composed for the dance until the German composer Christoph Willibald Gluck, who initiated the major reform of serious opera during the century, first turned his attention to a move for balletic reform involving a more dramatic style. In 1761 Gluck composed the music for *Don Juan,* a ballet by Gasparo Angiolini, the Italian ballet master at Vienna, who maintained that dancing should be self-expressive without recourse to verbal explanations.

Gluck's contribution to ballet music

Gluck's vividly descriptive score contains 31 musical pieces, alternating between formal dance and narrative drama. It made the music a foreground element in the ballet instead of a background accompaniment and could have brought about—if its example had been followed up—a revitalization of ballet music almost as significant as the operatic reform Gluck launched in *Orfeo ed Euridice* a year later. In the ballet, the fight scene near the beginning and the dance of the Furies at the end (itself later incorporated into *Orfeo*) have a concentrated intensity of musical expression, and the graveyard scene has a degree of imaginative orchestration that is unsurpassed in any other music at that date.

For reasons that belong more properly to the history of ballet, Gluck's influence on its future course was less fruitful than in opera. Perhaps his example, nevertheless, encouraged the participation of such composers as Mozart with *Les Petits Riens* (1778; "Sweet Nothings") and Beethoven in *The Creatures of Prometheus* (1801). It was, otherwise, an era theatrically dominated by opera of various kinds, so that there was at first little call for music in relation to spoken drama. Haydn, however, composed some music (1796) for an early German translation of Alexander Bicknell's *The Patriot King, or Alfred and Elvida,* and Mozart contributed a suite of superior choral and orchestral music for *Thamos, König in Ägypten* (1773; *Thamos, King of Egypt*), which was never used for the play in his lifetime but which has survived where the play has long been forgotten.

Eighteenth-century opera nourished musical developments in the theatre chiefly through establishing regular orchestras of some quality. Outside of cities with more than one theatre, such as Vienna, Prague, Paris, and London, the numerous court theatres needed to keep a resident and costly orchestra reasonably occupied, with interest divided between opera and drama. It therefore became customary either to commission incidental music for existing plays whenever possible (especially the historical classics, as more and more of them were translated from one language to another) or to commission new plays that would incorporate ample provision for orchestral and sometimes choral music.

Romantic expansion. Examples of commissioned incidental music have previously been cited in Beethoven's music for *Egmont,* which belongs to the first category just mentioned, and Schubert's for *Rosamunde,* which is in the second. The practice spread as a matter of rivalry and prestige to cities without a court but which maintained a municipal theatre (for example, Hamburg and Leipzig) and to other countries with a thriving theatrical interest and ample funds. In Russia, for instance, Mikhail Glinka composed music to *Prince Kholmsky* (1840), an otherwise obscure drama by Count Kukolnik, and the Shakespeare repertory brought the collaboration of such composers as Mily Balakirev (*King Lear,* 1861) and Tchaikovsky (*Hamlet,* 1891).

France and England, having different systems of patronage, produced different results during the 19th century. English theatre music was confined for most of its course to a taste for crude melodrama and burlesque at a low level, apart from a sporadic interest in mostly imported opera and ballet. Arthur Sullivan, however, provided incidental music for Shakespeare plays as well as cultivating, in his collaboration with the author W.S. Gilbert, a native variety of operetta derived from the French model. France fared somewhat better with the popularity of opéra bouffe, and the birth of romantic ballet in Paris also kindled a new kind of theatre interest, even though its musical quality was usually secondary.

Gilbert and Sullivan operetta

Music for Romantic ballet developed in two directions. From the time of the French composer Adolphe Adam's score for *Giselle* (1841), ballet composers made rudimentary attempts to express mood and scene, to create dramatic tension, and to characterize personality in music. The general level was somewhat raised by the French composer Léo Delibes in his music for *Coppélia* (1870) and more especially for *Sylvia* (1876); the latter was a score that Tchaikovsky came to know and admire. The second feature in many ballet scores of the period was the attempt to compose suitably flavoured music to match the new growth of interest in national and regional dances, which were regularly incorporated into the ballets.

Music in 19th-century ballet reached its peak of achievement with Tchaikovsky, whose instinct for the theatre was probably stronger than his talent for the subtleties of symphonic argument. He treated the art of ballet as worthy of real musical imagination and told a colleague who adversely likened some of his *Symphony No. 4* to ballet music: "I cannot understand why the term should be associated with something reprehensible. There is such a thing as good ballet music." Tchaikovsky demonstrated its possibilities in three original scores for ballet that enjoy continuing universal popularity in the theatre: *Swan Lake* (first performed 1877); *The Sleeping Beauty* (1890); and *The Nutcracker* (1892).

Swan Lake achieved lasting success only after the composer's death—a fact which accounts for the recurring problems of the relationship of music to choreography, because some of the original musical sequence was changed for the 1895 production at St. Petersburg (now Leningrad), from which most current versions of the ballet are descended. The two later scores benefitted from detailed choreographic specifications. According to Stravinsky, *The Sleeping Beauty* is "the convincing example of Tchaikovsky's great creative power," and *The Nutcracker* in its theatre context has a narrative vividness much beyond the limited charm of the concert suite that Tchaikovsky arranged from it.

Adolphe Adam's contribution to the development of ballet music had its parallel in the sphere of romantic operetta. By incorporating a measure of frivolous vaudeville into the otherwise conventional comedy of *Le Châlet* (1834), Adam stimulated a popular taste for what became the mainstream of operetta. Its source was in Paris, and it flowed in turn principally to Vienna, to London and thence to North America, submerging the German singspiel and its Scandinavian offshoots but leaving the Spanish zarzuela to cultivate its own regional idiom.

Adam's enterprise in opening a theatre in 1847 to stage his own works and those of other young composers disdained by the operatic establishment in Paris was brought to a premature end by the political uprising a year later, but Offenbach was poised to take advantage of the subsequent situation. He opened his Bouffes-Parisiens theatre in 1855, whence travelled such immediate hits as *Orpheus in the Underworld, La Belle Hélène, La Grande-Duchesse de Gérolstein,* and *La Périchole* over almost all of Europe. The Parisian operetta was principally continued to the end of the century by Charles Lecocq and André Messager.

Offenbach's influence in Europe

Offenbach meanwhile had paid several visits to Vienna

from 1858, when Franz von Suppé was quick to turn the French model to local advantage, notably with *Die schöne Galatea* (1865; *The Beautiful Galatea*). The younger Johann Strauss was eventually persuaded to follow this trend by turning the Viennese craze for his waltzes, polkas, and other social dances to theatrical purpose. With the aid of an unusually good libretto, Strauss created the supreme example of Viennese operetta in *Die Fledermaus*. The Viennese tradition was continued in turn by Franz Lehár and Emmerich Kálmán.

Offenbach's influence extended southward to Bohemia, where the composer Bedřich Smetana compared his first song-and-dialogue version of *The Bartered Bride* (1866) to an Offenbach operetta, and Antonín Dvořák composed an outstanding but little-known example in *The Peasant a Rogue* (1878). Otherwise, no particularly distinguished composer of operetta emerged in southeastern Europe, nor in Poland or Russia, where there were only occasional contacts with forms of musical theatre other than full-scale opera and ballet for the moneyed classes.

The northward spread of the Offenbach model reached England, where it influenced the character of Sullivan's first operetta, *Cox and Box* (1867). It led in due course to the success of *H.M.S. Pinafore* (1878), in collaboration with Gilbert, and the subsequent line of "Savoy operettas" (their collective nickname derived from the London theatre where they were first performed by the D'Oyly Carte Opera Company, Ltd.). England made no other contributions of comparable musical interest to the operetta repertory until it was overtaken in due course by the trend to musical comedy in the 20th century.

English operetta represented by Gilbert and Sullivan nevertheless put down fresh roots in North America after the D'Oyly Carte company first travelled there in 1879, in the wake of a pirated version of *H.M.S. Pinafore*. The impact of Sullivan's music in New York and Boston was comparable to that of Offenbach in Vienna. Instead of stimulating an American equivalent, it first opened the way to 20 years or so of European imports to the American stage. The composers Reginald De Koven and Victor Herbert later established a short-lived local counterpart to European operetta, before it was overtaken by the indigenous idiom of American musical theatre noted earlier.

The language of ragtime and early jazz, with its rhythmic syncopation and varying degrees of harmonic innovation within a common musical vernacular, brought the first new element to the idiom of musical theatre (in musical comedy) since the emergence of national folk characteristics in 19th-century Europe. As the trends already described succeeded one another during the 20th century, in and out of fashion, and the musical theatre tried to reconcile the nostalgia for its past heritage with the need to experiment in search of a viable future, the immediate present can be seen to represent only one turn of a larger wheel across seven or eight centuries. The religious rock musical of the contemporary musical scene is but a variant of the mysteries and miracle plays that initiated all our modern forms of musical theatre when Western civilization first groped its way out of the Dark Ages.

(N.Go.)

Opera

The English word opera is an abbreviation of the Italian phrase *opera in musica* ("work in music"). It names a theatrical form consisting of a dramatic text (libretto, or "little book") combined with music, usually singing with instrumental accompaniment. Besides solo, ensemble, and choral singers and a group of instrumentalists, the forces performing opera since its inception have often included dancers. A complex, often costly variety of musicodramatic entertainment, opera has attracted audiences for nearly five centuries. Although its supporters have greatly outnumbered its detractors, it has been the target of intense adverse criticism.

Charles de Saint-Évremond, a French man of letters in the 17th century, called it "a bizarre thing consisting of poetry in music, in which the poet and the composer, equally standing in each other's way, go to endless trouble to produce a wretched result." The 18th-century English statesman and writer Lord Chesterfield wrote to his son: "As for operas, they are essentially too absurd and extravagant to mention. I look upon them as a magic scene contrived to please the eyes and the ears at the expense of the understanding." At the opposite extreme of reaction to opera, it has been said that the mere existence of such a masterpiece as Mozart's *Le nozze di Figaro* (*The Marriage of Figaro*) suffices to justify Western civilization.

The unique characteristics of opera

Although the characteristic of opera that most clearly separates it from other theatrical forms is that its principals sing rather than speak their lines, to approach it or criticize it as simply one variety of the musical art is to misjudge it. Its multiple creators almost always have intended an opera to be a lofty and eloquent form of theatrical performance. What commonly differentiates it from other varieties of musicodramatic theatre such as operetta (literally "small opera") and musical comedy is sobriety of workmanship, density of texture, and (even in operas with comic and farcical librettos) accompanying seriousness of musical tone. On the other hand, some lighter works—by Jacques Offenbach, Johann Strauss the Younger, Gilbert and Sullivan, Kurt Weill, George Gershwin, and a few others—make neat categorization impossible.

In the preparation of an opera performance, many individual artists and artisans, sometimes spread out across a century and more, necessarily are or have been involved. The first, unintentional recruit is likely to have been the writer of the original story. Then comes the librettist, who puts the story or play into a form suitable for musical setting and singing, and the composer, who sets that libretto to music. Architects and acousticians have built an opera house suited or adaptable to performances that demand a sizable stage, a pit to house an ensemble of instrumentalists, and a reasonably large audience. A producer-director has to specify the work of designers, scene painters, costumers, and lighting experts. The producer, conductor, and musical staff have to work for long periods with chorus, dancers, orchestra, and extras as well as the principal singers to prepare the performance—work that may last anywhere from a few days to many months. All this does not even take into account the part played by the administrative staff.

Once the complete operatic score—the final libretto and music—is available, what must rule all of those involved is dedication to fulfilling the wishes of the librettist and the composer. Overemphasis or underemphasis of any larger component of an operatic performance can be as damaging to it as off-pitch singing or false entries by instrumentalists. More than one desirable balance among the constituents of performance is often possible. What is certain is that one or another of them must be decided upon, worked toward, and achieved.

THE EARLY HISTORY

Italian origins. Works in antiquity had combined poetic drama and music. The plays of the ancient Greek dramatists Aeschylus, Sophocles, and Euripides employed choral music in a manner that certainly reflected related usages in earlier times. During the Middle Ages, biblical dramas were commonly accompanied by some music, being known under various labels, including mystery and miracle plays. These and other related musicodramatic forms may or may not have become collateral ancestors of opera: their descent seems most certain in some 17th-century operas on religious subjects performed in Rome and at several places in Germany. Musical historians and musicologists continue to debate opera's ancestry. The earliest universally accepted direct ancestors of opera appeared in 16th-century Italy. Purely nonreligious works of edifying drama with music, they included intermezzos and *intermedii* played between the acts of spoken dramas, with which their purported subject matter often claimed a tenuous connection, and staged ballet. The latter, Italian by birth, achieved a complex, quasi-operatic state in the court ballet (*ballet de cour*) danced in France late in the 16th century and throughout the 17th: it approached ever closer to opera in the *comédie-ballet* evolved by Molière and Jean-Baptiste Lully in the 1660s, beginning with *Le*

Mariage forcé (*The Enforced Marriage,* first performed 1664).

Musicians, singers, poets, playwrights, and enthusiasts of the literary, musical, and theatrical arts had long cherished a desire for some more formally constituted and more stable form of drama with music, especially in Italy. One response to that expressed desire was the 16th-century "madrigal comedy," the singing of dramatic or semidramatic lines (often farcical, and most often with story and characters borrowed from the traditional commedia dell'arte as it had become formalized during the 16th century) in a linked series of more or less discrete madrigals and other varieties of polyphonic song.

16th-century "madrigal comedy"

But polyphony—the musical texture created by simultaneous, largely unaccompanied singing of interwoven melodies—was by nature alien to theatrical drama: it made extremely difficult, when not impossible, the delineation of individual characters through clearly understandable text words. This is noticeable even in the most celebrated of the madrigal comedies, Orazio Vecchi's paean to the "double Parnassus" of poetry and music, *L'Amfiparnaso* (Modena, 1594).

The gestation of opera required the simultaneous availability of a dramatic literary style and a musical texture suitable for incorporation into a new theatrical unity. The essential literary materials had begun to appear in Italy in such chivalresque epics as Lodovico Ariosto's *Orlando furioso* (published complete in 1532) and Torquato Tasso's *Gerusalemme liberata* (1575), both of which were to be mined for subjects by innumerable opera librettists. More immediately decisive in setting the first direction of opera was one sort of poetic drama: the shorter pastoral writings of 16th-century Italian poets, notably Tasso's *Aminta* (1573) and Giovanni Battista Guarini's *Pastor fido* (*The Faithful Shepherd,* completed in 1590). Idylls or eclogues that had sprung up in the 15th century, like the *Orfeo* of the Italian poet Poliziano (Politian) with music by Germi (one of the earliest examples, which was staged at Mantua in 1472, with solo song, chorus, and spoken dialogue), were seized on, adapted, and imitated by the men who had begun to evolve the musical texture essential to the birth of opera and who found apt subjects in the loves, joys, and sorrows of Arcadian shepherds and shepherdesses, often with the intervention of gods, demigods, and heroes.

Until the 1950s it was generally accepted that opera originated with a *camerata* (a sort of humanistic discussion group) that met in the late 1570s and early 1580s in the Florentine palace of Giovanni Bardi, count of Vernio. In 1953, however, the Roman musicologist Nino Pirrotta showed that the Bardi Camerata, far from having furthered innovation or interested itself in musical drama, was predominantly conservative, often acted in defense of the polyphonic madrigal, and showed no sympathy with the new combinations that would shortly produce opera. In fact, that literary-musical texture was evolved at Florence, but largely among a group of intellectuals, artists, and dilettantes who met informally in the palace of the theatrical theoretician Jacopo Corsi during the 1590s. This latter group also included Emilio del Cavaliere, the composer, impresario, and choreographer who was to write what is often called the first oratorio, *La rappresentazione di anima e di corpo* (*The Representation of Soul and Body,* an acted form unlike later oratorios); the singer-composer Jacopo Peri; and—although they attended infrequently—both the poet Tasso and the composer Claudio Monteverdi. Still active at the time, though a little out of favour, was the singer-composer Giulio Caccini. Corsi and his friends were by no means the first creators of solo vocal lines with instrumental accompaniment, and they shaped their musicotheatrical creations partly in the mistaken belief that their performances were reviving ancient Greek procedures. What, in fact, they did was to take hints from the French court ballet and simultaneously discard polyphony in favour of monody (or homophony)—accompanied singing or recitation on musical tones (recitativo) of one melody at a time. Thus, they insured both the relative comprehensibility of the words (which to them seemed much more important than the accompanying music) and the use of at least some instrumental support.

Florentines who "created" opera

An important "manifesto" of the monodic innovators was a collection of short vocal pieces with thorough-bass accompaniment (instrumental chords in sequence as accompaniment to melody) by Caccini, published in 1602: *Le nuove musiche,* a title that often has been extended to cover the novel musical texture itself. The interaction of these and other Italians with the texture of monody was what finally led, after some false starts, to the emergence not only of opera more or less as it is known today but also of the cantata and the oratorio.

The honour of being deemed "the first opera" usually is given to a setting by Peri of *Dafne* by the Renaissance pastoral poet Ottavio Rinuccini. It was staged at the Palazzo Corsi in Florence during the pre-Lenten Carnival of 1597–98. The text, divided into a prologue and six scenes, was published in 1600 and therefore survives, but neither Peri's music (the prologue and one aria excepted) nor that of an almost contemporary setting of the same text by Caccini can now be recovered. The earliest surviving opera is also Peri's: a setting of Rinuccini's pastoral *Euridice,* likewise in a prologue and six scenes, which was performed at the Palazzo Pitti in Florence on October 6, 1600. More unusual, the musical score also was issued in 1601 and reprinted several times thereafter.

However significant historically, the pioneering operas of Peri and Caccini were tentative in both style and structure; further, neither of the founding fathers of opera seems to have possessed notable dramatic talent.

Within 10 years of the premiere of Peri's *Dafne* at Florence, Mantua heard an opera that is a masterpiece and still is staged frequently. This was *La favola d'Orfeo* (*The Fable of Orpheus*), a setting by Monteverdi of a poetic text by Alessandro Striggio the Younger. Presented during the Carnival of 1607 (the libretto was published then, the score in 1609), it soon was presented elsewhere in Italy. In *Orfeo,* the accompanying instruments come into their own as a dramatic element: the score contains more than two dozen pieces for increased (though not precisely determinable) numbers of instruments. It not only introduces, as a preluding toccata, the idea of the operatic overture but also achieves some sectional unity by repeating brief instrumental numbers (ritornellos). More important, Monteverdi uses recitative expressively and gives it an organizational function by repetitions and developments in predetermined patterns.

Monteverdi's *Orfeo*

Monteverdi continued to compose operas for more than 35 years; meanwhile, the new manner of musicodramatic entertainment spread to other Italian cities. Rome probably first heard an opera as early as 1606, Bologna before 1610. Continuing to employ librettos based on Italian interpretations of Greek and Roman myth, legend, and pseudo-history, literary men and composers rapidly swelled the number of operas heard. At Venice in 1642, the 75-year-old Monteverdi created his masterpiece *L'incoronazione di Poppea* (*The Coronation of Poppea*). Gian Francesco Busenello's superior libretto carried a new note of realism into opera, particularly in the development of human character; it was to have a prolonged, important line of descent, and Monteverdi translated it blazingly into music. Throughout that first period of operatic history, the importance given by composers to emotional drama, to instrumental music, and to structural stability increased along with the capabilities (and pretensions) of singers and the magnificence and complexity of stage settings, stage machinery, and costuming.

The first opera house

The inauguration early in 1637 of the first opera house open to the general public, the Tron family's Teatro di San Cassiano at Venice, was another decisive factor in establishing opera. That action removed opera from the exclusive hands of royalty and nobility and placed it within reach of all but the poorest sectors of the Italian urban population.

A pupil of Monteverdi, Pier Francesco Caletti-Bruni, known as Francesco Cavalli (1602–76), became the most popular opera composer of his era by furnishing the opera houses of Venice with some 40 operas between 1639 and 1669. A highly talented but not always fastidious composer, Cavalli reacted to the librettos he used with dramatic force and directness. The most renowned of his

operas was *Giasone* (*Jason,* 1649), whose libretto by Giacinto Andrea Cocignini included farcical episodes. His chief Venetian rival and successor was Pietro Antonio (often called Marc' Antonio) Cesti (1623–69), about a dozen of whose nearly 100 operas have survived. Some notion of the extravagance to which imitation of Louis XIV's spectacles at Versailles had driven the production of opera elsewhere can be gained from descriptions of the Cesti opera *Il pomo d'oro* (*The Golden Apple,* 1667), composed for the wedding of Emperor Leopold I and Margarita Teresa of Spain in Vienna. Constructed in a prologue and five acts (the third and fifth of which have been lost), with 48 characters, it contained 66 scenes requiring 24 stage settings making use of complex stage machinery. Ballets occurred in every act, and a grand triple ballet brought the opera to its conclusion. *Il pomo d'oro* provided numerous purely instrumental introductions and interludes, gave relatively little importance to the chorus, skipped rapidly over the essential storytelling recitative, and concentrated on arias and duets that often were most sensuous and almost feminine in allure.

Opera in Venice and Rome

Venetian opera continued to flourish in the works of such greatly talented theatrical composers as Cavalli, Cesti, and Giovanni Legrenzi (1626–90). In some details, these Venetian operas reflected the pressures exerted by the tastes and wishes of the paying audiences for which they were designed. Not so lavish with choral interpolations as their Roman contemporaries, the Venetians demanded and received complex, strong librettos calling for large casts and special lavishness in staging. They also began to develop the sensuous melodic profiles that have come to be thought of as particularly "Italian." Furthermore, they all but separated the solo aria from the surrounding recitative. They also frequently prefaced and followed solos with purely instrumental music, so continuing the orchestra's elevation from a purely accompanying role. After the middle of the 17th century, the Venetian operatic style began to decline. Among the later Venetian operatic composers of talent and fame were Antonio Lotti (*c.* 1667–1740), Carlo Francesco Pollaroli (1653–1722), Antonio Vivaldi (*c.* 1678–1741), and Baldassare Galuppi (1706–85), who is often referred to somewhat loosely as "the father of opera buffa."

Several Italian cities soon developed recognizably indigenous operatic styles. At Rome, for example, a group of composers tended toward unified structure, gave ensemble and choral song expanded roles, and increased the difference between the solo (aria) and the Florentine type of continuous recitative by allowing arias to interrupt dramatic progress in order to express or comment upon emotional moods. Less emphatic about stage magnificence than their Venetian counterparts, such Roman composers as Stefano Landi (*c.* 1590–*c.* 1655), Domenico Mazzocchi (1592–1655), Luigi Rossi (1597–1653), and Michelangelo Rossi (1600?–70) also permitted comic episodes to lighten prevailingly tragic stories. They concentrated attention productively on instrumental overtures and on overture-like pieces preceding acts or sections of acts. Two Roman composers—Domenico Mazzocchi's brother Virgilio (1597–1646) and Marco Marazzoli (1619–62)—often are cited as having created the first completely comic opera, *Chi soffe speri* (*He Who Suffers, Hopes,* 1639). Its libretto was written by Cardinal Giulio Rospigliosi, who was to be elevated to the papacy in 1667 as Clement IX. The invited guests at its first performance, in the Palazzo Barberini, included the English poet John Milton and Giulio Mazarini, the future Cardinal Mazarin, statesman to Louis XIV.

Contributions of Zeno and Metastasio

With the 18th century the centre of Italian opera shifted to Naples, where so great a variety of styles evolved that the term Neapolitan opera eventually covered operas that dominated most of Italy and many foreign centres of operatic activity. With some exceptions, the earliest unmistakably Neapolitan operas changed their focus back from the music to the words. Two of its instigators were dramatic poets: Apostolo Zeno (1668–1750), born a Venetian, and the Roman Pietro Trapassi, known as Metastasio (1698–1782)—perhaps the greatest of the 18th-century librettists. Continuing the custom of basing librettos on Greco-Roman legend and pseudo-history (but dispensing almost entirely with classical mythology), Zeno and Metastasio wrote texts of formal beauty and linguistic clarity, preferring solemn, usually tragic subjects (opera seria) in three acts to comic episodes and characters. The aria came to dominate, and the use of chorus declined.

The term Neapolitan opera also came to indicate harmonically naïve, melodious lighter operas in the gallant tone of the Rococo style; the rich development of the bel canto styles (where beautiful singing *per se* was predominant), signifying supreme vocal agility and smoothness that was supplied first by castratos, men who had been castrated before puberty in order to preserve the high ranges of their boyish voices; and the appearance of the *centone* or pasticcio, a libretto set to a score made up of music borrowed either from scores (then uncopyrighted or otherwise legally protected) of several composers or from several operas by a single composer. The use of the orchestra also became limited. But perhaps the most discussed, and often senselessly maligned, feature that particularly designated Neapolitan opera was the aria da capo, an aria in three sections, the third part repeating the first. It had appeared in northern Italy early in the 17th century but was employed with comparative infrequency there. Some Neapolitan operas, however, consisted of up to 20 da capo arias separated by a minimum of story-advancing recitativo secco (narrative passages in which voice is accompanied only by a thorough bass).

Domination of the aria da capo

A masterly operatic composer of the transitional style who bridged the era between the Baroque and the pre-Classical Neapolitan style was Alessandro Scarlatti (1660–1725). In his many operas Scarlatti triumphed, by the strength of musical imagination, over librettos intended to provide vehicles for phenomenally trained singers in the prevailing pattern and the consequent reduction of dramatic interest to a narrow minimum. Talented and influential among Scarlatti's contemporaries were such composers as Nicola Antonio Porpora (1686–1768), Leonardo Vinci (1690–1730), and Leonardo Leo (1694–1744).

In 1720 the Venetian composer-poet-statesman Benedetto Marcello (1686–1739) published a mordant satire on the increasingly rigid and undramatic conventions that had taken hold of opera seria: *Il teatro alla moda, o sia metodo sicuro e facile per ben comporre ed eseguire opere italiane in musica* ("The Theater à la Mode, or The Secure and Easy Method of Composing and Performing Italian Operas"). The distress that it and other criticisms brought resulted in an improved genre, still in effect opera seria but showing attempts at reform of its mannerisms. The principal operas against which that reform later evolved were the often melodically seductive works of Gaetano Latilla (1711–88), Giuseppe Sarti (1729–1802), Antonio Sacchini (1730–86), Johann Christian Bach (1735–82), Antonio Salieri (1750–1825), and Mozart's *Idomeneo, rè di Creta* (1781) and *La clemenza di Tito* (*The Clemency of Titus,* 1791). Representative composers within the short "reform" movement itself were Niccolò Jommelli (1714–74) and Tommaso Traetta (1727–79). A more intellectually rigorous reformation was undertaken consciously by Christoph Willibald Gluck in collaboration with the librettist Ranieri de' Calzabigi, beginning with *Orfeo ed Euridice* (1762).

Comic opera. Comic opera meanwhile had expanded from its shadowy existence within and between the acts of opera seria. From the early, tentative efforts of several 17th-century Roman and Florentine composers, it had moved into a bustling, rude, independent vitality of its own, often in the form of satirical opera buffa (Italian: "comic opera"), generally shaped in two acts rather than the usual three of opera seria. Expelled from the precincts of opera seria by the librettos of Zeno and Metastasio, the comic spirit had taken refuge in such an expanded intermezzo as *La serva padrona* (*The Maid Mistress,* 1733), by Giovanni Battista Pergolesi. When it matured, the style borrowed back some of the more serious emotional qualities of opera seria, often including "serious" roles among those of the comedians. This led to a hybrid nature in many operas, including two works using librettos derived from the plays of Pierre de Beaumarchais—*Il barbiere di Siviglia* (*The Barber of Seville,* 1782), by Giovanni

Paisiello, and Mozart's *Le nozze di Figaro* (1786)—as well as *Il matrimonio segreto* (*The Secret Marriage,* 1792), by Domenico Cimarosa.

One of the determining characteristics of this mixed style was the elaboration of ensemble numbers concluding acts. These operas dispensed almost entirely with the magnificent display and grandeur of staging increasingly required of opera seria. Another of the drawbacks of the mixed style was well summed up by the 20th-century Italian musicologist Andrea Della Corte:

> With few exceptions among the great composers dedicated to instrumental music or to teaching, almost all the serious composers also collaborated in the comic theatre. Not so the literary men. The best dramatists were not equally tempted by this tendency.

The natural result was that the large majority of opera buffa librettos remained inferior to the serious texts by Metastasio and his imitators and successors, though not necessarily less workable in their own way.

Early opera in France. Opera was imported into France from Italy before 1650, but it long failed to take firm hold there with royal and other audiences, at first having to compete on unequal terms with the spoken drama (often with musical interludes) and the ballet. The *Pomone* (1671) of Robert Cambert, to a pastoral libretto by Pierre Perrin, is commonly called the first French opera. Its premiere almost certainly inaugurated the Académie Royale de Musique (now the Paris Académie de Musique or Paris Opéra) on March 3, 1671. Only fragments of the music of *Pomone* still exist.

Lully's important role

Opera really did not become a French art until the time of Jean-Baptiste Lully (1632–87). This highly talented, very shrewd, and dictatorial man borrowed freely from both the spoken French drama and the court ballet. Though himself an Italian, he played down the extended, formalized Italian aria in favour of shorter, more instantly captivating "airs." He formed recitative after the declamatory manner of the Comédie-Française theatre company and also evolved the "French overture" (one movement with a slow and a fast section) as distinct from the "Italian overture" (one movement with a fast, slow, and another fast section). His operas and those of his imitators and followers assigned great importance to dancing, choruses, instrumental interludes, and a dazzlingly complex stage setting. Lully became the virtual dictator of music in France partly because of the strengths of his literary collaborators: first the dramatist Molière (1662–73) in *comédie-ballet,* then the exceedingly able librettist Philippe Quinault (1635–88).

The pervasive Lullyan style, altered surprisingly little except in the direction of still more imposing grandeur, attained its culmination in the magnificent operas of Jean-Philippe Rameau (1683–1764), especially in his *Hippolyte et Aricie* (1733; libretto by Simon-Joseph de Pellegrin), *Les Indes galantes* (*The Courtly Indies,* 1735; libretto by Louis Fuzelier), and particularly *Castor et Pollux* (1737; libretto by Pierre-Joseph-Justin Bernard), which was performed at the Paris Opéra 254 times in 48 years. Except for the special instance of *Les Indes galantes,* which was billed as a *ballet héroïque,* Rameau's chief operas were each divided into a prologue and five acts, a pattern that many later French composers favoured. Rameau confirmed the still-enduring insistence of French operatic composers on setting their language to music with such probity and clarity that it can be understood properly when sung. His operatic works are regarded widely as the apogee of 18th-century French opera.

Early opera in Germany and Austria. Although Heinrich Schütz composed *Dafne,* the first known opera with a German text, and heard it played at Torgau on April 23, 1627, the active history of opera in Germany began with the Italian composers residing there. A remarkable Venetian composer-diplomatist-ecclesiastic, the Abbé Agostino Steffani, carried much of his native city's early operatic manner to Munich, Hanover, and other German centres, beginning his operatic production with *Marco Aurelio* (Munich, 1681), and continued thereafter to compose operas for 28 years. In his use of both Italian and French procedures, particularly in handling overture and recitative, Steffani evolved a sort of international Italian style that clearly influenced other "transplanted" composers.

For the next 100 years the influence of Italian opera was so pervasive that even native German composers adopted the Italian operatic style and used texts in Italian.

The German word *Singspiel* was originally used for all sorts of opera. The earliest known entertainments so designated were composed by a pupil of Heinrich Schütz, Johann Theile (1646–1724). One of them, *Adam und Eva,* eminently "serious" as to story, inaugurated the Hamburg Opera in 1678. During the mid-18th century the term singspiel came to be reserved for what the English called "ballad opera," the French *opéra-comique* light, usually comic operas including spoken dialogue. The comic singspiel of the 18th century was born with *The Devil to Pay* (London, 1731) and its sequel, *The Merry Cobbler* (London, 1735), English ballad operas with texts by Charles Coffey. These had pasticcio scores capitalizing, not very successfully, on the great popularity of *The Beggar's Opera* (1728), which had a text by John Gay and an assembled (pasticcio) score brought together by John Christopher Pepusch. The Coffey texts having been translated into German, scores were composed to them by J.C. Standfuss (died 1759?) as *Der Teufel ist los* (Leipzig, 1752) and *Der lustige Schuster* (Lübeck, 1759); they later were restaged as arranged by Johann Adam Hiller (1728–1804), who also composed several other singspiels and brought to culmination the so-called Leipzig School. Both Berlin and Vienna inevitably took up the singspiel, examples of which, composed in those cities and elsewhere, included *Der neue krumme Teufel* (Vienna, 1752, music lost), by Joseph Haydn; Mozart's *Die Entführung aus dem Serail* (*The Abduction from the Seraglio,* Vienna, 1782) and *Die Zauberflöte* (*The Magic Flute,* Vienna, 1791); *Doktor und Apotheker* (Vienna, 1786), by Karl Ditters von Dittersdorf; Beethoven's *Fidelio* (Vienna, 1805), which, like *Die Zauberflöte,* immeasurably transcends the common artistic scope of the singspiel; and *Die Zwillingsbrüder* (*The Twin Brothers,* Vienna, 1820), by Schubert.

Popularity of *The Beggar's Opera*

The most important opere serie composed in Germany during the early 18th century were created for the Hamburg Opera, at which both Reinhard Keiser (1674–1739) and, for a brief interval, the young George Frideric Handel worked. Keiser composed more than 125 operas, mostly to German texts. Of Handel's large operatic output, only two works with Italian texts—*Almira* and *Nero* (both 1705, the second now lost)—were staged during his Hamburg stay. Keiser doggedly tried to attract the widest possible public. His operas often succeeded in charming audiences, but most of them have vanished, and those that survive appear to possess only superficial allure, although they are historically of interest for their skillful exploitation of the orchestra and of solo instruments tellingly used during arias.

Handel went from Italy to England in 1710. In London, with the opera *Rinaldo* (1711), he began 30 years of stubborn dedication to the by then moribund (but still dominant) traditions of Neapolitan opera seria. He created, however, a dozen or more of the most inspired operas of the first half of the century, including *Giulio Cesare* (*Julius Caesar,* 1724), *Tamerlano* (1724), *Rodelinda* (1725), *Sosarme* (1732), *Orlando* (1733), *Ariodante* (1735), and *Alcina* (1735). Handel transcended the formal style of opera seria by his melodic inspiration and harmonic daring. He even managed an immense variety of characterization within the cramped style with which he had to comply.

Handel's operatic style

German by birth, but almost wholly Italianate by disposition, Johann Adolph Hasse (1699–1783) successfully carried on the Metastasian traditions of opera seria in a plethora of operas to Italian texts. The intensely Italian sensuousness of his best melodies, supported by some attractive adventurousness in harmonic placement and in instrumentation, did almost as much as Handel's operas to prolong past its true prime the glory of the Neapolitan style.

FROM THE "REFORM" TO GRAND OPERA

The "reform." Christoph Willibald Gluck (1714–87) has become an ambivalent figure in the evolution of opera:

he has been loosely and often incorrectly categorized, and both praised and condemned, for mistaken reasons. His operas to Italian texts that he composed up to about 1756 were conventional settings of Metastasian librettos. After settling in Vienna in 1750, though not abandoning the composition of traditional opere serie in Italian, Gluck began to react to the French operatic styles popular there. At first he merely added a few new numbers to trivial one-act opéras-comiques brought to Vienna from Paris, which he arranged and conducted for the court at Schönbrunn and Laxenburg. Then he began to compose similar operas in French.

Thanks to the enthusiasm of the superintendent of the imperial Vienna theatres, Conte Giacomo Durazzo, Gluck had been absorbing the example of the outstanding French dancer-choreographer Jean-Georges Noverre (1727–1810). Seminal in Noverre's call for reform was the insistence that a ballet should not be left as a simple collection of unconnected episodes but should be shaped into a mimed dance drama. Gluck then composed the ballet *Don Juan* (1761), the earliest of his scores to place him among the great composers. In the same year a very talented poet-librettist-adventurer, Ranieri Calzabigi, reached Vienna from Paris. Falling in with the anti-Metastasian intellectuals spearheaded by Durazzo, Calzabigi thereafter brought his acquaintance with Rameau's stately operas to the writing of three librettos for Gluck, for whose signature he also drew up the renowned preface to the publication of the Calzabigi–Gluck *Alceste* in 1769. That dedication is the central document of "operatic reform," summing up one side of the unending debate between supporters of the primacy of the opera libretto and supporters of the primacy of the music. The *Alceste* preface emphasized that superfluous, florid da capo arias were to be dispensed with: simplicity of expression and emotional truth were to take their place.

The influence of *Alceste*

Although some of the most accomplished composers of opera certainly would not have agreed that, as Calzabigi–Gluck stated, the "true office" of music is "serving poetry," and though a strict obedience to all the precepts of the *Alceste* dedication would have impoverished much of the richest operatic music (Gluck himself did not follow them with iron strictness), the pronouncement unquestionably summoned opera back temporarily to its best condition: as musicotheatrical drama. The most obvious, as well as the greatest, results of the attitudes it expressed were the magnificent Calzabigi–Gluck operas first staged in Vienna: *Orfeo ed Euridice* (1762), *Alceste* (1767), and *Paride ed Elena* (*Paris and Helen,* 1770). The two earliest of these became even more stately and Rameau-like when Gluck reconstituted them to French librettos for Parisian audiences.

A little below *Orphée* and the French *Alceste* in austere dramatic force stands the somewhat mixed, only partially "reformed" *Armide* (Paris, 1777). But Gluck was to produce his best results in *Iphigénie en Aulide* (*Iphigenia in Aulis,* 1774; libretto adapted from Racine's tragedy by Bailli du Roullet) and in his masterpiece, *Iphigénie en Tauride* (*Iphigenia in Tauris,* 1779; libretto adapted from Euripides by Nicholas-François Guillard).

Gluck's extraordinary power at his best derives from a reasonable, pliable adherence to the precepts of the *Alceste* dedication; a lean sparseness of means, particularly of harmonic density, with the result that the smallest shifts arrive with great power; and the ability to make the most of the dramatic strengths of the often excellent librettos he used. Yet Gluck did not really "reform" opera, for opera is an incorrigible art form. Its mood and manners shift with changes in society, dramaturgy, techniques of composition, and taste.

Followers and imitators of the Gluck reform

Gluck had some immediate followers and imitators, notably Antonio Salieri, who gave lessons to Beethoven, Schubert, and Liszt, was friendly with both Haydn and Rossini, and was ridiculously accused of having poisoned Mozart. Another, belated, Gluckian was Gluck's onetime "rival" in a Parisian polemic "war," Niccolò Piccinni (1728–1800), whose masterpiece, *Didon* (*Dido,* 1783; libretto by Jean-François Marmontel, Fontainbleau), joined a peculiarly Italianate melodiousness to Rameau-like solemnity and the massive simplicities of Gluck's style. Finally, there was Antonio Sacchini, remembered chiefly for his *Oedipe à Colone* (*Oedipus at Colonus,* 1786; libretto by Nicolas-François Guillard). On the highest level, however, the Gluckian "reform" produced only his own masterpieces, although it led indirectly to certain of the "international," though very French, operas of Gasparo Spontini (1774–1851), particularly *La Vestale* (*The Vestal Virgin;* Paris, 1807), and Luigi Cherubini, particularly *Médée* (1797). In part, Gluck also influenced the vast masterwork of Hector Berlioz, *Les Troyens* (*The Trojans,* composed 1856–58).

Opera in England. Just as immediate acceptance of opera had been made difficult in France by the entrenched ballet and the 17th-century drama of Jean Racine and Pierre Corneille, so it was delayed in England by the court masque, an aristocratic 16th- and 17th-century entertainment derived largely from ballet. Most often dealing with allegorical and mythical subjects, the masque mixed poetic text, instrumental and vocal music, dancing, and acting. The most familiar masque is *Comus* (text by John Milton and music by Henry Lawes), which was staged at Ludlow Castle in 1634. Many other embryonic operas were produced in the middle decades of the 17th century, often being more like plays with incidental music. The first (and, in the view of many, still the finest) English opera, *Dido and Aeneas,* by Henry Purcell (*c.* 1659–95), was originally sung about 1689 by the pupils at a girls' school in London. This musical masterpiece, with libretto by a future poet laureate, Nahum Tate, contains the earliest operatic aria (apart from "Lasciatemi morire" from Monteverdi's *Arianna*) still frequently heard: Dido's lament "When I am laid in earth." In this opera, Purcell succeeded in writing a real, albeit brief, music drama, breaking down the formal barriers between recitative and song.

The first English opera

England, however, was not ready for opera. Although later Purcell works, including *The Fairy Queen* (1692), *The Indian Queen,* and *King Arthur* (1691), have been called operas, they were actually suites of incidental music for plays. No other composer in England of Purcell's genius turned his attention to opera, and before many decades had passed after the scarcely noticed performance of *Dido and Aeneas,* the rage for Italian opera (particularly when the singers included a good castrato) barred that road to English composers. The arrival of Handel from Italy in 1710 decided the direction of opera in London for many decades. Beginning in 1711 with *Rinaldo* (libretto by Giacomo Rossi, indirectly derived from Tasso's epic *Gerusalemme liberata*) and continuing intermittently until *Deidamia* (libretto by Paolo Rolli) in 1741, Handel provided English audiences with his own remarkable variant of Neapolitan opera seria, acting as both composer and, most often, impresario. The greatest composer of opera in his age, Handel eventually outlasted his popularity in London's opera houses and turned to the creation of a magnificent series of oratorios set to English texts. His operatic reign was challenged at its height only by a faction that set up the very gifted Modenese composer Giovanni Bononcini in an unequal battle against him. Handel's operas all but vanished from the repertory in the 19th century, but after a burst of German interest in them in the 1920s, they began to be increasingly revived by some major opera houses, smaller opera companies, students, musicologists, and recording companies.

An event that contributed to the defeat of Handel as an opera impresario was the London production in 1728 of *The Beggar's Opera.* That bawdy, rollicking satire in English became phenomenally popular and spawned a family of imitations that finally accustomed audiences in London and elsewhere in the British Isles to hearing a staged play sung in the vernacular.

Viennese masters. Italian opera buffa strongly attracted Viennese audiences, and Austrian composers were naturally influenced by it. Perhaps the most interesting of the Vienna-born composers of 18th-century comic opera was Karl Ditters von Dittersdorf, whose Italianate *Doktor und Apotheker* (1786; libretto by Gottlieb Stephanie), though successful and lively, was overshadowed by the contemporary works of Mozart.

Haydn, who lacked a strong theatrical bent, nonetheless

composed about 20 musicodramatic scores: a singspiel, five short operas for marionettes, and several very Italianate opere buffe and opere serie for private performance in the Eisenstadt palace theatre of his employer-patrons, the Esterhazy princes. Several of Haydn's dramatically undistinguished operas have had modern revivals, including *Il mondo della luna* (*The World on the Moon,* 1777; libretto by Carlo Goldoni), *L'isola disabitata* (*The Deserted Island,* 1779; libretto by Metastasio), and *La fedeltà premiata* (*Faithfulness Rewarded,* 1780; libretto by Giovanni Battista Lorenzi).

Vienna, however, was to be one of the centres of the operatic career of Mozart, one of the greatest masters of opera. Mozart began to write theatrical music when only 10 years old and brought out the first of his important operas at Munich in 1781, when only 25. This was *Idomeneo.* Its libretto, by Giambattista Varesco, is an imitation of Metastasio's style. But Mozart rose above the conventional operatic patterns and filled them with richly expressive music so that the result is scarcely recognizable as an opera seria. As a work of musical (though not of dramatic) art, *Idomeneo* is as fine as Gluck's *Iphigénie en Tauride* and ranks as the supreme Italian opera seria of the late 18th century.

One year after *Idomeneo,* Mozart, with the versatility of his unique genius, wrote a masterly, charming singspiel to a German text: *Die Entführung aus dem Serail* (libretto by Christoph Friedrich Bretzner as edited by Gottlieb Stephanie). A sentimental farce full of immediately attractive music and graced with a fine part for a comic bass (Osmin), *Die Entführung* also contains in "Martern aller Arten," a soprano aria so extensive in plan and difficult to sing that it has challenged the foremost sopranos down to the present. The opera has been called the greatest of all truly comic singspiele, and it is notable for the seriousness with which it treats the relationship between its two principal characters and for the human nobility of its "moral."

Mozart's next completed opera—except for *Der Schauspieldirektor* (*The Impresario,* 1786), a trifling one-act comedy—is one of the treasures of Western civilization, the greatest of all seriocomic operas, *Le nozze di Figaro* (libretto by Lorenzo da Ponte, after Pierre de Beaumarchais's *Le Mariage de Figaro,* 1786), produced at Vienna. In addition to its purely musical beauty, this work shows Mozart to be a creator of individual characters of almost Shakespearean calibre; he goes far beyond the opportunities offered by his able librettist and creates, by musical means, believable, rounded human beings, often employed in ensembles as well as in solos and in elaborately constructed finales.

Production of *Figaro* at Vienna

In 1787 Mozart's next opera, written for Prague, was *Don Giovanni* (libretto by da Ponte, based on earlier Don Juan librettos and other writings related to plays by Tirso de Molina, Thomas Corneille, and others). The 19th century tended to regard *Don Giovanni* as the greatest opera ever composed, in part because musical elements in it foretold operatic romanticism. Aspects of da Ponte's libretto disturb some 20th-century critics—particularly the grim, morally justifiable ending of what up to then has been a comedy, followed by the "vaudeville" postlude, during which the singers step out of character to underline the "moral," in line with a then long-established convention. Musically, *Don Giovanni* shares many of the supreme virtues of *Le nozze di Figaro,* in beauty, in characterization, and in dramatic power.

In his last collaboration with Da Ponte, Mozart created another opera buffa, *Così fan tutte* (1790). Most musical opinion today considers it to be an opera of flawless workmanship reconciled with the dramatic claims of a seemingly artificial and cynical libretto, which in fact exposes the foibles of mankind. Farcical productions too often destroy its knife-edge balance between artificiality and reality. Too richly scored, too erotic, and too intense for Viennese taste of the time, it was not a success with the easy-going Viennese, but it now ranks as one of Mozart's greatest stage works.

In 1791, returning to the singspiel in German, Mozart composed *Die Zauberflöte* (libretto by Emanuel Schikaneder), an allegorical and Masonic opera with a seemingly nonsensical but in fact elaborately significant libretto in strong contrast with *Così fan tutte*'s cynicism about women. Here, Mozart created some of the most radiantly beautiful music ever composed, assigning it lavishly to both the serious and the comic, both the admirable and the vicious characters. George Bernard Shaw once said that the two arias given to the benevolent Sarastro in *Die Zauberflöte* were the only music he knew that would not sound out of place in the mouth of God—and they are but two of many numbers in this opera that have helped to place Mozart's theatrical works, together with his concertos, at the very apex of his astonishing and endlessly varied output.

Also in 1791 Mozart composed, to a Metastasio libretto slightly revised, another outdated opera seria, *La clemenza di Tito.* Created in 18 days for festivities surrounding the coronation of Emperor Leopold II as king of Bohemia in Prague, *La clemenza* provides numerous examples of Mozart's musical mastery, none of his mastery of dramatic creation through music.

Like *Die Zauberflöte,* Beethoven's *Fidelio* (1805, revised 1806 and 1814) rose above the limitations of the singspiel pattern, becoming something bigger and grander. In most of this, his only opera, Beethoven is musically at nearly his greatest. The libretto has never satisfied anyone entirely; also, some of the writing for the voices is instrumental rather than truly vocal. Beethoven lacked Mozart's theatrical sensibility and his ability to mix the comic-frivolous with the solemn and near tragic, as the text required. Yet the grandeur of much of the *Fidelio* music and the noble humanity of the central character (a wife, Leonore, who disguises herself as a young man, Fidelio, in order to rescue her husband, at terrible risk, from political incarceration in a dungeon) irradiates the opera from the moment of Leonore's first appearance. Its theme of the triumph of the human spirit over oppression has helped to place *Fidelio* among the world's most popular operas.

France, 1752–1825. Political changes and that intensity of intellectual discussion that has always played a role in determining the nature of artistic production in Paris led, in the early 1750s, to one of those polemic "wars"—this one called the *Guerre* (or *Querelle*) *des Bouffons* (War of the Buffoons)—that delight the French. This was a mainly literary confrontation of the solemn past of opera seria and *tragédie lyrique* with the farce and sentiment of opera buffa, though many of the writers saw it in nationalistic terms. It had a happy outcome: the subsequent composition by both French composers and resident foreigners of excellent examples of opéra comique, which became a French amalgam of the English ballad opera, the German singspiel, and the Italian opera buffa.

The *Guerre des Bouffons*

In 1752, the year of the first battles of the *Guerre des Bouffons,* Jean-Jacques Rousseau staged at Fontainebleau his one-act comic opera *Le Devin du village* (*The Village Soothsayer*). The libretto was his own. In the score he had brought together, in the pasticcio manner, melodies reflecting the very popular romances and vaudevilles being heard at the Paris fairs. It pleased battlers on both sides of the operatic war, being very French in manner and sentiment but Italian in being through-composed (continuously set) and employing recitative. Rousseau hoped to establish this combination as a standard for French comic opera, but his plan was not immediately successful. In 1755, however, a Naples-trained Italian, Egidio Duni, settled in Paris and began to compose (or perhaps, at first, merely to assemble) recognizably Rousseauesque opéras comiques. French and Belgian composers gladly adapted the new variety of opéra comique (not always with comic subject matter) and soon established its reign in the Paris and provincial theatres (nearly all of them simultaneously composed other sorts of musicodramatic works as well). Among them, several names stand out, together with the finest or most renowned of their operas. One of the most interesting of these opéra comique composers was François-André Danican (1726–95), called Philidor, also a famous chess player, who wrote about 20 works in the evolving manner.

More sentimental—in fact, tending toward the tenderly tearful—was Pierre Alexandre Monsigny (1729–1817),

never thoroughly trained in music but endowed with the ability to create winning melodies and to exploit for dramatic purpose the timbres of individual instruments. Probably the finest of the 18th-century composers of opéra comique was a Belgian, André Grétry (1741–1813), who most happily balanced the French and Italian styles. He was a very original and extremely productive composer over a 30-year period spanning the French Revolution.

Étienne-Nicolas Méhul (1763–1817), who used opéra comique conventions including the retention of spoken dialogue, also had a career spanning the Revolution. A devoted Gluckian, Méhul had composed numerous works in many genres when, in 1807, he produced his masterpiece, *Joseph,* which is a rarity among operas in several ways: its libretto by Alexandre Duval is derived from the Bible, a source of drama usually reserved for the oratorio; it has no female characters; and it mixes the most solemn classicism with the sentiment of the popular romances.

Boieldieu's immense success

Early in the 19th century, French opéra comique achieved a new equilibrium of classical tint in the best works of François-Adrien Boieldieu (1775–1834). He won truly astonishing and, to several composers (Berlioz included), maddening popularity with *La Dame blanche* (*The White Lady,* 1825; libretto by Eugène Scribe, based upon Sir Walter Scott's novels *Guy Mannering* and *The Monastery*). There were 1,669 performances of this work at the Opéra-Comique, Paris, between 1825 and 1926.

Le Pré aux clercs (*The Field of Honour,* 1832; libretto by François de Planard), the most accomplished opera of Louis-Joseph-Ferdinand Hérold (1791–1833), all but equalled the popularity of *La Dame blanche;* it had received 1,600 performances at the Paris Opéra-Comique by 1939. Hérold's other outstanding success was *Zampa* (1831; libretto by Anne-Honeré Mélesville), so much like the work of Carl Maria von Weber that it became vastly popular in Germany. An extraordinarily prolix composer, Hérold never succeeded in working out a dependable, unified manner of his own, with the result that his French operas are structurally weak. Opéra comique after Boieldieu became more Italianized, reflecting very largely Rossini's influence.

Italy in the first half of the 19th century. The splendid musical achievements of the classicial Viennese style during the late 18th century and early 19th threatened to leave Italy, opera's native home, to one side of the operatic highroad. Two accidents—one the voluntary expatriation to northern Italy of a German, Johann Simon Mayr, the other the unpredictable eruption of a genius, Gioacchino Rossini—saved the day for Italian opera in Italy and outside it.

Mayr, known in Italy as Giovanni Simone Mayr, composed nearly 70 operas in Italian between his first (1794) and his last (1815). He appears to have been influenced deeply by Mozart, and his intensely keen dramatic sense, together with the extraordinary pliability with which he employed the conventions of opera seria and his varied use of the orchestra (particularly of solo woodwinds and horns within it), would have made him a major composer of opera had he not lacked major gifts as a melodist. Many of his operas were for a long time extremely popular throughout Italy, and his immediate influence was beneficial, particularly on the practice of his most famous pupil, Gaetano Donizetti, and on another, less talented, but still admirable operatic composer, Saverio Mercadante.

The operas of Nicola Zingarelli (1752–1837) and of Ferdinando Paer (1771–1839) were transitional, between Classical and grand opera in mode and manner. Zingarelli's conventional opere buffe displayed a genuine humour and some liveliness of musical imagination; his most enduringly performed work, however, was an opera seria, *Giulietta e Romeo* (1796; libretto by Giuseppe Maria Foppa). He is now remembered chiefly as a teacher of Vincenzo Bellini. Paer, who composed more than 40 operas, worked mostly in Vienna, Dresden, and Paris; his musical style changed with his surroundings.

The production at Venice in 1810 of the first performed opera of Rossini, *La cambiale di matrimonio* (*The Bill of Marriage;* libretto by Gaetano Rossi), announced a new operatic genius. Into the genteel, often charming atmosphere of lingering 18th-century operatic manners, Rossini brought genuine originality marked by rude wit and humour and an entire willingness to sacrifice all "rules" of musical and operatic decorum. Both his opere buffe and his now sadly neglected opere serie soon became so popular throughout Italy and then throughout the Western world that they all but blotted out his unfortunate contemporaries—Donizetti and Bellini excepted.

Rossini's originality and wit

Rossini's dazzling career marked the zenith of the bel canto style, a singer-dominated manner of composition (and at times improvisation) that played to audiences' delight in vocal agility, smoothness of voice, and long, florid phrasing. From the period of Rossini's greatest Italian triumphs (he had a second career in Paris) and of Donizetti and Bellini come the names of now legendary voices such as Isabella Colbran (Rossini's first wife), Giuditta Pasta, Maria Malibran, Giovanni David, Giovanni Battista Rubini, Domenico Donzelli, Antonio Tamburini, and Luigi Lablache. For appearances by these singers, composers altered their scores; when they sang, they interpolated extraneous arias that displayed their prowess. Rossini tried to insist that his operas be sung as he himself composed or revised them, but it was a losing battle. The polished artistry and extreme technical training and technique of such singers, as well as their extraordinarily wide ranges, have left performance of the bel canto operas bristling with nearly insoluble problems for latter-day singers.

Perfection of Rossini's comic operas

Rossini's most famous opera is *Il barbiere di Siviglia* (*The Barber of Seville,* 1816; based on the libretto by Cesare Sterbini after the 18th-century play by Beaumarchais), the most nearly flawless of all opere buffe. Several others among his comedies rank only a little lower in musical invention, genuine comic brio, and opportunities for trained singers of vocal display and for farcical characterization: *L'Italiana in Algeri* (*The Italian Girl in Algiers,* 1813; libretto by Angelo Anelli), *Il Turco in Italia* (*The Turk in Italy,* 1814; libretto by Felice Romani); *La cenerentola* (*Cinderella,* 1817; libretto by Jacopo Ferretti), and the half Italian opera buffa and half French opéra comique *Le Comte Ory* (*Count Ory,* 1828; libretto by Scribe and Charles-Gaspard Delestre-Poirson). Rossini prefaced several of these operas with swift, witty overtures that have held a place in the repertory of symphony orchestras.

His style began to have a more serious bent with *Otello* (*Othello,* 1816; libretto by Francesco di Salsa), the opera semiseria (a serious opera with a happy ending), *La gazza ladra* (*The Thieving Magpie,* 1817; libretto by Giovanni Gherardini), and *Armida* (1817; libretto by Giovanni Schmidt), all of which show the composer adapting his florid style to more dramatic, and often eloquent, purposes. But it was only in his Parisian pieces, such as *Semiramide* (1823; libretto by Gaetano Rossi), *Le Siège de Corinthe* (*The Siege of Corinth,* 1826; a revision of the earlier opera, *Maometto II* [1820]; libretto by Alexandre Soumet and Luigi Balocchi), and *Guillaume Tell* (*William Tell,* 1829; libretto by Étienne de Jouy and Hippolyte Bis), his last opera, that his talent for works on a bigger scale, presaging Parisian grand opera, found its full flowering. Some of these later operas owe their revival in the middle of the 20th century to the appearance of a few singers able to project meaningfully their difficult vocal lines.

Gaetano Donizetti first composed a series of very Rossinian, well-made, and largely undistinguished operas but gradually developed dramatic strength, a latent gift for memorable melody, and a forceful deployment of the orchestra for theatrical drama. In 1830, the year after Rossini's farewell to operatic composition, Donizetti produced at Milan the first of his forward-tending, less Rossinian, dramatically remarkable operas: *Anna Bolena* (*Anne Boleyn*), with a libretto by Felice Romani, who worked with so many opera composers of the time. It immediately placed him with Bellini as an inevitable successor to Rossini. What became clear only in retrospect was that it also showed him to be the most important immediate predecessor—in some sense, teacher—of Giuseppe Verdi. Donizetti clung to the long, legato (smoothly flowing) melodies and the ornamented vocal lines of bel canto, but he also unmistakably foreshadowed Verdi's dramatic vigour and many of the younger man's compositional

methods. Several unconscious borrowings from Donizetti have been noted by students of Verdi's operas.

Like Rossini, but unlike Bellini, Donizetti moved freely back and forth between serious and comic subjects. He composed about 70 stage works in 25 years. After the success of *Anna Bolena,* with speed and facility that remain astonishing, he composed numerous operas of enduring quality. They include the sentimental comedy *L'elisir d'amore* (*The Elixir of Love,* 1832; libretto by Felice Romani); *Lucrezia Borgia* (1833; libretto by Romani) and *Maria Stuarda* (*Mary Stuart,* 1834; libretto by Giuseppe Bardari); the popular *Lucia di Lammermoor* (1835; libretto by Salvatore Cammarano was derived from Sir Walter Scott's *The Bride of Lammermoor*)—an opera that reflects Donizetti's acquaintance with the music of Bellini; *Roberto d'Evereux* (1837; libretto by Cammarano); the delightful opéra comique *La Fille du régiment* (*The Daughter of the Regiment,* 1840; libretto by Jules-Henri Vernoy de Saint-Georges and Jean-François-Alfred Bayard); the grand opera *La Favorite* (1840; libretto by Alphonse Royer, Gustave Vaëz, and perhaps Scribe); the opera semiseria *Linda di Chamounix* (1842; libretto by Gaetano Rossi); and—judged by many to be Donizetti's masterwork—the ever fresh and vivid opera buffa, *Don Pasquale* (1843; libretto by Giacomo Ruffini and Donizetti).

Altogether different from either Rossini or Donizetti was Vincenzo Bellini. His operas have come to seem the natural habitat of bel canto, of the unchallenged supremacy of vocal melody in amazingly long-breathed and highly decorated lines. Only his first student opera contains even a trace of humour. He and his librettists filled their collaborations with intensely amorous and other subjective emotion, ethical confrontations, and usually tragic involvements (of the seven finest among his 10 operas, only two—*La sonnambula* and *I puritani*—conclude happily for the principal characters). Bellini cultivated with meticulous care his unrivalled, native gift for convincingly melancholy melody, especially in arias and duets; he gave much less attention to ensembles, choruses, and the expressive potentialities of the orchestra. His orchestra, in fact, might have been what it was had Haydn, Mozart, Mayr, and Rossini never existed.

Bellini's innate gift of melody

Beginning in 1827 with *Il pirata* (*The Pirate,* libretto by Felice Romani, who thereafter supplied all of Bellini's librettos except that for *I puritani*), Bellini made his presence felt throughout Italy and then gradually throughout Europe and the Americas. In 1831 two of Bellini's enduring masterworks were produced: the pastoral opera semiseria *La sonnambula* (*The Sleepwalker*) and the heroic tragedy *Norma.* Bellini's previously faithful public temporarily deserted him when, in 1833, he gave it *Beatrice di Tenda.* In the year of his death after his final removal to Paris, he won another triumph with an opera very loosely connected with Cromwellian times in England, *I puritani* (*The Puritans;* libretto by conte Carlo Pepoli).

Unlike Rossini and Donizetti, Bellini exercised little or no influence upon the style of his successors: the most noticeable of his compositional means, his exclusively personal sort of melody, could only be debased in imitation by others. With these three men, both the late period of bel canto and the second period of opera buffa drew to a close. After the onset of Donizetti's crippling illness in 1847, the Italian opera houses in Italy, Paris, London, and elsewhere could look to Giuseppe Verdi.

GRAND OPERA AND BEYOND

French grand opera. Nineteenth-century Paris was to foster and witness the birth of "grand opera," an international style of large-scale operatic spectacle employing historical or pseudohistorical librettos and filling the stage with elaborate scenery and costumes, ballets, and phalanxes of supernumeraries. Dispensing almost entirely with the delicacies of bel canto, it vastly enlarged both the orchestra itself and its role in the dramatic happenings. Grand opera naturally had roots in the past, particularly in the Venetian "machine operas" of the 17th century, such as Cesti's *Il pomo d'oro,* as well as in the stately scores of Rameau and Gluck. But the immediate drive toward this new style of opera was instituted in Paris by Italian expatriates: Luigi Cherubini, who spent the last 54 years of his life in France, and Gasparo Spontini, whose most impressive operas were designed for Paris.

Cherubini was a greatly learned composer in almost all musical forms who won the admiration of Beethoven. His two most imposing operas were the embryonic grand opera *Médée* (1797; libretto by François-Benoît Hoffman) and a *comédie lyrique, Les Deux Journées* (*The Two Days,* 1800; libretto by Jean-Nicolas Bouilly). *Les Deux Journées* became something like a national German opera under its German title, *Der Wasserträger* (*The Water Carrier*). Spontini, in his French operas, ranged far beyond Cherubini and his other contemporaries in his demands for complex staging, finally reaching a sort of splendid megalomania. Daniel-François-Esprit Auber brought out a nearly total grand opera; *La Muette de Portici* (*The Mute Girl of Portici,* also known as *Masaniello,* 1828; libretto by Scribe). The popularity of *La Muette* became phenomenal in both France and Germany. This opera remains unique on several counts. Its title character neither sings nor speaks, the role being performed by a mime. A performance of it at Brussels on August 25, 1830, set off disorders that led to the separation of Belgium from The Netherlands. Eighteen months after the premiere of Auber's opera, the appearance of Rossini's *Guillaume Tell* showed that master of opera buffa and bel canto responding to the new genre. Auber's later operas include several charming comedies, among them *Fra Diavolo* (1830; libretto by Scribe).

The final, official birth of grand opera occurred in 1831, with the first French opera of another Parisian expatriate, the German Giacomo Meyerbeer: *Robert le Diable* (libretto by Scribe and Germain Delavigne). The popularity of this work became a sort of frenzy (by August 1893 it had been sung 751 times at the Paris Opéra). Although Meyerbeer's operas are rarely performed in the late 20th century, he remains a controversial figure. Using an expanded, powerful orchestra, with much emphasis placed on individual instrumental colours, requiring almost every kind of singing, filling huge stages with dazzling pageantry, employing characters who pretend to be actual figures from history, four of his operas held their leading positions even through the Wagnerian revolution and into the early 20th century. Besides *Robert le Diable,* they were *Les Huguenots* (1836; libretto by Scribe with the collaboration of Émile Deschamps), *Le Prophète* (1849; libretto by Scribe), and the posthumously staged *L'Africaine* (libretto by Scribe). The author of all of these, Eugène Scribe, was the most phenomenally productive librettist of his time, writing (with the help of various collaborators) a huge number of librettos for many composers, including Auber, Boieldieu, Cherubini, Donizetti, Gounod, Halévy, Meyerbeer, Rossini, and Verdi. He was, in fact, a major force in the evolution of French grand opera.

Imitators of Meyerbeer's successes naturally sprang up immediately. Later, numerous men totally unlike him stylistically—including Berlioz, Wagner, and Verdi—were influenced unwittingly by his practices. The first of the imitators was Fromental Halévy, whose works included at least one grand opera that could almost be mistaken for Meyerbeer's: *La Juive* (*The Jewess,* 1835; libretto by Scribe). After the times of Meyerbeer and Halévy, grand opera began to respond to new musical and intellectual currents, evolving into a variety of mixed forms.

Like most of Hector Berlioz's other compositions, his three operas stand apart from the mainstream of historical evolution. When first staged at the Paris Opéra in the shadow of *Robert le Diable* and *La Dame blanche,* his first opera, *Benvenuto Cellini* (1838; libretto by Léon de Wailly and Auguste Barbier), was a complete failure. The second, the lighthearted *Béatrice et Bénédict* (his own libretto, based upon Shakespeare's *Much Ado About Nothing*), finally was given its premiere at Baden-Baden in 1862 by Franz Liszt. And Berlioz's masterpiece, *Les Troyens* (his own libretto), is based on Virgil's *Aeneid* and divided into *La Prise de Troie* (*The Capture of Troy*), two acts, and *Les Troyens à Carthage* (*The Trojans at Carthage*), three acts. It was not performed complete during his lifetime; he

Modern revival of *Les Troyens*

heard only the second part as staged in Paris in 1863. Mid-20th-century complete (or very nearly complete) performances of *Les Troyens,* notably in London, showed it to be a great, noble, idiosyncratic work not without traces of grand opera, but in seriousness and scope much closer to the Wagner of *Der Ring des Nibelungen.* Berlioz's operas, like his other music, are distinguished by the individual arch of his melody, his revolutionary orchestration, and the dramatic thrust of the whole.

Even more popular than Auber as a purveyer of light operatic comedy was Jacques Offenbach, a German émigré to Paris who supplied the Second Empire and the early years of the Third Republic with a long series of very tuneful, witty, and satiric operettas of deliberate frivolity. Remembered among them are *Orphée aux enfers* (*Orpheus in the Underworld,* 1858; libretto by Hector Crémieux and Ludovic Halévy), *La Belle Hélène* (*Beautiful Helen,* 1864; libretto by Henri Meilhac and Halévy), *Barbe-Bleue* (*Bluebeard,* 1866; libretto by Meilhac and Halévy), *La Vie Parisienne* (*Parisian Life,* 1866; libretto by Meilhac and Halévy), *La Grande-Duchesse de Gérolstein* (1867; libretto by Meilhac and Halévy), and *La Périchole* (1868; libretto by Meilhac and Halévy). Left incomplete at Offenbach's death was his major serious opera, *Les Contes d'Hoffmann* (*The Tales of Hoffmann;* libretto by Jules Barbier and Michel Carré, after their play of the same name based on tales by the German Romantic writer E.T.A. Hoffmann). Recitatives replacing the original dialogue were provided by Ernst Guiraud, and the opera was staged posthumously in 1881. This fantasy involving supernatural interventions rapidly became a worldwide favourite.

German Romantic opera. Romanticism, part philosophical, part literary, part aesthetic, made one of its first appearances, and certainly its earliest overt appearance, in opera, in three works composed between 1821 and 1826 by Carl Maria von Weber. Beginning with his masterpiece, *Der Freischütz* (*The Freeshooter,* 1821; libretto by Friedrich Kind), Weber successfully challenged the outdated dictatorship of Spontini at Berlin. For the Italian's stiff grandeurs he substituted, in singspiel form, tender sentiment, grisly horrors, manly choruses, moral nicety, and music of extraordinary instrumental and vocal allure. *Der Freischutz* illustrates the German Romantic writers' love for dark forests, the echoes of hunters' horns, the threatening supernatural, the frustrations of pure young love. Its popularity in Germany and elsewhere was enormous.

Elements of German Romanticism

Weber smarted under the anti-Romantic criticism of *Der Freischütz* as a mere singspiel (a work with spoken dialogue) rather than a musically continuous opera. His next major composition, *Euryanthe* (1823; libretto by Helmina von Chézy), was something like a proto-grand opera and therefore contained no spoken dialogue. Almost since its premiere, writers have attacked the remarkable silliness (on paper) of its libretto, but most of them have never witnessed the work in performance and therefore cannot judge how the libretto works on stage with Weber's fine score. His last opera, *Oberon,* or *The Elf King's Oath* (1826; libretto, in English, by James Robinson Planché), returns to the singspiel form. Like *Euryanthe,* it has not held the stage, and again the libretto has been blamed. The overtures to all three of these operas are still played frequently, and whatever future opinion of the operas themselves may be, *Der Freischütz* opened the floodgates of musical Romanticism in Germany.

Louis Spohr (1784–1859), a violinist, conductor, and composer of instrumental music, sounds pallidly Romantic if compared with Weber, but certain of his harmonic innovations taught something to Wagner, of whose early operas he was a defender. Heinrich August Marschner (1795–1861), more Romantic by nature than Spohr, borrowed sufficiently from Weber's style to serve as one bridge to Wagner. He displayed talent as orchestrator and melodist, and he applied his gifts to intensely Romantic and equally Teutonic librettos. The finest of his now unheard operas is *Hans Heiling* (1833; libretto by Eduard Devrient).

The other German-language composers of opera active during the Weber–Spohr–Marschner period were less important. Albert Lortzing composed several operas that have been likened to genre painting. He travelled in the direction of operetta in his popular sentimental comedies, such as *Zar und Zimmermann* (*Tsar and Carpenter,* 1837; his own libretto) and *Der Waffenschmied* (*The Armourer,* 1846; his own libretto). The same direction was taken by Friedrich, Freiherr von Flotow, whose operetta-like *Martha* (1847; libretto by Friedrich Wilhelm Reise) continues to be performed frequently. This trend toward operetta as a less intense variety of Romanticism continued in *Die lustigen Weiber von Windsor* (1849; libretto by Salomon Hermann Mosenthal, based on Shakespeare's *Merry Wives of Windsor*), the major success of Otto Nicolai, and in the extremely popular works of Franz von Suppé, a Dalmatian of Belgian ancestry. It culminated in operetta on the highest level of musical accomplishment in the masterworks of Johann Strauss the Younger. Many of Strauss's operettas are known now only by their overtures and waltzes, but one of them, *Die Fledermaus* (1874; libretto by Carl Haffner and Richard Genée), has never left the stage for long. Only the finest opéras comiques and opéras bouffes of Auber and Jacques Offenbach match Strauss's elegance, wit, humour, musical invention, and scrupulous workmanship.

Strauss's operettas

Verdi. When, in 1839, an opera called *Oberto, conte di San Bonifacio* (libretto by Antonio Piazza, revised by Bartolomeo Merelli and Temistocle Solera) was staged at the leading Italian opera house, the Teatro alla Scala (La Scala) at Milan, its first audiences received it reasonably well. Rossini had not offered a new opera for 10 years, Bellini was dead, and Donizetti was composing for Paris, so the debut of a new talent was welcome. Those early audiences, however, could not know that *Oberto* had opened the active career of the greatest of all later Italian composers of opera, Giuseppe Verdi. Verdi's second opera, *Un giorno di regno* (*King for a Day,* 1840; libretto by Felice Romani), was a failure and was to remain his only comedy for 53 years. It was followed by *Nabucodonosor,* known as *Nabucco* (1842; libretto by Solera), which displayed the emergence of a musical dramatist of enormous vigour and rich melodic invention.

Verdi long suffered from his inability to obtain librettos worthy of his special talents, but each of the six operas that he wrote between *Nabucco* (1842) and *Macbeth* (1847) includes scenes and numbers of great power and immediately winning, memorable melody. Even *Macbeth* (libretto by Francesco Maria Piave, revised in 1865 by Verdi to a libretto in French), although it is marked both dramatically and musically by passages of astonishing vitality, has structural weaknesses.

Another period of lesser achievement by Verdi stretched from 1847 to 1851, the best of his five operas of those years having been *Luisa Miller* (1849; libretto by Salvatore Cammarano). Meanwhile, Verdi was on the way to becoming a public symbol of the risorgimento, the Italian movement of rebellion against foreign domination and toward political unification, both because of the patriotic emphasis in several of his librettos and because of his staunchly liberal public character (he was eventually to become a true national hero).

Beginning in 1851, Verdi produced three masterpieces, having found three librettos that fired aspects of his genius. The first of them was *Rigoletto* (libretto by Piave), in which his abundant creation of melody was at the service of his gift for musical characterization. *Rigoletto* was followed, less than two years later, by *Il trovatore* (*The Troubadour,* 1853; libretto by Cammarano), perhaps unmatched among his operas for its profusion of strong and memorable melodies.

Less than two months after the premiere of *Il trovatore* came *La traviata* (1853; libretto by Piave, after Alexandre Dumas *fils*'s *La Dame aux camélias*). At first a failure, it later came to be accepted as a masterpiece. It also established a composer's right to set librettos dealing with contemporary life and with characters not of exalted station. By comparison with the thunderous melodrama of *Il trovatore, La traviata* seems an intimate, quiet, almost chamber-music opera. The musical portrait of Violetta, the tubercular courtesan heroine, remains extraordinary for its depiction of the effects of love and sorrow on her character.

Production of *La traviata*

After *La traviata* came a comparative failure, a grand opera composed in French for Paris, *Les Vêpres siciliennes* (*The Sicilian Vespers,* 1855; libretto by Scribe and Charles Duveyrier). It was succeeded only two years later by *Simon Boccanegra* (1857; revised 1881), a gloomy opera of great power. Then came *Un ballo in maschera* (*A Masked Ball,* 1859; libretto by Antonio Somma, after Scribe's libretto for Auber's 1833 opera *Gustave III, ou Le Bal Masqué*), no less gloomy and powerful but including, in the page Oscar (sung by a soprano), a ray of light and youthful humour, and *La forza del destino* (*The Force of Destiny,* 1862; libretto by Piave), a kaleidoscopic mixture of the tragic and the farcical, with touches of matter not far from operetta and opera buffa.

For Paris, and again to a libretto in French, Verdi next composed *Don Carlos* (1867; libretto by François-Joseph Méry and Camille du Locle, revised by Verdi in 1884 to an Italian translation and again in 1887). This long opera, and particularly its fourth act, is majestic and subtle, its various musical confrontations—many of them duets—displaying a depth of characterization hitherto unknown in Italian or French opera, in spite of faults in the libretto.

By 1869 Verdi's fame had become so international that the Khedive of Egypt invited him to compose an opera for Cairo to mark the opening of the new Cairo Opera House (and possibly the opening of the Suez Canal). In fact, the canal began to operate in 1869, but the opera received its premiere at Cairo only in 1871. This was *Aida* (libretto by Antonio Ghislanzoni, based on a scenario by Auguste Mariette, the French Egyptologist, and Camille du Locle, with the collaboration of Verdi). The masterly libretto and its four well-delineated principal characters evoked from Verdi a Meyerbeerian opera of such unfailing melodic, orchestral, and dramatic richness that many have called *Aida* his masterpiece. For pageantry, combined as it is with harmonic, melodic, and instrumental skills and convincing, if generalized, characterization, it remains unrivalled—and probably has been sung more often than any other opera.

Verdi's Shakespearean operas

In 1869 the public and the writers on opera assumed that Verdi would continue to produce a new opera every few years. But 16 elapsed before the premiere of his next opera, *Otello* (1887; libretto by Arrigo Boito). Verdi's varied, intensely dynamic, compressed, and tragic score was the result not only of his ripened genius but also of nearly 50 years of operatic practice. Many critics consider it the finest tragic opera ever composed.

In the following six years, rumours grew that the aged Verdi not only was composing still another opera but that it was to be a comedy. The comic masterpiece *Falstaff* (libretto by Boito, derived largely from Shakespeare's *Merry Wives of Windsor* and *Henry IV*) was performed in 1893 at La Scala, where Verdi's first opera had been staged more than 53 years before. An opera buffa with serious overtones, *Falstaff* always has been praised by critics and enthusiasts, but it has never become a true popular favourite.

Arrigo Boito not only wrote the librettos of Verdi's last two operas but was also himself a composer, as well as a poet, polemicist, and man of letters. He completed only one opera, *Mefistofele* (1868; his own libretto, derived from Goethe's *Faust*). It was at first a failure and then became more popular. His command of technical musical resources was vast. Unfortunately, he placed them at the service of lofty but diffuse philosophical concepts and ideals mostly beyond his range of expressiveness. *Mefistofele,* for instance, is more impressive and admirable than theatrically convincing.

Wagner and his successors. Richard Wagner (1813–83) is a unique figure in the history of both opera and music. A concentrated egoist gifted with a powerful, tenacious, and at times stubbornly confused intellect, he wrote both the music and librettos of his operas. He began his career, except for a youthful attempt, *Die Feen* (*The Fairies,* completed, 1834; first performed, 1888), with two grand operas mixing the influences of Meyerbeer, Marschner, and Weber: *Das Liebesverbot* (*The Ban on Love,* 1836) and *Rienzi* (1842). In 1843, with *Der fliegende Holländer* (*The Flying Dutchman*), he began to develop what was to become an extremely personal, powerful manner of operatic construction. Turning to mythic legend for his subjects and making unacknowledged bows to the operas of Weber and Marschner, while dispensing with the trappings of grand opera, he composed an intensely German, Romantic opera. In it he instituted the use of brief melodic and other motifs as materials for evolving a more-or-less continuous web of music in which the separate numbers of earlier opera appeared only when the libretto demanded them. Already, at the age of 30, he was giving harmony, in very unclassical guise, a central constructive role in the creation of both drama and characterization.

Wagner's personal operatic style

Patiently and challengingly elaborating a vast, interlocked system of theories in many published books and essays, Wagner continued the ripening of his style in two large, transitional operas, *Tannhäuser* (1845) and *Lohengrin* (1850). *Tannhäuser* again displays some grand-opera characteristics (particularly in the revision of it that Wagner prepared for the 1861 Paris performance); *Lohengrin,* the last of Wagner's serious operas peopled by human beings of recognizable dimensions, has been called the Romantic opera par excellence.

The earliest example of what Wagner called "music drama" (a term he preferred to "opera") was the monumental *Tristan und Isolde* (1865), the libretto of which illustrates his obsession with the idea of man's redemption through woman's love. *Tristan und Isolde* advances harmonic language. The score is woven in a harmonic idiom so advanced chromatically that it speeded the destruction of orthodox concepts of harmony. *Tristan* requires singers possessed of powerful voices capable of penetrating a vastly enlarged orchestra. It came to be regarded as the greatest German opera of the late 19th century, and its influence upon compositional methods and techniques continued into the 20th century.

In *Die Meistersinger von Nürnberg* (*The Mastersingers of Nürnberg,* 1868) he partly deserted his most "advanced" style because central episodes in the libretto required self-contained numbers. Warmhearted, overflowing with young love and the bitter wisdom of age, *Die Meistersinger* ranks with Verdi's *Falstaff* among late-19th-century comic operas. From 1853 until 1874 Wagner worked intermittently on the four poems and the scores of *Der Ring des Nibelungen.* It is an epic, based on Teutonic myths, of such proportions and implications that it cannot be summarized. Musically, Wagner uses leitmotivs—constantly recurring fragments—and weaves them into a large, elaborate pattern. Performed in its entirety, and without intermissions, the *Ring* would last about 12 hours; many listeners, almost bewitched, would have been and now would be willing to attend such a continuous performance, so compelling is the musical power of this unique, all but inhuman, masterpiece.

The last of Wagner's operas, *Parsifal* (1882), introduced few structural elements not used in *Tristan und Isolde* and *Der Ring des Nibelungen.* Wagner called it *Ein Bühnenweihfestspiel*—a sacred festival drama—and it is heavy with religious and ethical messages. It perfectly illustrated both his musicodramatic theories and the unsmiling solemnity with which he approached operatic composition and demanded, successfully, that his audience absorb the results. *Parsifal* closed a career unparalleled in its aggressive demands on society and on operagoers, a career that would have seemed a form of madness if it had not produced some of the most lastingly impressive of all operatic creations and many pages of music of the greatest beauty.

Operatic composers influenced by Wagner

Curiously, Wagner's influence has been felt more in the evolution of post-Romantic harmony than in the constructive practices of later operatic composers. An adaptation of his leitmotiv usage marked the delightful fairytale opera *Hänsel und Gretel* (1893; based upon the tale by the Brothers Grimm), by Engelbert Humperdinck. Wagner's early theories about both libretto and music played a constructive part in the excellent comic opera *Der Barbier von Bagdad* (*The Barber of Bagdad,* 1858), by Peter Cornelius, and his mature style was wholly adopted in *Guntram* (1894), the first opera of Richard Strauss. Otherwise, the Wagnerian revolutions (in contrast with his at times unrevolutionary practice) are clearly seen in the

operas of some ardent French Wagnerians such as Ernest Reyer and Vincent d'Indy.

Later opera in France. The history of French opera contemporary with and later than Berlioz includes many talented composers and stageworthy works, but it degenerates quickly into a catalog of pieces of considerable charm and some originality seldom made arresting by the appearance of operas unmistakably of the first rank. Charles Gounod, who composed many operas, had a unique gift for sentimental melody but an uncertain sense of what is theatrically viable. In his ever-popular *Faust* (1859; libretto by Jules Barbier and Michel Carré), his talents were most creatively gathered together, but *Faust* took no place in the steady evolution of operatic styles. Among Gounod's other operas, the best, mixing in different proportions the virtues and flaws of *Faust,* are probably *Mireille* (1864; libretto by Carré, derived from Frédéric Mistral's Provençal poem *Mirèio*) and *Roméo et Juliette* (1867; libretto by Barbier and Carré).

The works of Georges Bizet are on a higher level in both their vigour and variety. He began to display his considerable ability with *Les Pêcheurs de perles* (*The Pearl Fishers,* 1863; libretto by Eugène and Carré) and *La Jolie Fille de Perth,* (1867; libretto by Jules-Henry Vernoy de Saint-Georges and Jules Adenis, based on Sir Walter Scott's *Fair Maid of Perth*). In 1875 Bizet produced his masterpiece, *Carmen* (libretto by Henri Meilhac and Ludovic Halévy, after a tale by Prosper Mérimée). Its then savage realism, broad but convincing characterization, and dazzling pseudo-Spanish ambience shocked its first audiences and strongly influenced Italian *verismo.* A lonely masterpiece, *Carmen* remains one of the steady props of operatic repertory everywhere.

Production of *Carmen*

Ambroise Thomas, as prolific as Gounod but not as gifted in emotional or musical persuasion, had composed many operas when Paris first welcomed his *Mignon* (1866; libretto by Barbier and Carré), probably his best opera. Two years later he composed *Hamlet* (1868; libretto by Barbier and Carré). Thomas, like Gounod, interlarded his operas with florid, often essentially undramatic and "showy" arias for a new type of lyric-coloratura soprano. One of the most frequently heard of such vacuous arias is the "Bell Song" from Léo Delibes' *Lakmé* (1883; libretto by Edmond Gondinet and Philippe Gille). Although Camille Saint-Saëns composed numerous operas, the only work by him to remain in the repertory is *Samson et Dalila* (libretto by Ferdinand Lemaire), originally sung under Franz Liszt's aegis in 1877 in German. It is lusciously melodic but so lacking in drama as to seem half oratorio.

Phenomenally popular when first composed were many of the operas of Jules Massenet, who had a surer sense of the stageworthy than Saint-Saëns but often made saccharine what to many had seemed too sweet in the earlier French opera of the 19th century. At his best however, Massenet was something better than "the daughter of Gounod": in *Manon* (1884) he produced not only one of the most enduringly popular of operas but also a stylistically unflawed reflection of the tragicosentimental 18th-century novel by the Abbé Prévost on which Henri Meilhac and Philippe Gille had based the libretto. Much the same qualities have kept alive Massenet's *Werther* (1892; libretto by Édouard Blau, Paul Milliet, and Georges Hartmann, derived from Goethe's *Leiden des jungen Werthers*), first performed at Vienna in a German translation. Some other operas by Massenet, particularly *Thaïs* (1894; libretto by Louis Gallet, after the novel by Anatole France), are important for their sensuous portrayals of seductive female characters.

Gustave Charpentier's *Louise* (1900; libretto by the composer) has remained in opera house repertories because of its loving, romanticized portrait of "Bohemian" Paris, the sentiment and surface allure, and the popularity of Louise's hymn to love, "Depuis le jour."

Claude Debussy, the greatest French composer after Berlioz and a decisive influence upon 20th-century music, completed only one opera: *Pelléas et Mélisande* (1902), an almost verbatim setting of Maurice Maeterlinck's play. Like *Tristan und Isolde*—which, having helped to shape Maeterlinck's drama, inevitably and against Debussy's will also shaped some of his compositional procedures—*Pelléas* remains unique. Listeners immune to the attraction of its aristocratic sensuality often find it monotonous. Nonetheless, it is a masterwork in its wholly apt amalgamation of text and score, the inescapable rightness for its quiet dramatic purposes of Debussy's individual harmonies, the marvelous manner with which he made the sounds of Maeterlinck's French an integral element in a shimmering orchestral web. In *Pelléas,* the Wagnerian ideal of continuous music without separate numbers was attained. Although *Pelléas* remains one of the handful of important operas composed in the 20th century, it has had few descendants. One of those few is Paul Dukas' *Ariane et Barbe-Bleue* (*Ariadne and Bluebeard,* 1907)—like *Pelléas,* an almost verbatim setting of a Maeterlinck play. It, however, is notably noisy where *Pelléas* is quiet, and it lacks Debussy's thematic invention.

The achievement of *Pelléas*

Maurice Ravel wrote one opera, *L'Heure espagnole* (*The Spanish Hour,* 1911; libretto by Maurice Legrand), and a *fantaisie lyrique* (really a ballet-pantomime-opera), *L'Enfant et les sortilèges* (*The Child and the Enchantments,* 1925; text by Colette). The former is opéra bouffe in Spanish dance rhythms overlaid with vocal lines that seem indebted to the works of Richard Strauss. The latter reverses the orchestra's domination over the voices in *L'Heure espagnole.* It is an edifying and hilarious fantasy about a child being punished for his mistreatment of his toys and other objects. Perhaps only its uncomfortable mixture of genres has kept it from widespread performance.

Of the professedly anti-Debussyan, anti-Impressionist group known as Les Six, three have places in the history of opera: Arthur Honegger, Darius Milhaud, and Francis Poulenc. Honegger, a Swiss, employed a somewhat Teutonic "neoclassical modern" idiom in thickly dissonant, heavily percussive operas that have failed to hold the stage. Milhaud's once sensational *opéras-minutes* (1927–28), three brief one-act compositions, were first staged in German translation in Germany. They parody Greek myths and have music composed in a jazz manner that inevitably has lost effectiveness with the passing decades. Milhaud also composed large modern versions of grand opera, but his persistently undramatic and often busily indecisive musical style have kept them from popularity. Poulenc composed one comic monodrama and one serious opera that seem likely to endure. The first, *Les Mamelles de Tirésias* (1947), is a wildly nonsensical opéra bouffe, the sardonic music of which is humorously appropriate to the text by the French poet Guillaume Apollinaire. The second, *La Voix humaine* (*The Human Voice,* 1959; text by Jean Cocteau), has as its only visible character a distraught young woman conversing by telephone with her lover. Poulenc's only large serious opera, *Dialogues des Carmélites* (*Dialogues of the Carmelites,* 1957; libretto by Georges Bernanos), appears to be the most impressive French opera since *Pelléas et Mélisande.* It makes telling operatic use of Poulenc's instantly identifiable style of melody, harmony (only very gently dissonant), and rhythm to tell a moving and tragic story of nuns martyred during the French Revolution.

Tragic and sardonic themes

Later opera in Italy. Viewed broadly, the story of Italian opera contemporary with and following Verdi parallels that of French opera after Berlioz, in the appearance of talented composers and stageworthy operas as well as in quickly becoming a tally of pieces of considerable charm and some degree of originality responding to shifting musical techniques and manners. It includes only two or three composers of the first rank.

Amilcare Ponchielli, shining clearly in light reflected from Verdi, composed one opera that remains in the international "standard" repertory—*La Gioconda* (1876; libretto by Arrigo Boito). The general turn toward realism began on a Roman stage in 1890 with Pietro Mascagni's dazzlingly successful one-act opera *Cavalleria rusticana* (*Rustic Chivalry,* libretto by Guido Menasci and Giovanni Targioni-Tozzetti). It soon evoked the descriptive term *verismo* (realism) and set a vogue for raw, violent, melodramatic librettos matched to music clearly descended from the middle-period operas of Verdi. Mascagni went on composing operas for 50 years after *Cavalleria,* but none won a permanent place on the stage. The best of them

is *L'Amico Fritz* (*Friend Fritz,* 1891; libretto by Nicolo Despure). And, two years after the premiere of *Cavalleria rusticana,* an equally successful product of *verismo* was staged in Milan: *I pagliacci* (*The Clowns,* 1892; libretto by the composer), by Ruggero Leoncavallo, who had no more staying power than Mascagni, though he produced operas for the remainder of his life.

The Italian counterpart of Massenet in France made his first important contribution to the operatic stage the year after *I pagliacci.* He was Giacomo Puccini, whose work is characterized by emotional directness of appeal and colourful, rich orchestration; the opera was *Manon Lescaut* (1893), based on the novel by the Abbé Prévost from which the libretto of Massenet's *Manon* had been derived.

Establishment of Puccini's reputation with *La Bohème*

Puccini established himself unmistakably as the most important post-Verdian Italian operatic composer with *La Bohème* (1896; libretto by Giuseppe Giacosa and Luigi Illica, after Henri Murger's *Scènes de la vie de bohème*). It, too, remains "standard," as do *Tosca* (1900; libretto by Giacosa and Illica) and *Madama Butterfly* (1904; libretto by Giacosa and Illica), which again capitalized upon Puccini's attraction to, and ability to characterize in music, sorrowing, attractive young women. Returning closer to violent *verismo,* Puccini (who always had to struggle to find librettos germane to his purposes) next composed an opera of the American "Wild West," *La fanciulla del west* (*The Girl of the Golden West,* 1910; libretto by Guelfo Civinini and Carlo Zangarini).

Fumbling for apposite literary materials, Puccini next proposed to write an operetta for Vienna; the outcome was a mixed, uncertain operetta-like piece, *La Rondine* (1917; libretto by Giuseppe Adami), produced by Monte Carlo, instead of Vienna, because of World War I. It was followed by a trio of one-act operas given its premiere at the Metropolitan, in 1918. *Il trittico* (*The Triptych*) consisted of the veristic and powerful *Il tabarro* (*The Cloak;* libretto by Adami), the sweetly sad, all-female *Suor Angelica* (*Sister Angelica;* libretto by Giovacchino Forzano) and the opera buffa of medieval Florence, *Gianni Schicchi* (libretto by Forzano). *Gianni Schicchi,* in its sarcastic humour and musical vitality, is the finest Italian operatic comedy after *Falstaff.*

Puccini died before finishing *Turandot* (libretto by Adami and Renato Simoni based on the Italian writer Carlo Gozzi's fable of the same name). It was produced posthumously in 1926. *Turandot* shows Puccini taking note of the then-recent developments in harmony, while giving them an Eastern flavour. The bloodthirsty story with a happy ending (for the two characters who least deserve it) alienates some operagoers, but many of those who accept *Turandot* as the brilliant, extremely melodious, highly pictorial representation of a legend consider it the finest of Puccini's operas. The music of *Turandot* was completed after the composer's death by the Italian composer Franco Alfano.

The other Italian operatic composers of the late 19th century and early 20th displayed neither the brash originality of the young Mascagni and Leoncavallo nor the varied theatrical genius of Puccini. They included Alfredo Catalani, whose best-known opera, shaped with extreme melodic refinement and mildly interesting orchestral commentary, is *La Wally* (1892; libretto by Luigi Illica). Another of these minor men was Umberto Giordano (1867–1948), whose bombastic *Andrea Chenier* (1896; libretto by Illica) and *Fedora* (1898; libretto by Arturo Colautti) are still staged. Francesco Cilea overtly copied the more sentimental aspects of Puccini in his biggest success, *Adriana Lecouvreur* (1902; libretto by Colautti). The 20th-century music critic Donald Jay Grout made an accurate description of nearly all of the post-Verdian Italian operas except *Cavalleria rusticana, I pagliacci,* and the best of Puccini when he wrote of *Adriana Lecouvreur* as "expertly contrived music of a lyrical-tragic sort . . . unadventurous harmonically or rhythmically, but good theatre and grateful for the singers."

Of much greater interest (though not of equal popularity) were two contrasted half-Italian, half-German composers active early in this century: Ferruccio Busoni and Ermanno Wolf-Ferrari. Busoni, a learned musician, wrote, in a then-advanced harmonic idiom and using his own librettos, four operas that have had scattered enthusiasts but no large public: *Die Brautwahl* (*Choice of a Bride,* 1912); two commedia dell'arte parodies—*Turandot* (1917; libretto after Gozzi) and the equally short *Arlecchino* (*Harlequin,* 1917)—and his major work, *Doktor Faust,* left incomplete at his death and completed by Philipp Jarnach (1925). Busoni's operas, and *Doktor Faust* in particular, are notable for their intellectual mastery, spiritual elevation, and other operatically peripheral virtues, but their almost total lack of dramatic cogency and musical allure have probably kept them from frequent performance.

At the other end of the operatic spectrum, Wolf-Ferrari possessed a fine talent for opera buffa of an especially light, airy sort, and also composed one of the rawest later examples of *verismo.* There is enormous charm in his comedies *Le donne curiose* (*The Curious Women,* 1903; libretto by Luigi Sugana), *I quattro rusteghi* (*The Four Ruffians,* 1906; libretto by Giuseppe Pizzolato), and *Il segreto di Susanna* (*The Secret of Susanna,* 1909; libretto by Enrico Golisciani). All three were first given in German translation. The melodrama *I gioielli della Madonna* (*The Jewels of the Madonna,* 1911; by Golisciani and Zangarini) has been well described as Donizetti plus *verismo.*

The "big three" Italian composers of the 1920s and '30s—Ottorino Respighi, Gian Francesco Malipiero, and Alfredo Casella—all composed operas and operalike works of considerable musical interest but little theatrical vitality. What historical influence they have had has operated largely outside the opera house.

Russian opera. After long subjection to imported Italian, French, and German composers, opera in Russia by Russians asserted itself in two well-known works by Mikhail Ivanovich Glinka (1804–57): *Zhizn za tsarya* (*A Life for the Tsar*), also known as *Ivan Susanin* (1836; libretto by Baron Georgy Fyodorovich Rosen), and *Ruslan i Lyudmila* (*Ruslan and Lyudmila,* 1842; libretto by Valeryan Fyodorovich Shirkov and others). Basically old-fashioned Italianate operas, they—*Ruslan* in particular—determined the nature of much future Russian music because of Glinka's approximations of Slavic folk music, his pre-Wagnerian use of a tentative leitmotiv technique, and the clarity and shifting colours of his orchestration. Glinka's operas, weakened by evidence of his lifelong dilettantism, remain in the repertory only in Russia, but their stylistic importance was decisive.

Glinka as father of Russian nationalism

Almost as influential as Glinka in shaping future Russian opera was his much less successful disciple Aleksandr Sergeyevich Dargomyzhsky. His *Rusalka* (1856; his libretto, after a fairy tale by Pushkin) illustrated his strong emphasis on a declamation midway between recitative and aria, as well as his musical amateurism. Even more influential, although left incomplete at Dargomyzhsky's death, was *Kamenny gost* (*The Stone Guest,* an integral setting of Pushkin's short Don Juan play; completed by César Antonovich Cui and Nikolay Rimsky-Korsakov and staged posthumously in 1872). It is couched in what were then advanced harmonic terms, powerful in characterization but musically all but sterile. Dargomyzhsky remains more interesting to historians than to operagoers.

The operas of Aleksandr Borodin, Rimsky-Korsakov, and Modest Mussorgsky are still performed. Borodin's incomplete *Knyaz Igor* (*Prince Igor,* his own libretto; completed and edited by Rimsky-Korsakov and Aleksandr Glazunov) was staged posthumously in 1890. It is dramatically shapeless but is splashed with Slavic and Oriental colours. Most of Rimsky-Korsakov's numerous fairy-tale operas have the nature of brilliantly illustrated books, but what may be his finest work is "the Russian *Parsifal,*" *Skazaniye o nevidimom grade Kitezhe i deve Fevroni* (*The Legend of the Invisible City of Kitezh,* 1907; libretto by Vladimir Ivanovich), a work of marked emotional strength. Of his lighter works, the best known are *Snegurochka* (*The Snow Maiden,* 1882; his own libretto), *Sadko* (1898; libretto by the composer and Byelsky), and the fantastic opera buffa, *Zolotoy petushok* (*Le Coq d'or,* or *The Golden Cockerel,* 1909; libretto by Byelsky, after Pushkin). Like *Prince Igor,* Rimsky-Korsakov's operas contributed largely to what many music lovers came to consider typically "Russian"

music, though the splashily coloured world they create was in reality Rimsky-Korsakov's own invention.

Mussorgsky composed all or part of several operas. Among them, *Khovanshchina* (to his own libretto; the score completed and orchestrated by Rimsky-Korsakov; posthumous premiere in 1886) bears a family resemblance to *Prince Igor,* particularly in its employment of real and simulated Orientalism, but is more serious and much more confident in tone. Mussorgsky's greatest achievement, and the most worthwhile Russian opera, is *Boris Godunov* (1874; his own libretto, based upon Pushkin's drama and a history of Russia by Nikolay Mikhailovich Karamzin). Boris, the guilty usurper of the throne, dominates this glittering but dour pageant in which the Russian people are present in remarkably forceful choral writing. Mussorgsky's ability to transmit textual points in very condensed music has possibly never been matched. Except at a few weak moments, he made a virtue out of amateurishness and naïveté, fearlessly extracting intense power and theatrical effectiveness from his newly developed techniques. The influence of *Boris Godunov* has been strong on numerous composers of opera both in Russia and elsewhere.

Greatness of *Boris Godunov*

The operatic practice of Peter Ilich Tchaikovsky was very different. For dramatic vigour he substituted clear characterization expressed lyrically, creating, among others, two highly idiosyncratic operas: *Eugene Onegin* (1879; libretto by the composer and Konstantin S. Shilovsky, after Pushkin) and the stronger melodrama *Pikovaya dama* (*The Queen of Spades,* 1890; libretto by Modest Ilich Tchaikovsky, after Pushkin). The personal emotion and the characterization of hero and heroine in *Eugene Onegin* are vivid. In all of Tchaikovsky's operas the highly subjective emotion that long made him the most often performed of orchestral composers is tellingly present. Many consider his other operas, containing much fine music, all unjustly neglected.

Igor Stravinsky turned to opera three times during his long composing career, to near-opera more often. First came *Solovey* (*The Nightingale,* 1914; libretto by the composer and Stepan Nikolayevich Mitusov, after Hans Christian Andersen), which clearly reveals the influence of Rimsky-Korsakov, who had been Stravinsky's teacher. Next among his true operas came *Mavra* (1922; libretto by Boris Kochno, derived from Pushkin), an opera buffa in the unmistakable musical style that made Stravinsky the foremost composer of his era. Then a long period marked by several near-operas (among them the urgent opera-oratorio *Oedipus Rex,* 1927) elapsed before the appearance of Stravinsky's full-length opera in English, *The Rake's Progress* (libretto by the poets W.H. Auden and Chester Kallman, after Hogarth's engravings, 1951), a neoclassical, austere, but compassionate work.

Sergey Prokofiev composed numerous operas both in his "modern" musical manner and in a harmonically less advanced "socialist realist" style after his return to the Soviet Union in 1934. Among the former, the best and most often staged are the opera buffa, *L'Amour des trois oranges* (*The Love for Three Oranges,* Chicago, 1921; his own libretto), in a musical style that might be called Rimsky-Korsakov updated, and the lurid opera of hallucination, *Angel of Fire* or *The Fiery Angel* (radio premiere 1954; his own libretto after a story by Valery Yakovlevich Bryusov). Of Prokofiev's Soviet-period operas, the most winning is the gay *Betrothal in a Monastery,* also known as *The Duenna* (1946; libretto by Mira Mendelson based on a play of that name by the 18th-century Irish-born dramatist Richard Brinsley Sheridan). The most ambitious is the massive *War and Peace* (1946; revised, condensed version, 1955; libretto by the composer and Mira Mendelson).

Prokofiev's Soviet-period operas

The best-known Soviet-period opera outside its homeland, however, is a grim tale of sexual repression and violence by Dmitry Shostakovich originally called *Ledi Makbet Mtsenskogo Uyezda* (*Lady Macbeth of the Mzensk District,* 1934; libretto by the composer and Y. Priess, after a story by Leskov), later revised, after a long period of eclipse caused by government disapproval, as *Katerina Ismaylova* (1963). Numerous other Russian operas have not been staged outside the country or have proved substantially unexportable when so staged.

Later opera in Germany and Austria. Richard Strauss was greeted as the obvious "heir to Wagner" (and Liszt). His worldwide reputation was being established by his orchestral music and lieder (songs) before he turned to opera for the first time. But his preeminence among non-Italian composers of opera was established by two "shocking" one-act operas: *Salome* (1905; libretto taken from Oscar Wilde's drama, translated into German by Hedwig Lachmann) and *Elektra* (1909). With the latter work Strauss began a long and fruitful association with the poet and dramatist Hugo von Hofmannsthal as his librettist. Couched in a violent harmonic idiom, requiring huge orchestral forces and leading singers of great vocal power and stamina, *Salome* and *Elektra* seemed to many critics to be Straussian tone poems with added voices, but they soon became, and have remained, part of the standard repertory. They were followed by an altogether different sort of opera, *Der Rosenkavalier* (1911), again with a libretto by Hofmannsthal, a bittersweet comedy notable for the superb musical creation of the central character (the Marschallin) and for three-quarter rhythms that placed this Strauss alongside Johann the Younger as a composer of Viennese waltzes. It marks Strauss's invention of a subtle *parlando* (conversational) style all his own, which he also used to great effect in his later opera.

Strauss's collaboration with Hofmannsthal

Strauss composed 10 operas after *Der Rosenkavalier.* All but one or two of them won wide popularity; none of them displays any constructive or musical characteristics not present in his earlier works. The most successful have been the "chamber opera" *Ariadne auf Naxos* (*Ariadne on Naxos,* 1912; revised 1916); the giant allegory *Die Frau ohne Schatten* (*The Woman Without a Shadow,* 1919), which some writers have called Strauss's masterpiece, whereas others denounce it as confused, even megalomaniac; and *Arabella* (1933), which closely resembles *Der Rosenkavalier* in many details. *Capriccio* (1942), his last opera, is an absorbing characterization of the old argument as to whether words or music should take precedence in opera.

Several harmonically conservative German composers active during and just after Strauss's long career were much less gifted and also less successful. Probably the most notable of them were Hans Pfitzner and Paul Hindemith. The antimodern Pfitzner, partly a belated Wagnerian, composed several operas of melodically long-lined, subjective, at times mystical content which have not reached beyond the German-speaking countries. The best-known is *Palestrina* (1917; his own libretto), dealing with the great Italian composer, in which the austerities of 16th-century counterpoint are oddly mixed with Pfitzner's often abrupt dissonances.

Hindemith damagingly lacked theatrical insight but was admired for his technical wizardry and lofty aims. He composed some satiric comedies but his work came to be heard in opera houses only with the serious *Cardillac* (1926, revised 1952; libretto by Ferdinand Lion, after a tale by E.T.A. Hoffmann) and *Mathis der Maler* (*Mathias the Painter,* 1938; his own libretto on the life of Matthias Grünewald).

If "modernism" seems to be struggling toward birth in the operas of Strauss, Pfitzner, Hindemith, and some others, it sprang fully armed from the music of three Viennese composers: Arnold Schoenberg, Alban Berg, and Anton von Webern, propagators and chief practitioners of what came to be called atonality and 12-tone composition. Webern composed no operas. Schoenberg's first theatrical works—the one-act *Erwartung* (*Expectation,* composed in 1909, performed in 1924; single-character libretto by Marie Pappenheim) and the one-act *"Drama mit Musik" Die glückliche Hand* (*The Hand of Fate,* 1924; his own libretto)—are extremely discordant, thickly and earnestly romantic, even expressionistic, and occasionally use *Sprechstimme,* a variety of vocal emission between speech and song that Schoenberg himself described as "the voice rising and falling relative to the indicated intervals, and everything being bound together with the time and rhythm of the music except where a pause is indicated." Their harmony is unremittingly chromatic.

Schoenberg's first theatrical works

Schoenberg's only comedy, the one-act *Von Heute auf*

Morgen (*From Today to Tomorrow,* 1930; libretto by Max Blonda), is in strictly construed 12-tone texture; following the theories attending that technique, it therefore returned to separate-number construction. Schoenberg's largest opera, left incomplete at his death, was the powerful, oratorio-like *Moses und Aron* (1957; his own libretto).

(H.We.)

The two operas of Alban Berg—*Wozzeck* (1925; libretto by the composer, after Georg Büchner's play *Woyzeck*) and *Lulu* (1937, libretto by the composer after Frank Wedekind's plays *Erdgeist* [*Earth-spirit*] and *Die Büchse der Pandora* [*Pandora's Box*])—are among the most powerful, effective music dramas of the 20th century. Well described as "expressionistic, morbid, neurotic, hysterical" as to story, *Wozzeck* seamlessly joins an intensely learned and appropriate score to a melodrama of a poor soldier's helplessness at the hands of his fate. *Wozzeck* is such an intense work that audiences who might be expected to be alienated by its extreme dissonance and "tunelessness" have accepted it as the great opera it is. *Lulu,* virtually finished at the time of Berg's death and later completed by others, is a part-tragic, part-comic drama; it adds film clips and spoken dialogue to the means employed in *Wozzeck.* Although Berg's score was elaborated from a single "tone-row" (arrangement of the 12 tones of a chromatic scale) and though the resultant tonal clashing is not bilked, many passages in *Lulu* appear to show Berg tending toward less dissonance.

Intensity of *Wozzeck*

The most appreciable Germanic musicodramatic composer outside the Viennese orbit has appeared to be Carl Orff (1895–1982), who has juggled many varieties of almost-operatic forms. Best known for his absorption of bawdy medieval student songs into a "scenic oratorio," *Carmina Burana* (1937), Orff worked that singular exploitation of repetitive rhythms, bare harmonies, *ostinati,* and crying vocal colours into a trilogy called *Trionfi* by adding to it *Catulli Carmina* (1943) and *Il Trionfo d'Afrodite* (1953). More conventionally operatic is his one-act comedy *Die Kluge* (*The Clever Girl,* 1943; his own libretto, after a tale by the Brothers Grimm). Probably his major effort in musical drama is another trilogy, consisting of *Antigonae* (1949), *Oedipus der Tyrann* (1959), and *Prometheus* (1968). In it a texture of spoken and declaimed texts is spaced out with incidental music of almost brutal force. Bernd Alois Zimmermann's opera *Die Soldaten* (*The Soldiers,* 1969) is the most successful of the multi-media operas.

Hans Werner Henze is the most recent major operatic composer to come out of Germany. His best-known works are *Elegy for Young Lovers,* his first collaboration with the poets W.H. Auden and Chester Kallman, and *Der junge Lord* (*The Young Lord*), which satirizes German provincial life. He has experimented with other forms of musicodramatic experiment.

Czechoslovakia. The specifically Russian operas of Glinka, Dargomyzhsky, and the Five have parallels in other countries. In what is now Czechoslovakia, the national school effectively began with Bedřich Smetana, best known outside his homeland for the vigorous, highly coloured folk comedy *Prodaná nevěsta* (*The Bartered Bride,* 1866; libretto by Karel Sabina), which determined many aspects of future Czech musical usage as clearly as Borodin and Mussorgsky had set Russian styles. Several of Smetana's other operas, both comic and tragic, remain on Czech stages—most notably the overtly patriotic *Dalibor* (1868) and *Libuše* (1881), both to librettos in Czech translation of originally German texts by Joseph Wenzig, and his comedy *Hubička* (*The Kiss,* 1876). The other leading Czech composer of Smetana's period, Antonín Dvořák, wrote nine operas but remained preponderantly an instrumental composer, never matching the older composer's stage success. Of Dvořák's mature operas, the best known outside Czechoslovakia is the melancholy fairy tale *Rusalka* (libretto by Jaroslav Kvapil), made attractive by his considerable melodic and harmonic gifts.

Production of *The Bartered Bride*

Leoš Janáček was specifically Moravian in musical background, far more harmonically advanced than Smetana and Dvořák, though less adroit technically. He was clearly a 20th-century composer, whose highly individual music, typified by a short-phrased melodic idiom used to catch the speech-rhythm of his native language, was rediscovered after World War II. A follower of Mussorgsky, whose much-discussed "dilettantism" his closely resembles, Janáček is now represented intermittently in non-Czech opera houses chiefly by *Její pastorkyňa* (*Her Foster Daughter,* 1904; changed to *Jenůfa* for Janáček's 1916 revision; his libretto derived from a story by Gabriela Preissová), *Kát'a Kabanová* (1921; libretto by Vincenc Červinky), *Příhody lišky bystroušky* (*The Cunning Little Vixen,* 1924; libretto by the composer), and *Věc Makropulos* (*The Makropoulos Case,* 1926; libretto by the composer), each of which has a character and milieu of its own while preserving the peculiarly individual setting of the Czech language.

Hungary and Poland. The most important Hungarian operas of the early 20th century, neither of them representing its composer at his finest, are the one-act *Duke Bluebeard's Castle* (1918; libretto by Béla Balázs), by Béla Bartók, and the ballad opera *Háry János,* by Zoltán Kodály (1926; libretto by Béla Paulini and Zsolt Harsányi), both of which have become more familiar in concert performance or excerpts than in staged productions. The most influential and popular of Polish nationalist operas, *Halka* (1854; libretto by Włodzimierz Wolski), was composed by Stanisław Moniuszko; he also wrote an admirable comedy, *The Haunted Manor* (1865; libretto by Jan Chichiński). Of 20th-century Polish operas, perhaps the most substantial is the much less popular *Król Roger* (*King Roger,* 1926; libretto by Jarosław Iwakiewicz) by Karol Szymanowski.

Spain. Spanish operatic nationalism began with Felipe Pedrell, more influential as teacher-propagandist than as producing composer. Of his 10 operas, the most imposing were to have been contained in a trilogy, based on a Catalan libretto by Victor Balaguer, but only the first two sections, *Los Pirineos* (*The Pyrenees*) and *La Celestina,* were completed and only the first was staged (1902). Of the more familiar Spanish composers, both Isaac Albéniz and Enrique Granados composed operas of strongly Spanish colour that have lapsed from the repertory—Albéniz particularly in the comic one-act *Pepita Jiménez* (1896), Granados in the semi-veristic *Goyescas* (1916; libretto by Fernando Periquet y Zuaznabar), the score of which clearly reveals its origin in a suite of piano pieces. The best results of Spanish operatic nationalism (possibly because more than a little tinged with internationalism) are two very different operas by Manuel de Falla: the specifically Andalusian *La vida breve* (*Brief Life;* libretto by Carlos Fernández Shaw; first staged in French translation, 1913) and the one-act *El retablo de Maese Pedro* (*Master Peter's Puppet Show,* 1923; text by the composer, after a scene in *Don Quixote*), in effect a chamber opera for marionettes.

(H.We./Ed.)

England. English opera, which had languished for centuries, was revitalized by the theatrical talent of the eclectic Benjamin Britten, whose stage works show a remarkable sympathy for the human predicament expressed in readily accessible, deeply felt music. His masterpiece is the gloomy, forceful *Peter Grimes* (1945; libretto by Montague Slater). Among Britten's other operas to win widespread stagings are the chamber operas *The Rape of Lucretia* (1946; libretto by Ronald Duncan) and *Albert Herring* (1947; libretto by Eric Crozier), the all-male *Billy Budd* (1951; libretto by E.M. Forster and Crozier; based upon Herman Melville's story), the eerily effective *Turn of the Screw* (1954; libretto by Myfanwy Piper, after the Henry James story), *A Midsummer Night's Dream* (1960; libretto by Britten and Peter Pears, from Shakespeare), three church operas to librettos by William Plomer (1964–68), and *Owen Wingrave* (1971; libretto by Myfanwy Piper). So far, less popular outside England are the idiosyncratic operas, to his own complex librettos, of Sir Michael Tippett: *The Midsummer Marriage* (1955), *King Priam* (1962), and *The Knot Garden* (1970).

Benjamin Britten's works

United States. American contributions to international opera, after a 19th-century desert of imitation German and French operas, became much more numerous after World War II. It is possible here to mention only one composer and a few isolated operas that have evoked enduring resonance. The most often performed of contemporary op-

Menotti's works

eratic composers has been the Italo-American Gian Carlo Menotti. Using his own librettos, he has produced, in a variety of structural styles, a series of Puccini-derived melodramas and sentimental tragedies of considerable popular appeal, among them *The Medium* (1946), *The Consul* (1950), *Amahl and the Night Visitors* (composed for television performance, 1951), and *The Saint of Bleecker Street* (1954). He also wrote the libretto for the first, mildly successful, opera of Samuel Barber, *Vanessa* (1958; awarded 1958 Pulitzer Prize). Barber's second large opera, *Antony and Cleopatra* (1966; libretto derived from Shakespeare by Franco Zeffirelli), commissioned to inaugurate the second Metropolitan Opera House in New York, was a failure and vanished quickly from performance.

A unique niche is occupied by the two operas that Virgil Thomson composed to texts by Gertrude Stein arranged by Maurice Grosser: the Spanish-tinted *Four Saints in Three Acts* (1934) and *The Mother of Us All* (1947), a delicious flow of invention around the figure of Susan B. Anthony. Their fragile but real durability has resulted from Thomson's singable, apt folk-based setting of texts that alternate among the apparently nonsensical, the satiric, and the emotionally moving. Perhaps the most important national opera consistently in repertory is George Gershwin's *Porgy and Bess* (1935; libretto by DuBose Heyward and Ira Gershwin), a blending of folk opera and American musical comedy, which has had no recognizable descendant of high quality. Within the United States—not to count the "workshop operas" and simplified semi-folk near-operas that many American composers recently have favoured—two of the most frequently performed recent American operas are the folklike "Western" *Ballad of Baby Doe* (libretto by John Latouche, 1956), by Douglas Moore (1893–1969) and the melodramatic, "Southern" *Susannah* (libretto by the composer, 1955) by Carlisle Floyd.

(H.We.)

Jazz

The difficulty of definition

Any attempt to arrive at a precise, all-encompassing definition of jazz is probably futile. Jazz has been, from its very beginnings at the turn of the 20th century, a constantly evolving, expanding, changing music, passing through several distinctive phases of development; a definition that might apply to one phase—for instance, to New Orleans style or swing—becomes inappropriate when applied to another segment of its history, say, to free jazz. Early attempts to define jazz as a music whose chief characteristic was improvisation, for example, turned out to be too restrictive and largely untrue, since composition, arrangement, and ensemble have also been essential components of jazz for most of its history. Similarly, syncopation and swing, often considered essential and unique to jazz, are in fact lacking in much authentic jazz, whether of the 1920s or of later decades. Again, the long-held notion that swing could not occur without syncopation was roundly disproved when trumpeters Louis Armstrong and Bunny Berigan (among others) frequently generated enormous swing while playing repeated, unsyncopated quarter notes.

Jazz, in fact, is not—and never has been—an entirely composed, predetermined music, nor is it an entirely extemporized one. For almost all of its history it has employed both creative approaches in varying degrees and endless permutations. And yet, despite these diverse terminological confusions, jazz seems to be instantly recognized and distinguished as something separate from all other forms of musical expression. To repeat Armstrong's famous reply when asked what *swing* meant: "If you have to ask, you'll never know." To add to the confusion, there often have been seemingly unbridgeable perceptual differences between the producers of jazz (performers, composers, and arrangers) and its audiences. For example, with the arrival of free jazz and other latter-day, avant-garde manifestations, many senior musicians maintained that music that didn't swing was not jazz.

Most early classical composers (such as Aaron Copland, John Alden Carpenter—and even Igor Stravinsky, who became smitten with jazz) were drawn to its instrumental sounds and timbres, the unusual effects and inflections of jazz playing (brass mutes, glissandos, scoops, bends, and stringless ensembles), and its syncopations, completely ignoring, or at least underappreciating, the extemporized aspects of jazz. Indeed, the sounds that jazz musicians make on their instruments—the way they attack, inflect, release, embellish, and colour notes—characterize jazz playing to such an extent that if a classical piece were played by jazz musicians in their idiomatic phrasings, it would in all likelihood be called jazz.

Nonetheless, one important aspect of jazz clearly does distinguish it from other traditional musical areas, especially from classical music: the jazz performer is primarily or wholly a creative, improvising composer—his own composer, as it were—whereas in classical music the performer typically expresses and interprets someone else's composition.

WEST AFRICA IN THE AMERICAN SOUTH: GATHERING THE MUSICAL ELEMENTS OF JAZZ

The elements that make jazz distinctive derive primarily from West African musical sources as taken to the North American continent by slaves, who partially preserved them against all odds in the plantation culture of the American South. These elements are not precisely identifiable because they were not documented—at least not until the mid- to late 19th century, and then only sparsely. Furthermore, black slaves came from diverse West African tribal cultures with distinct musical traditions. Thus, a great variety of black musical sensibilities were assembled on American soil. These in turn rather quickly encountered European musical elements—for example, simple dance and entertainment musics and shape-note hymn tunes, such as were prevalent in early 19th-century North America.

The music that eventually became jazz evolved out of a wide-ranging, gradually assimilated mixture of black and white folk musics and popular styles, with roots in both West Africa and Europe. It is only a slight oversimplification to assert that the rhythmic and structural elements of jazz, as well as some aspects of its customary instrumentation (*e.g.*, banjo or guitar and percussion), derive primarily from West African traditions, whereas the European influences can be heard not only in the harmonic language of jazz but in its use of such conventional instruments as trumpet, trombone, saxophone, string bass, and piano.

The element of syncopation

The syncopations of jazz were not entirely new—they had been the central attraction of one of its forerunners, ragtime, and could be heard even earlier in minstrel music and in the work of Creole composer Louis Moreau Gottschalk (*Bamboula,* subtitled *Danse des Nègres,* 1844–45, and *Ojos Criollos,* 1859, among others). Nevertheless, jazz syncopation struck nonblack listeners as fascinating and novel, because that particular type of syncopation was not present in European classical music. The syncopations in ragtime and jazz were, in fact, the result of reducing and simplifying (over a period of at least a century) the complex, multilayered, polyrhythmic, and polymetric designs indigenous to all kinds of West African ritual dance and ensemble music. In other words, the former accentuations of multiple vertically competing metres were drastically simplified to syncopated accents.

The provenance of melody (tune, theme, motive, riff) in jazz is more obscure. In all likelihood, jazz melody evolved out of a simplified residue and mixture of African and European vocal materials intuitively developed by slaves in the United States in the 1700s and 1800s—for example, unaccompanied field hollers and work songs associated with the changed social conditions of blacks. The widely prevalent emphasis on pentatonic formations came primarily from West Africa, whereas the diatonic (and later more chromatic) melodic lines of jazz grew from late 19th- and early 20th-century European antecedents.

Harmony was probably the last aspect of European music to be absorbed by blacks. But once acquired, harmony was applied as an additional musical resource to religious texts; one result was the gradual development of spirituals, borrowing from the white religious revival meetings that African Americans in many parts of the South were urged to attend. One crucial outcome of these musical acculturation

ations was the development by blacks of the so-called blues scale, with its "blue notes"—the flatted third and seventh degrees. This scale is neither particularly African nor particularly European but acquired its peculiar modality from pitch inflections common to any number of West African languages and musical forms. In effect these highly expressive—and in African terms very meaningful—pitch deviations were superimposed on the diatonic scale common to almost all European classical and vernacular music.

Unique to the United States

That jazz developed uniquely in the United States, not in the Caribbean or in South America (or any other realm to which thousands of African blacks were also transported) is historically fascinating. Many blacks in those other regions were very often emancipated by the early 1800s and thus were free individuals who actively participated in the cultural development of their own countries. In the case of Brazil, blacks were so geographically and socially isolated from the white establishment that they simply were able to retain their own African musical traditions in a virtually pure form. It is thus ironic that jazz would probably never have evolved had it not been for the slave trade as it was practiced specifically in the United States.

Jazz grew from the African American slaves who were prevented from maintaining their native musical traditions and felt the need to substitute some homegrown form of musical expression. Such composers as the Brazilian mulatto José Maurício Nunes Garcia were fully in touch with the musical advances of their time that were developing in Europe and wrote music in those styles and traditions. American slaves, by contrast, were restricted not only in their work conditions and religious observances but in leisure activities, including music making. Although slaves who played such instruments as the violin, horn, and oboe were exploited for their musical talents in such cities as Charleston, South Carolina, these were exceptional situations. By and large the slaves were relegated to picking up whatever little scraps of music were allowed them.

FIELD HOLLERS AND FUNERAL PROCESSIONS: FORMING THE MATRIX

Jazz, as it finally evolved as a distinct musical style and language, comprised what Max Harrison calls, in the *New Grove Dictionary of Music and Musicians,* a "composite matrix" made up of a host of diverse vernacular elements that happened to come together at different times and in different regions. This matrix included the field hollers of the cotton plantations; the work songs on the railroads, rivers, and levees; hymns and spirituals; music for brass bands, funeral processions, and parades; popular dance music; the long-standing banjo performing tradition (starting in the 1840s), which culminated half a century later in the banjo's enormous popularity; wisps of European opera, theatre, and concert music; and, of course, the blues and ragtime. These last two forms began to flourish in the late 19th century—blues more as an informal music purveyed mostly by itinerant singers, guitarists, and pianists and ragtime becoming (by 1900) America's popular entertainment and dance music.

Ragtime and jazz

Ragtime differs substantially from jazz in that it was (1) a through-composed, fully notated music intended to be played in more or less the same manner each time, much like classical music, and (2) a music written initially and essentially for the piano. Jazz, by contrast, became a primarily instrumental music, often not notated, and partially or wholly improvised. Ragtime had its own march-derived, four-part form, divided into successive 16-bar sections, whereas jazz, once weaned away from ragtime form, turned to either the 12-bar (or occasionally 8-bar) blues or the 32-bar song forms. What the two music genres had in common was their syncopated (thus "irregular") melodies and themes, placed over a constant "regular" $\frac{2}{4}$ or $\frac{4}{4}$ accompaniment.

The years from 1905 to 1915 were a time of tremendous upheaval for black musicians. Even the many musicians who had been trained in classical music but had found—as blacks—no employment in that field were now forced to turn to ragtime, which they could at least play in honky-tonks, bordellos, and clubs; many of these musicians eventually drifted into jazz. Hundreds of other musicians, unable to read and write music, nonetheless had great ability to learn it by ear, as well as superior musical talent. Picking up ragtime and dance music by ear (perhaps not precisely), they began almost out of necessity to embellish these syncopated tunes—loosening them up, as it were—until ornamentation spilled over quite naturally into simple improvisation. This process took on a significantly increased momentum once the piano rags of such master composers as Scott Joplin, Joseph Lamb, and James Scott appeared in arrangements performed regularly by bands and orchestras.

Jelly Roll Morton

That the pianist-composer Jelly Roll Morton was a braggart who claimed to be "the inventor of jazz" should not obscure his major role in the development of that music. As early as 1902 Morton played ragtime piano in the vaunted bordellos of Storyville, New Orleans's famous red-light district. Later he began working as an itinerant musician, crisscrossing the South several times and eventually working his way to Los Angeles, where he was based for several years. As the first major composer of jazz, Morton seems to have assimilated (like a master chef making a great New Orleans bouillabaisse) most of the above-mentioned matrix, particularly blues and ragtime, into a single new, distinct, coherent musical style. Others, such as soprano saxophonist Sidney Bechet, trombonist Kid Ory, and cornetists Bunk Johnson and Freddie Keppard—four of the most gifted early jazz musicians—arrived at similar conclusions before 1920.

Johnson and others regarded themselves as ragtime musicians. In truth, in the cases of many musicians of that generation—both black and white—who grew up with ragtime, the listener would be hard put to determine when their playing turned from embellished rags to improvisatory jazz. Musicians confirmed the tenuousness and variety of these early developments in statements such as that of reedman Buster Bailey (speaking of the years before 1920): "I . . . was embellishing around the melody. At that time [1917–18] I wouldn't have known what they meant by improvisation. But embellishment was a phrase I understood." And reedman Garvin Bushell said, "We didn't call the music jazz when I was growing up [in Springfield, Ohio]. . . . Ragtime piano was the major influence in that section of the country. . . . The change to jazz began around 1912 to 1915."

RAGTIME INTO JAZZ: THE BIRTH OF JAZZ IN NEW ORLEANS

In spite of the wide dissemination and geographic distribution of these diverse musical traditions, New Orleans was where a distinctive, coherent jazz style evolved. Between 1910 and 1915 a systematization of instrumental functions within an essentially collective ensemble took shape, as did a regularization of the repertory. Despite the fact that a limited set of instruments was available to black musicians (at that time, typically, cornet, clarinet, trombone, tuba or bass, piano, banjo, and drums—the saxophone did not become common in jazz for about another decade), they arrived at a brilliant solution emphasizing independent but harmonically linked and simultaneous lines. Each of the seven instruments was assigned a clearly defined individual role in the established polyphonic collective ensemble. Thus, the cornet was responsible for stating and occasionally embellishing the thematic material—the tune—in the middle range, the clarinet performed obbligato or descant functions in a high register, the trombone offered contrapuntal asides in the tenor or baritone range, and the four rhythm instruments provided a unified harmonic foundation.

Inability to read music

That this formation, which emphasized independent but harmonically linked simultaneous lines, was not only a brilliant solution but a necessity is confirmed by the inability of most players in those early years to read music. It was not long before musicians began to expand upon these materials and to improvise fresh new melodies and obbligatos of their own making. However, these explorations remained within the collective ensemble concept of New Orleans jazz. Few musicians before 1925 could have created independent, extended, improvised solos. And when the solo as an integral element of a jazz performance

arrived, the New Orleans format of a tightly integrated ensemble improvisation went out of fashion.

By approximately 1915 New Orleans had produced a host of remarkable musicians, mostly cornet and clarinet players, such as the legendary Buddy Bolden (legendary in part because he never recorded), Buddy Petit, Keppard, Johnson, and Bechet. Most New Orleans musicians, including scores of pianists, found steady employment in the entertainment palaces of Storyville, where, incidentally, the term *jazz,* initially spelled "jass," was the commonly used slang word for sexual intercourse. It is ironic that the first jazz recordings were made in New York City on January 30, 1917, by a second-rate group of white musicians from New Orleans called the Original Dixieland Jazz Band. Those recordings, with their entertaining but substanceless barnyard sound effects, present a misleading picture of true New Orleans jazz.

VARIATIONS ON A THEME: JAZZ ELSEWHERE IN THE UNITED STATES

New Orleans was not the only place where jazz was being developed. Depending on how narrowly jazz is defined, some early form of it was practiced in places as far-flung as Los Angeles, Kansas City, Missouri, Denver, Colorado, and the Colorado mining towns—not to mention Baltimore, Maryland, and New York City. The two last-mentioned cities were major centres of ragtime, early pre-stride piano, vaudeville entertainment, large-sized dance orchestras, and musical theatre, including theatre created exclusively by black performers. Several other at least embryonic jazz groups and musicians were active in New York during 1913–19, such as James Reese Europe and his various orchestras, Earl Fuller's Jass Band, Ford Dabney's band, and the pianists James P. Johnson, Abba Labba, and Willie "The Lion" Smith.

The closing of Storyville in 1917 was a disaster for New Orleans musicians, many of whom went on to play in Mississippi riverboat orchestras; Fate Marable's orchestra was the best and most famous of these and included, at times, the young Louis Armstrong. Others headed directly north to Chicago, which rapidly became the jazz capital of the United States. King Oliver, the much-heralded cornet champion of New Orleans, migrated to Chicago in 1918, and in 1922 he sent for his most talented disciple, Armstrong, to join his Creole Jazz Band as second cornetist. The two made history and astounded audiences with their slyly worked out duet breaks, and Armstrong had a chance to cut his musical teeth by freely improvising melodic counterpoint to Oliver's lead cornet. More important still, Oliver's band was able to forge a remarkably unified and disciplined style, integrating at a very high level the players' collective and individual instrumental skills, all couched in an irresistible, wonderfully stately, rolling momentum.

Chicago as jazz capital

LOUIS ARMSTRONG AND THE INVENTION OF SWING: THE CORNETIST BREAKS AWAY

In late 1924 Armstrong was wooed away by Fletcher Henderson in New York City. In his year there Armstrong matured into a major soloist and at the same time developed—indeed, single-handedly invented—a compelling, propulsive, rhythmic inflection in his playing that came to be called swing. Early examples of this feeling can be heard in Henderson band recordings and even more clearly on Armstrong's Hot Five and Hot Seven recordings of 1926–27—*e.g.,* "Potato Head Blues," "Big Butter and Egg Man," "S.O.L. Blues," "Hotter than That," and "Muggles." In effect, Armstrong taught the whole Henderson band, including the redoubtable tenor saxophonist Coleman Hawkins, how to swing.

More than that, Armstrong taught the whole world about swing and had a profound effect on the development of jazz that continues to be felt and heard. In that sense alone he can be considered the most influential jazz musician of all time. And beyond his artistic and technical prowess, Armstrong should be remembered as the first superstar of jazz. By the late 1920s, famous on recordings and in theatres, he more than anyone else carried the message of jazz to America; eventually, as entertainer supreme and jazz ambassador at large, he introduced jazz to the whole world. In this crusade Armstrong's unique singing style, in essence a vocalization of his improvisatory trumpet playing, played a crucial role. By often singing without words or texts, he popularized what came to be called scat, a universally comprehensible art form that needed no translation.

Armstrong and scat

After Armstrong's spectacular breakthrough recordings, such as "West End Blues" (1928), he embarked on a solo career for 10 years, fronting bands whose general mediocrity made him sound by comparison even more brilliant. In the 1940s he formed the Armstrong All-Stars, a group of older New Orleans-style musicians that included trombonist Jack Teagarden. Although by then well past his prime, Armstrong, through his physical vitality and uncompromisingly high musical standards, was able to preserve his art almost to the end of his life in 1971.

That Armstrong's playing, both technically and conceptually, was many levels above that of most of his contemporaries can be heard on virtually every recording he made between 1925 and 1940, whether he was paired with other soloists or with orchestras. He exerted a wide-ranging influence on all manner of players—not only trumpeters but trombonists, saxophonists, singers (such as Billie Holiday), and even pianists (such as Earl Hines and Teddy Wilson). Armstrong's influence was also absorbed by white musicians, including some of the better ensembles of the time, such as the New Orleans Rhythm Kings, Red Nichols and his Five Pennies, and, above all, the outstandingly gifted Bix Beiderbecke. Inheriting a lyrical, romantic bent from his German background, Beiderbecke presented another view of the Armstrong revolution, not only in his superb recorded improvisations of "I'm Coming Virginia" and "Singin' the Blues" (both 1927) but also in such pieces as the simply stated, virtually unimprovised "Oi' Man River" (1928).

ORCHESTRAL JAZZ

Fletcher Henderson, the originator. It was in the 1920s that the first forms of true orchestral jazz were developed, most significantly by Fletcher Henderson and Duke Ellington. Although large aggregations had begun to appear in the late teens, these were dance orchestras playing the popular songs and novelty pieces of the day, with nary a smattering of jazz. The credit for being the first to perform and record orchestral jazz must go to Henderson, who, starting in about 1923, gathered together from the small beginnings of quintets and sextets a growing number of notable New York-based players and formed a full orchestra. By the mid- to late 1920s, Henderson could boast a 13- or 14-piece band and had the arranging services of the outstanding alto saxophonist and multi-instrumentalist Don Redman. It was Redman who developed antiphonal call-and-response procedures in orchestral jazz, juxtaposing the two main choirs of brass and reeds in ever more sophisticated and challenging arrangements.

Duke Ellington, the master composer. Although he was very much aware of Redman's and Henderson's work, Duke Ellington took a somewhat different approach. From the start more truly a composer than an arranger, Ellington blended thematic material suggested to him by some of his players—in particular trumpeter Bubber Miley and clarinetist Barney Bigard—with his own compositional frameworks and backgrounds (*e.g.,* "East St. Louis Toodle-oo" [1926] and "Black and Tan Fantasy" [1927]). Once ensconced in Harlem's famous Cotton Club as the resident house band (a tenure that lasted three years, until early 1931), Ellington had the opportunity to explore, in some 160 recordings, several categories of compositions: (1) music for the club's jungle-style production numbers and pantomime tableaus, (2) dance numbers for the 16-girl chorus line, (3) dance pieces for the club's patrons (all white—blacks were allowed only as entertainers), (4) arrangements of the pop tunes or ballads of the day, and (5) most important, independent nonfunctional instrumental compositions—in effect, miniature tone poems for presentation during the shows. The most celebrated of these was "Mood Indigo" (1930), the first of many pieces with a blueslike character, usually set in slow tempos. In these and in such other song and dance numbers as "So-

Cotton Club house band

phisticated Lady" (1932) and "Solitude" (1934), Ellington was able not only to exploit the individual talents of his musicians but to extend and vary the forms of jazz. In addition, he expanded upon his already highly developed feeling for instrumental timbres and colours and his extraordinary forward-looking harmonic sense. In early works such as "Mystery Song" (1931), "Delta Serenade" (1934), and "In a Sentimental Mood" (1935), Ellington experimented with never-before-heard brass sonorities (using mutes peculiar to jazz, including the lowly bathroom plunger) and unusual blendings of brass and reeds, as in his grouping of saxophones and Juan Tizol's light valve trombone sound. Ellington's instinctive genius for harmonic invention, using the outer extensions of basic triadic and dominant seventh chords, led him to use bitonality (two keys at once) or polytonality (several keys) at least a decade before anyone else. Striking examples of this aspect of his work are, to name only a few, "Eerie Moan" (1933), "Reminiscing in Tempo" (1935), "Alabamy Home" (1937), and "Azure" (1937), the last verging on atonality at several points.

Harmonic invention

All these Ellington innovations, nuanced and fulfilled as they were by the extraordinary cast of characters and individual soloists in his orchestra, served to create a more personal expression and emotional depth than had previously been achieved in jazz. The heterogeneity of personalities and talents in Ellington's orchestra virtually guaranteed that even the least of their efforts would be superior to the best of most other orchestras of the time. Motored by a remarkably cohesive rhythm section, each instrumental choir boasted dramatically different, individualistic personalities (*e.g.*, Arthur Whetsol and Cootie Williams on trumpet; Rex Stewart on cornet; Lawrence Brown, Joe "Tricky Sam" Nanton, and Juan Tizol on trombone; and Johnny Hodges, Barney Bigard, Otto Hardwick, and Harry Carney on reeds) who nevertheless whenever needed would blend instantly into perfect ensembles.

Other notables of the 1920s. As remarkable as Ellington's innovations were, they had relatively little impact on the field in general. In the racially still-very-divided world of the 1930s, not only were white bands such as the Casa Loma and Benny Goodman orchestras much more popular than the great black orchestras of Ellington, Jimmie Lunceford, Chick Webb, and Bennie Moten, but Ellington's music in particular was considered formally and harmonically too challenging and at the same time too subtle for the tastes of the average 1930s swing fan. Ellington's big, worldwide success with the public did not come until the 1960s, when he and his orchestra made lengthy annual tours all over the world, had some hugely popular successes with "Satin Doll" (1953) and other compositions, and began to consistently receive accolades—including a Presidential Medal of Freedom and the French Legion of Honour—from the broader musical, artistic, and intellectual community.

Three other musical groups met with outstanding success in the 1920s: Jelly Roll Morton's Red Hot Peppers, Paul Whiteman's Orchestra, and William McKinney's Cotton Pickers. The 17 sides Morton and his Red Hot Peppers recorded for RCA Victor in 1926–27 are among the finest classics of early jazz. Blending late ragtime with the rapidly burgeoning improvisational advances of the time, Morton gathered a group of veterans of New Orleans-style jazz, then in their prime. By avoiding a random succession of solos—indeed, by careful structural planning that astutely distributed the seven players' efforts over the three-minute limit allowed by a 10-inch 78-rpm disc—and by painstakingly rehearsing the group before the recording sessions, Morton achieved an almost perfect balance of ensemble and solo. Miraculously, the improvisations and compositions enhanced each other; thus, solos were integrated into arrangements in a way that remained uncommon in jazz for decades thereafter. Morton recorded both multithematic ragtime pieces (including "Black Bottom Stomp" and "Grandpa's Spells"), each piece with several strains in different chord progressions, and monothematic 12- and 32-bar pieces featuring a single passacaglia-like repetitive harmonic sequence (such as "Smokehouse Blues," "Jungle Blues," and "Dead Man Blues"). These recordings had nothing to do with the typical dance music of the period. Moreover, by balancing compositional unity with a maximum of textural and timbral variety—to an extent that was remarkable in a three-minute miniature form, with only a small band—and by reconciling composition and improvisation as well as polyphonic and homophonic ensembles in one fell swoop, Morton pointed a way toward the future of jazz. Alas, in the quasi-commercial and career-driven world of the late 1920s and 1930s, his comprehensive lesson was learned by only a handful of musicians. But Morton's example may have influenced Ellington, who for reasons never made clear considered Morton his musical archenemy.

Morton's RCA Victor recordings

The case of Whiteman, though completely different, is almost equally important, and certainly Whiteman was of enormous influence. Although he is ignored or maligned by most jazz historians, Whiteman made considerable contributions to jazz, not only because of his orchestra's enormous popularity. More important, Whiteman explored hitherto uninvestigated avenues of expression.

By the mid-1920s Whiteman had expanded his band beyond the size of the standard jazz orchestra—five or six brass, five saxophones, a four- or five-piece rhythm section—to include a small violin section and had incorporated into his dance repertory a number of pieces associated with "serious" and "semiclassical" music. The accusations hurled at Whiteman—that he was "contaminating" jazz with classical affectations and trying to "make a lady out of jazz"—were patently unfair. He not only brought into his orchestra such bona fide jazz musicians as Beiderbecke, violinist Joe Venuti, saxophonist Frankie Trumbauer, and guitarist Eddie Lang but also hired such outstandingly gifted orchestrators and arrangers as Ferde Grofé, Bill Challis, William Grant Still, and Lennie Hayton. Furthermore, by adding multiple wind instruments—even oboe, bassoon, heckelphone, and bass clarinet—Whiteman expanded the registral range of his orchestra from the highest piccolo to the lowest tuba and thereby enriched the orchestra's timbral palette. In this way Whiteman's conception of a jazz orchestra was as original and unique as Ellington's, although entirely different. That the orchestra's arrangements and compositions sometimes suffered from severe instrumental and homophonic overweight cannot be denied. But at their best, when conceived by the likes of Challis and Grofé and imbued by Whiteman's improvisers with a true jazz spirit, his musical contributions are surely not to be sneered at.

McKinney's Cotton Pickers

Both Ellington and Henderson considered McKinney's Cotton Pickers, a Detroit-based band, their only serious rival. The distinctiveness of the Cotton Pickers' work during the band's heyday is attributable primarily to the remarkable leadership and the composing and arranging talents of John Nesbitt, whose work was mistakenly credited to Redman for many decades. Nesbitt was obviously aware and respectful of Ellington's fast-tempo "stomp" pieces. And like Morton, Nesbitt was intent on utilizing his 10- or 11-piece jazz orchestra to produce the most varied yet balanced integration of solo improvisation and arranged ensemble, as well as a maximum of textural and structural variety. In such recordings as "Put It There," "Crying and Sighing," and "Stop Kidding," Nesbitt and the band demonstrated their virtuosic command of what were for their time rather complex scores, replete with implied metre permutations, challenging rhythmic overlays, hard-driving solos, daring modulations, and—as Morton often urged—"plenty of solo breaks."

In these ways the orchestras of Morton, Whiteman, and McKinney (as well as that of Ellington) went considerably beyond Henderson's and Redman's method of setting solos off against arranged ensembles, showing that composition, and not mere arrangement, was completely compatible with jazz.

THE PRECURSORS OF MODERN JAZZ

Bennie Moten, Casa Loma Orchestra, and Benny Goodman. In the early 1930s two bands made important contributions to jazz: Bennie Moten's, with the recordings of "Toby," "Lafayette," and "Prince of Wails," and the Casa Loma Orchestra, with "Casa Loma Stomp" and "San Sue

Strut." The black Moten band had little immediate effect on the greater jazz scene, instead influencing an inner circle of black contemporaries, rivals, and jazz insiders. The driving, explosive, rhythmic energy of the Moten pieces, combined with an unprecedented instrumental virtuosity as well as a splendid balance of solos—by saxophonists Ben Webster and Eddie Barefield, trumpeter "Hot Lips" Page, and others—with riff-based ensembles, forged a breakthrough in orchestral jazz that can be seen as a precursor of modern jazz.

The white Casa Loma band exerted a tremendous influence on a host of dance bands (including, temporarily, some black orchestras, notably those of Jimmie Lunceford, Fletcher Henderson, and Earl Hines). The Casa Lomans' role in the history of jazz remains controversial, but it is clear that they were, at the very least, the first white orchestra to try to swing, though their rhythms were more often peppy than swinging. The Casa Loma Orchestra was also the first white band to feature jazz instrumentals consistently, rather than playing politely arranged dance tunes with an occasional hot solo. In these respects they influenced newly formed swing orchestras, including those led by Benny Goodman, Charlie Barnet, Artie Shaw, and Larry Clinton.

As far as the average jazz fan was concerned, the next big breakthrough occurred with Goodman's band, particularly on August 21, 1935, in the Palomar Ballroom in Los Angeles. On that night, after a weeks-long, dismally unsuccessful westward trek across the country, Goodman's band suddenly became a huge hit. That August night at the Palomar became the event that officially ushered in the swing era, with Goodman soon being hailed as the "King of Swing." That must have been interesting news to the bands of such black bandleaders as Ellington, Moten, Lunceford, Webb, Cab Calloway, and especially Henderson, who had been swinging for some five to seven years. Scores that Henderson had introduced in the late 1920s and early 1930s—"King Porter Stomp," "Wrappin' It Up," and "Down South Camp Meeting"—suddenly became big hits for Goodman, who had acquired both Henderson's arrangements of these numbers and the services of Henderson himself when Henderson's orchestra was forced to disband in 1934. As reinterpreted and energized by the Goodman forces, including the stellar trumpeter Bunny Berigan and the flashy drummer Gene Krupa, these pieces suddenly took on a new life. The Henderson-Redman formula of pitting soloists against ensembles and constantly juxtaposing the different choirs of the orchestra in call-and-response patterns became the widely emulated norm. When the Count Basie band from Kansas City, the successor to Moten's orchestra, reintroduced the riff as another extremely useful structural element, the scene was set for the hundreds of orchestras that had sprung up in the wake of Goodman's success to feed the enormous appetite for swing music of a generation of dance-crazy college-age jazz fans. By the late 1930s the country was awash with dance bands, all adhering to generic swing tenets: antiphonal section work, juxtaposition of solos and ensembles, and increasingly riff-based tunes. Though this led to a great quantity of dross, many talented young arrangers now rushed into the field and produced an impressive amount of astonishingly good music. This excellence is all the more remarkable since the music was created primarily to be danced to, with no pretensions (except in the case of bandleader Artie Shaw) to anything one might call art.

The "King of Swing"

Count Basie's band and the composer-arrangers. Among the innumerable orchestras that populated the jazz scene, Count Basie's achieved enormous importance. Perhaps the most magnificent "swing machine" that ever was, the Basie band strongly emphasized improvised solos and a refreshing looseness in ensemble playing that was usually realized through "head arrangements" rather than written-out charts. Its incomparable rhythm section—Walter Page (bass), Freddie Green (guitar), Jo Jones (drums), and Basie (piano)—supported an outstanding cast of soloists, ranging from the great innovative tenor saxophonist Lester Young and his section mate Herschel Evans to trumpeters Buck Clayton and Harry "Sweets" Edison, trombonists Dicky Wells and Vic Dickenson, and blues singer Jimmy Rushing. The Basie band's steadfast popularity can be measured by the fact that, except for a brief period in the early 1950s, it performed and toured successfully right up to Basie's death in 1984. Even after the height of the swing era, Basie continued to introduce swing masterpieces (including "Shiny Stockings," "The Kid from Red Bank," "Li'l Darling," and "April in Paris"), often featuring extraordinary solos by trumpeter-arranger Thad Jones and vocals by Joe Williams.

It was perhaps inevitable that in the excitement of the burgeoning swing era, jazz fans became obsessed with the reigning bandleaders, the new superstars of music. Little did swing fans realize that the music to which they kicked up their heels was the creation not of orchestra leaders but of arrangers who, behind the scenes, forged each band's distinctive style. The history of jazz has too often been described as the story of the improvising soloists, virtually ignoring the important contributions of the composer-arrangers who provided the soloists' framework. These included Sy Oliver (with the Jimmie Lunceford and Tommy Dorsey bands), Mary Lou Williams (with Andy Kirk's band), Walter Thomas (with Cab Calloway), Eddie Durham, Fletcher Henderson, Jimmy Mundy, Edgar Sampson, Eddie Sauter, Jerry Gray, and Benny Carter.

The swing soloists. Major swing soloists also emerged in the 1930s—most notably tenor saxophonists Coleman Hawkins, Lester Young, and Ben Webster; pianists Art Tatum and Teddy Wilson; and singer Billie Holiday. Hawkins had left the Henderson band in 1933 for what turned out to be a six-year stay in Europe, during which he not only taught most Europeans about jazz and swing but honed and perfected his personal style, which culminated—upon his return to the United States in 1939—in his recorded masterpiece, "Body and Soul." During that period Hawkins's slightly younger contemporaries Young and Webster developed quite divergent and highly distinctive improvisational styles. Webster exerted a powerful influence on Ellington during his 1939–42 tenure with the Ellington orchestra, while Young spawned an important new school of saxophone playing (epitomized by Stan Getz, Zoot Sims, and Al Cohn). In contrast to Hawkins's hyperenergetic, primarily chord-based approach, Young featured a more relaxed, sleek, linear, Southwestern blues-oriented style. Unlike Hawkins's pre-1940s improvisations, which were solidly anchored to their underlying harmonies, Young's lines glided over the harmonies and thereby freed those lines rhythmically.

Tatum and Wilson were both initially inspired by Hines but soon moved in directions different from Hines and from each other. Tatum, the supreme virtuoso technician, developed an astonishingly rich and advanced harmonic vocabulary, which he lavished on his solo improvisations on popular songs. Wilson, more of an ensemble player, led a memorable series of recordings between 1935 and 1937, featuring not only an elite of swing soloists in spontaneously created performances but also the incomparable Holiday.

Billie Holiday

Holiday's singing style was crafted out of an original amalgam of the vocal stylings of Armstrong and Bessie Smith as well as her own vocal-technical limitations—her range was barely more than an octave. With her unique timbre and diction, she reconstructed dozens of popular songs, streamlining and contracting the original melodies and embellishing them with highly personal ornamentations, many of which she absorbed from some of the great instrumentalists of her time. In this sense she was a true jazz singer, constantly re-creating, improvising, and inventing. Moreover, Holiday brought to her art a level of expression and philosophical depth unprecedented in jazz, ranging from abject melancholia and tragedy to the most joyous evocations.

The return of the combo and the influence of the territory bands. In the first decade of jazz, roughly 1915–25, almost all jazz worth considering had been played by small groups, but these were driven away in the 1930s by the arrival of the big bands. Later in the decade there was a return to smaller groups, ranging in size from trios to septets. Foremost among these new small groups were the various Goodman-led combos, starting in 1935. These were the

first racially mixed jazz groups to tour the United States: Goodman and Krupa were white, Wilson and vibraphonist Lionel Hampton black. By 1939–40 permutations of Goodman's small groups included guitarist Charlie Christian and trumpeter Cootie Williams. Among the several dozen recordings produced by these groups, the superb "Body and Soul," "Avalon," "Breakfast Feud," and "Seven Come Eleven" must be singled out.

In 1937 the 20-year-old Nat King Cole formed a trio, initially featuring himself as pianist; it was not until 1940 that Cole began singing and the trio began recording. Their big hits "Straighten Up and Fly Right" (1943) and "Route 66" (1946) made the group one of the top attractions of the mid-1940s, a success that eventually led to Cole's equally brilliant solo singing career. Piano trios and quartets—such as those of Page Cavanaugh, Clarence Profit, Barbara Carroll, Dorothy Donegan, Art Tatum, Lennie Tristano, and Joe Mooney—were among the many successful small groups of the 1940s.

The success of Goodman's small groups not only affirmed the artistic and commercial viability of a true chamber-jazz concept but inaugurated the notion of extracting a small combo from a larger orchestra. This "band within a band" idea spawned many successful groups, such as Shaw's Gramercy Five, Basie's Kansas City Seven, Tommy Dorsey's Clambake Seven, and, of course, Ellington's many small ensembles led alternately by Hodges, Williams, Stewart, and Bigard. Possibly the most perfect small group recordings are the four sides recorded in Paris in 1939 by three Ellingtonians—Stewart, Bigard, and Billy Taylor (bass)—and the great Belgian Gypsy guitarist Django Reinhardt.

The "band within a band"

Also important in the 1930s were the territory bands, notably Walter Page's Blue Devils (out of Oklahoma City, Oklahoma), the Jeter-Pillars band (based in St. Louis, Missouri), and those of Nat Towles (Omaha, Nebraska), Alphonse Trent (Dallas, Texas), Don Albert (San Antonio, Texas), Jesse Stone and Jay McShann (Kansas City), Zack Whyte (Cincinnati, Ohio), and others. Although their music was only sporadically recorded, these nomadic orchestras had considerable influence, for by roaming the Midwestern and Southern hinterlands in trains and broken-down buses and cars, they brought superb jazz to the public, especially the black population. In addition, these bands functioned as traveling music conservatories in which young talent could grow, develop, and gain vital experience.

Several major innovative soloists emerged during this period, among them trumpeters Roy Eldridge and Dizzy Gillespie, singer Pearl Bailey, xylophonist Red Norvo, alto saxophonist Charlie Parker, and Ellington's bassist Jimmy Blanton. With this roster of solo talent and the era's orchestral, compositional, and arranging developments—all inspired by a high sense of professionalism and an unprecedented artistic (but often also commercial) competitiveness—it was inevitable that a new jazz idiom would soon evolve. Ellington's harmonic lessons were finally beginning to be appreciated as arrangers forged beyond simple triadic and dominant harmonies into the various types of 9th, 11th, and 13th chords, all manner of substitute harmonizations, and wide-ranging modulations. On the rhythmic side, $\frac{4}{4}$ swing had by now completely taken over, providing the basis for a new fluency, freedom, and (as desired) complexity in rhythm sections; this in turn freed the soloists and ensembles to explore new structural territories—and all of these developments were expressed with a radically new virtuosity.

JAZZ AT THE CROSSROADS

Bebop takes hold. The first signs of these fresh musical sounds could be heard as early as 1941, particularly in works by such composer-arrangers as Buster Harding, Neal Hefti, Gerry Valentine, and Budd Johnson. Especially explorative and prophetic are such pieces as "The Moose" (1943; by Ralph Burns for the Charlie Barnet band), "Shady Lady" (1942; by Andy Gibson for Barnet), and "To a Broadway Rose" and "'S Wonderful" (1941 and 1944, respectively; both by Ray Conniff for Artie Shaw). Unfortunately, most of what was germinating at that time never got recorded because of a recording ban imposed by the American Federation of Musicians during much of 1942–43. This missing auditory link may have made the arrival of bebop seem more abrupt than it actually was.

While much of what happened between 1941 and 1945 may have appeared revolutionary to musicians and the public alike, the process was actually evolutionary and inevitable. The older guard held on as long as possible, dominating the airwaves well into the mid-1940s. But ultimately the experiments and forward thrusts of bebop—many of them initiated in such places as Minton's Playhouse in Harlem, in small lounges and obscure nightclubs, on tours, and in even more private situations such as homes and hotel rooms—had to break through to an expanding public via record companies and the larger, more popular club venues.

The leading figure in jazz was now Charlie Parker, who, along with his colleagues Dizzy Gillespie (trumpet), Bud Powell and Thelonious Monk (piano), Kenny Clarke and Max Roach (drums), Oscar Pettiford and Ray Brown (bass), and later Lucky Thompson (tenor saxophone), Milt Jackson (vibraphone), J.J. Johnson (trombone), and Miles Davis (trumpet), reshaped jazz on all three important fronts: harmonically, melodically, and rhythmically. Perhaps the most radical advance was rhythmic, when Parker, with his dazzling technique and fluency, turned the former $\frac{1}{4}$ metric substructures into $\frac{1}{8}$; quavers now superseded the basic quarter-note beats, and in effect the audible speed of the music doubled. Parker was, for all his startling innovations, a great blues player, as can be heard not only in his constant reference to earlier blues traditions but also in the depth and beauty of his tone and its often anguished expression. His co-innovators Gillespie and Powell, equipped with both a prodigious technical mastery and a keen sense for harmonic exploration, set dramatically new standards of improvisation. Drummers, too, became more intrinsically involved in the total ensemble effect by introducing a certain contrapuntal independence, expressed polyrhythmically and even melodically.

Charlie Parker

The new, onomatopoetically named bebop, or bop, used more chromatically convoluted melodic lines. Played at high speed, it was no longer aurally related to the sedate song repertory of the 1930s, and it required a greater variety of chord substitutions and passing harmonies. It also built a whole new jazz repertory by superimposing brand new themes onto older, well-known chord progressions, particularly on such standards as "I Got Rhythm" and "How High the Moon." This new repertoire was created mostly for small combos but also for larger ensembles such as Gillespie's, Billy Eckstine's, and Woody Herman's orchestras. As bebop took hold after World War II, the entire jazz scene changed dramatically. Many big bands, even those that tried to make the transition to modern jazz, began to falter both financially and artistically. Touring costs and musicians' salaries skyrocketed. The best musicians preferred to stay in Los Angeles, New York, and Chicago, where they could do the suddenly lucrative studio work. In any case, bebop was played mostly by small combos—quartets, quintets, and sextets. And bebop was made for listening, not dancing; it was not intended to be played to the accompaniment of clinking glasses and nightclub merrymaking.

Swing hangs on, soloists take off. Essentially, the audience for the more or less homogeneous jazz of the 1930s and early '40s (swing) was split three ways. A majority rejected bop and clung to swing, if and wherever they could still find it, or to even earlier styles, such as Dixieland and Chicago-style jazz. Another segment shifted its allegiance entirely to a new breed of singers—Frank Sinatra, Nat King Cole, Sarah Vaughan, Ella Fitzgerald, Mel Tormé, and Billy Eckstine—who came out of the bands and embarked on full-time careers as highly paid "single" acts. The third and smallest faction stayed with the boppers, relishing the music's technical and conceptual challenges and returning jazz to a minority art.

Two singular pianists emerged at this time: Thelonious Monk and Erroll Garner. After Morton and Ellington, Monk was the first major composer to enter the field, contributing in such pieces as "Criss Cross," "Misterioso," and

"Evidence" (all 1948) a uniquely individual repertory. Partly because he had developed a totally unorthodox piano technique, Monk created an inimitable style and touch, as well as highly unusual voicings and chord formations, as can be heard on his Blue Note quartet and quintet recordings of 1947–51 and on his later solo piano recordings of 1957 and 1959.

Equally sui generis yet completely different in intent, technique, and feeling, Garner had developed from his earliest professional days a prodigious both-hands technique (rivaled or surpassed only by Tatum) that allowed him to play asymmetrical rhythmic and melodic configurations and contours with his right hand while maintaining an absolutely steady beat with his left. Not a composer at all in the Monk or Ellington sense and given at times to a certain pianistic pomposity, Garner nevertheless brilliantly recomposed the hundreds of Broadway songs he played during his long career into astonishingly fresh, extemporized pieces.

Although the emphasis of this period was primarily on improvisation—a quintet or sextet did not require an arranger—a number of big bands did try to translate the newfound musical gains into orchestral terms. The results were uneven, inconsistent, and mostly commercially short-lived. Although the best efforts of the Woody Herman, Stan Kenton, Boyd Raeburn, Charlie Barnet, and Harry James bands of the mid- to late 1940s were not without considerable merit, it fell to the Claude Thornhill Orchestra, especially with its many scores by Gil Evans, to produce the only fully original contribution to orchestral jazz apart from Ellington's ongoing work. By adding French horns and woodwinds (including piccolo, bass clarinet, and at times multiple clarinets) and reinstating the tuba in a more melodic and contrapuntal role, Thornhill's orchestra acquired a totally fresh and subtle sound, one considerably softer and more opaque than the bright, loud, brash sonorities of the late swing-era bands. Moreover, with his extraordinary penchant for warm, dark instrumental colours and rich, bitonal harmonizations set in sparkling bop rhythms, Evans went quite beyond mere arranging into recomposing. The best examples can be heard in such pieces as "Robbins Nest," "Lover Man," and the Parker themes "Anthropology" and "Donna Lee."

Gil Evans

COOL JAZZ ENTERS THE SCENE

Chamber jazz and the Modern Jazz Quartet. Perhaps in reaction to the hot, more strident, more frenetic expressions of the postwar bands, or perhaps as a direct influence of the Thornhill-Evans approach, a cool strain entered the jazz scene in the late 1940s. Generated by Young and furthered by such reed players as Lee Konitz and Gerry Mulligan, cool jazz, along with its structural corollary—contrapuntal, harmonically slimmed-down (often pianoless) chamber jazz—was suddenly in. Understatement and a more relaxed expression replaced extroversion and high-tension virtuosity. Examples abound, beginning with the Miles Davis Nonet (1948–50)—a direct offspring in instrumentation and musical intent of the Thornhill band. In such pieces as "Boplicity," "Israel," "Move," and "Moondreams," fine improvised solos by Davis, Konitz, and Mulligan were meaningfully integrated into the arrangers' scores. Various octets, nonets, and other small ensembles soon followed suit, as did such West Coast-based quartets and quintets as those led by Mulligan, Chet Baker, Shelly Manne, Shorty Rogers, Jimmy Giuffre, and Chico Hamilton.

On a slightly different tack, the Modern Jazz Quartet (made up of John Lewis, piano; Milt Jackson, vibraphone; Percy Heath, bass; and Kenny Clarke, soon replaced by Connie Kay, drums) was formed in 1953. After his years with Gillespie, Lewis had been inspired further by his study of classical music, especially the work of Johann Sebastian Bach. Thus, Lewis brought a new kind of compositional (often contrapuntal) integration to the group's repertory, particularly in fugal or quasi-fugal pieces, such as the early "Vendome" or the later "Three Windows" and the album-length work *The Comedy*. Above all, in these performances Lewis sought to bring collective improvisation back from earlier times; many striking examples can be heard on the recordings made by the Modern Jazz Quartet over a period of 20 years, especially in the frequent, remarkable same-register duets of Lewis and Jackson.

Jazz meets classical and the "third stream" begins. It was also in the 1950s that a greater rapprochement between jazz and classical music began to emerge. Like Lewis, many other jazz musicians were studying much of the great classical literature, from Bach to Béla Bartók, to expand their musical horizons. Classical musicians, too, were listening more seriously to jazz and taking a professional interest in it. The ideological and technical barriers between jazz and classical music were beginning to break down. In that climate an apparently new concept or style, termed "third stream" by Gunther Schuller [Editor's note: the author of this article], arose. But third stream music was only apparently new, since European and American composers—including Claude Debussy, Igor Stravinsky, Charles Ives (using ragtime), Darius Milhaud, Maurice Ravel, Aaron Copland, John Alden Carpenter, Kurt Weill, and many others—had employed elements of jazz since early in the century. The difference in the 1950s and '60s was that (1) the third stream amalgams began to include improvisation and (2) the traffic was now no longer on a one-way street from classical music toward jazz but was flowing in both directions. Spearheaded by Lewis and Schuller, the movement produced a wide variety of works and varying approaches to the process of cross-fertilization. Third stream began, particularly in the cultivated hands of pianist Ran Blake, to mate classical concepts and techniques with all manner of ethnic and vernacular musics and traditions as well as with jazz.

Though the term is now seldom used, the concept of third stream remains alive and well; Charlie Haden and Carla Bley's Liberation Music Orchestra works and Randy Weston and Melba Liston's African-influenced compositions are cases in point. Third stream music is also called by other names: crossover, fusion, or world music. So lively and penetrating has the stylistic intercourse been that it is nowadays often impossible to identify a piece as jazz, classical, or ethnic, proof that the third stream ideal of a true and complete fusion (not always technically possible in the 1960s) has at least partially been achieved.

Inter-penetration of styles

Among the myriad contributions to third stream music over the years, Robert Graettinger's works for various Kenton orchestras are crucial. Major atonal, polyphonically complex Graettinger compositions such as *City of Glass* (first performed in 1948) and his remarkable arrangements of standard popular songs reveal a talent of astonishing originality—showing little influence of Stravinsky, Arnold Schoenberg, Bartók, or any major jazz figures—especially unusual for a man so young (he died at the age of 34).

THE MAINSTREAM ENLARGED: MILES DAVIS, JOHN COLTRANE, CHARLES MINGUS, AND OTHERS

In the meantime, the jazz mainstream continually broadened and expanded through the contributions of a wide range of talents from saxophonists Sonny Rollins, John Coltrane, and Eric Dolphy, bassist-composer Charles Mingus, and composer-theorist George Russell to pianists Cecil Taylor, Bill Evans, and Dave Brubeck. Miles Davis and Coltrane exerted the greatest influence, Coltrane especially; he inadvertently bred thousands of clones who copied his sound and turned his every move into a cliché. Much more difficult to imitate and to absorb was the music of Dolphy, who, along with his unequaled mastery of alto saxophone and flute, was the first to conquer the bass clarinet as a jazz instrument. "Stormy Weather" (1960), his nearly 14-minute-long duet improvisation on alto with Mingus, must be counted as one of the greatest creative efforts in all of jazz.

The great wonder of jazz is its open-endedness, allowing truly talented musicians to explore new stylistic and conceptual avenues. Such was the case with Rollins, who—instead of merely releasing a string of unrelated musical ideas—was the first to develop thematic improvisation in such a way that themes or motifs were varied and revisited within a single performance. Equally important was the work of Lennie Tristano, who not only as early as 1945 was successfully exploring the possibilities of atonal im-

provisation but later through his students (saxophonists Lee Konitz and Warne Marsh and composer Bill Russo) created yet another school of jazz playing that emphasized contrapuntal and polyphonic linearity and lean and clear textures of, at times, almost classical austerity.

Although he was a remarkably gifted musician with a deep humility regarding jazz and his art, Coltrane (probably under the influence of Davis) abandoned his earlier fascination with the burgeoning harmonic language of bop—especially Monk's unique tonal explorations—and fell into the trap of modal and single chord confinement. This led to extended improvisations, often lasting as long as an hour, that some observers regarded as "practicing in public."

Art Blakey's Jazz Messengers

Art Blakey's Jazz Messengers, the most renowned and respected of the "traveling conservatories," held forth in the world's jazz clubs and concert halls for more than three decades, hatching a long line of talented players ranging from Horace Silver, Kenny Dorham, and Lee Morgan (in the 1950s) to Freddie Hubbard, Keith Jarrett, Woody Shaw, and (in the 1980s) Wynton Marsalis.

Initially a loyal disciple of Gillespie, Davis by the late 1950s knew that he had neither the embouchure nor the ear for Gillespie's pyrotechnics. Under the benign influence of Gil Evans, John Lewis, and others, he turned to an opulent, more lyrical style with which he and Evans were to make dramatic musical history in such recordings as *Miles Ahead* (1957) and Evans's inspired recomposing of George Gershwin's *Porgy and Bess* (1958). Davis abandoned conventional major and minor harmonies for modal and pentatonic patterns (first fully aired in 1959 on the album *Kind of Blue*), a plunge into a vagrant harmonic no-man's-land that unfortunately infected much of jazz. Modal playing, with its endless pedal points and one-chord bass ostinatos, allowed by definition no harmonic progression or forward movement and resulted in a structural stasis that only, maybe, the greatest improvisers could overcome.

Mingus, together with Parker and Gillespie, was among the most gifted of all the postwar giants. A major composer in the full creative sense as well as a brilliant bass virtuoso and formidable bandleader, Mingus experimented with extended forms as early as the late 1940s ("Mingus Fingers" with Lionel Hampton). His oeuvre ranges from early simple blues and atonal free-form pieces to such poetically named jazz instrumentals as "Pithecanthropus Erectus" (1956), "Haitian Fight Song" (1957), "Fables of Faubus" (1959), and "Peggy's Blue Skylight" (1961) to the monumental two-and-a-half-hour, posthumously premiered *Epitaph*. Accumulated between the early 1940s and 1962 and composed for 31 instruments, *Epitaph* is a gigantic summation of everything Mingus felt and heard in music, from the gentlest lyric ballads and earthy blues to the most complex and advanced Ivesian and Stravinskian orchestral excursions.

FREE JAZZ: THE EXPLORATIONS OF ORNETTE COLEMAN

Whereas most of these postwar musicians worked out their individual styles through personal explorations within the central modern tradition, the arrival of saxophonist Ornette Coleman and trumpeter Donald Cherry constituted an even more radical break from the recent past. Eschewing conventional key and time signatures, Coleman also abandoned all the traditional jazz forms, arriving quickly at something that was to be called "free jazz."

Although partially inspired by the Parker revolution, Coleman's music also harkened back in its linear fragmentation, wailing blues sonorities, and unconventional intonation to a much older, primitive, folklike blues and work song tradition, incidentally more or less cleansed of jazz's earlier European borrowings. Given Coleman's abandonment of traditional forms such as 12-bar blues and 32-bar song forms, it would be wrong to conclude that such works as "Change of the Century" (1959) or *Free Jazz* (1960) are therefore formless. Rather, they are simply subject to a new kind of organization where—in *Free Jazz*, for example—the eight players are each assigned "solo" sections accompanied by all the other players, with the various sections partitioned from each other by predetermined, collectively played motivic materials and the overall formal subdivisions thus clearly delineated.

Though others who followed in Coleman's footsteps—for example, the saxophonists Albert Ayler, Archie Shepp, and George Adams—sought to expand on his free-form innovations, they lacked his innate talent and inherent musical discipline. A creative stasis set in during the 1970s and '80s that eventually led, on the one hand, to a gigantic eclecticism where no style or conception took priority and, on the other hand, to a profound sea change that dramatically altered the face of jazz. This fundamental shift can be seen in the fact that, in contrast to past decades when jazz produced a succession of highly individual artists whose musical styles and personalities could be recognized instantly, by the end of the 20th century jazz had no such distinctive artists.

JAZZ AT THE END OF THE 20TH CENTURY

Whether the past was inherently better than the present is questionable. Something was gained and something was lost. The personal, instantly recognizable distinctiveness of the great jazz players of the past was replaced by an astonishing technical assurance and stylistic flexibility. Most younger players in the 1990s sounded very much alike—with the exception of a few standouts such as trumpeters Wynton Marsalis, Tom Harrell, Randy Brecker, and Dave Douglas, saxophonists Steve Lacy and Joe Lovano, trombonist Albert Mangelsdorff, pianist Gonzalo Rubalcaba, and bassist John Patitucci. Whereas later players functioned well in any stylistic context—even beyond jazz in ethnic and classical realms—the earlier players, great as they were, could not reach out into other stylistic regions. The players of yore did not—could not, in most cases—go to music schools and were in essence self-taught, having learned on the job and to a large extent from each other and from their seniors.

Whether the eclectic versatility of these later generations is good for the future of jazz is as yet hard to say. One fact, however, is clear: in the wake of these changes, composition moved much more into the front and centre of activities—as in the works of Leo Smith, Henry Threadgill, and Dave Douglas—which suggests that the long-standing conflict between improvisation and composition may have finally been resolved. A good part of the reason for this is that most later jazz musicians went to music school—conservatories and university or college music departments—where they took theory, music history, and general music survey courses, and in most cases they also studied with teachers who were themselves major jazz figures. In addition, starting in the 1970s, the enormously expanding number of recordings made available an infinite variety of musical traditions encompassing all jazz styles as well as a rainbow of ethnic, popular, and vernacular musics of all persuasions and philosophies. The younger generations took advantage of this plethora of musical and stylistic resources.

Where this leaves jazz and where jazz goes in the future—indeed, whether jazz can endure as a distinct musical idiom or language—were unanswerable questions at the end of the 20th century. The one truism about jazz is that it remains distinguishable not by *what* is played but by *how* it is played. (G.Sch.)

BIBLIOGRAPHY

Development of musical form. Formal terms and genres are rigorously explored in individual entries in STANLEY SADIE (ed.), *The New Grove Dictionary of Music and Musicians*, 6th ed., 20 vol. (1980, reprinted 1994). DAVID WARD-STEINMAN and SUSAN WARD-STEINMAN (compilers), *Comparative Anthology of Musical Forms*, 2 vol. (1976, reprinted 1986), illustrates a variety of small- and large-scale musical forms, drawing on both Western and non-Western sources.

Instrumental music. *Chamber music:* WALTER W. COBBETT, *Cobbett's Cyclopedic Survey of Chamber Music*, 2nd ed. by COLIN MASON, 3 vol. (1963), is a comprehensive work containing analyses and descriptions of works and topics in the field; MELVIN BERGER, *Guide to Chamber Music* (1985, reissued 1990), covers the same repertory in a more synoptic fashion; and VICTOR RANGEL-RIBEIRO and ROBERT MARKEL, *Chamber Music: An International Guide to Works and Their Instrumentation* (1993), provides encyclopedic coverage of the repertory.

DONALD FRANCIS TOVEY, *Essays in Musical Analysis: Chamber Music* (1944, reprinted 1989), is an old standard with still-provocative ideas about critical and performance aspects of chamber music. HOMER ULRICH, *Chamber Music,* 2nd ed. (1966), is a historical account of the field before Haydn, with descriptive analyses and history of the repertory since 1750. JOHN H. BARON, *Chamber Music: A Research and Information Guide* (1987), gives a bibliographical overview of research on all composers and varieties of chamber music.

Fugue: General studies of fugal technique, form, and historical development include ROGER BULLIVANT, *Fugue* (1971), a good introduction to the repertory; IMOGENE HORSLEY, *Fugue, History and Practice: Workbook* (1966), an excellent survey of the relevant theoretical documents; ALFRED MANN, *The Study of Fugue* (1965, reprinted 1987), a standard work that considers the history of fugue textbooks; and EBENEZER PROUT, *Double Counterpoint and Canon,* 2nd ed. (1893, reprinted 1969), and *Fugue,* 4th ed. (1891, reprinted 1970), companion volumes that provide a comprehensive and clear account of the techniques of strict counterpoint.

Symphony: Two helpful introductions to the general form and development of the symphony are LOUISE CUYLER, *The Symphony,* 2nd ed. (1995); and PRESTON STEDMAN, *The Symphony,* 2nd ed. (1992). Other works that present a broad swath of symphonic history include BARRY S. BROOK, *La Symphonie française dans la seconde moitié du XVIIIe siècle,* 3 vol. (1962), an important survey of more than 1,200 works by 150 composers; ADAM VON AHN CARSE, *Eighteenth-Century Symphonies: A Short History . . .* (1951, reprinted 1979), with emphasis on pre-Classical and early Classical forms and the overture; ROBERT SIMPSON (ed.), *The Symphony,* 2 vol. (1966–67), a collection of analyses for the repertory from the late 18th to the mid-20th century; and DONALD FRANCIS TOVEY, *Essays in Musical Analysis,* 6 vol. (1935–39), new ed., 2 vol. (1981), old but containing perceptive discussions of chief works. A summary of late 20th-century scholarship is PRESTON STEDMAN, *The Symphony: A Research and Information Guide* (1990–).

The brief, well-written *BBC Music Guides* cover works by many symphonists, both major and minor—for instance, MICHAEL KENNEDY, *Strauss Tone Poems* (1984); JOHN MCCABE, *Bartók Orchestral Music* (1974); HUGH OTTAWAY, *Vaughan Williams Symphonies* (1972, reprinted 1987); and STANLEY SADIE, *Mozart Symphonies* (1986).

The symphonic performing ensemble—that is, the orchestra—is examined in JOAN PEYSER (ed.), *The Orchestra: Origins and Transformations* (1986, reissued 2000), essays that investigate the orchestra's development. ROBERT R. CRAVEN (ed.), *Symphony Orchestras of the United States: Selected Profiles* (1986), and *Symphony Orchestras of the World: Selected Profiles* (1987), treat the premier ensembles.

Sonata: The authoritative source for information on the sonata is a series by WILLIAM S. NEWMAN, *The Sonata in the Baroque Era,* 4th ed. (1983), *The Sonata in the Classic Era,* 3rd ed. (1983), and *The Sonata Since Beethoven,* 3rd ed. (1983). CHARLES ROSEN, *Sonata Forms,* rev. ed. (1988), reveals the variety of structural schemes that go by this term, primarily in the Classical period. WILFRID HOWARD MELLERS, *The Sonata Principle (from c. 1750)* (1957, reissued 1977), though dated, still attracts interest for its hegemonic view of sonata form. MELVIN BERGER, *Guide to Sonatas: Music for One or Two Instruments* (1991), provides an overview of the most important works in the repertory.

Concerto: ABRAHAM VEINUS, *The Concerto,* rev. ed. (1964), is the only broad survey in English, with good knowledge of the subject but generally not well documented; it may be readily supplemented by ROBERT LAYTON (ed.), *A Companion to the Concerto* (1988), an anthology of articles surveying the development of the genre and many of its representative works; and MICHAEL THOMAS ROEDER, *A History of the Concerto* (1994). ALFRED FRANKENSTEIN, *A Modern Guide to Symphonic Music* (1966), provides fine introductions to many of the standard concertos.

Electronic music: The history of electronic music from the listener's perspective is given comprehensive coverage in PETER MANNING, *Electronic and Computer Music,* 2nd ed. (1993), which accounts for both art and pop musics. Other valuable histories include TOM DARTER (compiler) and GREG ARMBRUSTER (ed.), *The Art of Electronic Music* (1984); DAVID ERNST, *The Evolution of Electronic Music* (1977); HERBERT RUSSCOL, *The Liberation of Sound: An Introduction to Electronic Music* (1972, reprinted 1994); and ELLIOTT SCHWARTZ, *Electronic Music: A Listener's Guide,* rev. ed. (1975, reprinted 1989). Also available is a CD containing early examples of historical recordings: *Pioneers of Electronic Music,* CRI American Masters (1991). Discussions of computer music may be found in DENIS BAGGI (ed.), *Computer-Generated Music* (1992); WAYNE BATEMAN, *Introduction to Computer Music* (1980); HAL CHAMBERLIN, *Musical Applications of Microprocessors,* 2nd ed. (1985); CHARLES DODGE and THOMAS A. JERSE, *Computer Music: Synthesis, Composition, and Performance,* 2nd ed. (1997); GOFFREDO HAUS (ed.), *Music Processing* (1993); F. RICHARD MOORE, *Elements of Computer Music* (1990); CURTIS ROADS (ed.), *The Music Machine: Selected Readings from Computer Music Journal* (1989); CURTIS ROADS and JOHN STRAWN (eds.), *Foundations of Computer Music* (1985); and ROBERT ROWE, *Interactive Music Systems: Machine Listening and Composing* (1993). Two excellent reference guides are RICHARD DOBSON, *A Dictionary of Electronic and Computer Music Technology: Instruments, Terms, Techniques* (1992); and WILLIAM J. WATERS (compiler), *Music and the Personal Computer: An Annotated Bibliography* (1989).

Vocal music. The best single-volume treatment may be that found in various chapters of DONALD JAY GROUT and CLAUDE V. PALISCA, *A History of Western Music,* 4th ed. (1988); less authoritative but sharply focused is HOMER ULRICH, *A Survey of Choral Music* (1973). More engaging accounts of individual periods may be read in RICHARD H. HOPPIN, *Medieval Music* (1978); HOWARD MAYER BROWN, *Music in the Renaissance,* 2nd ed. (1999); and CLAUDE V. PALISCA, *Baroque Music,* 3rd ed. (1991). The important—though often unrecognized—place of choral music in 19th-century culture is treated in CARL DAHLHAUS, *Nineteenth-Century Music* (1989; originally published in German, 1980), especially pp. 160–190.

A general survey of song literature is DENIS STEVENS (ed.), *A History of Song* (1960; reprinted 1982), a dated but still useful volume; it should be augmented by other studies dedicated to single genres, composers, or periods, such as EDWARD DOUGHTIE, *English Renaissance Song* (1986); MARJORIE WING HIRSCH, *Schubert's Dramatic Lieder* (1993); and JAMES MCMAHON, *The Music of Early Munesang* (1990).

ALFRED EINSTEIN, *The Italian Madrigal,* 3 vol. (1949, reprinted 1971), is a highly detailed account, but its presentation of the early madrigal must be modified in light of the evidence presented in IAIN FENLON and JAMES HAAR, *The Italian Madrigal in the Early Sixteenth Century: Sources and Interpretation* (1988).

Excellent examples of analytic techniques that may be applied to the repertories of vocal music from the 16th century and earlier may be consulted in MARK EVERIST (ed.), *Music Before 1600* (1992).

Theatre music. *Ballet music and music for dance:* The two primary introductory texts are dated but remain the most comprehensive overviews of their topics: HUMPHREY SEARLE, *Ballet Music: An Introduction,* 2nd rev. ed. (1973); and PAUL NETTL, *The Dance in Classical Music* (1963). Other studies, mostly of late 20th-century vintage—such as JAMES R. ANTHONY, *French Baroque Music from Beaujoyeulx to Rameau,* rev. and expanded ed. (1997)—provide detailed accounts of particular repertories.

Musicals and operettas: KURT GÄNZL and ANDREW LAMB, *Gänzl's Book of the Musical Theatre* (1989), gives synopses and dates of numerous European and American operettas and musicals. DAVID EWEN, *New Complete Book of the American Musical Theater* (1970), provides background information for many works and composers. GERVASE HUGHES, *Composers of Operetta* (1962, reprinted 1974), is a reliable critical and historical account of classical operetta; but it should be read alongside the more sophisticated RICHARD TRAUBNER, *Operetta: A Theatrical History* (1983).

Increasing attention has been paid to the historical importance of African American musical theatre. Two seminal studies are THOMAS L. RIIS, *More Than Just Minstrel Shows: The Rise of Black Musical Theatre at the Turn of the Century* (1992); and ALLEN WOLL, *Black Musical Theatre: From Coontown to Dreamgirls* (1989, reprinted 1991).

Music for film and theatre: The place of music in the works and performance history of the greatest English playwright is comprehensively evaluated in BRYAN N.S. GOOCH and DAVID THATCHER (eds.), *A Shakespeare Music Catalogue,* 5 vol. (1990); music in plays by Shakespeare's younger contemporary is discussed in MARY CHAN, *Music in the Theatre of Ben Jonson* (1980). The various Asian dramatic traditions that involve music are treated individually by TAN SOOI BENG (SOOI BEN TAN), *Bangsawan: A Social and Stylistic History of Popular Malay Opera* (1993); COLIN P. MACKERRAS, *The Rise of the Peking Opera, 1770–1870: Social Aspects of the Theatre in Manchu China* (1972); BELL YUNG, *Cantonese Opera: Performance as Creative Process* (1989); BONNIE C. WADE (ed.), *Performing Arts in India: Essays on Music, Dance, and Drama* (1983); and ELIZABETH WICHMANN, *Listening to Theatre: The Aural Dimension of Beijing Opera* (1991).

An excellent history of film music is WILLIAM DARBY and JACK DU BOIS, *American Film Music: Major Composers, Techniques, Trends, 1915–1990* (1990, reissued 2000).

Opera. Among books on opera in general, useful basic information and informed opinion may be found in DONALD JAY GROUT, *A Short History of Opera,* 3rd ed. (1988); JOSEPH KERMAN, *Opera As Drama,* rev. ed. (1988); STANLEY SADIE (ed.), *History of Opera* (1989); and an illustrated, more popularly ori-

ented volume, LESLIE ORREY, rev. and updated by RODNEY MILNES, *Opera: A Concise History,* rev. ed. (1987). The standard reference work for opera is STANLEY SADIE (ed.), *The New Grove Dictionary of Opera,* 4 vol. (1992). Another reference source is HAROLD ROSENTHAL and JOHN WARRACK, *The Concise Oxford Dictionary of Opera,* 2nd ed. (1985, reissued 1990). Plot synopses that analyze both libretto and music are numerous for both major and minor operatic works, and those by ERNEST NEWMAN and MILTON CROSS are among the most engaging and comprehensive. An index to the hundreds of volumes is WILLIAM E. STUDWELL and DAVID A. HAMILTON, *Opera Plot Index* (1990). CHARLES H. PARSONS (compiler), *The Mellen Opera Reference Index* (1986–), an immense undertaking, catalogs virtually all operas by composer, premiere, cast, subject, and so on.

Individual periods and composers belonging to the history of opera have been treated extensively by musicologists; among the best are HOWARD MAYER BROWN, "How Opera Began: An Introduction to Jacopo Peri's Euridice (1600)," in ERIC COCHRANE (ed.), *The Late Italian Renaissance, 1525–1630* (1970); NINO PIRROTTA and ELENA POVOLEDO, *Music and Theatre from Poliziano to Monteverdi* (1982; originally published in Italian, 2nd ed., 1981); ELLEN ROSAND, *Opera in Seventeenth-Century Venice: The Creation of a Genre* (1991); and F.W. STERNFELD, *The Birth of Opera* (1993). The most important studies concerned with opera's later development and with particular composers or works include WILLIAM ASHBROOK and HAROLD POWERS, *Puccini's Turandot: The End of the Great Tradition* (1991); WINTON DEAN and JOHN MERRILL KNAPP, *Handel's Opera, 1704–1726* (1987); ROBERT DONINGTON, *Opera and Its Symbols: The Unity of Words, Music, and Staging* (1990); DANIEL HEARTZ and THOMAS BAUMAN (ed.), *Mozart's Operas* (1990); STEVEN HUEBNER, *The Operas of Charles Gounod* (1990); DAVID KIMBELL, *Italian Opera* (1991), and *Verdi in the Age of Italian Romanticism* (1981); ULRICH MÜLLER and PETER WAPNEWSKI (eds.), *Wagner Handbook* (1992; originally published in German, 1986), trans. ed. by JOHN DEATHRIDGE; CURTIS ALEXANDER PRICE, *Henry Purcell and the London Stage* (1984); and ERIC WATLER WHITE, *A History of English Opera* (1983).

The *Cambridge Opera Handbooks* are an excellent source for in-depth analyses of specific operas. Contemporary trends in musicology—reflecting concerns of feminism, anthropology, and literary criticism, for example—have influenced opera criticism and are discernible in CAROLYN ABBATE, *Unsung Voices: Opera and Musical Narrative in the Nineteenth Century* (1991, reissued 1994); CATHERINE CLEMENT, *Opera, or The Undoing of Women* (1988, reissued 1997; originally published in French, 1979); and JOHN DIZIKES, *Opera in America: A Cultural History* (1993).

Jazz. *General histories:* MARSHALL WINSLOW STEARNS, *The Story of Jazz* (1956, reissued 1976), is ideal for the newcomer to the music; NAT SHAPIRO and NAT HENTOFF (eds.), *Hear Me Talkin' to Ya* (1955, reissued 1992), is a colourful history of jazz in musicians' own words; JOACHIM E. BERENDT, *The Jazz Book,* 6th ed., rev. by GÜNTHER HUESMANN (1992; originally published in German, 1954), is comprehensive. Particularly notable for its abundance of rare photographs is GEOFFREY WARD, *Jazz: A History of America's Music* (2000), based on a 10-part documentary film by Ken Burns that was written by Ward. RUDI BLESH and HARRIET JANIS, *They All Played Ragtime,* 4th ed. (1971); SAMUEL BARCLAY CHARTERS, *Jazz: New Orleans, 1885–1963,* rev. ed. (1963, reprinted 1983); and SAMUEL BARCLAY CHARTERS and LEONARD KUNSTADT, *Jazz: A History of the New York Scene* (1962, reprinted 1984), are all highly recommended for information about the musical precursors of jazz and jazz's early years. MEZZ MEZZROW and BERNARD WOLFE, *Really the Blues* (1946, reissued 1993), is a fascinating personal history of the halcyon early decades of jazz.

Specific topics: GUNTHER SCHULLER, *Early Jazz: Its Roots and Musical Development* (1968, reissued 1986), and *The Swing Era: The Development of Jazz, 1930–1945* (1989, reissued 1991), offer comprehensive, detailed technical analyses of the music. GEORGE T. SIMON, *The Big Bands,* 4th ed. (1981), is a largely anecdotal history; and ALBERT MCCARTHY, *Big Band Jazz* (1974, reissued 1983), is the most thoroughly researched book on the subject. BARRY ULANOV, *Duke Ellington* (1946, reprinted 1975); STANLEY DANCE, *The World of Duke Ellington* (1970, reprinted 1981); and MARK TUCKER (ed.), *The Duke Ellington Reader* (1993), examine jazz's greatest composer. LAWRENCE O. KOCH, *Yardbird Suite: A Compendium of the Music and Life of Charlie Parker,* rev. ed. (1999), is a brilliant and detailed exploration of Parker's art. LEONARD FEATHER, *Inside Jazz* (1997; originally published as *Inside Bebop,* 1949), was the first knowledgeable book about the bebop revolution. ERIC HOBSBAWM (FRANCIS NEWTON), *The Jazz Scene,* rev. ed. (1993), presents a highly intelligent, objective view of postwar jazz. WINTHROP SARGEANT, *Jazz: Hot and Hybrid,* 3rd ed. enlarged (1975); and FREDERIC RAMSEY, JR., and CHARLES EDWARD SMITH (eds.), *Jazzmen* (1939, reprinted 1985), were pioneering efforts in developing critical views of jazz and its performers. ANDRÉ HODEIR, *Jazz: Its Evolution and Essence,* rev. ed. (1980; originally published in French, 1954), was the first serious analysis of the music. S. FREDERICK STARR, *Red and Hot: The Fate of Jazz in the Soviet Union 1917–1991,* updated ed. (1994), is a fascinating study.

Collections of essays: WHITNEY BALLIETT, *The Sound of Surprise* (1959); MARTIN T. WILLIAMS (ed.), *The Art of Jazz* (1959, reprinted 1981); MAX HARRISON, *A Jazz Retrospect,* 2nd ed. (1991); and GARY GIDDINS, *Riding on a Blue Note* (1981), are superb, stimulating, wide-ranging collections of essays. RALPH ELLISON, *Shadow and Act* (1964, reissued 1995), includes moving and insightful personal essays on jazz.

Reference works: BARRY KERNFELD (ed.), *The New Grove Dictionary of Jazz,* 2 vol. (1988, reissued 2 vol. in 1, 1994); LEONARD FEATHER, *The Encyclopedia of Jazz* (1955, rev. 1960, and reprinted 1984), and *The Encyclopedia of Jazz in the Sixties* (1966, reprinted 1986); LEONARD FEATHER and IRA GITLER, *The Encyclopedia of Jazz in the Seventies* (1976, reprinted 1987), and *The Biographical Encyclopedia of Jazz* (1999); and JOHN CHILTON, *Who's Who of Jazz,* 5th ed. (1989), are indispensable reference works.

Musical Instruments

Musical instruments are almost universal components of human culture: archaeology has revealed pipes and whistles in the Paleolithic Period and clay drums and shell trumpets in the Neolithic age. It has been firmly established that the ancient city cultures of Mesopotamia, the Mediterranean, India, East Asia, and the Americas all possessed diverse and well-developed assortments of musical instruments, indicating that a long previous development must have existed. As to the origin of musical instruments, however, there can be only conjecture. Some scholars have speculated that the first instruments were derived from such utilitarian objects as cooking pots (drums) and hunting bows (musical bows); others have argued that instruments of music might well have preceded pots and bows; while in the myths of cultures throughout the world the origin of music has frequently been attributed to the gods, especially in areas where music seems to have been regarded as an essential component of the ritual believed necessary for spiritual survival.

Whatever their origin, the further development of the enormously varied instruments of the world has been dependent on the interplay of four factors: available material, technological skills, mythic and symbolic preoccupations, and patterns of trade and migration. Thus, residents of Arctic regions use bone, skin, and stone to construct instruments; residents of the tropics have wood, bamboo, and reed available; while societies with access to metals and the requisite technology are able to utilize these malleable materials in a variety of ways. Myth and symbolism play an equally important role. Herding societies, for example, which may depend on a particular species of animal not only economically but also spiritually, often develop instruments that look or sound like the animal or prefer instruments made of bone and hide rather than stone and wood, even when all the materials are available. Finally, patterns of human trade and migration have for many centuries swept musicians and their instruments across seas and continents, resulting in constant flux, change, and cross-fertilization and adaptation.

The sound produced by an instrument can be affected by many factors, including the material from which the instrument is made, its size and shape, and the way that it is played. For example, a stringed instrument may be struck, plucked, or bowed, each method producing a distinctive sound. A wooden instrument struck by a beater sounds markedly different from a metal instrument, even if the two instruments are otherwise identical. On the other hand, a flute made of metal does not produce a substantially different sound from one made of wood, for in this case the vibrations are in the column of air in the instrument. The characteristic timbre of wind instruments depends on other factors, notably the length and shape of the tube. The length of the tube not only determines the pitch but also affects the timbre: the piccolo, being half the size of the flute, has a shriller sound. The shape of the tube determines the presence or absence of the "upper partials" (harmonic or nonharmonic overtones), which give colour to the single note.

This article discusses the evolution of musical instruments, their structure and methods of sound production, and the purposes for which they have been used. Although it focuses on the families of instruments that have been prominent in Western art music, it also includes coverage of non-Western and folk instruments.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 624, and the *Index*.

General characteristics

Musical instruments have been used since earliest times for a variety of purposes, ranging from the entertainment of concert audiences to the accompaniment of dances, rituals, work, and medicine. The use of instruments for religious ceremonies has continued down to the present day, though at various times they have been suspect because of their secular associations. The many references to instruments in the Old Testament are evidence of the fact that they played an important part in Jewish worship until for doctrinal reasons they were excluded. It is also clear that the early Christians in the eastern Mediterranean used instruments in their services, since the practice was severely condemned by ecclesiastics, who insisted that the references to instruments in the Psalms were to be interpreted symbolically. Although instruments continue to be banned in Islāmic mosques (but not in religious processions or Ṣūfī ritual) and in the traditional Eastern Orthodox church, they play important roles in the ritual of most other societies.

Belief in the magical properties of instruments is found in many societies. The Jewish shofar (a ram's horn), which is still blown on Rosh Hashana (New Year) and Yom Kippur (Day of Atonement), must be heard by the congregation. The power of the shofar is illustrated by the story of Joshua at the siege of Jericho: when the priests blew their shofars seven times, the walls of the city fell flat. In India, according to legend, when the deity Krishna (Kṛṣṇa) played the flute, the rivers stopped flowing and the birds came down to listen. The birds are said to have done the same in 14th-century Italy when the composer Francesco Landini played his organetto, or portative organ. In China, instruments were identified with the points of the compass, with the seasons, and with natural phenomena. The Melanesian bamboo flute was a charm for rebirth.

Many of the instruments used in medieval Europe came from western Asia, and they have retained some of their original symbolism. For example, trumpets, long associated with military operations, had a ceremonial function in the establishment of European kings and nobles and were, in fact, regarded as a sign of nobility. In the later Middle Ages and for long afterward, they were associated with kettledrums (known originally as nakers, after their Arab name, *naqqārah*), which were often played on horseback, as they still are in some mounted regiments. Trumpet fanfares, heard on ceremonial occasions in the modern world, are a survival of medieval practice.

TECHNOLOGICAL DEVELOPMENTS

The earliest instruments may have been natural objects, such as bones, shells, or gourds, that had been modified slightly. Such instruments probably produced only one note or served only as a means of amplifying the human voice. The discovery that tubes possessed acoustic properties that enabled them, by vibration of the lips, to sound more than one note was a later development. From using natural objects, it was an obvious step to construct instruments that would serve a similar purpose, using wood or terra-cotta or any other available material.

Development of stringed instruments

Another far-reaching development was the discovery that a stretched string could produce a musical note. This resulted in the construction of the musical bow and the bamboo-fibre zither, instruments whose descendants remain important today. The sound produced by the simple string of such instruments is feeble, however, unless it is reinforced by means of a resonator—*i.e.*, a pot placed on the ground beneath the instrument, a gourd attached to the instrument, the player's mouth, or, in the case of the zither, the bamboo tube from which the instrument is made. The resonator vibrates in sympathy with the string, amplifying the sound.

The first step in the building of any instrument is the selection and preparation of material. Wood used for wind or stringed instruments needs to be seasoned, as do the reeds used in oboes, clarinets, and bassoons. Metals, which are widely used for strings, bells, cymbals, gongs, trumpets, and horns, must be manufactured and cast—often originally by secret processes. Next, the construction and tuning of all but the simplest instruments require skill and craftsmanship: the piercing of a tube to a uniform or expanding width, the flaring of the bell of a wind instrument to increase sonority, the measurement of the bars of a xylophone or glockenspiel, the curvature of the back of a lute, the internal and external structure of the body of a violin. All of these involve accurate workmanship from experts in wood and metal and, in many instances, a knowledge of the mathematics of sound.

The mathematical basis of accurate tuning systems has been the subject of philosophical and scientific speculation since ancient times; nevertheless, no single system has been deemed perfect. All practical tuning systems involve a series of compromises, a fact that instrument makers have known for centuries. The instrument maker's skill, like that of the cabinetmaker and the silversmith, was developed by long practice, and the principles that determine both tone and intonation were discovered by trial and error. The growth of instrumental playing in 16th-century Europe stimulated the production of instruments to be used not merely for ceremonial and official entertainment but also for social occasions and private pleasure. From this time, records began to be kept of the names of makers, many of whom established family businesses that lasted for several generations. These include, for example, Andrea Amati (16th century), violin maker in Cremona; Hans Ruckers (late 16th century), harpsichord maker in Antwerp; and Johann Haas (1649–1723), trumpet maker in Nürnberg.

Instrument makers, who usually have been a forgotten link in the musical chain, have always represented a blend of conservatism with the ability to quickly seize on and use a new constructional technique, a new tool, or a new ma-

terial. Their contribution to both the history of music and the history of musical instruments has been enormous and little appreciated. The older makers of instruments—in Europe and elsewhere—were craftsmen who took delight in the appearance of their work. In some cases, as when pictures were painted on the inside of harpsichord lids or elaborate patterns were carved onto Indian vinas, the ornamentation was purely decorative. Sometimes it served a practical purpose, as when rings of ivory concealed and strengthened the joints in woodwind instruments. In still other instances, it might best be termed symbolic or even totemic, as when the bell of a wind instrument was made in the shape of a dragon's head. Modern taste in most cases rejects ornamentation, but overall design and finish are as important as they have always been.

Modern changes in design

Modern technology has in many cases simplified or improved the construction of instruments. In the past, for example, the tubes of horns and trumpets were made from a sheet of brass cut to the right width, which was rolled into shape, leaving the edges to be joined by brazing. In modern manufacture the tube is drawn in one piece, and there is no seam. Evolution of design has been particularly notable in the construction of woodwind instruments, not only in the fixing of the metal keys and the mechanism that controls them but also in the piercing of holes in such a way that they are acoustically correct. This achievement was due mainly to the pioneering work of Theobald Böhm (1794–1881), who was not only a flute maker but also a performer and composer. His system, designed for the flute, was later applied to the clarinet, the oboe, and the bassoon. The early 19th century saw a revolution in the manufacture of brass instruments as well: the addition of pieces of tubing of different lengths through which the air could be directed by the depression of valves (or pistons), enabling an instrument to produce all 12 notes of the chromatic scale, in place of its earlier limitation to the notes of the natural harmonic (overtone) series.

The discovery of plastics in the 20th century also has influenced the manufacturers of instruments; for example, some makers have used plastic instead of quill or leather for the plectra that pluck the strings of the harpsichord, and plastic recorders have been built. Mechanization has made possible the mass production of instruments of all kinds. Insofar as this makes it possible for people to acquire an instrument at a moderate price, mass production is a good thing, and in education it has been beneficial to schools working on a small budget. A natural development has been the provision of kits consisting of the separate parts of an instrument, which can then be assembled by the purchaser. It remains true, however, that the production of an instrument of the finest quality still demands the highest degree of individual skill. A violin glued together from mass-produced parts cannot be the equal of one that has been meticulously constructed from the first by an individual craftsman who will not be satisfied with his work until every detail of it has been tested.

Importance of craftsmen

Technology has been of service to music by providing composers with instruments they have asked for, by eliminating some defects of instruments, and by making instruments more widely available to the community in general. Richard Wagner, for example, suggested the need for a baritone double-reed instrument akin to the oboe; the resulting heckelphone has been featured in Richard Strauss's opera *Salome* (1905) and subsequent works. Wagner also ordered a special type of tuba for use in his music drama tetralogy *Der Ring des Nibelungen* (*The Ring of the Nibelung*, 1869–76). Not all modern changes in construction have been wholly advantageous, however. It is easier to play in tune on a modern woodwind instrument, but the older examples, being less cluttered with metal fittings, had a purer tone. Similarly, the modern horn is inferior in tone quality to its 18th-century predecessor. Among Western orchestral instruments, only the trombone and the string instruments have remained, apart from minor modifications, unchanged in structure over the centuries (though the substitution of wire strings for gut has materially altered the tone of the violin). In contrast, the rate of technological change in electronic instruments has been almost bewilderingly fast.

CLASSIFICATION OF INSTRUMENTS

Instruments have been classified in various ways, some of which overlap. The Chinese divide them according to the material of which they are made—as, for example, stone, wood, silk, and metal. Writers in the Greco-Roman world distinguished three main types of instruments: wind, stringed, and percussion. This classification was retained in the Middle Ages and persisted for several centuries: it is the one preferred by some writers, with the addition of electronic instruments, at the present day. Some 16th-century writers excluded certain instruments from this classification; the musical theorist Ludovico Zacconi (1555–1627) went so far as to exclude all percussion instruments and established a fourfold division of his own—wind, keyed, bowed, and plucked. A different fourfold classification was accepted by Hindus at least as early as the 1st century BC: they recognized stringed instruments, wind instruments, percussion instruments of wood or metal, and percussion instruments with skin heads (*i.e.*, drums). This ancient system—based on the material producing sound—was adopted by the Belgian instrument maker and acoustician Victor-Charles Mahillon (1841–1924), who named his four main classes autophones, or instruments made of a sonorous material that vibrates to produce sound (*e.g.*, bells, rattles); membranophones, in which a stretched skin is caused to vibrate (*e.g.*, drums); aerophones, in which the sound is produced by a vibrating column of air (wind instruments); and chordophones, or stringed instruments. In their highly influential studies of musical instruments, the Austrian musicologist Erich von Hornbostel (1877–1935) and his German colleague Curt Sachs (1881–1959) accepted and expanded Mahillon's basic division, creating the classification now used in most systematic studies of instruments. The name idiophones was substituted for autophones, and each class was subdivided according to a method similar to that used by botanists. A fifth class, electrophones, in which vibration is produced by oscillating electric circuits, was added later. The table gives examples of instruments that fall within the various categories.

Sachs-Hornbostel system of classification

Classification and Examples of Some Musical Instruments

Idiophones	
Struck	
against each other	cymbals, castanets
with a beater	triangle, glockenspiel, xylophone, slit drums
Shaken	rattle, jingles
Scraped	scraper
Plucked	Jew's harp, music box
Rubbed	musical glasses
Membranophones	
Struck	side drum, bass drum, timpani
Rubbed	friction drum
Blown	mirliton (or kazoo)
Chordophones	
Zithers	
plucked	harpsichord
struck	hammered dulcimer, piano
Lutes	
plucked	lute, guitar
bowed	violin, viola da gamba
Lyres	
plucked	Greek kithara, Ethiopian *beganna*
bowed	Welsh crwth
Harp	Celtic small harp, orchestral chromatic harp
Aerophones	
Free (air not confined)	
without keyboard	bull-roarer, harmonica
with keyboard	harmonium, melodeon
Flutes (air blown against an edge)	recorder, flute
Reedpipes	
single reed	clarinet, saxophone
double reed	shawm, crumhorn, oboe, bassoon, sarrusophone
Lipped	horn, cornet, trumpet, trombone, tuba, serpent
Electrophones	
Monophonic (producing a single line of melody)	theremin, trautonium, Ondes Martenot
Polyphonic (producing harmony and simultaneous melodic lines)	many synthesizers

Many instruments can be played using more than one system of tone production and hence might reasonably appear in several subcategories. The double bass, for example, is usually considered a chordophone whose strings may be bowed or plucked; sometimes, however, the body of the instrument is slapped or struck, placing the double bass among the idiophones. The tambourine is a membranophone insofar as it has a skin head which is struck; but, if it is only shaken so that its jingles sound, it should be classed as an idiophone, for in this operation the skin head is irrelevant. Open flue stops are the foundation of organ tone, but the instrument also has a number of free reed stops, so that the organ belongs equally to the first and second order of aerophones. Modern composers not infrequently require players to treat their instruments in unorthodox ways, thus changing their position in the classification system.

It must be understood that the Sachs-Hornbostel system was created for the purpose of bringing order to the massive collections of musical instruments in ethnographic museums. It is directly analogous to the various book classification systems of libraries and, like them, is arbitrary. Musicians themselves generally think of instruments in terms of their technological features and playing method. To them, therefore, it is logical to group keyboard instruments together, ignoring the fact that in the Sachs-Hornbostel system such instruments fit into several categories.

HISTORY AND EVOLUTION

Man has speculated about the origin of instruments since antiquity. Older writers were generally content to rely on mythology or legends. In the 19th century, partly as a result of theories of evolution put forward by Darwin and Herbert Spencer, new chronologies based on anthropological evidence were advanced. The British writer John Frederick Rowbotham argued that there was originally a drum stage, followed by a pipe stage, and finally a lyre stage. The Austrian writer Richard Wallaschek, on the other hand, maintained that, although rhythm was the primal element, the pipe came first, followed by song, and the drum last. Sachs based his chronology on archaeological excavation and the geographic distribution of the instruments found in them. Following this method, he established three main strata. The first stratum, which is found all over the world, consists of simple idiophones and aerophones; the second stratum, less widely distributed, adds drums and simple stringed instruments; the third, occurring only in certain areas, adds xylophones, drumsticks, and more complex flutes.

Chronologies of origin

The development of musical instruments among ancient high civilizations in Asia, North Africa, and the Mediterranean appears to have emphasized stringed instruments. In Central and South America, wind and struck instruments seem to have been most important. It is not always easy to say whether instruments are indigenous to a particular area, however, since their cultivation may well have spread from one country to another through trade or migration. Nevertheless, it is known that the harp was used from early times in Mesopotamia, Egypt, and India and was imported into China after the end of the 4th century AD. In Greece it was regarded as a foreign instrument: the standard plucked instrument was the lyre, known in its fully developed form as the kithara (or cithara). Apart from the trumpet, the only wind instrument in normal use in Greece was the aulos, a double-reed instrument akin to the modern oboe. The Egyptians used wind instruments not only with double reeds but also with single reeds and thus may be said to have anticipated the clarinet. Peculiar to China was the *sheng,* or mouth organ; the Chinese also used as an artistic instrument the panpipes (*hsiao*), which in Greece had merely a rustic function.

In medieval Europe, many instruments came from Asia, having been transmitted through Byzantium, Spain, or eastern Europe. Perhaps the most notable development in western Europe was the practice, originating apparently in the 15th century, of building instruments in families, from the smallest to the largest size. A typical family was that of the shawms, which were powerful double-reed instruments. A distinction was made between *haut* (loud) and *bas* (soft) instruments, the former being suitable for performance out-of-doors and the latter for more intimate occasions. Hence, the shawm came to be known as the hautbois (loud wood), and this name was transferred to its more delicately toned descendant, the 17th-century oboe. By the beginning of the 17th century the German musical writer and composer Michael Praetorius, in his *Syntagma Musicum* ("Musical Treatise"), was able to give a detailed account of families of instruments of all kinds—recorders, flutes, shawms, trombones, viols, and violins.

Percussion instruments. Drum ensembles have achieved extraordinary sophistication in Africa, and the small handbeaten drum is of great musical significance in western Asia and India. The native cultures of the Americas have always made extensive use of drums, as well as other struck and shaken instruments. In Southeast Asia and parts of Africa, xylophones and, since the introduction of metals, their cousins the metallophones play significant roles. Europe, however, has not placed great emphasis on drums and other percussion instruments.

Stringed instruments. Many varieties of plucked instruments were found in Europe during the Middle Ages and the Renaissance; but bowed instruments eventually came to characterize the area, and they played an important role in the rest of Eurasia and in North Africa as well. The idea of playing a stringed instrument with a bow may have originated with the horse cultures of Central Asia, perhaps in the 9th century AD. The technique then spread rapidly over most of the European landmass.

Origin of viols and violins

The European fiddle existed in various forms: by the 16th century these had settled down into two distinct types—the viol, known in Italy as viola da gamba (leg fiddle), and the violin, or viola da braccio (arm fiddle). The viol has a flat back, sloping shoulders, and six or seven strings; the violin has a rounded back, rounded shoulders, and four strings. The viol, unlike the violin, has frets—pieces of gut wound at intervals around the fingerboard—which make every stopped note (*i.e.,* the string being pressed by the finger to produce a higher pitch) sound like an open (unstopped) string. The violin, being the smallest member of the family, came to be known by the diminutive violino: the tenor of the family was called simply viola, while the bass acquired the name violoncello, a diminutive of violone ("big fiddle").

Keyboard instruments. Only in Europe did the keyboard develop—for reasons that are not clear. The principle of the keyboard has been used successfully to control bells (the carillon), plucked and struck stringed instruments (the piano and harpsichord), and wind instruments (the organ, the accordion, and the harmonium).

Of all instruments, the organ showed the most remarkable development from the early Middle Ages to the 17th century. Originally, sound was admitted to the pipes by withdrawing sliders or depressing levers. Both of these methods were clumsy: they gave way to a reduction in the size of the levers, which eventually could be depressed by the fingers, while the larger pipes were controlled by pedals. A further development was to separate the various rows of pipes, so that each row could be brought into action or suppressed by means of a draw stop. Once a manageable keyboard had been produced, it could be applied to the portable organ, carried by the player, which was already in use by the 12th century. Scientific experiments with the monochord, a stretched string that could be divided into various lengths by means of a metal tangent, were followed by the construction of an instrument with a whole range of strings and a keyboard similar to that of the organ—the clavichord. A similar adaptation of the plucking of stringed instruments led to the harpsichord, the ingenious mechanism of which had been perfected by the 16th century. It is curious that a similar method was not applied to the dulcimer, which was struck with hammers, until the early 18th century, when the Italian maker Bartolomeo Cristofori constructed the first pianoforte, so-called because, unlike the harpsichord, it could vary the tone from soft (*piano*) to loud (*forte*).

The clavichord, harpsichord, and piano

Wind instruments. In Europe, the practice of constructing instruments in families continued from the 17th century onward. English composers wrote for the tenor

hautbois, the intermediate oboe d'amore, and the bass, or baritone, oboe. The clarinet (the name means "little trumpet") emerged at the end of the 17th century and, like the oboe, developed into a family extending to a contrabass clarinet in the 19th century and later a subcontrabass. It established itself only gradually in the orchestra in the course of the 18th century.

Trumpets and horns were used in most areas of Eurasia for ceremonial and military purposes. They remained relatively unchanged until the early 19th century, when valves were added to European instruments. This modification also led to the creation of new types. A pioneer in the field was the Belgian instrument maker Antoine Joseph Sax, who in 1845 built a family of valve instruments called saxhorns, using the bugle as the basis for his invention. Similar instruments were widely adopted in military and brass bands, but only the bass, under the name bass tuba, became a normal member of the orchestra. Sax also invented the saxophone, a single-reed instrument like the clarinet but with a conical tube. This, too, was made in various sizes, which came to be used both in military bands and in jazz ensembles. The saxophone never became a normal member of the orchestra, but the alto and the tenor have been used by composers, largely as solo instruments, and occasionally a complete quartet of four different sizes has appeared in an orchestral work.

Use of instruments based on volume of sound

Ensembles. The variety of musical ensembles used throughout the world is vast and beyond description, but the following principles apply nearly everywhere. Outdoor music, often ceremonial, most frequently involves the use of loud wind instruments and drums. Indoor music, for passive listening, emphasizes such quieter instruments as bowed and plucked strings and flutes.

The establishment of orchestras, as opposed to chamber groups, in the early 17th century led to a slight revision of these principles in Europe. The orchestra's sound is founded on a large ensemble of bowed strings, but it adds the once-outdoor instruments (wind and percussion) for colour and climax. As concert halls increased in size and popularity, so too did the sound-volume requirements of so-called indoor instruments. One result was that the violin family was favoured at the expense of the quieter viols. The latter, along with other instruments whose tone was too weak for orchestral music, gradually dropped out of use until the 20th century, when earlier styles of music experienced a revival in popularity.

Automatic instruments. Water power, clockwork, steam, and electricity have all been used at various times to "power" musical instruments, enabling them to produce sound automatically. Examples include church bells, automatic organs, musical clocks, automatic pianos and harpsichords, music boxes, calliopes, and even automatic orchestras. Most of the impetus behind this phenomenon ceased with the development of the phonograph and other recording devices of the 20th century.

Electric and electronic instruments. The development of electricity led not only to its use for mechanical purposes—for example, to control the key action and wind flow in the organ—but also as a means of amplification (*e.g.*, in the vibraphone). With advances in electronics technology, players can now also make use of computers to generate and store tones and musical patterns. The growth of companies manufacturing electronic and digital instruments has been rapid, and the use of electronic equipment such as sound synthesizers and tape recorders to produce and combine sound unrelated to the musical scale has become common. (J.A.W./T.Gr.)

Percussion instruments

CLASSIFICATION

Two distinct groups of musical instruments, namely, idiophones and membranophones, make up the large classification known as percussion instruments. Idiophones are instruments whose own substance vibrates to produce sound (as opposed to the strings of a guitar or the air column of a flute); examples include bells, clappers, and rattles. Membranophones emit sound by the vibration of a stretched membrane; the prime examples are drums. Although many idiophones and some membranophones are tunable and hence may be melody instruments, both groups serve typically to delineate or emphasize rhythm. Percussion instruments form the third section of the modern Western orchestra, stringed and wind instruments making up the other two sections. The term percussion instruments dates to 1619, when Michael Praetorius wrote of *percussa, klopfende Instrument* (German *klopfen*, "to beat") as any struck instrument, including struck chordophones (stringed instruments). The same combination, including pre-bow chordophones, constituted the *divisio rhythmica* in the 7th-century *Etymologiae* of Isidore, archbishop of Seville.

Types of idiophones

Idiophones. Idiophones form a diverse and disparate group. Concussion instruments, consisting of two similar components struck together, include clappers, concussion stones, castanets, and cymbals. Percussion idiophones, instruments struck by a nonsonorous striker, form a large subgroup, including triangles and simple percussion sticks; percussion beams, such as the *semanterion;* percussion disks and plaques, single and in sets; xylophones, lithophones (sonorous stones), and metallophones (sets of tuned metal bars); percussion tubes, such as stamping tubes, slit drums, and tubular chimes; and percussion vessels varying from struck gourds and pots to gongs, kettle gongs, steel drums, bells, and musical cups.

Shaken idiophones, or rattles, include vessels filled with rattling material, such as pellet bells and gourd, basketry, and hollow-ring rattles; strung rattles, such as dancers' leg rattles or anklets; stick rattles, including the sistrum, originally a forked stick with crossbars on which rattling shells, etc., were strung; pendant rattles with suspended rattling objects; and sliding rattles.

Other categories include scraped idiophones, comprising scrapers and cog rattles; split idiophones made of split hollow cane, including the Southeast Asian "tuning fork" idiophones and the chopstick; plucked idiophones, or linguaphones (so named because of their plucked tongues), such as the Jew's harp, sansa, and music box; friction idiophones, including friction sticks, simple or combined, and musical glasses; and blown idiophones, such as the 19th-century *Aolsklavier* and *piano chanteur.*

Membranophones. Musical instruments in which the sound-producing medium is a vibrating membrane fall into four main groups: kettledrums and bowl-shaped drums; tubular drums—whether cylindrical, barrel, conical, double conical, hourglass, goblet, or shallow—and rattle drums, the membranes of which are set in motion by enclosed pellets or by knotted ends of a thong or cord; friction drums, with membranes caused to vibrate by friction; and mirlitons, whose membranes are set in motion by the sound of an instrument or the human voice. Strictly speaking, mirlitons are voice modifiers rather than true musical instruments inasmuch as they have no pitch of their own.

Kettledrums and tubular drums occur in both tunable and nontunable forms; friction drums and mirlitons are not tunable. The membranes of the first two groups are either glued, nailed, lapped, or laced to the body, or shell; if they are glued or nailed, the pitch can be modified by exposure to heat. Lapped and laced heads are readily tunable by tightening the lacings or screws, and wooden wedges may be inserted between the shell and lacings to further increase the membrane's tension and thus raise the pitch. The membranes of such instruments and of friction drums are set in vibration by percussion, while those of mirlitons vibrate by impact of sound waves. In all groups the shell plays a subordinate acoustical part, acting as resonator only. The greater the diameter of a head, the deeper is its sound; and the greater its tension, the higher is the pitch. In Western culture the only drums tuned to a definite pitch are kettledrums (the orchestral timpani).

Methods of sounding membranophones

Kettledrums and tubular drums may be struck with the hands, with beaters, or with both combined or with the knotted ends of a thong or cord. Beaters can be cylindrical, club-shaped, straight, curved, or angled, with or without knobs or padding, or may take the form of a switch or wire brush. Friction drums are sounded by rubbing the membrane with a piece of hide or by the more usual

method of working an inserted friction stick or cord up and down or by rubbing the membrane with a player's wet fingers. Acoustically, they are subject to the same laws as other membranophones, but the speed of friction is an influencing factor. They occur in Africa, America, Europe, Asia (India and Japan), and Hawaii. Mirlitons are sounded by directing against the membrane the vibrating air column of a voice, be it human (as in a kazoo) or instrumental (as when affixed, for example, to African xylophone resonators), or by holding the membrane against the player's vibrating vocal cords.

In addition to the four major categories of membranophones, a small group of "predrums" composed of ground drums and pot drums, can also be distinguished. Ground drums, consisting in their simplest form of an animal skin stretched over the opening of a pit, are still found in many parts of the world. The skin may also be held taut by several players, each beating it with a stick. These and similar ground drums are played by women in Africa and Australia, and in North America usually by men. By their very nature ground drums are nonportable; when need arose for a smaller "drum," a skin was stretched over the opening of a gourd, clay pot, or other object. Among the Swazi of South Africa such skins are not attached but held taut. Pot drums are found in Asia, Africa, and America—in Africa and America often in connection with exorcism.

PERCUSSION INSTRUMENTS IN EUROPE

Antiquity. Europe received most of its percussion instruments either directly or indirectly from the sophisticated cultures of the ancient Middle East or from Egypt, a country regarded by the Greeks and Romans as forming part of Asia rather than Africa.

Idiophones. European antiquity knew many idiophones. Dancers' clappers, held pairwise in the hands of maenads (women participants in Dionysian rites) and other female dancers, often stressed the rhythm of accompanying *auloi* (the ancient Greek reed pipes). The time-beating foot clappers of chorus leaders, attached to the right foot like a sandal, were known in Greece as *kroupezai,* or *kroupala,* and adopted by Rome as the *scabella.* Other idiophones included bells, cymbals, the unidentified *ēcheion,* and an instrument simply called "the bronze" (*chalkos*), probably a metal percussion disk. When the cult of Isis spread to Greece and Rome, her sistrum followed, always in the hands of a priest or—rarely—priestess.

Roles of instruments

With the exception of clappers, all these instruments were of bronze; as such they were credited with the apotropaic powers (the special protective powers against evil) accorded this metal in the East. For example, both in various Asian islands and in Greece it was customary to "sound the *chalkos* at eclipses of the Moon because it has power to purify and to drive off pollutions" (a scholiast, writing on Theocritus). According to the Roman poet Ovid, the annual visit of ghosts of the dead to their former homes was terminated by requests to depart emphasized by the clanging of a bronze plate. The thin, bronze percussion disks were affixed to metal handles; one from Pompeii is even garnished with pellet bells. Small bronze bells, which made a clanging rather than ringing sound, warded off evil spirits, averted the evil eye, served as sentinels' and watchmen's signal instruments, or were attached to the handle of a Greek warrior's shield in order to terrify the enemy by their clamour. Small bells were also frequently worn on anklets by jesters, dancers, and courtesans, particularly in Hellenistic times. In Rome, *tintinnabulae* ("bells") served as signal instruments or were suspended from the necks of herd animals—again to ward off evil.

Deeply cupped cymbals, played together with a frame drum, were sounded in religious rites and at secular dances. Forked cymbals known as *crotala* traveled from Egypt to Greece and Rome, and finger cymbals were introduced from the East, chiefly for dancers, a pair being attached to thumb and middle finger of each hand.

Among the oldest instruments of mankind, rattles originally combined the functions of prophylactic amulets and children's toys, and both functions continued to coexist as late as Roman times.

Membranophones. Only a few kinds of drum, none indigenous, were known to antiquity. The frame drum came from Mesopotamia at an early date. The barrel drum was possibly known in Hellenistic times, for it appears in the Greco-Indian culture of Kushān. A shallow drum is depicted on a Greco-Scythian metal *gorytus,* or bow and arrow case, of the 4th century BC, but no evidence exists of its having been known to Greece. Frame drums, traditionally women's instruments in the Middle East, remained in the hands of female players and dancers in Greece, and the Eastern playing technique was maintained: held upright on edge in the palm of one hand, the drum was tapped with the fingers of the other. Probably introduced into Greece in the 6th century BC with the cult of the great mother-goddess Cybele, the frame drum is depicted as being played by maenads and was also a cult instrument in rites of the Orphic religion. From Greece the frame drum passed into Rome, where it was also associated with Cybele. Romans also had double-headed drums and spread them as far north as the Isle of Wight, in Britain, where one is represented on a mosaic pavement as a dancing girl's instrument. In the late days of the Roman Empire, frame drums became instruments of street musicians and *joculatores* (professional entertainers); the latter are probably responsible for spreading them beyond the Italian Peninsula.

The frame drum

The Middle Ages. *Idiophones.* Greek and Roman idiophones were passed on to postclassical Europe, their distribution undoubtedly aided by *joculatores* and civic or court musicians (minstrels). Whereas prior to the adoption of Christianity most were ritual instruments, their function in medieval times—with the notable exception of the bell—was strictly secular.

Clappers (*tabulae*), flat pieces of bone or wood, were used to flush out birds for hunting and to provide rhythm for popular dancing. Lepers also sounded them to warn others of their approach.

Dancers' castanets, hollow clappers in bivalve form, were played in Spain throughout the Middle Ages; they are illustrated from the 11th century on. Already in Roman times, dancers of Cádiz are known to have played metal castanets, but those of sonorous hardwoods have been preferred since. They are mentioned in the *Cantigas de Santa Maria* by Alfonso X (The Wise). Cymbals remained virtually unchanged throughout the medieval period, resembling closely those used by the Greeks and Romans. Probably cast rather than spun, they were held horizontally, one above the other. Small, cup-shaped cymbals called *acetabulae,* made of brass or silver, are mentioned by Cassiodorus (d. *c.* 580) and Isidore of Seville. Although the modern practice of striking a single cymbal with a stick was anticipated by Isidore and by the *Suda* lexicon (late 10th century), larger cymbals continued to be played pairwise and—at least in the later Middle Ages—were found among the "loud" instruments that accompanied dancing and were played at seigneurial festivities.

Bells were still thought to possess apotropaic powers; with their adoption, the Christian church took over the belief that ghosts and demons could be put to flight by the sound of metal, a power henceforth augmented by the protection afforded by association with the divine cult and, more specifically, by baptism. The rite of baptizing bells is first recorded in a capitulary (civil ordinance) of Charlemagne of 789. Exorcizing celebrants sounded handbells or wore bells on their garments. St. John Chrysostom (d. 407) felt compelled to protest the custom of attaching bells to the clothing or bracelets of children in order to preserve them against demons, yet small bells or pellet bells continued to adorn the vestments of priests, a practice inherited from the ancient Middle East (51 bells ornamented the cope of Lanfranc, an 11th-century archbishop of Canterbury). The tolling of passing bells was intended to ward off evil spirits from dying persons. Church bells announced the time of day, summoned the faithful to worship, sounded alarms, fought off lightning, broadcast the news of peace or the birth of a princeling, and praised God. In secular life handbells were played in mixed instrumental ensembles, usually one bell in each of the player's hands.

Symbolic importance of bells

Tuned bells strung together to form chimes were the

most highly regarded percussion instruments of the Middle Ages. They appear frequently in manuscript illuminations from the 10th century onward, particularly associated with representations of King David. Chimes are generally shown in groups of from four to nine as clapperless, hemispheric bells struck on the outside by a hammer. According to the monk Theophilus (12th century), their pitch was determined by the thickness of the casting rather than the size. From the 13th century, thanks to the wholesale adoption of Islāmic techniques for making astronomical hardware and automata, linkwork, and gearing, chimes were connected to clockwork and struck mechanically. As bells grew larger and the compass of the chime was extended, it became known as a carillon. The distinction today is merely one of compass, any set exceeding $1\frac{1}{2}$ or 2 octaves in compass being considered a carillon.

In secular life, pellet bells were suspended from ladies' belts or worn by jesters. During the 15th century in particular, dancers of the popular moriscas, or Morris dances, attached small bells to their hose.

Before the introduction of bells in the Greek Orthodox church in the 11th century, the *semanterion,* a percussion beam sounded by a striker, summoned the congregation, and in the Roman Catholic church it has been used as a substitute for bells during Holy Week. Triangles first appear in the 14th century; originally a number of loose, rattling rings were threaded on the lower portion, as though the ancient sistrum had projected itself through the centuries. Scraped idiophones, known in Europe since Paleolithic times, are encountered as scraped pots intermittently from the 12th century on; such noisemakers were played—to judge by a 14th-century miniature—with other percussive instruments, such as jingle-rings and pellet bells, for merrymaking. Few instruments are as suitable for personal music making as the Jew's harp; coming from Asia, it passed through Rome, but there is no evidence of its presence in the West before the mid-14th century, although it is unlikely to have disappeared completely during the intervening centuries.

Noise-making and musical improvisation

Most of the above idiophones are nontonal; with the exception of bells and percussion beams, they form part of the *musica irregularis* decried by writers such as the German organologist Sebastian Virdung in 1511 and as such were restricted to popular entertainment or signaling. Written music of this period does not help to determine whether, or how, idiophones were played with voices or with other instruments.

Membranophones. Frame drums, possibly introduced into medieval Europe through Spain, were popular from the era of the Crusades. The most common form was the tambourine, or timbrel, a single head on a shallow body, furnished with four or more sets of jingles placed equidistantly around its rim. Pictorial sources show the instrument being played by both males and females, particularly for accompanying the voice. Literary evidence supports this as well, and in the 14th century Boccaccio writes of it as accompanying singing, too. Jingle rings and pellet bells were also found during this era in popular music making.

Double-headed drums served to provide rhythmic accompaniment in the Middle Ages; and in the 7th century is found the first evidence of their being played with drumsticks, a technique adopted from Asia. The small, rope-strung cylinder drum known as the tabor entered western Europe during the Crusades; the earliest known pictorial evidence is a 12th-century English illumination showing a *jongleur* disguised as a bear striking a barrel drum suspended from his neck. Varied in size and depth, the tabor was provided with a snare (material such as gut stretched across the head to produce a rattling sound) and struck with a stick. Played together with the three-holed pipe, it formed a lively one-man band and was found in both aristocratic and popular circles as an accompaniment for the dance. The larger double-headed cylindrical, or long, drum was associated with the military. Slung at an angle to the player's left, it was played with two sticks and was popularized by Swiss mercenary troops serving in European armies from the 15th century.

The naker

The naker (*naqqārah*), a small kettledrum of Arabic or Saracenic origin, was made of clay, wood, leather, or metal. It was shaped like a kitchen mixing bowl with a diameter ranging from 15 to 25 centimetres. Carried in pairs at the player's waist by means of a belt or harness, each tuned to different indistinct pitches, nakers were played with two short wooden sticks. The skin was tensioned by means of a lattice of ropes, which could be tightened or loosened. Nakers spread rapidly throughout Europe during the 12th and 13th centuries. They are mentioned in epic poems of the time, and records indicate that almost every court employed a nakerer among its regular stable of musicians.

Larger kettledrums were known for some time to the crusaders, merchants, and other travelers to the Middle East, but it was not until the 15th century that the instrument, mounted in pairs on horseback, found its way into western Europe. They created a sensation in 1457 when a Hungarian embassy entered Paris; such "large cauldrons" had never before been seen, and the horses pranced to the rhythm of the drums. The skins, mounted on rims attached to the instrument by screws, could be tensioned precisely, thus producing true musical notes. Henceforth, following Eastern custom, kettledrums were associated with nobility as an adjunct to pomp and circumstance and a symbol of power and prestige.

The less common friction drum first appears in the late 12th-century sculpture of the archbishop's palace at Santiago de Compostela, in Spain, complete with friction rod. Although it undoubtedly continued to be used, it is not known to be either pictured or mentioned again until the 17th century.

The Renaissance, Baroque, and Classical periods. *Idiophones.* Additional idiophones came into use from the Renaissance on. The xylophone, long widespread throughout Asia and Africa, was illustrated in 1529 by Martin Agricola. In 1618 Praetorius depicted an instrument with 15 bars from 6 to 21 inches (15 to 53 centimetres) in length, tuned diatonically. It remained little exploited until the Flemish carillonneurs combined it with a keyboard and transformed it into a practice instrument in the first half of the 17th century. The older form remained a folk instrument, chiefly in and east of Germany.

Gongs were always considered alien instruments: although the word gong was known in the 16th century, its use is not further recorded until the late 18th century. It was first employed in orchestral music by the French composer François-Joseph Gossec in 1791. Since then, gongs of indefinite pitch have been included in orchestral scores by Giacomo Meyerbeer, Tchaikovsky, and others for arresting effect. For generations both flat and bossed (knobbed) gongs also performed the lowly task of summoning the family to meals.

Cymbals were apparently forgotten during the Renaissance; they reappear in the German composer Nicolaus Adam Strungk's opera *Esther* (1680) to provide local colour but seem not to have been in general use until the craze for Turkish Janissary music gripped Europe a century later. Gluck used cymbals in *Iphigénie en Tauride* (1779), as did Mozart in *Die Entführung aus dem Serail* (*The Abduction from the Seraglio,* 1782) and Haydn in his Symphony No. 100 (*Military Symphony*) some 11 years later. By the time of Beethoven they had acquired a permanent place in the orchestra.

Bells grew larger until the largest ever produced, the Tsar Kolokol III (Emperor Bell III; 1733–35) of Moscow, weighing about 400,000 pounds (180,000 kilograms), proved too cumbersome and heavy for hanging. The hemispheric form was abandoned early as chimes became larger, culminating in tower-borne carillons brought into existence by progress in casting methods and mechanization. Chime bells were connected to town clocks and then hung in separate bell towers, along with a mechanism of external hammers—Chinese in origin—for hitting the bells. Carillons in the Low Countries and northern France had in addition one of the first examples of the stored program. A large wooden barrel or metal cylinder revolved by weight and pulley, furnished with appropriately placed iron pegs indicating the melody; the pegs activated the levers and jack work releasing the hammers that struck the bells. Chorale preludes, hymns, and popular melodies

Carillons

announced the time of day in European carillons, while in Britain, short chime sequences activated by a clock fulfilled the same role. In addition, British tower bells could be rung in "changes"—a series of mathematical permutations—on bells hung dead. The role of small bells became negligible, although handbell ringing was (and still is) a hobby in England.

Metallophones reached northern Europe from Indonesia in the second half of the 17th century and, like the xylophones, were promptly adopted by carillonneurs. In both the Low Countries and the regions to which such instruments spread from there, steel was the metal employed for bars. A specially constructed instrument with keyboard-activated hammers was employed by Handel in 1739 in his oratorio *Saul* and in his revival of *Acis and Galatea* (1718); another, struck with a beater, is found in Mozart's *Die Zauberflöte* (*The Magic Flute,* 1791).

Plucked idiophones became more important after the Middle Ages. Jew's harps were part of the regular stock-in-trade of instrument dealers in the 16th and 17th centuries, and in the mid-18th century the playing of multiple Jew's harps is mentioned. Several of these little instruments combined in a single frame were played by virtuosos in the late 18th and 19th centuries and enjoyed enormous popularity. Miniaturization of musical clocks resulted in the creation of the music box, a linguaphone provided with a metal-comb mechanism made from about 1770 on, chiefly in Switzerland. In its heyday—1810 to 1910—it was an immensely popular household instrument with a repertoire of opera arias, folk songs, popular tunes of the day, and waltzes (after the mid-century). In the late 19th century it was transformed into a free-reed wind instrument (aerophone) by the substitution of free reeds for the metal comb, but both forms were rendered obsolete by the phonograph.

Experimental instruments

During the 18th century several friction idiophones were introduced, among them the nail violin of Johann Wilde (*c.* 1740), with its tuned nails bowed by a violin bow. More characteristic of the period were the friction-bar instruments arising as a result of the German acoustician Ernst Chladni's late 18th-century experiments, particularly those concerned with the transmission of vibrations by friction. Chladni's own instrument, the euphone of 1790, and the aiuton of Charles Claggett of about the same time were first in a series of models, some with piano keyboard and horizontal friction cylinder or cone acting on upright bars and others with bars stroked by the player's fingers or bowed by a continuous bow.

Musical glasses are considerably older: the tuned metal cups or bowls of Asia (sometimes played in India as friction vessels) were transformed in Europe into tuned glasses and are first seen in the *Musica theoretica* (1492) of the Italian musical theorist Franchino Gafori. One hears of them intermittently thereafter until they come to the fore in the mid-18th century as concert instruments. The rims of glasses of graduated sizes containing enough water to tune them were rubbed by the player's moistened fingers. By the 1760s they had attracted the attention of the American scientist and philosopher Benjamin Franklin, who proceeded to convert them into a more efficient and, above all, a polyphonic (many-voiced) instrument, which he called armonica—now known as the glass harmonica. Its popularity was immediate. Mozart's *Adagio und Rondo* K 617 was written for it, as was his *Adagio für Harmonika* K 356, both performed in 1791. Efforts to combine it with a keyboard enjoyed only a passing vogue. Among the last to write for it was the French composer Hector Berlioz in his *Fantasia on The Tempest* of 1830; a decade later it was replaced by the growing family of free reeds.

Membranophones. By the Renaissance, Europe had a variety of drums performing specialized functions: frame drums and small tabors accompanied dance and song; larger tabors served as time beaters in small mixed ensembles; great cylinder drums with fifes were placed at the disposal of foot troops; large kettledrums and trumpets were restricted to cavalry and ceremonial music of the aristocracy. The music was at first improvised; later both outdoor carousel music and indoor polychoral sacred music were written for one or two pairs of instruments, sometimes in two contrasting ensembles or choirs—for example, Johann Heinrich Schmelzer's *Arie per il balletto a cavallo* (1667).

Kettle-drums

Kettledrums were introduced into the orchestra about 1675–90 by Jean-Baptiste Lully in *Thésée* and by Henry Purcell in his *Ode for St. Cecilia's Day.* With the development of new playing techniques, modified drumstick heads, and the possibility of notating their music (hitherto prohibited by the rules of secrecy imposed upon guild members), kettledrums, henceforth called timpani, triumphantly entered orchestra, opera, and church, soon becoming the most important percussion instrument in the orchestra. J.S. Bach included a timpani solo in his Cantata No. 214 (*Tönet, ihr Pauken!*) and again in his *Christmas Oratorio* (1735). Haydn also wrote significant parts for the instrument. It was Beethoven, however, who liberated the drums from merely rhythmic functions and their conventional tunings; he was also one of the first to write chords for the instrument.

The snare drum remained primarily a military instrument, although Handel used it in his *Musick for the Royal Fireworks* (1749) and Christoph Gluck wrote for it in his opera *Iphigénie en Tauride* (1779). The bass, or "Turkish," drum was rare in Europe until the craze for Janissary music in the later 18th century; it was found in Gluck's *Le Cadi dupé* (1761), Mozart's *Die Entführung aus dem Serail,* and Haydn's *Military Symphony.*

The northern frame drum, or tambourine, was given the status of a salon instrument by 18th-century French society, and, combined with harp or keyboard instrument, it could be heard at fashionable soirees.

Friction drums maintained an existence (and still do to this day) in various parts of Europe, where they were played at Christmas, during the carnival season, or to greet the New Year.

Developments after 1800. In general, until the early 19th century, the trend in Western musical culture had been to make diminishing use of nontonal percussion instruments. Those that succeeded in gaining access to the orchestra were used sparingly, often only as special effects or indications of local colour. By the mid-20th century, this trend had been reversed, especially in popular music, in which percussion instruments, both traditional and alien, play a basic part. Castanets, for example, either clicked together rhythmically or in sustained rolls, had been little more than dancers' instruments since the 16th century. Wagner was probably the first major composer to use them, in the Paris version of his opera *Tannhäuser* (1861); 14 years later Bizet employed them with great effect in his opera *Carmen.* Now, modern rhythm bands frequently include one or two single castanets or a pair attached to a long handle for ease in clicking.

On the other hand, tonal percussion instruments have assumed increasing importance. Those inherited from the Middle Ages, such as xylophones and Jew's harps, were expanded to the limit of their potential; others were imported and modified to meet local requirements. Influenced by the great popularity of the piano, keyboards were adapted to numerous 19th-century idiophones in an attempt to render hitherto monophonic (single-voiced) instruments polyphonic.

The 19th century. The 19th century saw a rise in the use of percussion instruments in orchestral music. For example, Berlioz called for 10 cymbals in his *Requiem* (1837), some struck together, others to be hit with various drumsticks. Tchaikovsky used syncopated cymbal crashes in his overture *Romeo and Juliet* (1870). The solo triangle appeared in Liszt's First Pianao Concerto(1849), and Wagner called for rolls or tremolos on the instrument in both *Die Walküre* (*The Valkyrie*) and *Die Meistersinger* (*The Mastersingers*). Saint-Saëns included a xylophone solo in his *Danse macabre* (1874). Among membranophones, the snare drum is given a solo in Rossini's overture to *La Gazza Ladra* (*The Thieving Magpie,* 1817), and Berlioz, Wagner, and Richard Strauss each made use of the tenor, or long, drum. The bass drum was employed by Beethoven in his Ninth Symphony (1824) and by Verdi, who asked for hard, loud blows in his *Requiem* (1874).

Several new instruments—or at least new versions—were

New instruments

introduced in the 19th century. The glockenspiel (from the German *Glockenspiel,* "bell chime") was originally a bell chime, as its name indicates. Its transformation into a metallophone was in response to the need for a portable instrument. For marching bands the bars were hung in a lyre-shaped frame; for symphony and opera orchestras—and today rhythm bands as well—a large, horizontal glockenspiel shaped like a xylophone is used. Graduated steel bars struck from a keyboard by piano hammers form the celesta, patented in 1886 by Auguste and Alphonse Mustel of Paris; Tchaikovsky used the celesta in his ballets *The Sleeping Beauty* (1890) and *The Nutcracker* (1892), and it is found in opera scores and light orchestral music as well. Late 18th-century experiments with graduated sets of tuning forks struck by hammers from a keyboard produced the 19th-century "tuning-fork pianos," the most noteworthy of which were different models of Victor Mustel of Paris from 1865 on. Tubular bells are European adaptations of Southeast Asian bamboo chimes. They started appearing as substitutes for traditional bells, which were both expensive and cumbersome, in the 19th century, first in the form of steel bars, then hollow bronze cylinders, and finally brass tubes struck with wooden mallets.

Mirlitons, with their ability of amplifying and colouring tone, had been known in Europe since at least the 16th century, but they did not gain popularity until the early 19th century. From 1883 on, a French toy maker named Bigot brought out a series called bigotphones, which were shaped like orchestral instruments. Popular in the mid-20th century was the tubular kazoo.

The importance of timpani in the orchestra became firmly established in the 19th century. Meyerbeer wrote a melodic solo for four timpani for his opera *Robert le Diable* (1831). Berlioz required 10 players on 16 drums in his *Requiem,* and Wagner used 2 players, each with a pair of drums, throughout his opera tetralogy *Der Ring des Nibelungen.* Russian composers often wrote for small kettledrums with high pitches. Pedal, or machine, drums, which allow players to make almost instantaneous pitch changes, were developed in the 1880s and were soon featured in the tone poems and operas of Richard Strauss and Vincent D'Indy's Second Symphony (1902).

Contemporary percussion

The 20th century. The exploitation of various and unusual tone colours and effects characterizes the use of percussion instruments in 20th-century music, classical and popular alike. Clappers, for example, have been used sparingly but to great effect in, among others, Richard Strauss's *Elektra* (1908), to simulate the cracking of a whip, and Mahler's Sixth Symphony (1904). Claves, of Cuban origin, consist of two cylindrical hardwood sticks and are found primarily in dance orchestras, but symphonic composers write for them as well (Edgard Varèse in *Ionisation* [1931] and Aaron Copland in his Third Symphony [1946]). Castanets are found in Richard Strauss's *Salome* (1905).

The xylophone appeared in Mahler's Sixth Symphony; it is also scored, in two different sizes, in Puccini's *Turandot* (1926). Alan Hovhaness called for a xylophone solo in his *Fantasy on Japanese Wood Prints* (1965). The marimba, a xylophone with metal resonating tubes suspended beneath its wooden bars, is featured in Darius Milhaud's *Concerto for Marimba and Vibraphone* (1947). The vibraphone is similar to a celesta but has motor-driven revolving vanes inside each resonator, giving it its unique pulsating tone. Since its development in the 1920s, it has found widespread use in jazz but is also heard increasingly in art music such as Alban Berg's *Lulu* (1934) and Michael Tippett's Third Symphony (1972). The glockenspiel is featured throughout the modern era, from Debussy's *La Mer* (1905) to Pierre Boulez's *Pli selon pli* (1962) and beyond. Tubular bells were employed effectively in Ernst von Dohnányi's *Variations on a Nursery Tune* (1914).

Rattles are used primarily in modern rhythm bands, but various types are found, for example, in Carl Orff's *Weihnachtsspiel* (1960) and Benjamin Britten's *The Prodigal Son* (1968). Scraped gourds are now part of the professional percussionist's equipment, and scrapers, in the form of blocks covered with sandpaper, are rubbed together in Morton Gould's *Latin-American Symphonette* (1941). Scrapers also survive today as carnival noisemakers.

Unusual playing techniques

Twentieth-century composers frequently call for instruments to be played in new and unusual ways. The gong, for example, is played on the rim with a triangle beater in Richard Strauss's *Die Frau ohne Schatten* (*The Woman Without a Shadow,* 1919), set in vibration by a violin bow in Krzysztof Penderecki's *Dimensions of Time and Silence* (1960), and lowered and raised into a tub of water after being struck in John Cage and Frank Harrison's *Double Music* (1941). Likewise, cymbals have been rubbed together in a circular motion in Bartók's *Second Rhapsody for Violin and Orchestra* (1944), played by drawing a cello bow over the edge in Arnold Schoenberg's *Five Orchestral Pieces* (1909), and placed on the heads of a pair of timpani in Arthur Bliss's *Meditations on a Theme of John Blow* (1955). In William Walton's *Façade* (1923) the triangle is used to strike a cymbal, while William Russell's *Fugue for Eight Percussion Instruments* (1933) requires three muffled triangles of different sizes. The tambourine is dropped on the floor in Stravinsky's *Petrushka* (1911), its jingles flicked in Walton's *Façade,* brushed in Constant Lambert's *The Rio Grande* (1927), and played without jingles in Manuel de Falla's *El retablo de maese Pedro* (1922).

Drumming in the 20th century in the West gained an important place outside its traditional preserves of orchestra and military band. Film and musical theatre scores are full of percussion, and their metamorphoses into symphonic suites by arrangers such as Robert Russell Bennett take optimum advantage of all percussion instruments. Both jazz ensembles, or combos, and experimental music have explored new fields. In the former, the drum, or trap, set—bass drum with foot-operated beater, snare drum, set of tom-toms (cylindrical drums graduated in size), and suspended cymbals—is treated as a solo instrument among its peers. The latter has been preoccupied with rhythmic stress and has exploited drum tones for their own sake. On a popular level, rhythm is stressed or punctuated, often by the clarity and opposing pitches of Latin-American drums. Consequently, both the role of the drum and playing techniques have become freer—in orchestral as well as popular music. The snare drum, for example, plays an important solo role in Ravel's *Boléro* (1928) and an unconventional improvisatory one in Carl Nielsen's Fifth Symphony (1922). Glissando passages on the timpani are found in Bartók's *Music for Strings, Percussion, and Celesta* (1936), and stepwise ascending and descending chromatic passages are used in Britten's *Nocturne* for tenor solo, seven obbligato instruments, and string orchestra (1958). Franco Donatoni's *Concerto for Strings, Brass, and Timpani* (1953) calls for the drum to be hit in the centre of the head, while other composers stipulate that it be struck on the head and rim simultaneously (a rim shot). Britten directed that the bass drum be hit with a snare-drum stick in *Peter Grimes* (1945), but soft wire brushes or other types of sticks may also be used, as in Harold Farberman's *Concerto for [Five] Timpani and Orchestra* (1962).

PERCUSSION INSTRUMENTS IN ASIA

Ritual, social, and musical uses of clappers

Idiophones. Still preserved today are actual clappers from ancient Egypt and from Sumer of about 3000 BC. Their use seems never to have died out. Copts still ritually strike clappers of a type that has probably been in existence since the 3rd or even 4th millennium BC. Modern Vietnam also retains clappers in its religious observances. On the Indian subcontinent circular wooden clappers are played by beggars and fakirs in some regions and are used as rhythm instruments in others. In East Asia they have a role in the theatre, as signal instruments, at funerals, or, as in the Ryukyu Islands, accompanying traditional dances. Castanets probably originated in ancient Phoenicia; they appear in Egypt in the 24th dynasty (*c.* 730–709 BC) and are typical dancers' instruments.

Cymbals are indigenous to Asia; ancient Assyria had a unique form, funnel-shaped with long necks serving as handles. Known in ancient Israel from about 1100 BC on, cymbals were the only permanent idiophones of the Temple orchestra. Egypt did not have true metal cymbals until the 24th dynasty. Today they remain in ritual use in northern India, Japan, Tibet, and Vietnam. They appeared

in the 5th century AD in India, where they are now also found at secular festivities. In China they play a prominent part in the theatre. Turkey, in contrast, has traditionally connected cymbals with military usage. In some parts of Southeast Asia their ancient metal-connected function of dispelling evil spirits still prevails.

Xylophones reach their highest development in Southeast Asia. They vary in form from the most primitive log type to the highly developed orchestral instruments found in Indonesia. Trough xylophones were depicted in Java in the 14th century but are not restricted to Southeast Asia; those of Japan, for instance, are rhythm rather than melody instruments, and in Myanmar (Burma) they are associated with royalty. Xylophones of the Indonesian gamelan, or percussion orchestra (and some mainland ensembles), have various complementary compasses.

Stone chimes (lithophones) of two types occur: oblong bars like xylophone keys resting horizontally, found in Vietnam only, and vertically suspended plaques. In China their generic name is *ch'ing;* there, single sculpted musical stones and also 16-stone chimes are suspended from ornate frames. Stones forming a chime, carved in a typical L-form and struck with a mallet on their larger portion, are very ancient; a chime of this form dating from the late Shang era (*c.* 1401–*c.* 1123 BC) was excavated at Anyang, in northeastern China. Both in China and in Korea, where the oldest chime goes back to the 14th century, the lithophone is a Confucian ritual instrument. Single stones and chimes are still in use in rural Annam (Vietnam).

Indonesia and Indochina have metallophones constructed like xylophones, of which they are indeed metal counterparts. But in China the *fang-hsiang* with its 16 bars is a metal imitation of the lithophone. Among important components of the gamelan is the *saron,* a trough metallophone depicted as early as about AD 800 on the Borobudur stupa (Buddhist monument), Java, and the frame metallophone *gender,* now usually supplied with tubular resonators, which has been known from the 12th century on. Introduced to China by a Turkic people in the 7th century, the horizontal type of metallophone reached Korea in the 12th century and is still occasionally played there. In Japan it is a Buddhist ritual instrument.

Slit-drums

The slit-drum is made by hollowing a log or wood block through a slit. Those of East Asia and Indonesia are of great antiquity and of a high degree of development. The Chinese *mu yü* (traditionally fish-shaped) is a Buddhist and Taoist ritual slit-drum. Its Korean and Japanese counterparts are likewise ritual time markers, while in Vietnam the slit-drum is both a temple and a watchmen's instrument. On Java slit-drums can be traced to the Hindu-Javanese period (1st–9th century AD). Small models are generally suspended vertically, whereas larger ones rest horizontally; some underscore dance rhythms, while others are signal instruments.

Southeast Asia is the home of tubular chimes; resonant, tuned bamboo tubes are united to form a chime in rural Annam and Java. In western Java up to 16 tubes are strung in ladder formation and suspended from a house or a tree and played with padded beaters.

Western Asia is believed to be the home of the gong, which reached China in the 6th century and Java by the 8th. Originally, it seems to have afforded protection against evil spirits, and even today the Iban people of Borneo beat gongs during a storm. Chinese gongs serve a whole gamut of purposes: as signal instruments of the army, as rhythm makers to accompany a song and, in the case of the bossless *lo,* as a Buddhist ritual instrument. In Japan the employment of the gong varies from temple to theatre to folk festival.

Gong chimes

In Indonesia and eastern Asia tuned gongs are united to form gong chimes. The Chinese upright *yung lo* is a Buddhist and Confucian cult chime and was formerly also played at court. The horizontal gong chimes of Indonesia (called *bonang* in Java) are outstanding components of Southeast Asian orchestras and have been known from the 10th or 11th century on. Frames of Thai gong chimes arch upward at both ends to form an upright semicircle. Ancient kettle gongs, products of Bronze Age culture, are found only in China, Indochina, and Indonesia. They are hung so that the striking surface is vertical and are struck in the centre of this surface (the head). Kettle gongs were cult instruments connected with rainmaking; those of the Dong Son culture area of northern Vietnam may be dated from the 5th to the 3rd centuries BC.

Bells of bronze dating from about 1000 BC have been excavated in India, from the 22nd dynasty (945–730) in Egypt, and from about 700 in Assyria. An intimate connection existed in ancient India between bell sound and mystic experience, and today a handbell is still rung in temple ceremonies in India and other areas of Buddhist influence. The Chinese differentiate between clapper bells (*ling*) and clapperless ones (*chung*); their temple bells, like those of Japan, are always of the *chung* type. Temple bells usually assume the form of chimes in China; one from the 6th century has 13 bells, but more modern chimes consist of 16 bells hung in two rows of a frame. In addition to metal bells of the high-culture domains, rural areas still use primitive wooden bells with single or multiple clappers.

The sistrum in its earliest form, that of a U, is seen in Sumer in the mid-3rd millennium BC, and a little later, about 2100/2000, a rectangular form appears in Horoztepe, Anatolia (modern Turkey). Egyptian sistrums are characterized by being closed at the top: the *sesheshet* was shaped like a temple, the *iba* like a closed horseshoe. Sacred to the Egyptian goddess Hathor, the *iba* was played only by women, and after Hathor's metamorphosis into Isis it remained sacred to Isis.

A sliding rattle called *angklung,* found only in Indonesia, consists of several tuned bamboo tubes with cut-back tongues, inserted into a frame; they slide back and forth when the frame is shaken.

Scraped idiophones are Confucian ritual instruments in East Asia. The "tiger" of China is a vessel scraper of wood with a series of notches cut along its back; known as early as the Chou dynasty (*c.* 1122–221 BC), it is scraped with a split bamboo stick. Split idiophones (made of hollow cane split between nodes) are slapped against the player's wrist or thigh in South China and Southeast Asia, producing a fixed-pitch buzz.

Jew's harps have idioglott tongues (cut from the same material as the frame) in Indonesia, while both idioglott and heteroglott (the tongue made separately and attached to the frame) forms occur in China and on the Indian subcontinent. More recent are those of metal having the outline of an onion. In the Philippines and some other areas Jew's harps are important adjuncts to courtship.

Musical cups

Musical cups, the forerunners of musical glasses, are depicted on the Borobudur stupa. The Indian *rastrarang* can be played either with small sticks by percussion or by rubbing wetted fingers along the rims—the cups do not contain water. But the *jaltarang,* also of India, makes use of water for fine tuning and for the playing of *gamakas* (ornaments) by carefully bringing the sticks into contact with the surface of the water. Similar musical cups are played in Japan in Buddhist temples and in the music of the Kabuki theatre.

Membranophones. Unlike the drums of Western musical tradition, those found in ancient (and parts of modern) Asia are primarily cult and ceremonial instruments. Most, if not all, Western drums are their descendants, and western Central Asia may well be their common homeland. Babylonia already had a variety of forms: cylinder, hourglass, goblet, and bowl-shaped, all of terra-cotta and all beaten with bare hands. Assyrians also carried in procession a large, conical drum played in the same manner.

Temple drums were of considerable proportions: huge frame drums existed from the 3rd millennium on in Mesopotamia, and the waist-high *lilissu* had a goblet form—a bowl on a stand—and may have been the ancestor to the kettledrum. All these were played by men, but the smaller frame drums appearing in Sumer about 2000 BC are depicted in the hands of women; a king's granddaughter was appointed player of the *balag di* in the Temple of the Moon at Ur around 2400 BC. Ever since, frame drums have been predominantly women's instruments. The Bible says that in ancient Israel "Miriam, the prophetess, the sister of Aaron, took a timbrel in her hand; and all the women went out after her with timbrels

and dancing." They are still played throughout the Middle East, in some areas in art music ensembles, in others only in popular and folk music.

Wherever the Muslim presence has made itself felt, large and small kettledrums are encountered. In Turkey classical monophonic singing is accompanied solely by a small kettledrum, played either in the centre of the head or close to the rim, depending upon whether clear or muffled beats are desired.

Association of drums with thunder

In many regions of the ancient and modern East drums were believed to create or imitate thunder. Sets of thunder drums are depicted on East Turkistan art objects from the 9th to the 11th century. In China, Lei Kung, duke of Thunder, is traditionally surrounded by numerous drums on which he creates thunder, and in Japan thundering drums were even automated by attaching a number of them to the outer circumference of a wheel that, when revolved, caused them to rattle—an early application of the rattle drum principle. As in Africa and America, cult drums of Asia have been associated with human sacrifice; in China, drums were consecrated in the 7th and 6th centuries BC by smearing them with the blood of a sacrificial human, usually a war captive.

Rattle drums, either containing in their cavities objects that rattle when the drum is twirled by a handle or with attached cords having knotted ends that strike the heads, can be traced back to the Shang dynasty (*c.* 1766–*c.* 1122 BC) and are now in use from Tibet and India to Japan. Still a cult drum in some areas—it is an attribute of Śiva (Shiva), the third member of the Hindu trinity—in others the rattle drum has degenerated to a mere toy. On the giant stupa of Borobuḍur, Java, an archetypal image of the known cosmos, are sculpted the musical instruments in use at the time of its erection (*c.* 800). These include cylinder, conical, hourglass, and pot drums—all Indian instruments. Yet, today's Indonesian orchestra, the gamelan, virtually ignores drums in favour of metallophones. Drumming is exclusively a man's business on some islands of the Malay archipelago, where drums are kept in the men's house, out of sight of women.

Drums played an important part in early court orchestras of China and Korea, judging by their surviving elements in *gagaku,* court orchestral music of Japan. Here, the leader beats time on a drum, either cylindrical or hourglass-shaped, having projecting heads, a characteristic feature of Japanese hooped drums. Larger barrel-shaped drums with nailed heads are suspended from elaborate frames. On the Indian subcontinent a variety of membranophones participate in art music ensembles or accompany dances, while small kettledrums are played pairwise in processions; large, single kettledrums are temple instruments or may be mounted in pairs on elephants' backs in outdoor ceremonies. Many smaller drums have laced and wedged heads, the skin being further tensed by an application of tuning paste. In Myanmar, Thailand, and south Nias Island (Indonesia) a number of tuned barrel drums of varying sizes are suspended in a low circular pen to form drum chimes; such a chime may consist of from 16 to 24 drums, all played by a single musician with his fingers and palms, occasionally with a drumstick. These chimes form part of the theatre orchestra and are even played in processions.

Drum chimes

In East and Southeast Asia a mirliton device is applied to many woodwinds in order to obtain a characteristic modification of tone quality. To this end an additional aperture is cut in the tube and covered with a thin membrane. A different application of this principle is encountered in India, where a pair of short, wooden mirliton "trumpets" are placed against the throat of a humming performer.

PERCUSSION INSTRUMENTS IN AFRICA AND AFRO-AMERICA

Idiophones. *North Africa.* Idiophones of Muslim Africa are mainly those of the Middle East or derivations thereof. Outsize hollow clappers shaped like a dumbbell sliced lengthwise are clicked by Moroccan singers, who hold a pair in each hand. An inverted bowl set afloat in a larger, water-filled bowl, is beaten with a single stick by the Saharan Tuareg as their substitute for the West African water gourd. Finger cymbals are worn pairwise on finger and thumb of each hand by dancers. Basically, however, the percussion of this area is executed by drums.

Black Africa. In contrast, Black Africa has an almost bewildering variety of idiophones. Clappers, generally of wood, are played from coast to coast. Simple percussion sticks are known in East and West Africa. Scrapers in both solid and vessel form are widespread.

Xylophones vary from the primitive pit xylophone, with a few wooden bars placed over a pit or trench, to the leg xylophone, with a couple of bars placed on the outstretched legs of a woman player, to the large instruments with independent framework and tuned keys graduated in size. African xylophones are usually provided with a gourd resonator suspended from each key, often containing a mirliton device that adds a buzzing quality to the tone. Ensemble playing of several xylophones, reported by 17th-century travelers, is still practiced. In some areas xylophones form small orchestras with several players to one larger instrument. Unmistakable similarities of form, playing technique, tuning, and even of the music performed confirm the African xylophone's Southeast Asian origin.

Xylophone ensembles

Slit-drums occur in the Western "Bend" (of the Niger River, in modern Mali) and the Congo basin. They may be cylindrical, boat-, wedge-, or crescent-shaped, and zoomorphic with a dorsal slit. Possibly related to the drummed tube zither, a cylindrical slit-drum with from two to five slits is encountered in West Africa; the Kissi people of Guinea strike not only the slats formed by the multiple slits but the ends of the slit-drum as well.

Bells occur in a large variety: metal and wooden, single or double, clapperless and with single or multiple clappers, played as rhythm or signal instruments. The apotropaic qualities of metal bells are recognized in Africa, where such bells may be associated with chieftainship. Double bells, usually of metal, share a common handle but differ in length or in diameter and, consequently, always in pitch. Metal double bells are devoid of clappers and are often made of sheet iron soldered down the side, whereas double bells of wood often have multiple clappers.

Water gourds—half gourds floated open side down in a pan of water and struck rhythmically with small sticks—are played in West Africa; in Benin their chief use is at funeral rites.

Rattles are the instruments par excellence of dancers, although they can also be worn on the leg simply to provide walking rhythm. Strung and gourd rattles are common, with the latter often serving in religious cults or magic rites in the Congo basin area. In West Africa the surface of a gourd is covered by a network of dried fruit seeds threaded on a cord; a player holds the gourd handle in one hand and shakes the plaited ends of the cords with the other. Sistrumlike forked sticks strung with threaded pairs of calabash fragments have an important part in fertility and initiation rites among the Mande of West Africa. The ancient horseshoe and rectangular forms of sistrum are still played in Ethiopia in the Monophysite Christian church.

The African linguaphone is known to the West as the sansa (zanza), by the Bantu name *mbira,* or, in English, by the misnomers "kaffir piano" and "thumb piano." It consists of a varying number of cane or metal tongues fitted to a wooden board or resonator so as to permit one end of the tongues to swing freely; their different lengths determine the pitch. Sansas show affinity of tuning with xylophones that cannot be considered accidental; thus they may be considered small, portable versions of the latter.

Afro-America. West African idiophones introduced into the Americas with the slave trade are still flourishing. Clappers originating among the Yoruba (a Nigerian people) are played in Cuba; the claves, or pair of cylindrical percussion sticks of Haiti and Cuba, are standard equipment in Western rhythm bands. The xylophone may already have entered America in pre-Columbian times. Known chiefly as the marimba, one of its African names, it has been accepted in Western musical culture. Bells frequently figure as voodoo cult instruments in Caribbean and Afro-Brazilian communities. In Cuba water gourds are played at funeral rites for Afro-Cubans.

Steel drums originated in Trinidad during World War II

Steel drums

and have become vehicles for popular music in the U.S. since. Actually a single "drum" forms a chime, as one head of an ordinary oil drum is divided into sections of different sizes by punched grooves, each section then being tuned to its own pitch. Today only a greater or lesser rim, depending upon the range required, is left but originally the oil drum was left intact.

Rattles play an important part in African cults of the New World, both gourd rattles with internal and external percussion and a distinct variety consisting of two metal cones joined at their widest part. (The maraca gourd rattle is probably indigenous to South America.)

Scrapers are highly popular. The notched gourd with natural handle, called guiro, is another Afro-American instrument taken over by the West. Notched turtle carapaces are scraped in the Caribbean. The jawbone of a horse, mule, or donkey, with its teeth left in, is played in both North and South America and in the Caribbean; its use among coastal Negroes of Peru goes back to the 18th century. In the United States it is still encountered in Louisiana and the Carolinas.

Sansas in the Caribbean and in South America bear such names as *marimbula* (Cuba) and *marimbao* (Brazil), clearly indicating their origin.

Membranophones. *North Africa.* Drumming tradition in the Muslim north centres on smaller, portable drums, such as frame, goblet, and small kettledrums. Frame drums are made in a number of forms: circular with single membrane, square, even diamond-shaped (ancient Egypt had circular, square, and rectangular ones). Although the human voice is the preponderant instrument in Islāmic religious music, the frame drum plays an important role as vocal accompaniment. It also lends rhythm for dancing and is the basic percussion instrument of Muslim art-music ensembles. In Morocco groups of women may sing to the accompaniment of a frame drum supplied with jingles, a spike fiddle (one in which the handle traverses the body and emerges at the lower end to form a spike), small cymbals, and a pair of kettledrums, each playing her own instrument.

Black Africa. Black Africa makes perhaps wider use of its membranophones than does any other culture. Numerous variant forms of drums and lacings make classification difficult; indeed, a study of types remains to be established. Some drums are played as musical instruments, others transmit messages ("talking" drums), some are restricted to cult and funerals and others—partly desacralized—to royalty, while still others participate in everyday life. Ethiopia admits drums to the church, while West African cult drums may not be seen by the uninitiated. Drums are beaten with bare hands or with rectangled or knobbed sticks. Footed drums (*i.e.*, with a base prolonged to form "feet") attain a height of 10 feet (3 metres) in the Loango area of western Central Africa (coastal areas of modern Congo, Cabinda province of Angola, and Zaire) and must be tilted to bring the head within the performer's reach. The playing head of hourglass drums may be struck with one hand and with a stick alternately. Kettledrums are royal, ritual, or ceremonial, and unlike their North African counterparts they are of wood, often with sculpted shells. Their traditional pairing with trumpets reaches as far as south of the Congo.

"Talking" drums

That portion of West Africa known as the Bend is the area of talking drums, by means of which messages are conveyed for up to 20 miles, to be relayed by another drummer. Languages of this area are characterized by pronounced high and low pitch tones (tone languages), a quality exploited when two drums—a lower-pitched, or male, drum and a higher-pitched, or female, one—transmit low and high tones respectively. Accent, number, and pitch of the syllables are transmittable. Among the Yoruba a talking drum set consists of four hourglass drums and a kettledrum; the leather lacings of the former are gripped by its player, enabling him to change the pitch as he exerts more or less pressure on them; the chief drum of the set is capable of an octave range and, in addition to tones, produces also the typical Yoruba glides by manipulation of the lacings.

East African drum chimes, of Asian heritage, are tuned to specific pitches; these instruments attained royal status in Uganda, where the largest chime consists of 15 drums requiring 6 musicians to play them.

Friction drums of the lower Congo area were once exclusively cult instruments but are now becoming desacralized. Whereas in Central Africa they are played only by men, women of the South African Pedi play them at female initiation rites.

African mirlitons can be most imaginative: standard material is a spider's egg membrane, and this may be added to apertures pierced in the bottom of xylophone resonators or applied to one end of an independent cane tube that is inserted into a nostril, as among the Fang (Fan) of Gabon.

Afro-America. West Africans reconstructed their native drums in the New World, preponderantly as cult instruments. Small sets of two or, more often, three drums of graded sizes form an integral part of Afro-American rituals and, in the Caribbean, also of voodoo dances. Only the skins of sacrificial animals may be used for membranes among Afro-Bahians in Brazil, who baptize their new drums, preferably with "holy" water obtained from a Roman Catholic church. Drums in Haiti are sacred objects and may even represent the deity itself: as such they receive libations. One type of bongo drum—there exist at least four of these—has been adopted by Western rhythm bands, as has the conga.

PERCUSSION INSTRUMENTS IN AMERICA

Idiophones. A wide assortment of idiophones is available to American Indians, but many of these are restricted to nonmusical uses. Concussion sticks, for instance, serve as game calls in North America, while concussion stones are invariably ritual: they are clashed to make thunder. Small, conical bells of metal and multiclapper bells of wood were known in ancient Peru.

Slit-drums have been played in Central and South America since pre-Columbian times, but their occurrence in South America is now rare. Characteristic of the well-known *teponaztli* is the form of its slits, cut to form an H with tongues of different thicknesses, thus allowing it to emit two sounds. Formerly, Zapotec warriors of Ixtepeji, Mex., went into battle carrying an idol and singing to the accompaniment of the *teponaztli*, while Indians of 16th-century Hispaniola danced to their slit-drums.

Strung rattles

Strung rattles are worn as leggings to emphasize a dancer's movements, but when the strung material consists of a dead enemy's teeth, as among the Brazilian Mundurucú, the rattle becomes a source of magic strength to the wearer; elsewhere, strung deer or caribou hooves attract game during the hunt. Vessel rattles of gourd and pottery imitations of gourds have been in use since Aztec times. Cult instruments in prehistoric America, they are still used by medicine men during their incantations. Hollow, seed-filled staffs were ceremonial rattles of Aztec and Maya, and descendants of these instruments are still played in North America.

Scrapers are seen on the 8th- or 9th-century frescoes of the temple at Bonampak in Chiapas state, Mexico, played in a procession. Today among the Pima Indians of Arizona, scrapers play an important part in rainmaking ceremonies. Elsewhere in North America they serve as time markers. Scraped sticks of animal or human bone or of antler, with a series of notches along one side, were sounded at Aztec sacrificial or memorial ceremonies. In modern times they have been played in North America by medicine men. Split idiophones were employed in western coastal areas of North America chiefly for ceremonial purposes; some tribes slapped them against their chests, others against their palms. Finally, a friction-instrument vessel of Central and South America, the rubbed tortoise carapace, is a ritual instrument and taboo to the noninitiated; the instrument is rubbed with the fingers, not scraped.

Membranophones. Pre-Columbian drums of Central America appear to have been played without sticks, regardless of their size, and to have been devoid of lacings, whether they were small pottery drums, such as those excavated in Costa Rica, or the large footed drums of Mexico. Slender pottery drums of the Guatemala highlands, open top and bottom, can be dated to the late Classical Period

(*c.* 700–1000). Skeletons of wooden cylinder drums, very shallow, have been found in Peru.

The North American shallow drums are "medicine" (magic) and dance drums, having a heavy hide head struck by a hard beater and emitting a loud, staccato sound. Larger models are suspended and struck simultaneously by up to 10 drummers seated in a surrounding circle. The "dream-dance" drum, a tub-shaped shallow drum, is elaborately decorated and has a bell suspended in its interior; it is credited with great medicine power.

Cylinder drums made of a hollowed log were traditionally war and dance drums of tribes of the southwestern United States and are now sold in tourist shops. Pottery drums, either potbellied, bowl-shaped, or footed, were formerly common among the eastern and southern tribes of the United States; the potbellied type remains in use among the Pueblo Indians of the Southwest.

Frame drums

American Indian frame drums are usually circular; square shapes are rare, but rectangular frame drums are found in California, Mexico, and Bolivia and octagonal ones among the Cherokee of the southeastern United States. All were war drums, regardless of whether they had one or two membranes. By adding a rattling device, a frame drum is converted into a medicine drum. The Inuit frame drum, a shaman's instrument, is distributed over Greenland, northern Siberia, North America, and among the Lapps of northern Scandinavia; it differs from other frame drums in that it has a fixed handle and is struck on the hoop, not on the membrane.

Friction drums are rare; in Venezuela one is formed from a small barrel over which a piece of leather is stretched, with central perforation to admit a friction stick.

PERCUSSION INSTRUMENTS IN THE PACIFIC

Idiophones. The different cultures of this wide area where singing and dancing form so prominent a part of the musical life include a number of primitive idiophones, some of which are played with considerable sophistication. Concussion sticks are clashed by an Aboriginal Australian singer to lend emphasis. The Maori breathe words of a song onto a carved stick held between their teeth while tapping it with a second stick. In Hawaii concussion stones were held pairwise by dancers who clicked them together like castanets. In Papua New Guinea primitive log xylophones are played, consisting of two banana stems or other logs placed on the ground with a few keys placed across them.

A percussion gourd of New Guinea has an hourglass form, open at both ends; when plunged in and out of water, it is said to emit the sounds "uh-ah-uh-ah." Split-bamboo percussion tubes, doubling as rattles, are indigenous to the same area, while the percussion board *o-le-polotu* of Samoan and Tongan chiefs accompanies solo songs. Slit-drums

Slit-drums can be huge. Made from a tree trunk, living slit-drums in Vanuatu (the New Hebrides) are carved with the faces of ancestors, and in New Guinea roofed drum houses are built over large, horizontal slit-drums to protect them from the weather. The Maori, one of the relatively few peoples who have no membrane drums, use their slit-drums as signal instruments. Related to these is a percussion tube of Fiji, partly hollowed and tapering at the ends and struck with two sticks on the side opposite the slit.

Idioglott Jew's harps of bamboo are the major tonal idiophones of the area; here the tongue is vibrated either by the player's finger or by jerking it with a cord. A friction vessel of New Ireland (in Papua New Guinea) consists of a rounded and hollowed block of wood, its upper portion carved into three tongues of different lengths and hence emitting as many pitches. Already rare nowadays and taboo to women and children, it is played at death commemoration rites by a male performer who rubs well-oiled hands over the tongues.

Membranophones. Two forms of drum are distributed over this huge area. Elongated hourglass drums, usually with wooden handles of a piece with the drum shell, often beautifully carved and ranging up to 6 feet (1.8 metres) in height, are commonly in the hands of dancers and singers and are said to symbolize the transition from earth to heaven. Among the Wapenamundu of New Guinea they lack handies and are war drums. Such hourglass drums are not found in Polynesia. The other form is a conical, footed drum made of a tree trunk, reaching great dimension. Those of Polynesia are sometimes 8 feet (2.4 metres) high and have elaborately carved pedestals. They are usually made of breadfruit tree wood or hollowed coconut palm, with a single, sharkskin head. Throughout the area drums are beaten with bare hands.

Whirled friction drums are met with in Hawaii, where a large nut or a calabash is furnished with a friction cord and swung through the air. (S.Ma./E.A.Bo.)

Stringed instruments

All stringed instruments, or chordophones, produce sound by the vibration of strings, which may be made of vegetable fibre, metal, animal gut, or plastic. In nearly all stringed instruments the sound of the vibrating string is amplified by the use of a resonating chamber or soundboard. The string may be struck, plucked, or rubbed (bowed); in each case the effect is to displace the string from its normal position of rest and to cause it to vibrate in complex patterns.

Since most stringed instruments are made from wood or other easily perishable materials, their history before written documentation is almost unknown, and contemporary knowledge of "early" instruments is limited to the ancient cultures of East and South Asia, the Mediterranean, and Mesopotamia; but even for these places historians must depend largely on iconographic sources rather than surviving specimens.

Stringed instruments seem to have spread rapidly from one society to another across the length and breadth of Eurasia by means of great population shifts, invasions and counterinvasions, trade, and, presumably, through sheer cultural curiosity. In the Middle Ages the Crusades stimulated Europe in the adoption of a whole set of new instruments; similarly, the Chinese accepted many new instruments from their Central Asian invaders. Indeed, the only world area that did not echo to the sound of strings was pre-Columbian America.

No system of classification can adequately categorize the interactions of natural material, craftsmanship, and man's exuberant imagination that produced an endless variety of stringed instruments. The most widely accepted system of classification is that developed by Hornbostel and Sachs, a method based on the type of material that is set into vibration to produce the original sound. Thus, stringed instruments are identified as chordophones—that is to say, instruments in which the sound is produced by the vibration of chords, or strings. This main category is then further divided into four subtypes—lutes, zithers, lyres, and harps—according to the manner in which the strings are positioned in relation to the body of the instrument. Within these categories, the descriptive nomenclature of an instrument is given in terms of parts of the human body: for example, the belly (front), back, sides, and neck. Instruments are not necessarily related only to others in the same classification. Transformations continually occur, and "hybrids," according to the Sachs-Hornbostel system, may in fact represent altogether viable subtypes of their own. Classification

THE PRODUCTION OF SOUND

The ear, because of its own structure, adds to and subtracts from the outside sound. It is, for instance, relatively insensitive to low-frequency sound pressure but is extremely sensitive to fine degrees of pitch change. At the same time it can accept a great number of pitch and tuning systems. On a worldwide basis, there is a large and varied number of tonal systems. The oldest known of these in the West is the so-called Pythagorean system; others include mean-tone tuning, just intonation, and the even-tempered system, methods of tuning calculation that vary slightly in the exact size they assign to the intervals within an octave. All of these systems represent theoretical mathematical concepts to some degree, and their origins must be sought in arcane numerological systems rather than in practical musicianship. Thus, "tuning" and

"playing in tune" do not necessarily refer to the same thing; players and tuners make constant adjustments to any basic mathematically determined framework according to their judgment and experience. In other words, even though a given "scientific" tuning system outlines scales and modes, the instrumentalist who plays an instrument with great pitch flexibility (the violin, for instance) spends much time in the spaces between the notes assigned in the given scale. The Japanese zither (koto), for example, can be tuned according to a number of fixed systems; nevertheless, its player produces many microtonal variations on these fixed pitches by manipulation of the strings. Even in such a technological society as that of the modern West, the well-tempered scale is honoured more in the breach than in the observance: a piano tuner would not think of tuning altogether according to its dictates and uses a so-called stretched tuning, in which he imperceptibly sharpens (raises) pitches as he ascends, thus making the highest notes relatively sharper than the lowest ones. Investigation has disclosed that string players tend to play in the Pythagorean rather than the well-tempered system.

Inconsistencies, then, are inherent in all tuning systems; makers of fretted lutes (the guitar or the Greek lute, *laghouta,* for example) operate according to a combination of ear and rule of thumb when they insert frets (note-position markers—*e.g.,* of gut or wire) in the fingerboard. Such instruments are fretted according to the "rule of the eighteenth," in which the first fret is placed at one-eighteenth of the distance from the top to the bottom of the string, the second, one-eighteenth of the distance from the first fret to the bottom, and so on. Even if this method produced an acoustically perfect scale (which it does not), the player would not be able to reproduce this exactly, for as he presses the string to the fingerboard, the string is stretched and is thus slightly lengthened. That is why the act of stopping a string at its exact centre gives a note slightly sharper than the expected octave above the open string. Despite all of this, the search for an acoustically perfect tuning system goes on.

Though constructional methods differ widely from one area and instrument to another, there are a limited number of basic problems to be overcome by the maker of stringed instruments. The very principle that makes it possible for chordophones to sound is string tension; at the same time, tension is destructive to the instrument since it tends literally to pull it apart. So the body of an instrument must be made of strong material; it must be reinforced, and at the same time it must not be so rigid that it cannot easily resonate—*i.e.,* produce a supplementary vibration intensifying that of the string. The challenge of reconciling these opposite needs is the central one for the chordophone maker. Climate, too, has a marked effect on musical instruments: humidity expands a wooden instrument, and dryness contracts it. Of these factors, dryness is the most harmful, since the contraction of the wood actually pulls the instrument apart. Much energy has been expended over the centuries in investigations of various varnishes, shellacs, glues, and sealers. Many makers prefer to make their instruments in dry conditions, for the expansion caused by humidity is unlikely to prove as harmful as the contraction caused by dryness.

Effect of climate on instruments

However common the practice may have been in the past, wooden instruments are not now usually gouged out of one piece of wood (though the Japanese lute, *biwa,* portions of the koto, and often the Puerto Rican lute, *cuatro,* are thus fashioned); it is too painstaking and time-consuming for the maker. Instead, the instrument is built up of many pieces of wood glued together; the shaping of curved pieces is accomplished by gouging and planing (as in the belly of the violin) or by heating and pressing in a frame (the sides of the violin or guitar). Soundboards, the most important part of the resonance system of stringed instruments, are carefully planed to close tolerances. Mass-production methods are unsuitable for the production of high-quality chordophones because no two pieces of wood are precisely alike in their acoustical qualities; each piece of wood requires special judgment and treatment. Ideally, therefore, stringed instruments of the highest quality must be individually made. Piano manufacture is a partial exception to this rule, but even in a piano factory, individual treatment and craftsmanship are allowed full sway. The modern piano is a product of several different factories. The cast-iron frames are made by specialized foundries, and the steel strings, the keyboards, and the actions by specialized firms. Each of these processes requires experienced craftsmen; and the work of assembly, polishing, tuning, and tone regulation calls for hours of individual attention to each instrument.

The construction and maintenance of stringed instruments has been complicated over the centuries by a continual rise in standard pitch, requiring strings to be tightened. Older instruments (such as a Stradivarius violin) have been subjected to additional physical strain and therefore needed heavier bass-bars (braces under the belly).

As already stated, the three possible methods of sound production on a stringed instrument are plucking, striking, and bowing. A string vibrates in a complex way: the entire string vibrates in one segment (producing the fundamental pitch), and various segments at the same time vibrate independently to produce overtones. The resulting sound is weak indeed unless the instrument is provided with a resonator to amplify the sound. The shape of the resonator varies greatly. It has been influenced by the materials, tools, and technology available in the society, the symbolic meaning of the shape, and the sound desired by the culture. The last factor seems to be governed by the first three: that is to say, the prescribed shape of the resonator affects the overtone structure of the instrument, producing a certain timbre, which the society in question then defines as attractive-sounding.

Importance of the shape of the resonator

One of the clearest illustrations of the basic importance of the shape of the resonator to a musical instrument is the African mouth bow (a musical bow in which the player inserts the bow in his or her mouth). By varying the size and shape of the oral cavity while striking or plucking the single, unfingered string, the player produces a clearly perceptible, if quiet, melody that exists only because the changes in the mouth emphasize various overtones. On stringed instruments with permanently fixed resonators, the size, dimensions, shape of apertures, thickness, and bracing of the resonating surfaces largely determine which overtones will be emphasized and, thus, what the instrument will sound like. On a good violin, for example, the resonances of the body of air enclosed in the body of the instrument and of the belly should be close in pitch to the two strings A and D, thus amplifying and colouring these pitches and their overtones. The sound quality of a stringed instrument is also influenced by the thickness and material of the strings; primarily, however, it is the size and shape of the resonating body and especially the material, density, and thickness of the soundboard that determine the sound of an instrument. A well-known Spanish guitar maker, in a successful attempt to prove the importance of the belly of the guitar, once constructed an instrument—an excellent one—from the acoustically dead material papier-mâché, except for a carefully chosen and wrought wooden soundboard. Makers, then, devote a large part of their skill and knowledge to the choice of material for the soundboard; the maker of wood-bellied instruments prefers old wood because it is dry and well seasoned. Thus, some guitar makers find the soundboards of discarded pianos unusually suitable for their purposes; makers of the classical Chinese zither, *ch'in,* preferred old coffins or well-seasoned wood from an old tree.

The timbre of a struck or plucked stringed instrument is also affected by the manner of setting the string into motion. A string plucked with a sharp point (the player's fingernail or a plastic plectrum) emphasizes the higher overtones, thus creating a "bright" tone quality. By contrast, a soft pad, such as that on a piano hammer, emphasizes the fundamental pitch. The relative hardness of the hammer on the piano is thus of critical importance to the sound of the instrument, and the final process in piano manufacture is voicing. A skilled worker adjusts the timbre of the instrument by the simple expedient of pricking the felt hammers with needles until he achieves a unified quality throughout the range of the instrument. The tone of an instrument is also markedly affected by

the place where the string is struck. The permanently fixed striking place on keyboard instruments has to be chosen with a combination of concern for the timbre and the mechanical requirements of the instrument. On all other stringed instruments the player varies the tone quality by choosing to pluck, strike, or bow at various places along the length of the string.

Another way in which musicians and musical instrument makers influence the sound of their instruments is by the use of sympathetically vibrating strings. On the piano, for example, when the so-called damper pedal is raised, thus leaving all the strings free to vibrate, the act of striking one note causes all closely related pitches to vibrate in sympathy, thus modifying the loudness and tone of the struck note. This effect (which is encountered also on the zither and harp) is not a central feature of these instruments, but there are numerous Eurasian chordophones on which the principle is of fundamental importance. The North Indian plucked instruments, sarod and sitar, each possess about a dozen sympathetic strings tuned according to the notes of the mode being played. The Indian fiddle, *sāraṅgī,* has from 35 to 40 sympathetic strings; the Norwegian Hardanger fiddle (*Hardingfele*) has 4 sympathetic strings, the viola d'amore 6 or more. Sympathetic strings are generally made of thin brass or steel, and their vibration reinforces the upper harmonics, thus producing a bright, silvery sound.

Sympathetic strings

TYPES OF INSTRUMENTS

Lutes. Probably the most widely distributed type of stringed instrument in the world is the lute (the word is used here to designate the family and not solely the lute of Renaissance Europe). The characteristic structure consists of an enclosed sound chamber, or resonator, with strings passing over all or part of it, and a neck along which the strings are stretched. The player moves his fingers up and down the neck, thus shortening the strings and producing various pitches.

In the lute the part of the resonating chamber over which the strings pass is called the belly, and the other side of the resonator is called the back. The portion between the back and belly is the side, or rib. A lute may be plucked with the fingers or a plectrum or may be bowed, but the means of sound production do not affect the essential morphological identity of plucked, struck, and bowed lutes.

Lutes may be subdivided into those with skin and those with wood bellies; in most Eurasian cultures examples of both types exist side by side. In Japan the wood-bellied lute is the *biwa,* the skin-bellied one the samisen; in the Middle East the wood-bellied one is the *'ūd* and the skin-bellied, the *tār;* in the United States it is the guitar and the banjo, respectively. The two different varieties of lute are distinct in sound and structure; and methods of construction, timbre, history, and symbolic associations differ markedly. A second subdivision concerns the shape of the instrument; for instance, the lute proper has a round back, the guitar a flat one. These two basic constructional principles (the shape of the resonator and whether the belly is constructed from wood or skin) constantly interact, producing all sorts of combinations.

The string vibrations of the lute are transferred to the resonating chamber by the bridge, which holds the strings above the lute's belly; the resonator magnifies the vibrations and transmits them to the air. Makers lavish great attention on the choice and fashioning of material for the belly: if it is of wood, it must be selected and aged with much care and planed to a prescribed thickness; if it is of skin, it must be made only from certain materials. (The belly of the Japanese samisen is preferably made from the skin of a female cat; the wooden belly of the Puerto Rican *cuatro* is best constructed from wood from a female *jagrumo* tree that has been well seasoned and, if possible, taken from an old house.) In the late 20th century, synthetic materials have frequently replaced skin bellies.

Lute strings

Lute strings have traditionally been made of animal intestines (gut) or metal or silk, though nylon has now replaced these older materials all over the world. Whatever the material, each string must be of equal thickness throughout its length. Some lutes have only a single string, but the great majority have three, four, or more. Very often there are sets, or courses, of two strings to a pitch, so that an instrument that produces four pitches with open strings actually has eight strings arranged in pairs.

In the tunings of lutes, though fourths and fifths (intervals the size of four and five tones of a Western seven-note scale, as C to F and C to G) predominate in many places, any given instrument is likely to be tuned differently from one location, piece, or player to another. Functionally more important is the question of whether a lute is fretted or unfretted. It is clearly easy to change from one pitch to another on an unfretted instrument by sliding the finger along the string, but it is also possible to do this on an instrument with extremely high frets (Japanese *biwa,* Indian vina) by pressing—hence stretching—the string into the cavity between two frets. Instruments with low frets (the guitar, banjo, European lute, viola da gamba) are found mainly in the West, where a limited and clearly defined tonal system is in use and where significant microtonal changes in pitch are not necessary. Even here, however, players manage to produce microtonal inflections, slides, and vibrations on fretted instruments.

The fiddle can be distinguished from other lutes only by the manner in which it is played—with a horsehair bow. The practice of rubbing the strings with this implement is of uncertain age and origin, but it seems to have appeared almost simultaneously (9th–10th centuries AD) in China, Java, the Arab world, Byzantium, and Europe. As with the other lutes, there is a fundamental division between skin- and wood-bellied instruments. (The former are far more common on the fiddle than the latter, which occur mainly in Europe.) Musically more significant, however, is the division between the stick fiddle, in which the player's finger does not actually press the string to a fingerboard (but rather slides up and down the string itself), and the fiddle with a fingerboard (for example, the violin). On fiddles without fingerboard (including the Chinese *erh-hu,* the Javanese and Arab *rabāb,* various African fiddles, and the North Indian *sāraṅgī*), the player's left hand is able to move with extreme flexibility up and down the string, thus making the subtlest kind of inflection possible.

As with other lutes, fiddles may have only one string (the Tuareg *imzhad*) or as many as 40 (the *sāraṅgī*); on the latter, sympathetic strings are not directly touched or sounded by the player but vibrate sympathetically when other strings are set into motion, thus giving a fuller resonance. Examples, in addition to the *sāraṅgī,* include the Norwegian Hardanger fiddle, the Swedish *nyckelharpa,* and the viola d'amore.

The fiddle bow

The fiddle bow itself generally is constructed so that the player can tighten or loosen the hair at will; on most stringed instruments the player is able to make immediate changes by manipulating his hand on the bow hair while playing, thus producing various tone qualities. The modern Tourte bow of the violin has a screw mechanism that cannot be changed while playing. Most bows are actually bow-shaped, but the Tourte bow is made in a compound curve to which considerable tension can be applied, making it possible to apply much pressure to the strings.

The bowing principle has been applied to nonlutes from time to time: the old Icelandic *fidla* was a bowed zither; the Scandinavian *talharpa* was a bowed lyre.

Zithers. Instruments of the zither family, in which the strings lie parallel to and are of the same length as the string bearer (often also the resonator), are widely distributed in Eurasia, the Americas, and Africa. There are two important subdivisions of this category. The so-called long-zither family is found only in East Asia; its characteristic resonating chamber is slightly convex, as much as 6 feet (180 centimetres) long, and about 1 foot (30 centimetres) wide; there is a varying number of strings frequently provided with movable bridges. These instruments, of which the best-known example is the koto, seem to devolve ultimately from tube zithers made directly from lengths of bamboo. The bamboo prototypes are said to be idiochordic because their strings, part of the bamboo itself, are worked loose from the tough surface of the tube, to which they remain attached at either end. The maker then inserts small bridges at the extremes of the strings.

(Various modifications and transformations of this principle exist, such as the bamboo-tube *valiha* of Madagascar and Malaysia, in which wire strings replace the idiochordic ones). All long-bodied, curved-surfaced Asian zithers of the koto type may owe something to this idiochordic principle. In Eastern tradition the most ancient zither is the seven-stringed *ch'in,* which seems to have originated in the Shang dynasty (*c.* 1400 BC). The Japanese *wagon* and koto, the Korean *kayagum,* and the Chinese *cheng* fit into this general category. All these ancient instruments are rich in symbolic associations.

The flat zither

The other important subdivision of the zither family is the flat zither; in Africa it is made either from a hollowed plank over which strings are fastened (board zither) or from individual narrow canes lashed together, each having one idiochordic string (raft zither). The box zither, which seems to be native to the Middle East, is a rectangular or more often trapezoid-shaped hollow box the strings of which are either struck with light hammers or plucked. Examples of the former are the Persian *santūr* and its modern Chinese derivative, the *yang ch'in* ("foreign zither"), the cimbalom of east-central Europe, and the piano (which is a sort of cimbalom with keyboard). The most prominent plucked box zither is the Arab *qānūn* and its various derivatives, including the harpsichord (a plucked zither controlled by a keyboard). In Europe a variety of plucked zithers developed having a fretted fingerboard under one or a few of the strings. In the United States, popular plucked box zithers include the hammered dulcimer, which is widely used in folk music, and the autoharp, which is equipped with damper bars that prevent unwanted strings from sounding, making it relatively easy to play chords.

Struck zithers are occasionally termed dulcimers, and unfretted plucked ones psalteries, after European instruments using those names.

Lyres. The lyre family, though it was of great importance in the ancient centres of Babylonia, Egypt, and Greece, is now found only in a few areas of East Africa. A lyre is made from an oval, round, or rectangular sound chamber (usually skin-bellied); from this resonator two arms protrude; they are joined at the top by a crosspiece; the strings extend from this crosspiece over the belly, with which they are connected by a bridge. These strings are not normally stopped but are allowed to vibrate throughout their entire length when plucked by the performer.

The *beganna* and the *krar*

In Ethiopia, where the lyre remains in extensive use, there are two distinctive types, as there were in ancient Greece. The 10-string *beganna* (which corresponds to the ancient Greek kithara) is a large, heavy, rectangular instrument that is considered by the Christian Ethiopians to be a God-given instrument that came to them from King David; it is used, of course, for sacred music. The smaller lyre, *krar* (the ancient Greek *lyra*), has a bowl-shaped resonator and is emphatically secular in its use and connotations; indeed, Ethiopians think of it as the instrument of Satan. The construction of this five- or six-stringed instrument illustrates the sort of change that is of wide occurrence in contemporary instrument making everywhere, for though the traditional *krar* was made from wood, the resonator of the present-day instrument is made of an easily available metal pan. The *krar* can be played in two ways: in the first (called muting) the left hand mutes the unwanted strings while the right hand strums with a plectrum; in the second, the fingers of the left hand pluck while the right hand plucks a drone on tonic strings tuned to the tonic, or focal note, of the melody.

The lyres of medieval western Europe (4th–12th centuries) had from five to seven strings and, to judge from iconographic evidence, were played in a way that closely resembled the muting technique of Ethiopia. Later northern European lyres were sometimes played with a bow; their shapes are considerably varied, but both the rectangular kithara-like shape and the rounded *lyra* shape apparently existed.

Harps. The harp family exhibits an extraordinary variety of constructions, but in all harps the strings are of unequal lengths and are fastened at either end to a frame that lies in the same plane as the strings. The least complex, and prototypical, harp type of instrument is the musical bow, shaped very much like a hunter's bow. (The musical bow is sometimes classified as a zither rather than a harp.) The bow's single string is tapped or struck, and the pitch can be varied by varying the tension of the string or by using the player's mouth as a resonator and varying its size and shape, thus emphasizing different harmonics. It is a favourite instrument in equatorial Africa.

The arched, or bow-shaped, harp, known in Egypt as early as 3000–4000 BC, is a multistringed version of this musical bow; its player kneels or stands, supporting the harp on the shoulder. Harps of this type may be found in West and Central Africa, where they are often provided with elaborate anthropomorphic carvings and skin-covered resonators. The bow harp, then, is a traditional African form that has been in use in that continent for at least 5,000 years.

On an angle harp the bowlike support is replaced with two crosspieces at right angles to one another; the strings are stretched between these at an angle of 45°. This type seems to have originated in Assyria, though occasionally it is found in Egypt and Greece.

The frame harp

The closed, or frame, harp is characteristic of both medieval and modern Europe; the shape of its frame is more or less triangular, the frame being strengthened by a pillar that encloses the strings in a kind of tripartite structure. It is to this category that the modern orchestral harp of Europe and the old Irish and Scottish harps belong. In all of these instruments the crosspiece held nearest the player is a hollow resonating chamber. The so-called Brian Boru harp (14th century), now at Trinity College, Dublin, is 32 inches (81 centimetres) high, with 36 brass strings; the sound box is carved from a single piece of willow, and the harp was plucked by the fingernails.

THE MUSIC OF STRINGED INSTRUMENTS

Solo uses. Music for a solo instrument is often, though not always, used to accompany dancing or is derived from dance music. In Europe and America, the violin is widely used to play dance music; for instance, the Norwegian Hardanger fiddle player performs rhythmically complex polyphonic music to accompany the *halling, gangar,* or *springar.* In Scotland, Ireland, and rural North America, the violin is favoured for accompanying country dances. It is known that a single fiddler played for dancing among the upper classes in medieval Europe and also probably among the common people, with whom the fiddle was popular. In all areas, the fiddler has an additional repertoire not for dancing, which shows off his compositional and improvisational ability as well as his virtuosity. A skillful medieval fiddler constantly improvised new pieces. It is no coincidence that the violin solo sonatas and partitas of J.S. Bach, like their country cousins, are polyphonic compositions having a liberal sprinkling of stylized dance movements.

A second genre of solo piece is the descriptive composition. In such diverse places as Ireland, West Africa, and the United States are found fiddle pieces picturing the hunt, in which the player delights in the depiction of such realistic sounds as the baying of the hounds, the sound of hooves, and the groans of the exhausted animal. In China there is a genre of highly realistic descriptive compositions for *p'i-p'a*—including some that depict famous battles from start to finish. Among numerous descriptive pieces in Renaissance and Baroque Europe, a well-known example is a sonata for viola da gamba, by the French virtuoso gamba player Marin Marais (1656–1728), that graphically and in detail describes a gallstone operation in the days before anesthetics.

Solo music of the Middle Ages and Renaissance

In the European Middle Ages and Renaissance, an important type of composition for solo stringed instruments was the transcription of polyphonic songs; in the medieval period fiddle and hurdy-gurdy players frequently rendered elaborated versions of well-known strophic songs. In northern Europe, songs intended to accompany dance could also be played on the fiddle, and in Spain the *vihuela de arco* filled a similar function. In the Renaissance, a string player was expected to have the ability to perform highly elaborated versions of preexistent melodies on the

viol, lute, or keyboard: and many manuals provided the player with exercises designed to teach him to elaborate the basic melody in a stylistically correct manner. Similar techniques continued to be practiced during the Baroque period and even into the 19th century.

For accompaniment. All over the world, stringed instruments have as one of their central functions the accompaniment of bards, who sing tales of heroes and otherwise reflect the preoccupations of their societies. The example of Homer and his lyre is of course the best known, and the 19th-century European art song for solo voice and piano also belongs to this genre. Other examples, include the harpers of Celtic Ireland and Scotland, who devoted their skills to the accompaniment of learned bards. The *azmari* of Ethiopia sings lengthy historical epics and strophic love songs to his own accompaniment on the fiddle or lyre. In Japan, blind *biwa* players chant a narrative style of music known as *katarimono;* here the *biwa* is used only between verses for interludes and commentaries. A similar technique is in use among the minstrels of North Africa: the lute, *gunbri,* is played only between verses of the story, as a descriptive comment.

Ensembles. Musical ensembles everywhere have their own internal social structure, mirroring that of their society at large in the degree of authoritarianism, type of leadership, amount of freedom available to the individual players, and so on. The audience for a given ensemble also tends to be socially stratified. Large, authoritatively ruled ensembles tend to be found in societies that have a complex bureaucratic and pyramidal social order. Such groups are most typically to be found clustered around the royal or princely courts of China, Japan, Korea, Java, Bali, and North Africa and in the court-derived music of Europe and America. In all of these instances a more or less fixed and archaic repertoire remains in use. In Japan, Korea, and, to an extent, Southeast Asia, the court music has derived from an archaic (and no longer extant) court music of China. The two types of stringed instruments in use in Japanese court music are the zithers, koto and *wagon,* and the lute, *biwa.* The koto has 13 strings and the *biwa* 4.

The gamelan orchestras of Indonesia employ but two chordophones in ensembles, which are otherwise dominated by struck metallophones, or metal instruments, such as tuned gong sets and xylophone-like instruments with metal bars. The bowed *rebab* probably entered the orchestra from the Middle East, where it was called *rabāb,* ancestor of the European rebec, when Java was converted from the Hindu religion to Islām. It plays in sliding fashion around the fixed pitches of the orchestra; its player is thought of by Javanese as the "rajah" of the gamelan, with the drummer as his "prime minister."

In Islāmic countries and in the West, stringed instruments predominate numerically in the orchestra; the classical ensembles of the Maghrib, which mainly perform the ancient Andalusian suites, typically consist of about one dozen musicians. The instrumentalists include a number of violin or viola players, a *rabāb* player, lute players, drummers, and sometimes flutists, cellists, and a pianist. All of the string players play the melody together but not in unison, for they are expected to vary it individually with ornaments and improvised passages. A true unison, therefore, is neither expected nor desirable. The ensemble is normally led by an *'ūd* (lute) player who indicates the pitch, mode, mood, the changes of tempo, and so on.

Orchestral stringed instruments

The greater number of stringed instruments in use in Western and North African orchestras are bowed; Western orchestras, however, are distinctive in that these bowed chordophones exist and are played in families of graduated size (violin, viola, cello, bass), and this phenomenon derives from the extent to which Western musicians have been preoccupied with harmony and multipart composition. In the development of the Western orchestra two great—but gradual—changes have occurred over the centuries: first, stringed instruments have increased dramatically in number in the orchestra, and, second, higher and higher notes and hence finger positions have been demanded of string players. Socially and musically, the role of the player in an early 18th-century symphony (in which there would be no more than two or three players to each part) is very different from the anonymous function allowed the violinist in a symphony by Berlioz, say, or Mahler. The symphonic orchestra seems to represent the merger of two functionally and aesthetically different groups that medieval Europe probably derived from Arab civilization. One of these, used for outdoor ceremonial music, consisted originally of shawms (oboes), drums, and trumpets; the other, for indoor (chamber) use, was made up of stringed instruments, quiet percussion instruments, and flutes. The modern orchestra preserves vestiges of these two ensembles in its seating arrangements, orchestration, and leadership.

The Western concept of chamber music is nowadays thought of as being entirely distinct from orchestral music; in the 17th and early 18th centuries, however, the distinction would have been difficult to draw, since there was no clear difference either in the music, the size, or the sociological position of the two types of ensembles. The symphonic orchestra arose because of middle-class demand for public concerts and from the desire of composers after the French Revolution to provide democratic music for the masses; thus, mass audiences demanded large orchestras, and the striking multiplication of instrumentalists affected the strings above all others.

Modern Japan cherishes a number of traditional chamber-music ensembles; of these, the commonest one consists of the koto, the samisen, and the *shakuhachi* (flute). The *jiuta* is a common form played by this group; here, the koto plays the principal melody, and the samisen and *shakuhachi* simultaneously produce a variant of it. The Japanese picturesquely describe this ensemble by saying that the koto is the bone, the samisen the flesh, and the *shakuhachi* the skin.

Basic elements of Indian ensembles

The basic ensemble in South Indian music consists of a drone instrument (usually the tamboura), a tuned drum (mridanga), a violin, and a singer. The group is often augmented to include a number of other instruments, but the basic elements must be present. The violinist is an accompanist to the singer; he must be able to play in unison with him in fixed pieces and to follow him in immensely complicated improvisational sections, maintaining all the while the correct raga (melodic mode) and tala (rhythmic mode). An analogous group in North India might include the sitar or sarod as solo instrument, with the accompaniment of the drums, tabla, and a drone. Often the fiddle, *sārangī* (with 3 main strings and 35–40 sympathetic ones), accompanies a singer.

Rather similar principles apply in the eastern Mediterranean: a chamber-music ensemble must include instruments—usually strings—to play the melody and to improvise in the introductory sections known as *taqsīm* and percussion instruments to deal with the rhythmic modes, known as *īqā'āt.* To these, in modern Greek music, the element of harmony has been added so that a solo instrument (clarinet or violin) plays the highly ornamented melody and another instrument (guitar, or *laghouta*) plays the chordal background and maintains the reiterated rhythmic pattern. Similar ensembles are found in the Americas and in Africa.

In Puerto Rican traditional music, a guitar plays the harmony, the five double-stringed lute (*cuatro*) plays the melody with the singer, and the scraper (guiro) and drums (*timbales*) produce the rhythmic part. Among the Berbers of North Africa, groups of itinerant professional musicians typically play one or two *gunbrī* (lutes), a one-stringed fiddle (rendering a highly adorned melody), and percussion. In Senegal, lutes similar to the *gunbrī* are played by the musicians known as griots, often in ensembles of three or four flutes, drums, and rattles. The bluegrass style of Appalachian North America largely conforms to this Mediterranean and African pattern; the ensemble typically includes only bowed and plucked strings and singers.

Rock groups also adhere to these general principles: they also represent a blend of African and European traditions. The typical rock ensembles use plucked electric stringed instruments, electric keyboard instruments, voice, and drums. The electric guitar plays the melody, and the electric bass renders the bass part. In various North and South American blends of Mediterranean, African, European,

and indigenous tradition, the African element includes the percussion instruments and the skin-bellied lute (banjo); the Mediterranean element includes the wood-bellied guitar and *cuatro.* The bass parts are derived from Europe, the scraper from the American Indians, and the singing style from various of the four traditions.

SOCIAL AND CULTURAL ASSOCIATIONS

Throughout the world, particular instruments are associated with particular functions, social levels, areas, ages, and sexes. Certain instruments preserve the same function all over the world: singer-poets recount tales of heroes, recite the genealogies of the great, and preserve and disseminate the precious traditions of a given society—everywhere accompanying themselves on a stringed instrument. An early example would be the blind Homer, who, presumably accompanied by his lyre, sang of gods and heroes. Similar traditions still survive in Greece and the Balkans, but the instrument of the modern "singer of tales" is the fiddle. In Ethiopia, where so many traditions are reminiscent of Greece, the *azmari* accompany themselves with a lyre or fiddle. In North and West Africa griots sing and play skin-bellied lutes called *gunbrī* or *halam;* in Morocco they play and sing alone in the squares of the towns for coppers; in Senegal (where they perform in groups) they are employed by the wealthy. The Japanese *biwa* (often played by blind bards) was used to accompany epic narratives, the texts of which usually concern the adventures and battles of the samurai, and to accompany Buddhist chanting. In medieval Europe, minstrels, self-accompanied on the *vielle* (fiddle), sang of the heroism of such as Charlemagne.

Very often, stringed instruments are identified with a certain social class, either in the sense that the player himself occupies a particular caste position or in that the instrument is the prerogative of a particular rank in society.

Social standing of string players

A well-known example is that of the Irish and Scottish harp of the periods during which the Celtic kingdoms flourished; harpers, who were highly respected members of society, were employed in the households of only the very wealthy and the high nobility. By the same token, harpers were regarded with great suspicion by English officials in Ireland, for they were suspected of spreading sedition. In sharp contrast is the attitude of respectable members of medieval Arab society toward lute players; their status was low indeed (certain judges even held that the lute was an unlawful possession which could be destroyed at will). Paradoxically, the *'ūd* player's skill and imagination was highly valued by the courts. These attitudes are old indeed in the Mediterranean; Aristotle regarded professional kithara players as low-caste and of questionable morals. In his view (and this is still prevalent in the West) the highborn should learn to play as an accomplishment but not professionally. In the 17th century, members of the English upper class were swept with a craze for playing consort music for ensembles of various sizes of viola da gamba ("leg viols," held, cello-fashion, between the knees). It was a common—and much valued—accomplishment to be able to play a part in a viol consort, and, as Samuel Pepys recorded in his diary, servants were often chosen because of their ability as violists.

The violin family in Europe has had two very different social connotations. In the string quartet and orchestra the instrument has been associated with the entertainment of the upper class and the bourgeoisie, and this represents the continuity of the medieval tradition under which the fiddle was highly regarded by the upper class. Alfonso X the Wise, king of León and Castile, was one of many rulers who supported a group of fiddlers at his court.

In opposition to this, the violin has long had great popularity among the folk. In almost every country in Europe and the Americas the rural fiddler has provided the music for dances and entertainments. This country fiddler is distinguished from his urban colleague by his nonstandardized technique, playing position, and tunings and by his learning process, which is totally aural. His virtuosity may be of a high order. The pleasures of the common folk have long been associated with the fiddle, though the medieval fiddler usually played the bagipes, sang, juggled, and told jokes as well.

The role of musical instruments in religious and healing practice is complex: at one time or another Judaism, Islām, and Christianity have each been hostile to the use of instruments in places of worship. The Church Fathers made frequent allegorical and symbolic reference to instruments, and it is common to find depictions of angels, cherubs, or of King David playing on the very instruments that were not permitted to sound in Christian worship. The Hindu attitude toward stringed instruments is very different. Though Vedic chanting is the oldest known music of India, the Rigveda nevertheless mentions the use of such chordophones as the *karkari* and a number of vinas.

Caste and symbolic associations of the *ch'in*

The Chinese scholars' zither, *ch'in,* had definite caste and symbolic associations. No scholar would have been without one, for it restrained licentiousness and purified the heart; it compelled man to return to his divine origin and restrain his passions. Thus, the *ch'in* could not be played when drunk or after sexual intercourse; it could not be played for a courtesan, a merchant, or a barbarian. The *ch'in* was often played by Buddhist monks; complex cosmological and symbolic meanings existed for every aspect of its shape, constructional material, tone, and playing technique. The *ch'in,* therefore, was involved with healing, religion, and philosophy; and of these three, its therapeutic function was perhaps the most pervasive. This instrument harmonizes the blood circulation and regulates breathing; it leads to health and long life. It cures melancholy and can, it is claimed, even make a devoted player immortal.

The function of stringed instruments in the healing process is often an indirect one: a healing specialist may sing powerful songs to the accompaniment of a lute (the *gunbrī* of the North African Gnāwa) or a fiddle (Central Asia). Beyond this relatively prosaic association, stringed instruments have symbolic meanings that transcend their technological, sound-producing function. The horse-headed fiddle of the Mongols is directly a part of the Mongol system of belief in the horse as a symbol of fecundity and rebirth; the winged horse that the shaman is believed to ride in his quest for enlightenment and healing power is equivalent symbolically to the fiddle.

This close connection of stringed instruments with ideas of birth and rebirth explains why so often a particular instrument is typically played, or even listened to, by members of one sex only; in certain instances instrumentalists, whether they were Greek kitharodists or Arab *'ūd* players, were slaves with a low moral reputation. The playing of many stringed instruments by women has been either a low-caste occupation or an accomplishment to be savoured in the confines of the home. In India during the Vedic period there seem to have been stringed instruments (such as the *kāṇḍa-vīṇā*) that were played only by women; and Chinese tradition has it that the long zither, *cheng,* was invented by a woman. In the Western continents, instrument makers seem usually to be men, since in most societies the manipulation of woodworking tools has been a male occupation. In medieval Europe, minstrels made their own instruments, as they do in Puerto Rico today. Since the making and playing of instruments in such places have until recently been mainly in male hands, women have not had available to them this particular link to musical instruments through manufacture.

CRAFTSMANSHIP IN STRINGED INSTRUMENTS

There is no reason to suppose that the shape of an instrument is governed only by acoustic requirements; it seems often to be the other way around: the symbolically appropriate shape preferred by a given culture produces a particular tone quality, which then becomes the desirable one. Available materials, manufacturing techniques, and complex historical, symbolic, and artistic considerations guide the craftsman who creates musical instruments. Transformations occur as old meanings are lost: the scroll surmounting the pegbox of the violin may well be a faint visual echo of the horse's-head carving that surmounts the fiddle in its ancestral lands in Central Asia. Craftsmen are well aware that the soundboard of an instrument is responsible for the best part of its resonance; they are aware that other portions can be considerably altered without making much change in the sound quality. Instrument

makers have long delighted in producing modifications of existing designs and in experimenting with new materials. In all this they are limited only by the essential technological requirement of a chordophone—ability to withstand the constant strain imposed by the tension of the strings coupled with sufficient resonation.

A limited number of basic woodworking techniques are used almost the world over in the production of stringed instruments. In lute construction the entire sound box (and sometimes the neck as well) can be hewn from one block of wood. Instruments that often are made in this fashion are the Japanese *biwa,* the North African *gunbrī,* and the Puerto Rican *cuatro.* Existing side by side with this technique is another, in which the lute is made out of a kind of composite box in which any angular or curved portions are fashioned by heating and bending the wood (common examples include the violin and the guitar). Again, the resonator can be made of preexistent natural materials, as in the case of the Malagasy *valiha* zither (bamboo), the South Indian vina (gourd), or the lyre said to be invented by Hermes (tortoiseshell).

Though occasionally (as in the case of many harpsichords and virginals) instruments with pictures painted on them are encountered, this decorative technique is most unusual—probably because it requires a separate craftsman—and most instrument makers prefer to show their skill by the choice of woods, by complex inlays, and by carving.

The anthropomorphic harp

Anthropomorphic and zoomorphic shapes surmount many ancient harps and lyres. The anthropomorphic harp of ancient Egypt and modern Africa represents an example of this visually symbolic approach to instrument making, which has been described as producing "sounding statues." In Europe anthropomorphic and zoomorphic carving exists side by side. Notable examples are the Irish Brian Boru harp, which exhibits a profuse variety of animal shapes; the Norwegian Hardanger fiddle, surmounted with a dragon's head; and the viola d'amore, which often is surmounted with the head of a blindfolded woman. The Balkan fiddle, *gusla,* and the Central Asian horse fiddle are usually crowned with a carved horse's head, and the South Indian vina features a carving of a dragon. These shapes are not mere decoration or fancy; they represent important symbols in the society from which the instruments come.

In East Asia the craftsman's emphasis is on the beauty of wood, excellence of finishing, and apparent simplicity of construction. Occasionally, on instruments such as the *ch'in,* one finds pictures painted or calligraphy inscribed. The proper material is extremely important: a *ch'in,* for example, should be made of wood taken from an old tree that had nestled next to a bubbling stream. Phoenix-bird symbolism of rebirth is abundant in the nomenclature of East Asian instruments, and this fact serves to point up a profoundly important truth about musical instruments everywhere: they are intimately connected in folktale, myth, and legend to local symbols of rebirth. Thus, legend relates that Hermes made the first lyre from a turtle carapace; similarly, the first Arab lute was modeled after the body of a beloved male child; the Finnish culture hero Väinämöinen made the first zither, kantele, from the body of a giant pike; the Celts made their first legendary harp from whalebones. In each case, the symbolically significant creature is "reborn" as an instrument which "sings" as well as appears in a shape reminiscent of the creature modeled.

THE DEVELOPMENT OF STRINGED INSTRUMENTS

Little or no evidence is available concerning the chordophones of prehistoric times: the earliest iconographic evidence and the oldest surviving specimens come from Mesopotamia and Egypt, and evidence concerning instruments earlier than these can be gleaned only from myth and legend.

The harp. The harp clearly evolves from the musical bow, which must have been in existence prior to the establishment of Mesopotamian and Egyptian civilizations. Since the musical bow is identical in shape with the simple hunter's bow, it has been assumed that the instrument derives from the hunter's implement. There is, however, no evidence for this; quite the opposite: the musical bow is very often played by women, who do not usually hunt, and, further, there is absolutely no way of knowing whether or not man hunted with a bow-shaped implement before he made musical sound with a bow. The three early harps found in the burial chambers at Ur were bow-shaped instruments with 12 to 15 strings; nearly identical instruments were played in Egypt at roughly the same time. Iconographic evidence suggests that in both Egypt and Mesopotamia the harp, often played by women, was used in secular, erotic entertainments, although it had sacred uses as well.

Although the harp family is known to exist in Myanmar and to have been in use in China and India, it is not characteristic of these areas; it is, rather, musically important in equatorial regions of Africa, in Europe, and, since European incursions, in the Americas. In modern Africa it clearly is related to the Egyptian harps, and again it is associated with women.

The harp has maintained and increased its importance in Europe. It is omnipresent in folktales and legends; it is the national symbol of Ireland. The Celtic harp must have been in use as early as the 10th century, and fragments of one were found in the 7th-century Sutton Hoo burial ship unearthed at Suffolk, Eng. In Gaul, Ireland, Wales, and Scotland the harp was an important and favoured symbol; it was said that there were but three things necessary to a comfortable household—a virtuous wife, a chair cushion, and a harp. By the end of the 18th century the harp had almost gone out of use in the Celtic realms, but by then the large orchestral harp had made its appearance in other places in Europe.

The Celtic harp

This basic instrument (with the addition of a set of pedals for instantaneously altering the pitch of a note) is found—often still played by a woman—in the modern symphony orchestra; but the older European harp tradition flourishes best in Mexico and South America, where the harp is a component of various folk ensembles.

The lyre. Greek legend credits the invention of the lyre to Hermes, who had stolen Apollo's cows and, in order to atone for his transgression, presented the god with the lyre, which he had accidentally discovered when he had brushed against a turtle carapace that lay on the ground and, as he did so, heard its sinews begin to vibrate. The tale is interesting for two reasons: first, the turtle shell was, in fact, frequently used as the resonator of the Greek *lyra,* and, second, the tale makes an explicit relationship between the lyre and cattle. Similarly, in Mesopotamia the lyre was surmounted with a carved bull's head, and in modern East Africa the lyre is most frequently encountered in cattle cultures.

A famous lyre from Ur (now at the University Museum, Philadelphia) is one of nine dug up at the burial ground; these and similar instruments seem to have been used both to accompany bardic recitations and for religious purposes. The "harp" that the Hebrews hung in the tree in their Babylonian captivity was actually a lyre, as was the instrument used by Homer (*phorminx*). In view of the importance of the bull in the worship ceremonies of Crete and Mycenae, it is not surprising to find lyres among the stringed instruments of these peoples. In Celtic society depictions of lyres are found on the coins of pre-Christian Gaul. These instruments, which were U-shaped, may have come to western Europe from southwestern Asia with groups of Indo-European peoples who spread across Europe. Other types of lyres were found in Europe, too, and it is possible that these variously shaped but still related instruments might be analogous to the various Indo-European languages in that they are basically closely related but quite different in detail.

In medieval Germany and Scandinavia long, narrow lyres with four to seven strings were played, and similar lyres (the Finnish *jouhikantele,* the Swedish *talharpa,* the Welsh *crwth*) were played with a bow in parts of Europe until the early 20th century. Today the lyre flourishes only in Ethiopia, in The Sudan, among the fishermen of the Persian Gulf, and in restricted areas of East Africa.

The zither. Several different types of instruments are

classified as zithers; they are used today in all continents. The long zithers of China, Japan, and Korea are venerable indeed. Their curved surface and long, narrow shape betray their affinity with the prototypical idiochordic bamboo zithers of the Pacific, Southeast Asia, and southeastern Africa. The importance of bamboo to music in Asia is literally legendary; in Java, music is thought to have been first produced by the accidental admission of air into a bamboo tube. In China, the source of East Asian civilization, musical instruments are classified according to their constructional material; one of the eight substances in the system is bamboo, which the Chinese relate to the direction East, the season Spring, and the phenomenon Mountain. The Chinese zither *cheng* includes the radical meaning "bamboo" in its ideograph. The ideographs of the older zithers, *ch'in* and *se,* are more difficult to interpret; but the narrow, curved shapes of the instruments themselves betray their affinity with the ancient principle. Zithers of this type are known to have existed in the Shang period (*c.* 1766–*c.* 1122 BC); the *cheng,* with either 13 or 16 strings, came into use during the Ch'in period (221–206 BC). By the 18th century, interest in this instrument had waned in China, but at an early date it was introduced to Japan, where, as the 13-string koto, it flourishes today. The koto, like the *cheng,* is played frequently by women.

Bamboo zithers

A relative newcomer to the spectrum of Chinese zithers is the *yang ch'in* (foreign zither), which reached China from Persia a number of centuries ago; it is the only representative of the box zither in East Asia. The history of this type of chordophone is obscure indeed, but two instruments of this general shape that may be very old are the African raft and board zithers. The raft zither is constructed on the idiochordic principle, but it uses a number of canes about half an inch in diameter; each of these has one string raised out of its own surface, and all of the canes are then lashed together. The board zither is made from a hollowed-out board over which a number of strings are attached. This latter instrument is found only in restricted areas of East Africa; it is possible that its principle of construction was carried to the Middle East by traders. Medieval Arab authors (including Ibn Khaldūn) mention the plucked trapezoidal zither, *qānūn* (derived from Greek *kanōn,* "rule"). Nowadays, the instrument has a range of three chromatic octaves with three strings to each pitch, and a complex system of levers by which its many strings may be finely and quickly retuned to the various Arab scales. Closely related is the Persian-derived *santūr,* another trapezoidal zither that is struck by two light hammers. Versions of this zither are found in China (*yang ch'in*), Greece (*santouri*), and eastern Europe (cimbalom). These trapezoidal zithers are the prototypes for the later keyboard instruments of western Europe: the *qānūn,* which is played with two plectrums, became, with the addition of a keyboard, the harpsichord; the cimbalom, with the addition of a keyboard, became the piano. In the Middle Ages, the keyboard was attached to a number of instruments, including the lute, the hurdy-gurdy, and the various Scandinavian keyed fiddles, of which the Swedish *nyckelharpa* survives. The experiment was truly successful, however, only on the clavichord, harpsichord, and later the piano; on the fiddle, it always remained of peripheral importance.

The lute. The first surviving evidence of the existence of the lute comes from Mesopotamia and Egypt. One of the earliest Babylonian delineations (*c.* 2500 BC) shows a shepherd with a long-necked, small-bodied lute; this instrument, which was doubtless skin-bellied, had a rounded back that might well have been made from a turtle carapace (as in modern North Africa) or a gourd (as in Puerto Rico). A similar instrument is also found in Egypt, and from specimens surviving from ancient times it is known that the stick forming the neck passed through the body of the instrument, ending at the sound hole, where it served as a fastener for the ends of the strings. This instrument, like the harp, survives in West Africa and in North Africa (as the *gunbrī* or *halam*).

Earliest known lutes

The Greeks of old seem to have made rather sparing use of the lute, but it was commonly encountered in Rome. Though the skin-bellied lute predominated in the ancient Mediterranean, the wood-bellied lute has been more typical of Europe; indeed (with the exception of the African-derived banjo), all currently used European lutes and fiddles have wood bellies. The model for the European lute was the classical Arab lute, *al-'ūd* ("the wood"), which has been the most important instrument of classical Arab music for 1,000 years. The instrument, with its characteristically curved back, probably entered Europe through a number of different gateways, including Sicily, Andalusia, and Palestine with the crusaders. Though European and Arab lutes are very similar in general construction, the Arab lute is not fretted as is the European lute, and the European lute little by little acquired additional courses of strings during the Renaissance, when it became a standard instrument for solo playing and the accompaniment of singers. The many courses of strings caused numerous problems: "When a lute-player is 80 years old," wrote the 18th-century German theorist Johann Mattheson sarcastically, "he has spent 60 years tuning his instruments."

The many lutelike instruments of modern India (tambura, vina, sitar, and sarod) are, technically speaking, lute-zithers, since their fingerboards are hollow; in appearance and playing technique, however, they are indistinguishable from lutes. They seem to represent a special, and quite recent, subfamily of chordophones.

In East Asia the lute family exists only in a comparatively recent manifestation, but both in wood-bellied form (Chinese *p'i-p'a,* Japanese *biwa*) and skin-bellied version (Chinese *san-hsien,* Japanese samisen). In Japan, these instruments existed in the year 752, and the Imperial Treasury at Nara preserves three *biwas* used at a great concert held in that year. The *biwa–p'i-p'a* family can be traced ultimately to Persia, where, as the *barbat,* it influenced the music of Afghanistan and Turkestan on its way to China and Japan. The skin-bellied lute, *san-hsien,* can be traced in China only to the 13th century; from there it was taken to the Ryukyu Islands and thence to Japan (mid-16th century), where it still plays an important musical role as the samisen.

Lutes of East Asia

Bowed instruments. The principle of bowing is nearly always applied to stringed instruments of the lute class, though one occasionally finds it used with zithers or lyres. It is difficult, if not impossible, to make a clear-cut distinction between plucking with a plectrum and bowing, since plucking sometimes involves rubbing the string. But bowing, defined as the use of the almost universally encountered horsehair bow, can be traced as far back as the Islāmic civilization of the 10th century. The stroked *rabāb* evidently possessed a long neck and up to four strings. There is no iconographic evidence of such instruments before the 13th century in Islām itself, though an illustration (*c.* 930) from Christian Spain delineates a bowed instrument with three strings. In Byzantium, too, the bowed *lira* (lute) existed by this time, and it seems likely that the principle of bowing originated among the horse cultures of Central Asia, whence it spread quickly through Islām and the East, so that by 1000 it had almost simultaneously reached China, Java, North Africa, the Middle East and Balkans, and Europe. Modern scholarship has shown that a word meaning "horse" is given to the bridge of the fiddle throughout Eurasia, from Japan (*koma*) to western Norway (*hest*). In China the fiddle is acknowledged to have come from the "barbarians" of Central Asia; in those days it was in China an instrument of the people; later, at the time of Kublai Khan, it began to be used in court music. In Africa, the fiddle seems to have entered the continent with Islām.

In Europe the bow appears first in Spain and shortly thereafter in Italy, and it is suspected that it entered through Muslim Spain and Sicily, though it is possible that other fiddles entered Europe through the Balkans, Hungary, and Scandinavia. Even in early illustrations, evidence is found of the uniquely European method of holding the fiddle against the shoulder. At the same time, other European fiddles were held vertically, the manner in which fiddles are held everywhere else in the world. Early European fiddles were made (by their players) in only two parts: the belly was a thin piece of spruce or fir wood, and the back was hollowed out of one piece of

The bowed instrument in Europe

hardwood. These medieval fiddles divide into two types, one of which has a clearly discernible neck; the other possesses a neck that merges imperceptibly into the body; this second type, exemplified by the rebec, is equivalent to the North African *rabâb* and the Byzantine-Greek *lira*. As the centuries passed, Europe continued to have two distinct types of fiddles: one, relatively square-shaped, held in the arms, became known as the viola da braccio ("arm viol") family and evolved into the violin; the other, with sloping shoulders and held between the knees, was the viola da gamba ("leg viol") group. The gambas, which were important and elegant instruments during the Renaissance, eventually lost ground to the louder (and originally less aristocratic) braccio-violin family.

Electronic technology. In the second half of the 20th century, electronic technology has made remarkable changes in the structure and function of many stringed instruments by making amplification and tonal change possible. The best known and most pervasive example is the electric guitar, which, strictly speaking, may be considered a chordophone but is often classified as an electrophone. The electric guitar may be hollow-bodied like a traditional guitar or solid-bodied, but in either case amplification of the strings is provided by a "pickup" (or contact microphone) that creates artificial resonance through its connection to amplifiers and loudspeakers. Pickups are often attached to violins, lutes, and other instruments, as well as to guitars, making these instruments usable in noisy environments and vast amphitheatres. Musicians who use such instruments (especially electric guitars) have developed feedback and other techniques that can alter the timbre beyond recognition. (T.Gr.)

THE VIOLIN FAMILY

The violin family at present comprises the violin, viola, violoncello, and double bass; it forms the backbone of the modern symphony orchestra. In addition, the violin and viola are widely used in the music of South India and North Africa, in modern Greek and Arab music, in European and American folk music, and by Romany musicians. The term violin, a diminutive of viola (itself an abbreviation of viola da braccio), is linked etymologically to words ranging from the Icelandic *fidla* to the Provençal *viula*.

Bowed chordophones seem to have originated in Central Asia and spread rapidly throughout Eurasia in perhaps the 10th century. Though many different applications of the bowing principle existed in medieval and Renaissance Europe, one direct ancestor of the violin may have been the *polnische Geige* (Polish fiddle), mentioned as early as 1545 by Agricola, and later by Praetorius.

The immediate precursor of the violin is the *lira da braccio*, an elaborate instrument of the Renaissance, whose form foreshadows the physical essentials of the violin body: the arched modeling of the belly and back and the shallow ribs. This shallow arched form probably encouraged or suggested another important detail: the use of a short vertical stick to prop the front and back apart and prevent the collapse of the belly arch under pressure of the strings. This device, the sound post, is peculiar to the violin family, although it was later used on the viola da gamba family (known as the viols). It is the acoustic effect of the sound post that imparts to the violin its lively response and generous singing tone, for it couples and coordinates the vibrations of the body as a whole, under the influence of the strings.

The sound post

Although the generic name for the family is the Italian *viola* (whence violino, "small viola"; violone, "large viola"; violoncello, "small violone"), the treble instrument very soon became its most important member, from which the others took their main characteristics. Unlike the treble viols, whose tone was reticent and impersonal, the violin was always recognized both for its superior cantabile and for its inherent sprightliness and smart attack, especially in Italy, its birthplace, where the earliest makers, Gasparo da Salò, Andrea Amati, and Giovanni Paolo Maggini, had settled its average proportions before the end of the 16th century. Thus the violin arrived at exactly the right time to lend impetus and conviction to the innovations of the Florentine school of composers, whose preoccupation with the expressive qualities of the solo voice marked a breakaway from the older polyphony. To this movement, the violin formed the perfect instrumental counterpart.

Two other features contributed to the character of the violin, the first being the tuning of the strings in fifths and their numerical limitation to four. This wide regular tuning was ideal in furnishing a uniform diatonic fingering technique, reducing the amount of string-crossing the bow has to do, generally freeing the bridge from too many strings and permitting better clearance on each string for bowing. The second additional feature is the unfretted fingerboard, in which the violin followed the *lira da braccio*. No doubt frets, if they were ever used, were removed from the arm viols because they impeded the use of the hand in supporting the instrument and in fingering. It is also true that the direct stopping of the strings by the fleshy part of the fingertips produces a tone quality that, although slightly damped, is more assertive and flexible than the tone obtained from the use of frets, as on the viols.

The violin family came to be used in a way that was entirely new in instrumental music—*i.e.*, as a massed "choir" in which the several parts were doubled at unison by instruments of like kind. This string ensemble, so different in its effect from the chamber music of the preceding "golden age," owes its first organization, if not its invention, to the French at the court of Louis XIV, whose *vingt-quatre violons du Roi* was the model for Europe of the embryo orchestra-to-be.

Morphology. All members of the violin family are basically similar in structure, nomenclature, and playing method. The shape of members of this family represents an extremely efficient method for the production and amplification of tone, as well as flexibility and convenience for the player. Instruments of the violin family are, however, difficult to play, requiring many arduous years of practice for their mastery. They are made, following builders' experience and convention, of several different woods that have been dried and aged with the greatest care. The creator of a successful instrument in this family must be a master craftsman in wood selection, carving, shaping, and assembly. The nomenclature of these instruments is basically anthropomorphic, with the playing surface being termed the belly, the opposite side the back, and the sides the ribs. Names of some parts, however, seem to hint at the origins of bowed instruments among the horse cultures of Central Asia—*e.g.*, tailpiece, saddle, and tailpin.

Structure of the violin body

All members of the violin family have a body that consists of a belly of spruce or pine and a back of sycamore, maple, or a similar hardwood, spaced apart by shallow ribs of the same material. The arching of the belly and back is both transverse and longitudinal, creating a central bulge, flattening off in all directions to the edges. In most cases the bulge changes from convexity to concavity as it approaches the edges, which are given a slight upward curl. The arching is worked from solid wood of suitable thickness, which is dug out on its undersurface to a curve that follows the general contour of the outward modeling but not exactly, for the finished thickness is graduated in all directions, being thinnest in the margins of the outline just inside the ribs. The adjustment of these thicknesses is one of the prime skills in the craft of violin making. The wood used in both back and belly is usually, though not always, cut "on the quarter"—*i.e.*, in wedge-shaped segmental planks from the centre to the outside of the log. To form a plate, two wedges are glued "back to back" with the thin edges outward. This not only provides the basis for the modeling but also ensures that the annular rings of the tree are evenly disposed about the centre line of the plate, the oldest growth being on the outside edges.

The familiar outline of the violin body is visually satisfying, perhaps because its balance and proportion are largely functional. Its master makers have evolved a form based on an artistic unity of opposed curves that allows free play to individual nuance with scarcely any measurable deviation from the norm. The rounded, outward-curving sections of the body, called the upper and lower bouts, are separated by the indented waist, or middle bout, which provides clearance for the bow on the outer strings.

The middle bout meets the upper and lower to form outturned corners, where the ribs are brought together and glued firmly to corner blocks within the instrument. Other blocks, called end blocks, are mounted top and bottom centre to provide firm bearings for the neck and the tailpin, which between them have to resist the tension of the strings. The ribs are slightly inset from the outline of the belly and back, so that the edge overhangs all around. The internal corners between the ribs and the plates are strengthened by a narrow fillet of pine, called the linings, which runs between the blocks. Despite the very considerable stresses to which it is subject, the violin body is held together by simple flush glued joints, which can in emergency be opened up, without damaging the instrument, for repairs.

The arched belly or soundboard of the violin and its relatives is supported in a curiously unorthodox and individual way, quite different from the regular barring of instruments with flat soundboards. The sound post has already been mentioned. It is a loose stick of pine, carefully cut to size, that is wedged between the plates of the finished instrument under, but a little behind, the top-string side of the bridge. It is not fixed: its position is critical and must be adjusted with great care for the best tonal result. This adjustment is made through the sound holes in the belly. The other side of the bridge is supported by a bar glued under the belly and running lengthways along the grain of the wood. This bar, called the bass bar, is deepest under the bridge, but tapers to nothing at either end, since it fits into the internal curvature of the belly. Externally, the plates are finished off at the edges with a narrow inlay of laminated woods, the purfling, which follows the outline close to the edges. This, the only decoration normally permitted, has the function of preventing incipient splits from running.

The bass bar

The neck and head are cut from a solid block of sycamore wood. The lower end is formed into a shoulder that abuts against the ribs at the top of the body and, in fact, passes through them into a shallow mortise cut in the end block within. The back end of this shoulder is covered by a projection of the wood at the top of the back, known as the button. The pegbox carries the four tuning pegs, two on each side. It is slotted to the front to receive the strings. The pegs are tapered and pass through two holes in the cheeks of the head. At the top of the head is the scroll, again a typical embellishment of the violin, its austere purity of line and curve being both the challenge and the sign manual of the master craftsman. The front face of the neck is flat, and to this is glued the curved fingerboard, which projects beyond the shoulder and over the belly toward the bridge. At the top of the neck is the nut, which is grooved to take the strings, keeping them correctly spaced apart and slightly raised over the fingerboard. The neck is raked back at an angle with the plane of the belly, so that the fingerboard rises with the strings toward the bridge. The bridge is high and arched because of the bowing technique. It is formed with two feet that are carefully cut to fit the transverse arch of the belly and is given a conventional perforated or fretted design, which is said to aid its free vibration. In section it is wedge-shaped, tapering to the thin, notched edge over which the strings pass. It is not a fixture but is kept in position only by the pressure of the strings. Its correct position is between the sound holes and just above the lower corners of the middle bout. The sound holes are of italic *f* form, sweeping outward and downward from the waist to the lower corners. A line joining the crosses of the *f*s marks the approximate position of the bridge. The lower ends of the strings are held by the long tailpiece below the bridge, whose function is to reduce the length of unused string behind the bridge and to keep the strings pulling radially inward on its top edge. The lower end of the tailpiece is anchored by a loop of gut to an ebony button (the tailpin) set in a hole in the lower end block. The saddle takes the pull of the tailgut off the edge of the belly.

The sound holes

Tuning. The violin itself is normally tuned in fifths (g, d′, a′, e″), although other tuning systems (called scordatura) have been used for special musical purposes; the viola is tuned one-fifth lower than the violin (c, g, d′, a′); and the violoncello exactly one octave below the viola (C, G, d, a). The double bass, which has had many different tunings and various numbers of strings over the years, is now tuned in fourths (E, A, D, G).

Playing positions. The violin and viola are played in the horizontal position—*i.e.* "under the chin." The cello (customary abbreviation of violoncello) and double bass both stand vertically on the floor, the first resting on a long steel rod called the end pin, with the player holding the instrument between his knees while seated. For the double bass the player stands or rests on a high stool. As is done with every other necked stringed instrument, the player's left hand fingers the instrument, the bow being

held in the right. The highest string is to the right, viewing the instrument from the front, the lowest to the left.

In contemporary usage, the violin and viola are held between the chin and the collarbone with the aid of a chin rest, thus leaving both hands free for manipulation of the instrument. In earlier styles and in folk music, the violin was held so that it sloped downward, almost resting on the chest.

Violin. During its history the violin has been subject to modifications that have progressively adapted it to its evolving musical functions. In general, the older types have been more deeply arched in the plates, and the more modern, following the innovations of Antonio Stradivari (1644–1737), have been shallower, which has affected the overall tonal characteristics. The stresses to which the instrument is subjected under working conditions have increased not only because of the rise in pitch from the 17th century onward but also because of certain changes in physical design from about the beginning of the 19th century. Before that time the height of the bridge and its arching were lower, the neck thicker and wider, and the bass bar shallower and shorter. These, with the type of bow then in use and the lower pitch, produced the small, delicate tone that served composers up to the time of Mozart. With the advent of larger auditoriums and the development of the violin virtuoso, however, greater power was demanded, and this demand was met by raising the height of the bridge, lengthening and slimming the neck slightly and setting it back at a greater angle, and putting in a stronger bass bar. The sum effect of these alterations was to develop the optimum sonority of which the instrument was capable, and the long experience of makers and players has shown that the Stradivari type with its shallower arching has stood up best to this metamorphosis. All fine violins now in use have been thus modified to bring them into line with modern technique and modern conditions.

19th-century design modifications

Viola. This instrument is similar to the violin in every essential, but, owing to its larger size, it has never been completely standardized in its main dimensions, since, whatever these are, they are bound to tax the human frame and fingers when the instrument is played. A compromise has to be effected between what is the ideal size for the best tonal results and what is practicable to the player in handling. Too large an instrument is simply unplayable; too small an instrument is weakest where it is most wanted—on the lower strings. The problem has never been solved to complete satisfaction, but a characteristic viola tone has been produced that is darker, more weighty, and more sombre than the violin.

Violas have been made at various times with a body length (the most convenient measure of their maneuverability) of 15 to 18 inches (38 to 46 centimetres); probably the majority of the most manageable and successful instruments are midway between these extremes. However desirable it may appear in theory, too big a body, whether in length or depth, is not only difficult to play because of its size but also tends to develop a "tubby," aggressive, unmanageable tone that lacks the blending qualities of the traditional instrument.

Violoncello, or cello. The true bass of the violin, and the member of the family most nearly approaching it in character, is the violoncello. In build it differs somewhat, the ribs being proportionately much deeper and the much higher bridge standing on legs rather than feet. The neck is raked back at a sharper angle to allow for the height of the bridge. The instrument is held between the knees while it rests on an end pin, which is telescoped through the tailpin and can be clamped in any position to adjust the height of the instrument above the floor. This playing position leaves both arms exceptionally free; in particular, the left-hand technique is more fluid and covers a wider range than in any other stringed instrument. This is strikingly shown by the ease with which a good cellist commands the brilliant solo register of the top (A) string, high above the normal tessitura of the instrument.

Double bass. The double bass has numerous features that set it apart from other members of the violin family. For example, it only rarely serves as a solo instrument. In the symphony orchestra, it often serves simply to double the cello part one octave lower, and it is not even included in such standard musical ensembles as the string quartet. Furthermore, even though double basses have been in use for as long as the violin, they are not yet completely standardized in number of strings, tuning, shape, or body size.

The bass is sometimes made with the blunt corners, sloping shoulders, and flat back associated with the viola da gamba family, and in fact the instrument is commonly known as the bass viol. But true double bass violins, with arched back and outturned corners, have existed since the early 17th century and are still in use. The unusual tuning in fourths, which is almost universal on the bass, was adopted because the great length of the strings (42½ inches, or 108 centimetres) makes the whole-tone interval in the fingering so large that it can be covered only by the span of the first and fourth fingers. The closer tuning therefore brings the technique of fingering more into line with what is possible on the smaller instruments, namely a scalewise (diatonic) fingering that reduces hand movements to a minimum. The normal tuning, E_1, A_1, D_1, G, means that the bass cannot descend an octave below the cello's bottom string, and it is for this reason that a low fifth string is sometimes added, tuned to B_0 or C_1. The latter note occurs in symphonic works from the Classical period onward—for example, in Richard Strauss's *Also Sprach Zarathustra* (1896; *Thus Spoke Zarathustra*)—and is being more specifically demanded by modern composers.

Bass tuning

Another method of obtaining C_1 is to fit an attachment mechanism that lengthens the existing E string (which is carried up to the top of the head on an extension bar) when these low notes are wanted. This has the advantage that it preserves the normal four strings and their normal tuning for all ordinary purposes and imposes no extra load on the bridge, as does the fifth string.

On the double bass the pegs are replaced by a "machine head," such as is commonly used on guitars and other plucked instruments, each tuning peg being fitted with a worm-and-wheel screw adjuster. The pegs themselves are made of solid brass. The "tailgut" of the smaller instruments is also replaced by metal, usually a thick copper wire but preferably a stranded steel cable. An extending end pin, similar to the pin used on the cello, is now in universal use. On most basses the ribs are not of equal depth all around but are cut away at the top so that the back slants toward the shoulder of the neck in its upper part. This enables the player to bring the neck and upper portion of the body closer to him and makes for ease of handling. The normal size of the bass, around 6 feet (1.8 metres) high, is about as large as the average person can manage for modern technical requirements. This size has been known since the early 17th century, but larger and smaller basses have been made at all times, and in the late 20th century the small electronic bass has become common in popular bands and orchestras.

Other violins. J.S. Bach, along with other composers, occasionally wrote for the small, high-pitched instrument known as the violino piccolo; now and then his works also require the viola d'amore (a fretless hybrid shaped like a viol but sized and played like a viola with sympathetic strings) or the elusive violoncello piccolo (a small cello). These instruments have been in disuse for many years, except for historical reconstructions of earlier music.

The violin and cello are obtainable in several sizes suitable for young children, who, as they grow, move progressively from quarter- to half- to full-size instruments. This practice has been encouraged particularly by adherents of the Japanese Suzuki method of string instruction who have exported their philosophy, methods, and instruments to all quarters of the globe.

The bow. The violin bow consists of a strong, light, flexible wooden stick, sprung so that a ribbon of horsehairs can be stretched between its ends. Before playing, the hair is drawn across a solid cake of resin and rubs off a small quantity in powder form; this supplies the frictional element that is necessary to make the string vibrate. Proper design is as important in a violin bow as in the violin itself, for it must give the player a feeling of complete control over the tone he is producing and must respond to every nuance of pressure and attack imposed upon it.

Until the late 18th century, the bow stick was either straight or (as on a hunting bow) bent outward from the horsehair, which was under comparatively low tension. This type of bow, which was used during the Baroque and Classical periods, was short and had a light head and a narrow ribbon of horsehair.

The modern bow, which is really the culmination of a long line of evolution, was perfected late in the 18th century by Francois Tourte of Paris. Its chief point of departure is that the curve of the bowstick is concave rather than convex, thus putting the horsehair under considerable pressure (necessary for modern bowing technique). The light tapering stick now is made of brazilwood (Pernambuco wood) with a hatchet-shaped head formed at the thinner end. At the other end is a movable frog, which has a threaded eye projecting into a mortise or groove cut in the stick and runs on a screw that can be turned at the lower end of the stick. The hank of hair is stretched between the head and frog, and its tension is adjusted by the screw. The hair is retained as a flat ribbon by passing through a specially shaped ferrule and a shallow channel in the frog before it is wedged into a socket farther along. The hair is usually concealed in the channel by a small sliding panel made of mother-of-pearl. The hair is similarly wedged in the head, the front of which is faced with ivory or silver to protect it from damage. When the screw is slackened off and the hair is loosened, the stick curves toward the hair. When the hair is tightened, the stick straightens out, or rather the curve flattens somewhat. It is the correct setting of this curve, which is put into the stick by bending under dry heat, and the exact shaping of the tapering section of the stick that give a good bow its desired qualities.

The Tourte bow

The larger instruments have followed the violin in bow design, adapting it to their special purposes by adjustments of dimension and weight. For a long time the double bass lagged behind, and during the first half of the 19th century this instrument was still being played with a broad, heavy version of the earlier outcurved bow. This was supplanted in France, and in other countries under French influence, by the violin-type bow and in Austria and German-speaking countries generally, a little later, by the Simandl bow, named after a contemporary professor of the Vienna Academy. This bow is really an adaptation of the older type but with an incurved stick, wide frog, and narrow head. (E.Hy./T.Gr.)

Keyboard instruments

Keyboard instruments include all musical instruments on which different notes can be sounded by pressing a series of push buttons or parallel levers. This large group of instruments has assumed great importance because the keyboard enables a performer to play many notes at once as well as in close succession. This versatility enables the modern pianist or organist to play, in transcription, any work of Western music, whether it involves chordal harmonies, independent contrapuntal parts, or only a single melody. The capabilities of keyboard instruments have influenced the composition of music for other media, because virtually every major composer from William Byrd (*c.* 1543–1623) to Igor Stravinsky (1882–1971) and beyond has been at least an accomplished keyboard performer, if not a renowned virtuoso. The evolution of an idiomatic keyboard compositional style has been linked to technological and theoretical developments within Western urban culture; keyboard instruments are not normally associated with folk music, and only during the 20th century has their use spread widely outside the Western world.

In its broadest sense, the term keyboard instrument may be applied to any instrument equipped with a keyboard and thus may be used to refer to accordions, percussion instruments such as the celesta and the carillon, and many electronic instruments—for example, the Moog synthesizer and the Ondes Martenot. In a narrower sense, such as is employed in this discussion, the term is restricted to instruments in which sound is produced from strings, whether by plucking, striking, or rubbing, or from pipes or reeds.

DEVELOPMENT OF THE KEYBOARD

Evolution from early forms. Long before the appearance of the first stringed keyboard instruments in the 14th century, the keyboard was developed and applied to the organ. A keyboard of the kind familiar today—a series of parallel levers hinged or pivoted so that they can be pushed down by the fingers—first appeared on the hydraulus, an organ probably invented in Alexandria in the late 3rd century BC. This type of keyboard seems to have disappeared after the fall of the Roman Empire, and the organs of the early Middle Ages generally had sliders that were pulled out to sound different notes; some may have had keys that turned like the key for a lock. Keys of the last type were certainly used on the organistrum, a large medieval hurdy-gurdy operated by two players: one turned a crank rotating a wheel that rubbed against one or more strings to make them sound, while the other produced different notes by turning the key-shaped levers that stopped the strings at various points (much as guitar strings are stopped against the fingerboard).

Some small portable organs had push buttons instead of keys as late as the 1440s, but a keyboard resembling the modern type existed in the 14th century, although the arrangement of naturals and sharps (corresponding to the white and black keys on the modern piano) was only gradually standardized. The arrangement of the keys depended in part on the music played and partly on the current state of musical theory. Thus, early keyboards are reported with only a single raised key in each octave (B♭), and there were organs that had both B and B♭ as "natural" keys, with C♯, D♯, F♯, and G♯ as raised keys. The colours of the keys—white for naturals and black for sharps—became standardized much later, about 1800, depending on fashion or on the relative cost of such materials as bone, ivory, or boxwood for the "white" keys and stained hardwood or ebony for the "black" keys. Flemish instruments had bone naturals and oak sharps by 1580; French and German instruments had ebony or fruitwood naturals and bone or ivory sharps until the 1790s.

Key arrangements and colours

Special key arrangements. *The short octave.* Even after the present arrangement of five raised keys and seven natural keys per octave had become standard in the 15th century, two exceptions existed. The first of these—the "short octave"—concerned only the lowest octave at the bass end of the keyboard. In the short octave, not all keys actually sounded notes of the expected pitch; their

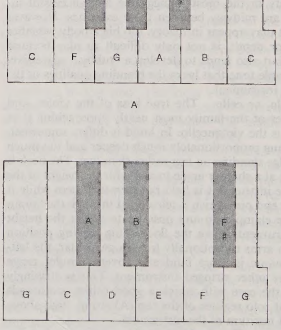

Figure 2: *Special key arrangements.*
Short octave (A) beginning on C and (B) beginning on G (see text).

respective strings were tuned to lower notes. In the earlier form (Figure 2A), the keyboard apparently started on E, but the string for this key was tuned to the C below. The apparent F♯ was tuned to D and the G♯ to E, so that the notes of the entire octave from C to c were encompassed within an apparent key span of only E to c. With this arrangement C♯, E♭, F♯, and G♯ were not available in the bass octave, but these notes were rarely required in the bass in music of this period. When the missing F♯ and G♯ later became necessary, short-octave keyboards were made with these keys divided into two parts, the fronts sounding D and E and the back parts sounding F♯ and G♯. Later still, a second short octave was developed (Figure 2B) in which the keyboard apparently began on low B. This key actually sounded the G below, and the apparent C♯ and E♭ were tuned to A and B (or B♭). Eventually, as musical styles changed, the two retuned sharps were divided in this arrangement as well, providing C♯ (or sometimes B♭) and E♭ at the back of these keys while retaining A and B at the front.

Divided sharps. The second type of exceptional keyboard arrangement was originally required by the so-called meantone tuning system generally used in the 16th–18th centuries. Meantone tuning provided significantly purer tuning for a relatively small number of tonalities than does equal temperament, the system now in use (in which all tonalities are somewhat out of tune; see MUSIC, THE ART OF: *Music and sound: Tuning and temperament*), but only at the expense of restricting the usefulness of the remaining tonalities. This characteristic arose because in meantone tuning each of the raised keys could be used in only one way: for example, if the key between D and E was tuned to E♭, it could not be used as D♯ without retuning. One solution was to build keyboards with the raised keys divided, the front half of the key sounding the appropriate sharp while the back half sounded the equivalent flat. The keys most commonly divided were A♭/G♯, E♭/D♯, and B♭/A♯. Instruments with up to three divided keys in each octave were commonly made in the 16th and 17th centuries, especially in Italy. Since the 1590s still more complicated keyboards have been built, permitting even more refined tunings; some in the 19th century had more than 50 keys per octave. Instruments have also been made with the octave divided into 24 rather than 12 equal parts to permit playing music utilizing quarter-tone intervals.

Impact of tuning systems

Keyboard size and range. Although some early organs had very wide keys that could be played only with the fists, stringed keyboard instruments seem always to have had natural keys no more than an inch wide, yielding an octave span of 7 inches (17.8 centimetres). The octave span on the modern piano is about $6\frac{1}{2}$ inches (16.5 centimetres), much the same as on Flemish and Italian harpsichords of the 16th–18th centuries, whereas that of English keyboards was generally $6\frac{3}{4}$ inches (16.2 centimetres). On most French and German instruments of the 18th century, the octave span was even narrower ($6\frac{1}{4}$ inches [15.9 centimetres]), permitting the playing of tenths—such as C to the second E above—by a hand of average size.

The range of the keyboard gradually expanded from a single octave for some early organs to $2\frac{1}{2}$ or 3 octaves in the 15th century and 4 or $4\frac{1}{2}$ octaves in the 16th century. By the early 18th century, except in Italy and Spain, a range of five octaves was common: from the F below low C to the F above high C (F_1 to f'''). This range began to be expanded only at the very end of the century, usually upward toward c'''' (C above high C) but occasionally downward to C, (C below low C). A few pianos with a range of six octaves (from C, to c'''') were built before 1800, and Beethoven's *Hammerclavier Sonata,* Opus 106 (completed 1818), requires $6\frac{1}{2}$ octaves from C, to f''''. A seven-octave range was reached before 1830, and the usual modern piano keyboard consisting of 88 keys provides the only slightly greater range of seven octaves and a third, from $A_{,,}$ to c''''.

THE CLAVICHORD

The earliest known reference to a stringed keyboard instrument dates from 1360, when an instrument called the *eschiquier* was mentioned in account books of John II the Good, king of France. The *eschiquier* was described in 1388 as "resembling an organ that sounds by means of strings." There exists no more complete description of the *eschiquier,* however, and it is not known whether the instrument was a variety of clavichord, in which the strings are struck by blades of metal that must remain in contact with them as long as they are to sound; a harpsichord, in which the strings are plucked; or a type of keyboard-equipped dulcimer, in which—as in the piano—the strings are struck by small hammers that immediately rebound from them. All three types of instruments were described and illustrated about 1440 by Henri Arnaut of Zwolle, personal physician of Philip the Good, duke of Burgundy.

Despite the uncertainty regarding the *eschiquier,* it seems probable that the clavichord was the earliest stringed instrument having keys that could be pushed down by the fingers. The term "clavichord" first appears in a German document from 1404, and the instrument is recognizable in a German altar carving from 1425. Its principle of operation resembles that of the medieval organistrum, and it is apparently closely related to the monochord, an instrument consisting of a shallow closed box over which one or two strings were stretched and supported by movable bridges. The monochord was in continuous use by theorists from ancient Greece onward as a device for explaining and measuring musical intervals. The kinship of the clavichord to the monochord was so close that, as late as the 16th century, clavichords were often called *monocordia.*

Principle of operation. The clavichord is rectangular in shape, and its strings run from left to right across the keys, which are placed along one of the longer sides of the rectangle. The soundboard of the instrument is at the right-hand end of the case, and the vibrations of the strings are communicated to it by a bridge on which the strings rest. The soundboard amplifies the sound of the strings by permitting them to set a large mass of air into vibration rather than the very small mass of air that contacts the string itself. (This is the same principle that makes a tuning fork sound louder when its stem is pressed against a tabletop.)

Shape and layout

The clavichord's operation is extremely simple. A brass blade rather like the end of a screwdriver is driven into the top surface of each key near the back of the key (Figure 3); a smaller piece of wood, whalebone, or horn is driven into the back end of the key. (This piece fits into a fixed slot behind the key and prevents the key from moving from side to side as it moves up and down.) When the front end of the key is pushed down by the finger, the back end rises, and the brass blade, called a tangent, strikes the strings (which in most clavichords are arranged in pairs), causing them to vibrate. To the left of the tangent a strip of cloth is woven between the strings. When the key is struck, only the portion of the strings to the right of the tangent—*i.e.,* between the tangent and the bridge—sounds; the cloth prevents the string section to the left of the tangent from sounding. As soon as the key is released, the tangent falls away from the strings, which are then entirely silenced by the cloth. Because the sounding portion of each string is the segment between tangent and bridge, the tangent serves not only to set the strings in vibration but also to determine their sounding length. Thus, a series of tangents striking a given pair of strings at different points will produce a series of different notes, and all the earliest clavichords were designed to take advantage of this fact. Arnaut of Zwolle's clavichord used only 9 or 10 pairs of strings to produce all the 37 notes of its 3-octave keyboard, and the clavichord represented in

From N. Bessaraboff, *Ancient European Musical Instruments* (1941), Harvard University Press

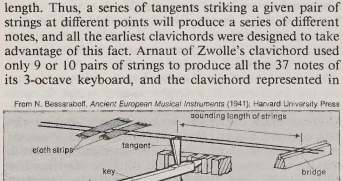

Figure 3: Clavichord action (see text).

an Italian intarsia (picture in wood inlay) of about 1480 (Palazzo Ducale, Urbino) used only 17 pairs of strings to produce 47 notes in a 4-octave range.

Making a single pair of strings serve several keys had two important disadvantages. Because each pair of strings can sound only one note at a time, it is impossible to play any two notes sounded from the same strings simultaneously, making it impossible to play certain chords. Furthermore, an unpleasant clanking sound is likely to result if the performer attempts legato playing of successive notes sounded from the same strings, making it necessary to play in a semidetached fashion.

As early as the time of Arnaut of Zwolle, the first of these disadvantages was minimized by allowing no more than four keys to sound from the same pair of strings and by carefully choosing the points at which such groups of four keys were placed, so that only dissonant chords would be unplayable. The second problem could be solved only when a maximum of two keys were served by the same strings, so that each natural key shared its strings only with the sharp or flat next to it. G, for example, was paired with G♯, and in the music of the period the two notes were seldom needed at the same time or in immediate succession. Of course, if one wanted to use the G♯ key as an A♭, the problem would reassert itself; but, as long as meantone tuning was in use, the G♯ could not serve as A♭ in any case.

Eventually, however, it was felt necessary to be able to play in all tonalities without restrictions either of style of playing or in the use of dissonant chords, and clavichords began to be built with one pair of strings for each key.

Fretted and unfretted clavichords

Such clavichords are called "unfretted," in contrast to those having several keys for each pair of strings, which are called "fretted." Although the unfretted clavichord was known as early as 1693, the oldest extant example, built by Hieronymus Albrecht Hass of Hamburg (Ger.), dates from 1742. Fretted clavichords were being made well into the 1780s; they had fewer strings to go out of tune, and the smaller number of strings permitted all the keys to be shorter and more equal in length, giving the instrument a superior touch. In addition, the smaller number of strings imposed a smaller downward force on the soundboard, resulting in a brighter, clearer tone.

Tone quality. The greatest disadvantage of the clavichord is its extremely soft tone. Because it arises directly from the way in which the sound of the instrument is produced, this disadvantage cannot readily be overcome. It is impossible to impart very much energy to a string by striking it at one end (it is for this reason that a guitarist makes less sound when he strikes the strings against the fingerboard with his left hand than when he plucks them with his right, even though the pitches produced are the same). In compensation, the clavichordist alone of all keyboard-instrument players has control over a note once it has been struck. As long as a note is sounding, he has contact with the string through the tangent and key, and by changing his pressure on the key he can vary the pitch of the note, produce a controlled vibrato, or even create the illusion of prolonging or swelling the tone. Although the maximum loudness of which a clavichord is capable is not great, its softest pianissimo is very soft indeed, and the clavichordist controls an infinite number of gradations in loudness between these two extremes. As a result of this touch sensitivity, the clavichord was highly valued as a teaching and practice instrument. In addition, its relative cheapness made it the normal domestic keyboard instrument in Germany, Iberia, and Scandinavia.

The quiet tone of the clavichord made it impractical to use the instrument in ensemble music, except for providing a discreet accompaniment for a flutist or a singer. Although much of the solo keyboard music of the 16th–18th centuries can be played on the clavichord, it cannot be stated that much of it before the latter part of the 18th century was especially composed with the clavichord in mind. At that time, however, the clavichord experienced a great revival in Germany, and music composed with its singing tone and unique capabilities of dynamic shading and vibrato was written for it by such masters as Carl Philip Emanuel Bach (1714–88).

Clavichords in the 19th century

Clavichords continued to be made in Germany and Scandinavia well into the 19th century, long after the piano was popular. Indeed, many instrument makers built both clavichords and pianos (and harpsichords as well). The continued demand for the older instruments may have been a consequence—among other things—of musicians' recognition of the three instruments' differing capabilities.

The clavichord owes its modest modern revival in the United Kingdom and America largely to the efforts of Arnold Dolmetsch, who began building clavichords and performing on them in public in the 1890s. Both his style of playing the clavichord and the design of his instruments were influential for a long period. Today, however, increasing numbers of clavichord makers and players are exploring earlier forms of the instrument.

THE HARPSICHORD

Principle of operation. *Plucking mechanism.* The sound of the wing-shaped harpsichord and its smaller rectangular, triangular, or polygonal relatives, the spinet and virginal, is produced by plucking their strings. The plucking mechanism, called a jack (Figure 4), rests on the key and consists of a narrow slip of wood with two slots cut into its top. The larger slot holds a pivoted tongue from which protrudes the quill, plastic, or leather plectrum that does the actual plucking; the smaller slot holds a piece of cloth that rests on the string and silences it when the key is not depressed. When the harpsichordist pushes down on a key, the back end rises, lifting the jack and forcing the plectrum past the string, plucking it. When he releases the key, the jack falls, and when the plectrum touches the string on the way down, it forces the pivoted tongue backward so that the plectrum can pass the string again without plucking it. Once the plectrum has passed beneath the string, a light spring made of bristle or metal pushes the tongue forward again. Finally, when the key is completely at rest, the cloth damper touches the string, silencing it. A wooden bar, padded on its underside, is placed over the jacks. The purpose of this bar is to prevent the jacks from flying out of the instrument and to limit the depth to which the keys can be depressed.

Although slight variations in loudness and timbre, or

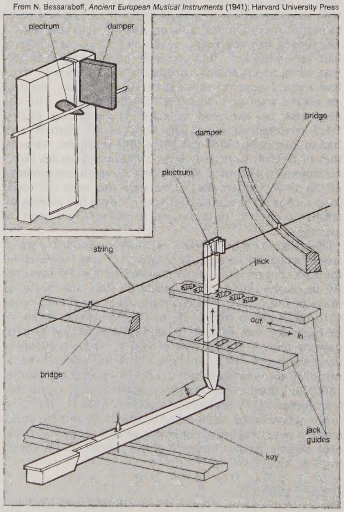

Figure 4: Harpsichord action (see text).

Variations in loudness and timbre

tone colour, can be obtained by differences in the firmness with which the harpsichordist depresses the keys, no sustained crescendos are obtainable by the action of the fingers alone. For this reason, most harpsichords made since about 1550 have had at least two strings and two jacks for each key. Each can be engaged or disengaged at will by a slight shift of the uppermost of two slotted guides through which the jacks pass. Moving the guide in one direction brings its entire row of jacks close enough to the strings for the plectra to pluck them; moving the guide in the opposite direction takes the jacks far enough from the strings so that the plectra cannot reach them. Two rows of jacks can provide three different levels of loudness or three differing tone colours, depending on whether the performer uses each row separately or both together.

Two-manual instruments. Even given two rows of jacks, it would not ordinarily be possible to produce the rapid changes in loudness required for pieces in echo style, for example, or to play loudly with one hand while providing a soft accompaniment with the other. To accomplish this, it is necessary to have two keyboards or "manuals," one of which operates a single row of jacks while the other operates two or more. It then becomes possible to play loudly on one keyboard and softly on the other, either simultaneously or in rapid alternation. Two-manual harpsichords of this kind were invented at some point before 1620 in Flanders and gradually became known throughout the rest of Europe during the 17th century. These instruments commonly had three sets of strings, two unison sets at normal pitch (called eight-foot pitch because the low C at this pitch is produced by an organ pipe eight feet long) and a third set of shorter strings tuned an octave higher, or at four-foot pitch; this shorter set passed over its own bridge and was fastened to pins driven through the soundboard into a rail fixed to its underside. There were three rows of jacks (Figure 5). The front row plucked one set of unison strings and was made in such a way that it would be moved by the keys of both the upper and the lower keyboards. Both the middle and back rows operated from the lower manual only; the second row plucked the second set of unison strings, and the back row plucked the octave strings. For most purposes a one-manual harpsichord sufficed: each row of jacks provided a continuously changing tone colour from one end of the keyboard to the other, permitting individual lines in the music to be articulated clearly. For this reason, as well as because of their lower price, the old harpsichord makers built far more single-manual instruments than doubles, and many more singles survive today.

Couplers. There is, however, one type of music that can only be played on a two-manual instrument. Called in French the *pièce croisée,* this kind of music involves separate lines that cross and recross in the same range, frequently employing the same note either simultaneously or in close succession. The parts in such pieces cannot be distinguished when played on a single manual, and they cannot even be played on two manuals if the manuals are not completely independent. (For example, if a note is already being held on the lower manual, it cannot be restruck on the upper manual when the lower manual lifts the upper-manual jacks.) The solution to this problem was found in France in the 1640s. Instead of providing the upper-manual jacks with an extension that reached down to the keys of the lower manual, they were made to rest entirely on the upper-manual keys; the lower-manual keys were then fitted with small upright pieces of wood called coupler dogs, which reached upward toward the underside of the upper-manual keys. The upper manual was constructed to slide forward and back by about ¼ inch. When it was pushed into the instrument, the coupler dogs were positioned below the back ends of upper-manual keys. As a result, when any lower-manual key was pushed down and its back end rose, the coupler dog would push up on the underside of the corresponding upper-manual key, lifting its jack as well. When one wished to uncouple the two keyboards in order to play *pièces croisées,* one could do so by pulling the upper manual outward. The coupler dogs then passed slightly beyond the ends of the upper-manual keys, so that they were not lifted when the lower-manual keys were depressed.

Music played on the two-manual instrument

Two-manual harpsichords of this kind permit players to exploit the difference in the tone colours produced by the two rows, or "registers," of unison jacks. This difference depends on the distance along the string at which it is plucked. The closer the plucking point is to the end of a string, the brighter is the sound; the farther away from the end that a string is plucked, the fuller and rounder the tone becomes, until one approaches the centre; plucking near the centre of a string produces a sweet, flutey, but somewhat hollow sound. In order to emphasize the difference in tone colours produced by the two rows of unison jacks, French harpsichord builders put the row of octave jacks between them, thereby increasing the distance between the two unison plucking points and the difference in tone of the two unison registers.

Special effects. A set of jacks plucking very close to the end of the string yields a very brassy, nasal sound. This type of register, called a lute stop, was first used in Germany in the 16th century and later spread to Flanders and to England, where it was added to the normal three registers on two-manual instruments. It did not have its own set of strings but, rather, plucked those of one of the existing unison registers. In England the lute stop plucked the same set of strings as the set of jacks operated by both keyboards; but, because the lute-stop jacks rested only on the upper-manual keys, they could also be used to provide a completely independent register on the upper manual. It was thus possible to play *pièces croisées* by taking off the unison register controlled by both manuals, using the lute stop for the upper manual and leaving the lower manual with its own unison register. Many harpsichords of all countries were also equipped with a buff stop (sometimes also called a lute stop), a device that presses pieces of soft leather against one of the sets of unison strings, producing a muted, pizzicato tone.

Lute and buff stops

In Germany in the 18th century, harpsichords were made with still more strings and jacks for each key. Some had three unison strings in addition to an octave string; some had two unisons, an octave, and a suboctave (or 16-foot) register; and some even had a 2-foot register, with very short strings tuned two octaves above the unisons. Harpsichords with three keyboards were apparently built throughout the 17th and 18th centuries, although only one authentic three-manual harpsichord is known today.

It should be emphasized, however, that the harpsichord of the 16th–18th centuries normally had only one or two keyboards and only two or three sets of strings and jacks per note. In the 16th and early 17th centuries, one-manual instruments usually had only two registers (either two unisons or a unison and an octave) with or without a buff stop; in the second half of the 17th century a second unison register became common, increasing the number

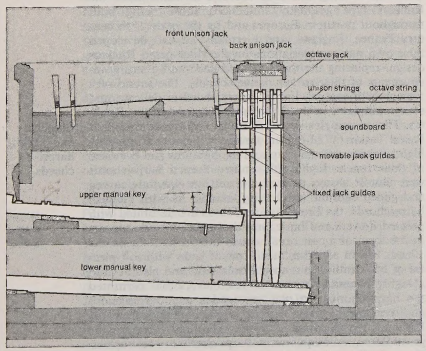

Figure 5: Flemish two-manual harpsichord action (see text).

of jacks and strings to three per note. Two-manual instruments, likewise, had no more than three sets of strings (two unisons and an octave) and three sets of jacks throughout the 17th century. In the 18th century, a fourth row of jacks was sometimes added. In Britain and Flanders, this row was the close-plucking lute stop; in France, if a fourth row was added, it was placed behind the other three and equipped with plectra of soft buff leather that provided a gentle, flutey tone, which was highly prized in the rather decadent period of the harpsichord's decline. Until the last half of the 18th century, it was usually possible to change registers only by moving knobs at the side of the instrument or above the keyboards, which could be done only when one hand or the other was not playing. This fact and the surviving written evidence suggests that the harpsichordists of earlier times changed registers relatively infrequently, avoiding monotony of sound by relying on variations of touch and the changes of texture and pitch level written into the music.

History. The harpsichord may have evolved from devices invented by medical astrologers for the purpose of investigating the effects of cosmic musical harmonies on the human body. The wing-shaped instrument was described by Arnaut of Zwolle in the mid-15th century and was apparently known throughout Europe by the end of the century, although no 15th-century examples have survived. The harpsichords depicted in sculptures, paintings, and miniatures of the period all appear to be shorter and to have thicker cases than the earliest surviving 16th-century examples, all of which are Italian and are constructed of very thin cypress.

Earliest surviving harpsichords

Italy. The thin-cased style of harpsichord construction appears to have been developed in Italy about 1500, and it rapidly influenced the design of harpsichords throughout the rest of Europe. The strings of the Italian harpsichords were rather short, with the strings for c‴ (C above middle C) generally being about 10 inches (25 centimetres) long on instruments tuned to what is today considered normal pitch. On some Italian harpsichords, however, the strings for c‴ are about 14 inches (36 centimetres) long; it is thought that these were tuned to a pitch a fourth below that of the shorter-strung ones, the key for C sounding what today would be the G below. The comparatively short strings imposed a relatively low tension on the case of the Italian harpsichord, allowing it to hold up with so light a structure.

In general, Italian harpsichords had only one keyboard with two rows of jacks and two strings tuned in unison or unison and octave. The fragile Italian instruments were normally housed in thick outer cases of softwood, which were either painted or covered with stamped leather. The cases, in turn, rested on separate legs or elaborate stands. The tone of these lightly constructed instruments is surprisingly loud and penetrating, making them ideal as accompanying instruments in an orchestra and suiting them perfectly to the rattling scale passages typical of Italian harpsichord music.

Flanders. As the new Italian design spread northward, first into Germany and then to Flanders, France, and England, it was modified to the extent that the 16th- and 17th-century northern European instruments had somewhat longer strings (11½ to 12½ inches [29 to 32 centimetres] for c‴) and thicker cases (3/16 to ¼ inch [5 to 6 millimetres] in contrast to the ⅛ inch [3 millimetres] found on Italian instruments). In the 1560s in Flanders, however, this type of instrument was replaced by still another design, which ultimately dominated all northern European harpsichord making. These instruments had long strings (about 14 inches for c‴ at normal pitch) and thick cases with substantial internal bracing to withstand the greater tension imposed by the greater string length. Because the longer strings made it unfeasible to double the string length for each octave below middle C, harpsichords of the newer Flemish design have less gracefully curved bentsides and wider tails than either Italian harpsichords or the intermediate instruments built elsewhere north of the Alps.

The name most often associated with Flemish harpsichord building is that of the Ruckers family, which for four generations (from about 1580 to 1680) dominated Flemish harpsichord making and whose instruments were exported to all parts of Europe—one was even shipped as far as Peru. At first sight, Ruckers harpsichords appear crude compared to their Italian counterparts, and their thick softwood cases give the impression of being clumsily cobbled together on the inside. Nonetheless, the tone of unaltered or properly restored examples is extraordinarily good, and it is easy to see why Ruckers instruments were so highly prized that a lively business in making forgeries of them flourished in the 18th century.

Harpsichord building of the Ruckers family

In addition to a wide variety of virginals (discussed below), the Ruckers family made several different harpsichord models. The most popular was apparently six feet long, having a four-octave keyboard from C to c‴, with a short octave in the bass; one unison and one octave register; and, occasionally, a buff stop on the unison. They were typically painted in imitation of marble on the outside and decorated on the inside with block-printed paper on which a Latin motto was painted. The soundboard was usually decorated with paintings of flowers, leaves, and birds. (This decoration should be contrasted with that of Italian harpsichords, which, except for their finely profiled moldings and lavish outer cases, were generally unadorned.) Flemish harpsichords were set directly on fairly massive stands, examples of which may be seen in the numerous Dutch paintings of musical groups of the period. Similar harpsichords were made in smaller sizes tuned a fifth or an octave above normal pitch (the key c′ sounding either g′ or c″). By the mid-17th century, some single-manual instruments had a range of 4½ octaves from F_1 or G_1 to c‴.

The Ruckers family appears to have been the first to make two-manual harpsichords. These were of two types: in one (which may have been the earlier type and was not built after about 1650), both keyboards were served by a single set of unison and octave strings and were not meant to be played at the same time. Instead, the keyboards were so arranged that c‴ on the upper keyboard was placed over f‴ on the lower keyboard, which meant that playing a piece on the lower keyboard automatically transposed it to a pitch a fourth below that of the upper keyboard. Whether this arrangement was used to facilitate routine transpositions or whether it was intended to provide in a single instrument the same resources as those available from both an Italian instrument with a 10-inch c‴ and one with a 14-inch c‴ is still a subject for controversy. The second type of two-manual harpsichord built by the Ruckers family was basically the type one finds today, with keyboards aligned over one another and intended to provide contrasts in loudness. Because the only set of upper-manual jacks was also played directly from the lower manual, it was not possible to play *pièces croisées.*

France. During the 17th century, instruments of the Ruckers type gradually influenced those being built throughout northern Europe; and by the early 18th century France, England, and Germany all had developed their own national variations on the thick-cased Ruckers design, replacing the thinner-cased and shorter-strung instruments of their earlier native schools. The sound of a typical 18th-century French harpsichord is delicate and sweet compared to the more astringent sound of a Ruckers. Those examples by the Blanchet family and their heir Pascal Taskin (1723–93) are noted for their extraordinarily high level of craftsmanship and the lightness and evenness of their touch. Eighteenth-century French harpsichords were almost always painted and rest on elaborate carved and gilded cabriole (curved-leg) stands. As with Flemish harpsichords, the French soundboards are decorated with painted flowers and birds, and the maker's mark appears in the form of a cast ornament in the sound hole. In the 1760s, Taskin added a fourth row of jacks with soft plectra of buff leather as a special solo stop and also devised a highly ingenious system of knee levers that permitted the harpsichordist to play crescendos and decrescendos and to change registers without taking his hands from the keyboard. By the time of these inventions, however, the great Baroque composers of harpsichord music, such as François Couperin, J.S. Bach, Jean-Philippe Rameau, and

Blanchet and Taskin harpsichords

Domenico Scarlatti, were dead, and these devices have no relevance to the historically accurate performance of harpsichord music of the Baroque era or earlier.

Great Britain. In Britain the making of harpsichords in the 18th century was dominated by two London families, the Kirkmans and the Shudis. Both families made instruments for several generations and eventually moved on from harpsichord building to piano building. Their harpsichords are very similar, and the two-manual instruments all have a close-plucking lute stop in addition to the usual two unisons and octave. They are invariably veneered in walnut or mahogany and rest on simple stands, usually with straight or tapered legs. The tone of a Kirkman or Shudi harpsichord is both more robust and more brilliant than that of a French or Flemish instrument, making it a superb instrument for filling in the harmonies in orchestral music as well as for the performance of the solo harpsichord literature.

Germany. Two German schools appear to have existed in the 18th century. One in the southern part of the country has left very few surviving instruments, which is unfortunate because these are the kind probably played by J.S. Bach. As far as is known, the southern German instruments were fairly plain, veneered ones, having only three registers and a rather darker tone than either French or Flemish instruments. The second German school was centred in the city of Hamburg and is best represented by the work of the Hass family. The Hass instruments are among the most elaborate ever made, in both decoration and complexity. They are the only 18th-century harpsichords with 16-foot and 2-foot registers, and some have lute stops as well. Their tone does not, unfortunately, live up to the quality of their craftsmanship or the ingenuity of their design, seeming overly brilliant and too thick in all the surviving examples that have been restored to playing condition.

Hass family instruments

Decline of the harpsichord. Although many of the finest surviving harpsichords date from after 1750, few composers of the first rank were writing for the instrument by that time. Furthermore, the emergence of a newer, lighter style of music and an increased interest in crescendo and decrescendo effects led to the addition of various new devices foreign to the essential nature of the instrument. These include the knee- and foot-operated contrivances for the rapid changing of registers or for producing crescendos and decrescendos. Such devices represent the harpsichord builders' response to the same musical needs that eventually caused the harpsichord's replacement by the piano; but they were created before the real rise in the piano's popularity and must not be thought of as attempts to stave off the competition of the newer instrument.

As with the clavichord, builders continued to make harpsichords side by side with pianos. In England, Shudi's son-in-law, John Broadwood (see below), continued to make harpsichords until after 1800 (although in decreasing quantity), producing at the same time an ever-increasing number of pianos. There is even a small but interesting group of compositions by British, German, and French composers calling for both instruments.

Modern revival. The harpsichord had all but vanished except as a curiosity or in rare historical concerts when the modern revival began in the 1890s with the building of new harpsichords by the piano firms of Érard and Pleyel in Paris. Almost immediately, the full brunt of 19th-century piano technology was applied to the manufacture of the revived instruments, and they became increasingly massively strung and framed as time passed. Pedals for changing registers were included from the beginning, and Pleyel first added the 16-foot stop in 1911. The Pleyel's sound, as preserved in the recordings of the Polish virtuoso Wanda Landowska and her numerous pupils, typified the harpsichord for most music lovers until the 1950s, and it is for a heavy, metal-framed instrument of this type, with pedals for changing registers and a 16-foot stop, that most 20th-century harpsichord music has been composed.

Pleyel instruments

In 1905 modern harpsichord building was begun in Germany, initially taking the new Pleyel and Érard instruments as inspiration. Subsequent German building produced a highly characteristic instrument somewhat reminiscent of the harpsichords of the 18th-century Hamburg school in sound. Taking as their model an improperly restored instrument falsely said to have belonged to Bach, these instruments generally had the unhistorical stop arrangement of one 8-foot and the 4-foot on the upper manual, with the second 8-foot and a 16-foot on the lower manual.

Arnold Dolmetsch, who began the modern revival of the clavichord, also built harpsichords, working in Paris and Boston as well as in England. He deserves to be considered the "godfather" not only of the present British school of harpsichord making but also of the flourishing American school, most of whose members are, however, building a very different and far more historically based instrument than any that Dolmetsch made after about 1910.

The virginal, spinet, and clavicytherium. The virginal, spinet, and clavicytherium are all varieties of harpsichord that differ from it primarily in size, shape, and musical resources. Virginals and spinets usually have only a single set of strings and a single row of jacks. The clavicytherium is basically a harpsichord set upright so that its soundboard is vertical. The earliest known mention of the clavicytherium dates from about 1460; the oldest extant example (Royal College of Music, London) was probably made in Ulm, Ger., about 1480. Instruments of this form were made from the 15th through the 18th centuries. In general, their mechanism has to be fairly complicated because the jacks must move horizontally rather than vertically and cannot therefore return to their rest position solely by the action of gravity. As a consequence of this complexity of its mechanism, the touch of the clavicytherium tends to be heavy, although the instrument takes up less floor space, and the vertical soundboard projects sound outward far more effectively than the horizontal soundboard of the conventional harpsichord.

The virginal and spinet are small varieties of harpsichord, but the precise usage of the terms differs. Some writers reserve the term virginal for rectangular instruments and call all small triangular or polygonal instruments spinets. Others apply the term virginal to all plucked stringed keyboard instruments whose strings run more or less from left to right across the keys (a usage followed in this article), reserving the term spinet for instruments in which the strings run obliquely away from the player. The terminological question is complicated by the fact that the word virginal in 16th- and 17th-century England referred to all plucked stringed keyboard instruments, including harpsichords and spinets as well as those today termed virginals. The term *épinette* ("spinet") had a similarly broad usage in France.

Italian builders of the 16th and 17th centuries made virginals and spinets employing a thin-cased construction similar to that of their harpsichords, and, like Italian harpsichords, these smaller instruments were kept in stout outer cases. The typical Italian virginal was either rectangular or polygonal in shape, with its keyboard projecting from the front of the case, and many of the surviving examples are sumptuously decorated with inlay or intarsia. Most Italian spinets are constructed as an irregular quadrilateral, but in the 17th century a new form was developed that more closely resembles a small harpsichord in having a bentside at the player's right and a long straight back slanting away from him. The new form was copied throughout Europe and became the standard domestic keyboard instrument in England in the late 17th century.

In Flanders, early virginals were polygonal and resembled Italian ones except that their keyboards were inset rather than projecting. In the 1560s, at the same time as the thick-cased harpsichord is believed to have emerged, thick-cased rectangular virginals made their appearance. By the end of the 16th century, two distinct types existed. They can readily be distinguished by the position of their keyboards: off-centre either to the left or to the right in one of the long sides of the rectangular case. Virginals with the keyboard at the right were far more common. They produce a characteristic flutey tone because the placement of the keyboard causes the strings to be plucked near their centre for most of the instrument's range. In virginals with the keyboard at the left, the strings are plucked off-centre except in the extreme treble, and the tone changes

Types of Flemish virginals

gradually from reedy in the bass, through full in the middle register, to flutey in the treble, much as on a harpsichord. Flemish builders produced virginals of both types in several sizes, the smaller ones being tuned to higher than normal pitches. They also made "double" virginals, consisting of a large virginal at normal pitch and a smaller one tuned an octave higher, which could be stored in a recess next to the keyboard of the larger instrument. The two virginals could be coupled together by placing the smaller instrument on top of the larger one.

The virginals made in England were of the left-keyboard type. Those made elsewhere in Europe (some having the keyboard centred) were also built with strings plucking off-centre.

THE PIANO

Principle of operation. Although the basic principles of the piano's operation are simple, the refinements required in developing the powerful yet sensitive modern piano make it also the most complex of all mechanical instruments except the organ. The strings of the piano are struck by a felt-covered hammer that must rebound from the strings instantaneously or it will dampen their vibrations in the very act of initiating them. The hammer must thus be allowed to fly freely toward the strings. For the pianist to retain maximum control of loudness, the distance of the hammer's free flight must be as small as possible; but, if the distance is too small, the hammer will bounce back and forth between the strings and the part of the mechanism that pushed it, producing a stuttering sound whenever the keys are struck firmly. As a consequence, all truly simple piano mechanisms—those in which, say, a rigid rod at the back of the key simply pushes the hammer upward until the key is stopped by a rail and the hammer flies free—must be adjusted to provide a large distance for free flight and can therefore give the pianist only limited dynamic range and control.

History. *Invention.* Piano mechanisms as unsophisticated as that described above continued to be devised and built throughout the 18th century. Nevertheless, the first successful piano—made in Italy by Bartolomeo Cristofori—solved the problems inherent in such simple mechanisms, as well as nearly every other problem facing piano builders until well into the 19th century. Cristofori reportedly experimented with a "harpsichord with hammers" in 1698. By 1700 one of these instruments, together with six of his harpsichords and spinets, was included in an inventory of instruments belonging to the Medici family in Florence. In 1711 the instrument was described in detail in the Venetian *Giornale de' letterati d'Italia* by Scipione Maffei, who called Cristofori's invention *gravicembalo col piano e forte* ("harpsichord with soft and loud")—whence the present names pianoforte and piano.

Cristofori's pianos

In the three surviving examples of Cristofori's pianos, which date from the 1720s, the mechanism, or "action," differs somewhat from that described and pictured by Maffei; however, rather than merely representing an earlier phase of Cristofori's work, Maffei's diagram may be in error. In the surviving instruments a pivoted piece of wood is set into the key (Figure 6). The pivoted piece (which in a modern piano would be called a jack and should not be confused with the jack in a harpsichord) lifts an intermediate lever when the key is depressed. The lever, in turn, pushes upward on the hammer shaft near its pivot in a rail fixed above the keys. When the key is pressed completely down, the jack tilts and disengages itself from the intermediate lever, which then falls back, permitting the hammer to fall most of the way back to its rest position, even while the key is still depressed. This feature, called an escapement, is the heart of Cristofori's invention; it makes possible a short free flight for the hammer, after which the hammer falls so far away from the string that it cannot rebound against it, even when the keys are struck firmly. Cristofori provided a check (a pad rising from the back of the key) to catch and hold the falling hammer. At the end of the key he included a separate slip of wood, resembling a harpsichord jack, to carry the dampers that silence the string when the key is at rest.

Utilizing an intermediate lever to act on the hammer

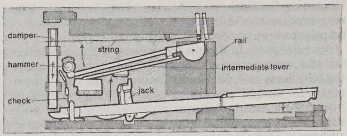

Figure 6: Cristofori's piano action (see text).
From R.E.M. Harding, *The Piano-Forte* (1933); published by Cambridge University Press

near one end of its shaft provides an enormous velocity advantage, and the hammer flies upward toward the string much faster than the front end of the key descends under the pianist's finger, adding to the crispness and sensitivity of Cristofori's action. In addition to his innovative mechanism, Cristofori also introduced a unique double-wall case construction that isolated the soundboard from the pull of the strings. The sound of his instruments is strongly reminiscent of the harpsichord. The dynamic range is surprisingly wide, but it should be emphasized that the instrument's loudest sounds are softer than those of a firmly quilled Italian harpsichord and do not begin to approach the loudness of a modern piano.

German and Austrian pianos. As a piano builder Cristofori had few immediate successors in Italy, but word of his invention became known in Germany through a translation of Maffei's account published in 1725. Before 1720 there had been independent attempts in France as well as in Germany to devise hammer mechanisms, although none was comparable to Cristofori's in sophistication or practicality. In the 1730s Gottfried Silbermann, of Freiberg in eastern Germany, a builder of organs, harpsichords, and clavichords, began constructing pianos patterned on Cristofori's. The surviving ones, probably from the 1740s, appear to have been directly copied from an instrument imported into Germany rather than derived from Maffei's description, but the ones he made earlier (and of which Bach is said to have disapproved in 1736) may have owed their failure to an attempt to follow Maffei's diagram exactly. By 1747 Silbermann had sold several of his pianos to King Frederick II the Great of Prussia, and one of these is reported to have met with Bach's approval in 1747.

Gottfried Silbermann's instruments

Subsequent German piano building did not follow the path charted by Silbermann. Instead, various German builders attempted to devise actions that were simpler than Cristofori's, generally adapting them to the clavichord-shaped instruments now called "square" pianos. In the most characteristic German actions, the hammers point toward, rather than away from, the player, and, instead of being hinged to a rail passing over all the keys, they are attached individually to their respective keys. As the front of the key is depressed, the back rises, carrying the hammer with it. A projecting beak at the rear of the hammer shank catches on a fixed rail above the back of the keys, so that the hammers are flipped upward as the keys are stopped by a second rail set just above them. This action had no escapement, and (on the evidence of a letter of 1777 from Mozart to his father) many German instruments of the 1770s still lacked this highly important feature.

Johann Andreas Stein of Augsburg in southern Germany is generally credited with devising the first German action to include an escapement. As a replacement for the fixed rail that caught the projecting beaks at the rear of the hammer shanks, Stein provided an individually hinged and sprung catch for each key (Figure 7). As the back of the key reaches its highest point, this catch (the escapement) tilts backward on its hinge and releases the beak at the back of the hammer shank. The hammer is then free to fall

From R.E.M. Harding, *The Piano-Forte* (1933); published by Cambridge University Press

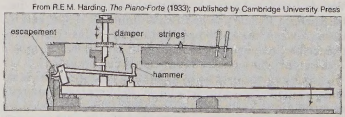

Figure 7: The German action (see text).

back to rest position even when the key is still depressed. This action is often called "Viennese," because it was used by all the important 18th- and early 19th-century piano makers in Vienna, including Stein's daughter and son-in-law, Nannette and Johann Andreas Streicher; Anton Walter, Mozart's favourite piano builder; and Conrad Graf, maker of Beethoven's last piano. It was used in German-speaking countries until the late 19th century, when it was replaced by mechanisms derived from a Cristofori-based action developed in England.

Although the tone of a piano by Stein or Walter is not loud, it is very sweet, with a singing treble and a clear tenor and bass that blend superbly with the sound of stringed instruments. The touch is extremely light and shallow: the force required to depress a key is only one-fourth that required on a modern piano, and the key need only be depressed half as far. In their sensitivity to the finest differences in touch and their singing tone, the Viennese pianos suggest the responsiveness of a clavichord, although producing a louder sound.

Special effects

Austrian and German pianos of the early 19th century often feature an array of pedals. Only one of Cristofori's surviving pianos has any special effects: levers on the underside of the instrument permit the player to shift the action sideways so that the hammers strike only one of the two strings provided for each note. By the time Silbermann built his pianos for Frederick the Great, a second special effect had been introduced—a mechanism to lift the dampers from the strings so that they could vibrate freely whether or not the keys were depressed. (These two effects, the sideways sliding of the action—to produce a softer sound and different tone colour—and the lifting of the dampers—to produce a louder, more sustained sound and another variation in tone colour—are the only ones found on all modern grand pianos.) Silbermann's pianos had hand levers for raising the treble and bass dampers separately and an additional hand lever for muting the strings. Stein's pianos normally had two knee levers for raising the treble and bass dampers and a third knee lever that interposed a strip of cloth between the hammers and the strings to produce a velvety pianissimo. Later instruments might have five or more pedals that, for example, pressed a roll of parchment against the bass strings to produce a buzzing sound or rang small bells and banged on the underside of the soundboard in imitation of the cymbals and drums of the then-fashionable "Turkish" music.

The English action. In the late 1750s a number of German piano builders emigrated to Britain, and one, Johann Christoph Zumpe, invented an extremely simple action for the square pianos he began building in the mid-1760s. Zumpe's action goes back to the Cristofori-Silbermann system in which the hammers point away from the player and are hinged to a rail over the keys. A metal rod tipped with a padded button is driven into the back of the key (Figure 8). When the key is depressed, the rod pushes the hammer upward; the key is stopped by a padded rail over its back end, and the hammer then flies freely. Despite the lack of an escapement, Zumpe's square pianos were an enormous commercial success and were copied in France, the Low Countries, and Scandinavia.

Zumpe had worked for the harpsichord builder Burkat Shudi when he first came to England, and around 1770 three other workmen in Shudi's shop, John Broadwood, Robert Stodart, and Americus Backers, devised for grand pianos an adaptation of Zumpe's action that included an escapement. This important development made London a major centre of piano building and created a characteristic English piano of fuller and louder sound than the Viennese piano but with a heavier, deeper touch and a

consequent inability to play repeated notes as rapidly. In the English grand-piano action (Figure 9), the fixed rod of Zumpe's square-piano action was replaced by a pivoted jack, similar to that in Cristofori's action. The upper end of the jack fits into a notch at the base of the hammer shank, slipping out of the notch as the back of the key reaches its highest point; the hammer then flies free, strikes the string, and falls back to be caught by a hammer check even when the front of the key is still held down. The tone of a typical 18th-century English grand piano is surprisingly reminiscent of the tone of an English harpsichord, suggesting that the English piano makers were, like Cristofori, seeking to make an expressive harpsichord, unlike the German builders who, in effect, appear to have been trying to build a louder clavichord.

Unlike their Austrian and German counterparts, English pianos had two or, at most, three pedals. One of the two ordinary pedals shifted the keyboard sideways so that the hammers struck two or only one of the three strings provided for each note. The second pedal raised all the dampers. It was sometimes replaced by two pedals—one for the treble dampers, the other for the bass dampers—or, occasionally, by a single damper pedal divided into two parts that could be depressed separately or together with one foot, as on the piano presented by Broadwood to Beethoven in 1817.

Although the pianos of the late 18th and early 19th centuries were perfected instruments ideally suited to the music of their period, the increasing popularity of public concerts in large halls and concerti with large orchestras stimulated attempts by piano builders to produce an instrument of greater brilliance and loudness. Their efforts gradually created today's vastly different piano. In recent years, the special merits of the earlier instruments (sometimes called "fortepianos" to distinguish them from modern pianos) have come to be appreciated, and several builders have begun to make replicas of them.

Other early forms. As previously mentioned, many 18th-century pianos were "squares," built in a form resembling the clavichord. More compact and less expensive than wing-shaped grands, the square piano continued through much of the 19th century to be the most common form of piano in the home. But as square pianos became larger and larger, these advantages diminished, and the square piano was eventually replaced by the upright. In the 18th and early 19th centuries, upright pianos (*i.e.*, pianos with vertical strings and soundboard) took three different forms. In the "pyramid piano" the strings slanted upward from left to right, and the case above the keyboard took the form of a tall isosceles triangle. Or a grand piano was essentially set on end with its pointed tail in the air, producing the asymmetrical "giraffe piano." Placing shelves in the upper part of the case to the right of the strings yielded the tall rectangular "cabinet piano." Because the lower end of the strings, which ran nearly vertically, was about at the level of the keyboard, all such instruments were very tall. Although there were attempts to construct lower instruments by, in effect, positioning a square piano on its side, the American builder John Isaac Hawkins made the first truly successful low uprights in 1800 by placing the lower end of the strings near floor level. Robert Wornum in England built similar small uprights in 1811, and in 1842 he devised for them his "tape check" action, the direct forerunner of the modern upright action.

Pyramid, giraffe, and cabinet pianos

Development of the modern piano. In the early 19th century, piano makers were principally concerned with

two problems whose solutions led to the modern piano. These were the relatively small volume of sound that could be produced from the thin strings then in use and the difficulty of producing a structure that could withstand the tension even of such light strings once the range of the instrument exceeded 5½ octaves.

Bracing and frame. Like 18th-century harpsichords, the pianos of the 18th and early 19th centuries were constructed entirely of wood, with the case (supported by a structure of internal wooden braces) sustaining the entire stress exerted by the strings. The only metal bracing in such instruments appears in the form of flat or arched pieces bridging the gap through which the hammers rise to strike the strings. These braces eventually proved insufficient when the walls of the case itself and the pinblock (the long piece of wood into which all the tuning pins were driven) were incapable of withstanding the increasing tensions placed upon them. For this reason, ever-increasing quantities of metal bracing came into use, first in the form of individual bars running parallel to the strings from the side of the case to the pinblock but finally in the form of a single massive casting that took the entire tension of the strings upon itself. The one-piece cast-iron frame was first applied to square pianos by Alpheus Babcock of Boston in 1825, and in 1843 another Bostonian, Jonas Chickering, patented a one-piece frame for grands. With the adoption of such frames, the tension exerted by each string (about 24 pounds [11 kilograms] for an English piano of 1800) rose to an average of approximately 170 pounds (77 kilograms) in modern instruments, the frame bearing a total tension of 18 tons.

Babcock and Chickering pianos

Overstringing. The strings in early pianos, like those in harpsichords or clavichords, ran parallel to one another, causing the grand pianos of the 18th and early 19th centuries to retain much of the graceful shape of the harpsichord. In the 1830s it was realized that the bass strings could be made longer and their tone improved if they were made to fan out over the treble strings. This idea was first applied to square pianos, but in 1855 Steinway & Sons built a grand piano with a complete cast-iron frame embodying this "overstrung" plan, in which the strings of the treble and the middle registers fan out over most of the soundboard and the bass strings cross over them, forming a separate fan at a higher level. Because the bass strings fan out, the tail of the modern grand piano is far wider than that of the earlier "straight-strung" instruments.

Modifications in the action. The gradual strengthening of the piano's structure to permit the use of heavier strings eventually gave rise to hitherto unforeseen problems. The thicker strings could yield the louder sound of which they were capable only if they were struck by heavier hammers; any increase in the weight of the hammer, however, required a manyfold increase in the force required to depress the keys. This difficulty was present to a minor extent even in the 18th-century English grand-piano action, and the touch on these instruments was both deeper and heavier than on Viennese pianos. Moreover, the deeper touch meant that it took longer for a key to return to rest position so that a note could be restruck. Consequently, English pianos were not capable of the rapid repetition of Viennese instruments. This problem became quite severe as the hammers grew heavier and as musicians wished increasingly to use tremolo effects in imitation of orchestral music.

What was necessary was an action that would permit a note to be restruck before the key returned to rest position. The first successful action of this type was devised by the Frenchman Sébastien Érard, who as a young man had built a harpsichord with a particularly elaborate system of pedals and knee levers and in 1810 devised the system of pedals still in use on the harp. Érard's first "repetition" or "double-escapement" action was patented in 1808, and an improved version that is the basis of the modern action was patented in 1821.

The double-escapement action of Érard

A further consequence of the use of thicker strings was that, if the sound of the instrument were not to become unduly harsh, the hammers had to be softer than those used on 18th-century instruments—light slips of wood covered with a few layers of thin leather. Felt-covered hammers were patented in 1826 by the Parisian builder Jean-Henri Pape, who also contributed a number of other ingenious and important improvements, but the use of felt instead of leather did not become universal until after 1855.

With the adoption of the one-piece cast-iron frame, overstringing, and felt hammers, the piano achieved its modern form in all but a few details. One was the invention in 1862 by Claude Montal of Paris of a pedal that kept the dampers off the strings only for notes already held down. Individual notes could thus be sustained without the overall blurring caused by raising all the dampers by the ordinary damper pedal. On three-pedal pianos, this device is included as the middle pedal, with the damper ("loud") pedal at the right and the action-shifting (una corda, or "soft") pedal at the left.

Types of modern piano. Since the abandonment of the square piano, only upright and grand pianos are regularly manufactured. The grands range in length from a minimum of about 5 feet (150 centimetres) for a "baby" grand to a maximum of about 9 feet (270 centimetres) for a "concert" grand, although both shorter and longer instruments have been constructed. Among upright pianos, the models over 4 feet (120 centimetres) tall—which frequently had an excellent tone because of their relatively long bass strings—have largely been superseded by the lower models, the "console" (about 40 inches [100 centimetres high) and the "spinet" (about 36 inches [90 centimetres] high). Because the spinet's case rises such a small distance above the keyboard, it usually has "drop" action, most of which lies below the level of the keys.

Console and spinet models

Modern piano actions. In 1636 Marin Mersenne, the author of the treatise *Harmonie universelle,* quoted a remark that the harpsichord of his time contained 1,500 different parts. The modern piano contains 12,000, most of which are found in the action. The modern grand piano action (Figure 10) is a simplified version of Érard's double-escapement action of 1821, and, although different manufacturers' actions differ in detail, they all work in much the same way. When the key is depressed, its back end rises, lifting the wippen. The wippen raises a pivoted L-shaped jack that pushes the hammer upward by means of a small roller attached to the underside of the hammer shank. The hammer flies free when the back of the L-shaped jack touches the adjustable regulating button. At the same time, the upper end of the repetition lever—through which the upright arm of the jack passes—rises until it is stopped by the drop screw. When the hammer rebounds from the string, the roller falls back until it is stopped by the intermediate lever, enabling the tip of the jack to return to position beneath the roller, even if the key is still partially depressed. The jack is then ready to raise the hammer again should the player restrike the key before it returns to rest position. In the meantime, the hammer is prevented from bouncing back up toward the strings by the padded hammer check, and the damper is raised above the strings by a separate lever lifted by the extreme end of the key.

Player pianos. The history of automatically playing stringed keyboard instruments dates at least to the 16th century. The inventory of musical instruments owned by

From E. Q. Norton, *Tuning and Care of the Pianoforte*

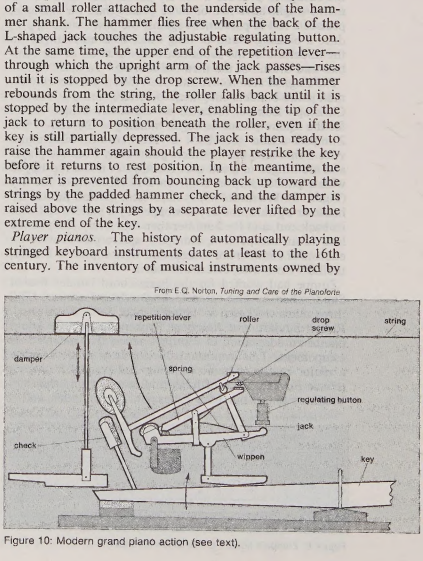

Figure 10: Modern grand piano action (see text).

King Henry VIII at his death in 1547 included "an instrument that goethe with a whele without playing upon," and three spinets equipped with a pinned barrel like that of a music box or barrel organ survive from the workshop of the Augsburg builder Samuel Bidermann (1540–1622). The most common type of player piano operates by means of a roll of punched paper that controls a pneumatic system for depressing the keys. Its heyday was the 1930s, and it was largely rendered obsolete by the increasing popularity of the phonograph and the radio. In the 1980s, electromagnetic player-piano actions equipped with laser sensors and computer controls were developed, allowing a pianist to record and immediately play back or edit his performance. Such sophisticated player pianos are especially useful in recording and teaching studios.

RELATED STRINGED KEYBOARD INSTRUMENTS

Stringed keyboard instruments have sometimes been altered slightly for various reasons. For example, as early as the 16th century harpsichords were occasionally strung with gut rather than with metal wire in order to imitate the sound of a lute. Such gut-strung harpsichords, one of which was owned by J.S. Bach, were called in German *Lautenwerck.* The 18th-century tangent piano dispensed with pivoted hammers and instead had loose slips of wood or metal supported vertically in a rack above the backs of the keys; as a bar abruptly halted the motion of a key, its slip, or tangent, continued to rise to strike the strings and rebound. While inexpensive to make and easy to maintain, this simple mechanism allowed the player relatively little control of loudness and articulation.

Stringed keyboard instruments have as their principal defects an inability, first, to sustain a tone indefinitely and, secondly, to alter the tone's loudness once a key has been depressed. Various attempts have been made to build stringed instruments sounded by other means than plucking or striking—including vibrating the strings by blowing a current of air past them, as in the *piano éolien* of 1837. The most successful of these other instruments adopted the principle of the hurdy-gurdy—*i.e.,* vibrating the strings by friction.

An instrument of this kind appears in several diagrams in the notebooks of Leonardo da Vinci (1452–1519). Some apparently highly successful ones (none of which, unfortunately, has survived) were made by the Nürnberg builder Hans Haiden, who described them at length in pamphlets published in 1605 and 1610. These instruments had a series of rosined wheels that rubbed the strings when they were drawn against them by the action of the keys. According to Haiden, the instrument, which he called a *Geigenwerck,* was capable of recreating the sound of an ensemble of viols and produced sounds of different loudness, depending on the force with which the keys were depressed.

Haiden's *Geigenwerck*

In 1772 a device called a celestina was patented by Adam Walker of London; it employed a continuous horsehair ribbon (kept in motion by a treadle) to rub the strings of a harpsichord. Thomas Jefferson, who ordered a harpsichord equipped with a celestina in 1786, commented that it was suitable for use in slow movements and as an accompaniment to the voice. Similar devices, some using rosined rollers, were applied to pianos by various ingenious inventors throughout the 19th century.

(E.M.R./I.a.L.)

THE ORGAN

An organ is a keyboard instrument in which sound is produced by pipes or reeds to which wind is supplied through a mechanism under the control of the organist. Pipe organs of the kind commonly encountered in Christian churches since the late Middle Ages are among the largest, most complicated, and most expensive musical instruments; they are products of sophisticated craftsmanship blended with artistry.

Reed organs such as the foot-pumped harmonium and melodeon, types developed and mass-produced during the 19th century, are simpler and cheaper to construct than pipe organs. They were widely used domestically and in small churches before becoming virtually obsolete by the mid-20th century, when electronic substitutes became commercially available. These electronic substitutes are versatile and relatively compact, though not necessarily inexpensive, and are chiefly useful in situations where tonal beauty, sensitivity, and imposing visual presence are not essential—for example, in popular music ensembles or homes. For more demanding purposes, electronic organs have given way in the late 20th century to even more versatile and portable synthesizers (see below *Electronic instruments*).

The enormous and varied pipe organ repertoire is especially rich in solo music intended for performance in churches, either during the liturgy or before and after services. The organ's most familiar ensemble role is accompanying choral and congregational singing, a function in which the organist may also conduct the singers. Organ recitals, a favourite form of public entertainment before the advent of radio and recordings, most often take place in churches but also occur in municipal auditoriums, concert halls, and other secular buildings where organs have been installed.

Perhaps most important among such venues in the early 20th century were theatres where organs were used to accompany silent films. Theatre organs, while not generally very large, were highly innovative in tonal and mechanical design and made use of technological improvements that were slow to find their way into more conservative church organs. Among the special effects produced by theatre organs are colourful sounds made by percussion devices that act independently from the pipes.

Parts, mechanism, and production of sound. Conventional pipe organs consist of four main parts: (1) the keyboard or keyboards and other controls that collectively are called the console, (2) the pipes that produce the tone, (3) the mechanism, or action, and (4) the wind generator. Ideally, the pipes, action, and supporting framework are encased in a free-standing structure, or case, that protects the delicate interior parts and blends and projects the sound through generous openings into the surrounding space. Traditionally, rows of dummy or real pipes and carved woodwork in attractive arrangements partially screen the openings in the case. Because organ pipes are not uncommonly up to 32 feet long, organ cases can be very large and form a significant architectural component of the space.

Importance of organ placement

The proper placement of an organ is acoustically crucial, and for most organ music a resonant room with three seconds or more of reverberation time is desirable. Organs having pipes that are installed in deep chambers adjoining the room occupied by the listeners, or placed in an acoustically "dead" environment, are likely to lack musical vitality. Fully exposed pipes without encasement, seen in many mid-20th-century organs, may produce a raw, unfocused sound.

The simplest type of organ has one keyboard, or manual, and one pipe to each key. The pipes, supported vertically by a rack, stand in a row, or rank, on an airtight chest that is supplied with wind from bellows or a rotary blower. While rotary blowers driven by electric motors are highly efficient and tireless, the turbulence and inflexible pressure of their air flow can adversely affect the tone of the pipes. Many organ builders and players, especially of smaller instruments, therefore prefer hand-pumped bellows, which are responsive to musical demands if close coordination exists between the player and the pumper.

Under each pipe is a valve, or pallet, connected by a system of cranks and levers to its respective key. A reservoir, loaded by weights or springs to maintain sufficient wind pressure, is ordinarily interposed between the wind generator and the wind-chest. This reservoir has a safety valve that operates to relieve excessive pressure when the reservoir becomes full.

The pitch of each note is determined by the length of its pipe; the longest pipe emits the deepest note, the shortest pipe the highest note. If two comparable pipes sound an octave apart, the effective length of the higher-pitched pipe is exactly half that of the lower-pitched.

Since the tone of a pipe sounding on a constant pressure of wind is immutable, both as to quality and loudness,

the expressive potential of an organ with only one pipe to each key is limited. All but the smallest portable organs, therefore, have at least three ranks, or sets, of pipes, and large church and auditorium organs may have 100 or more ranks. The pallet controlled from each key admits wind to all the pipes belonging to that key; but, in order that the organist may be able to use any of the ranks of pipes, alone or in combination, an intermediate mechanism is provided by which he may stop off any rank or ranks. From this function the control by whose operation the ranks are stopped off has come to be known in English as a stop, a term also used loosely for each rank of pipes.

Stop and key mechanisms. The operative part of the stop mechanism lies between the pallet and the foot holes of the pipes. It normally consists of a strip of wood or plastic running the full length of each rank of pipes. In it is drilled a series of holes, one of which registers exactly with the foot hole of each pipe. The perforated strip, or slider, is placed in a close-fitting guide in which it may be moved longitudinally. When it is moved a short distance, so that its holes no longer register with the pipes, wind is cut off to that rank, even when the organist opens the pallets by means of the keys. Wind-chests in which the stops operate in this way are called slider chests. Other ways of working the stops will be referred to later; but the simple, reliable slider chest was in almost universal use before the 20th century. The slider is connected to the console by a system of levers and cranks, and it terminates in a knob that the organist pulls outward to bring the stop into play or pushes in to silence it. The name of the particular rank governed by the stop is usually engraved on the knob or appears on a label next to it. An organ's tonal specifications are customarily defined by a list of the names of its ranks and their respective pitches.

The slider chest

Often the organist needs to play two or more inter-

From S. Sadie (ed.), *The New Grove Dictionary of Musical Instruments*, vol. 2, © Macmillan Press Limited 1984

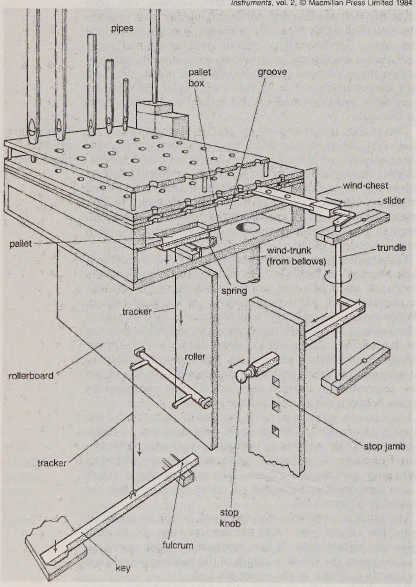

Figure 11: Stop and key mechanisms of a single-manual organ with tracker action (see text).

weaving, contrasted melodic lines, to give prominence to a melody against a quieter accompaniment, or to play loud and soft passages in rapid succession. None of these effects can be achieved on an organ with one manual, as so far described. For this reason, organs of more than about seven or eight stops usually have two manuals, each controlling its separate wind-chest and stops. Each manual department is self-contained, so that the organ is really a composite instrument. By prearranging the stops on the manuals, the organist may perform in any of the three ways mentioned above. The organist, therefore, may vary the sounds produced in one or both of two ways: by changing the stops on the manuals being played or by leaving the stops as they are and changing from one manual to another.

Since the 18th century organists have had yet a third way of controlling the volume of sound. The pipes of one or more manuals may be enclosed in a box, one side of which consists of hinged and movable shutters (similar to Venetian blinds) that are connected to a pedal at the console. By opening and closing the shutters, the sound from the stops of the manual concerned is made louder or softer. Such enclosures are called swell boxes. In pursuit of still greater expressivity, organists since the 16th century have often employed an accessory called a tremulant, which by repeatedly interrupting the flow of wind to the wind-chest creates a pulsation in the tone of the pipes.

Since the 14th century, one department of the organ has commonly been played from a keyboard controlled by the organist's feet. The pedal department is basically like the manual departments but controls predominantly longer pipes. Modern organs normally have pedal keyboards of up to 32 notes.

The organist sometimes wishes to combine the stops of two different manuals or to couple one or more of the manuals to the pedals. This is effected by a simple mechanism, called a coupler, that is controlled at the console.

Certain combinations of stops on each manual are more commonly needed than others; in order that these combinations can be readily available, the console may be provided with several short pedals disposed above the pedal keyboard, or pedalboard. Each of these short pedals, called combination (or composition) pedals, is connected to one commonly needed combination of stops. When a combination pedal is depressed, the stops connected to it are drawn on, and any others that are already drawn are pushed off.

In the simplest mechanical action, the connection from key to pallet is by a series of cranks, rollers, and levers that transmit motion horizontally and vertically from keyboard to wind-chest. The overall distance may be considerable, and the main distance is bridged by trackers, slender strips of wood, metal, or plastic, which are kept in constant tension. Adjustment screws are employed to take up slack occasioned by wear and changes of humidity.

The trackers

The mechanism of the organ as described so far is entirely mechanical, and such organs, including the great majority of those built before the late 19th century, are said to have tracker action. Tracker action is also used in many modern organs, especially those built according to historical principles. Many organists prefer tracker action to all other forms because it affords superior sensitivity of touch. Organs may, however, have pneumatic, direct electric, or electropneumatic action, although these actions result in a loss of sensitivity and responsiveness. In very large organs with tracker action, considerable strength may be necessary to depress the keys. Also, where the layout of the building is inconvenient and the departments of the organ have to be widely separated, tracker action is not practicable. To overcome these difficulties, especially with the object of lightening the touch, other forms of action were devised.

The first effective system was developed in the 1830s by Charles Spackman Barker, an Englishman. It consisted of a series of small, high-pressure pneumatic bellows or motors, one attached to each key of the main manual at the console. When a key was depressed, compressed air was admitted to the motor, which, in turn, operated the tracker action. Lacking encouragement at home, Barker

went to France, where the great French builder Aristide Cavaillé-Coll employed the Barker lever almost exclusively from 1840 on.

Later, the trackers were supplanted by lead tubes, and the connection from key to pallet was solely by compressed air traveling through these tubes. This system was called tubular pneumatic action. At its best, it was remarkably effective, being reliable, long-lived, reasonably silent in action, and perfectly prompt in operation. At anything but its best, it was none of these things, and its worst fault usually lay in sluggish operation. Tubular pneumatic action is almost never used in modern times.

As early as 1860, electric action was used experimentally, and it came into wide use at the end of the 19th century. Direct electric action, in which an electromagnet pulls the pallet open, is sometimes used, but a combination of electric and pneumatic mechanism is more general. In this system the depression of a key completes an electrical circuit, which energizes an electromagnet, allowing wind to enter a pneumatic motor attached to the wind-chest, and this motor opens the pallet. The stops may be operated in exactly the same way, but, where they are operated electrically, the sliders are often replaced by a series of valves, one to each pipe. The organ is then said to have a sliderless chest, and the most usual type is the pitman chest, so called because it contains a type of floating valve called a pitman. This action is commonly known as electropneumatic.

The pitman chest

The combination pedals can also be operated electropneumatically. They are usually supplemented by a series of buttons, or pistons, placed below each manual, where they are conveniently operated by the organist's thumbs. The pistons may easily be made adjustable so that the organist can quickly alter the combination of stops controlled by each one.

A compromise has been used successfully with tracker action for each department, with the coupler action operated electrically. This arrangement has considerable merit, since the coupling together of three or four manuals with tracker action results in a very heavy touch. Electric stop action may also be combined with tracker key action, enabling the use of electric (including solid-state) combinations—an invaluable aid in quickly changing groups of stops, especially in larger instruments.

Flue pipes. There are two main categories of organ pipes: flue pipes and reed pipes. Flue pipes (made either of wood or metal; their construction is basically similar in principle) account for about four-fifths of the stops of an average organ. Figure 12 shows a front view and a vertical section of the most typical sort of metal flue pipe. The pipe consists of three main parts: the foot, the mouth, and the speaking length.

The pipe stands vertically on the wind-chest, and wind enters at the foot hole. The foot is divided from the speaking length by the languid, a flat plate; the only airway

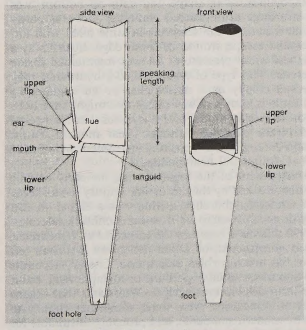

Figure 12: Typical flue pipe (principal).

connection between the foot and the speaking length is a narrow slit called the flue. The wind emerges through the flue and strikes the upper lip, producing an audible frequency, the pitch of which is determined by and amplified in resonance by the speaking length of the pipe. A pipe of this kind is, in fact, identical in principle with a recorder or a tin whistle; but, whereas they have holes along the speaking length, which the player covers and uncovers with his fingers to secure the notes of the musical scale, in an organ there is a separate pipe for each note.

The tone of a pipe is determined by many factors, including the pressure of the wind supply, the size of the foot hole, the width of the flue, the height and width of the mouth, and the scale, or the diameter of the pipe relative to its speaking length. The material of which the pipe is made also exerts an influence; it may be an alloy of lead and tin, wood, or, more rarely, pure tin or copper, and for the bass pipes zinc. The pipes may also vary in shape, a common variant being an upward taper in which the pipe is smaller in diameter at the top than at the mouth. Or, the top of the pipe may be completely closed by a stopper. Such a pipe is said to be stopped; a stopped pipe sounds an octave lower in pitch than an open pipe of the same speaking length.

Factors affecting tone

Open pipes of large diameter are said to be of "large scale," and open pipes of small diameter are said to be of "small scale." Large-scale pipes produce a fluty or foundational quality of tone that is free from the higher harmonics (the numbered series of partials, or component tones). Small-scale pipes produce a bright quality of tone that is rich in harmonics, recalling bowed strings. Stopped pipes can be particularly foundational in tone, and they favour the odd-numbered at the expense of the even-numbered partials. Tapered pipes are somewhere between stopped and open pipes in tone quality.

Flue pipes are tuned by increasing or decreasing the speaking length. In the past, several methods of tuning were employed, but in modern times this is often done by fitting a cylindrical slide over the free end of the speaking length and sliding it up and down, lengthening or shortening the pipe as required. In stopped pipes the stopper is pushed farther down to sharpen the pitch or is pulled upward to lower it.

Tuning and voicing

The pipe maker thus broadly fixes the type of tone that a pipe will produce; but this is further controlled within fairly wide limits by the wind pressure and, finally, by the voicer, who adjusts the tone of each pipe by manipulating the foot hole, flue, and upper and lower lips. The attack of the note may also be greatly influenced by cutting a series of small nicks in the edge of the languid. Heavy nicking, commonly practiced in the early 20th century, produces a smooth and sluggish attack. Light nicking or no nicking, as used up to the 18th century and in some more advanced modern organs, produces a vigorous attack, or chiff, somewhat like tonguing in a woodwind instrument. If not excessive, this chiff enhances the vitality and clarity of an organ. The voicer is the artist upon whom the ultimate success of any organ depends. The tonal designer or architect is hardly less important, however; it is he who decides upon the choice of stops, their disposition in the organ, and the scales to be followed by the pipe maker. A completely successful organ depends upon the effective cooperation of designer and voicer.

Reed pipes. Organ reeds were probably originally copied from instrumental prototypes. A reed stop may have a beating reed like that of a clarinet or a free reed (a type discussed below in connection with reed organs).

The shallot of a beating reed pipe, seen in cross section in Figure 13, is roughly cylindrical in shape, with its lower end closed and the upper end open. A section of the wall of the cylinder is cut away and finished off to a flat surface, as shown in the inset to Figure 13. The slit, or shallot opening, thus formed is covered by a thin brass tongue that is fixed to the upper end of the shallot. The tongue is curved and normally only partially covers the shallot opening. But, when wind enters the boot, the pressure of the wind momentarily forces the tongue against the shallot, completely closing the opening. Immediately, the elasticity of the brass asserts itself, and the tongue

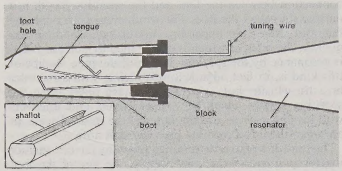

Figure 13: Section through a reed pipe (trumpet).

reverts to its curved shape, thus uncovering the opening. This process is repeated rapidly. The frequency of the pulsations of air that enter the shallot is determined by the effective length of the reed and, in turn, determines the pitch of the note. Thence, the pulsations pass out into the tube, or resonator, which further stabilizes the pitch and decides the quality of the note. Most reed resonators have a flared shape, as shown in Figure 13. As in flue pipes, a wide scale favours a fundamental tone, and a narrow scale favours a bright tone. Cylindrical resonators produce an effect similar to that of stopped flue pipes, the note being an octave lower than the equivalent flared pipe and the tone favouring the odd partials. Some reed pipes, such as the vox humana, have very short resonators of quarter or eighth length. Pipes the resonators of which have no mathematical relationship to the pitch are known as regals; regal stops were popular in the 17th century, particularly with the North German school, and their use has been revived in modern times. Their short resonators have varying and peculiar shapes, which produce a highly characteristic snarling tone; they can be difficult to keep in tune.

Reed length and pitch

Reed pipes are tuned by moving the tuning wire, thus shortening or lengthening the tongue (Figure 13). As in flue pipes, the scale and shape of the resonator largely determine the quality of tone to be produced; but the wind pressure, the shape and size of the shallot, and the thickness and curvature of the tongue also have important influence. The tongues may also be weighted with brass or felt; this weighting produces a smoother quality of tone, especially in the bass notes.

Organ stops. It has already been explained that the pitch of any pipe is proportional to its length. Most modern organs have a manual compass of five octaves, from the second C below middle C to the third C above; an open pipe sounding the low C is about 8 feet (2.5 metres) in speaking length (64 vibrations per second). The shortest pipe in the same rank, or stop, is thus about 3 inches (8 centimetres) long (2,048 vibrations per second). While large- and small-scale ranks often imitate the tones of flutes and bowed strings respectively, and are named accordingly, the most characteristic tone of the organ is produced by its diapason, or principal, stops. These are of medium scale (usually about 6 inches diameter at the 8-foot open pipe) and moderate harmonic development—*i.e.*, neither particularly dull nor bright. Such a tone quality becomes boring if heard for a long time. Also, when greater power is required, there is a distinct limit to what can be done by adding more stops of unison pitch. From the earliest times, stops, especially the principals, were arranged in choruses, and the principal chorus is the very backbone of any organ.

Diapasons, or principals

A chorus consists of stops of roughly similar quality and power but at a variety of pitches. A unison principal is known as principal 8 foot because of its longest (8-foot) pipe, and the figure 8 appears on the stop knob or tablet (rocking tablets are often used in place of knobs with electric action) at the console to give an indication of its pitch. The first step toward a chorus is to add a stop sounding an octave above 8-foot ranks (*i.e.*, at octave pitch), the largest pipe of which is therefore 4 feet long. Next comes a 2-foot stop, while the suboctave pitch is represented by a 16-foot stop. The top pipe of a 2-foot stop has a speaking length of only three-quarters of an inch, and this is about the practical upper limit. Nevertheless, an organ with nothing higher in pitch than a 2-foot stop would be lacking in brilliance, especially in the lower parts of the compass.

From the earliest times, organs have, therefore, been supplied with what are known generically as mixture stops, which have several high-pitched pipes to each note. But, since, for example, a 1-foot rank could not be carried right up to the top note, it breaks back an octave at some convenient point in the compass. Ranks pitched even higher will break back more than once. Thus, in the bass, a mixture adds definition to the slow-speaking, low-pitched pipes; in the treble, where the small pipes tend to be lacking in power, it duplicates the unison and octave ranks. A mixture, therefore, helps to maintain a balance of power between bass and treble, while adding harmonious power of a kind that is completely peculiar to the organ and can be produced in no other way.

Mixtures and mutations

Mixture stops also contain ranks sounding at pitches other than in octaves with the 8-foot principal. In chorus mixtures these sound at a fifth above the unison (*e.g.*, G above C), although ranks sounding at a third above and even at a flat seventh (*e.g.*, E and B♭ above C) and their respective octaves are also found; but these are best restricted to mixtures intended for somewhat special effects. The theoretical justification for these quint- (fifth) and third-sounding ranks is that they reinforce the natural upper partials of the harmonic series, but they were included in organs long before this was understood. The fact is that they were found to sound well, and large organs without mixtures and off-unison ranks have been generally unsuccessful. The colourfulness and vitality of organ music depend largely upon copious, artistically voiced mixtures.

Off-unison ranks are also available as separate stops, mostly sounding at an interval of a 12th (an octave and a fifth; $2^2/_3$ feet), 17th (two octaves and a third; $1^3/_5$ feet), or 19th (two octaves and a fifth; $1^1/_3$ feet) above the unison. These are used melodically to colour the unison and octave stops, and they may be wide or narrow in scale. Such stops are known as mutation stops, as opposed to the mixtures, or chorus stops. Their use is essential for the historically (and therefore artistically) correct performance of organ music written before 1800 and of much modern music as well. After a period of disuse throughout the 19th century, they are again included in all but the smallest modern organs.

History of the organ to 1800. The earliest history of the organ is so buried in antiquity as to be mere speculation. The earliest surviving record is of the Greek engineer Ctesibius, who lived in Alexandria in the 3rd century BC. He is credited with the invention of an organ very much on the lines of the single-manual, slider-chest organ already described, except for its wind supply, which made use of a principle that was most ingenious, though applicable only to a very small instrument. A piston pump operated by a lever supplied air to a reservoir; at its upper end, this reservoir communicated directly with the wind-chest. The reservoir, cylindrical in shape and with no bottom, was placed in a large drum-shaped container that was partly filled with water. As the reservoir became filled with air, the air would escape around its lower edge. In this way a more or less equal pressure of air was maintained inside the reservoir. This type of organ, called a hydraulus, may have served chiefly as a noisemaker or an engineering marvel. Little is known of any music that might have been played on it. A clay model of a hydraulus was discovered in 1885 in the ruins of Carthage (near modern Tunis, Tun.), and the remains of an actual instrument were found in 1931 at Aquincum, near Budapest.

The hydraulus

The development of the organ during the early Middle Ages is obscure, but by the 8th or 9th century it was being used in Christian churches, perhaps as a signal to call congregations to worship or in other nonliturgical roles. About 990 a famous organ in the cathedral at Winchester, Eng., was constructed, of which the monk Wulfstan left a famous but much garbled description. Literary accounts of early organs are often hyperbolic or metaphorical, but it appears from descriptions such as Wulfstan's that organs like that at Winchester were loud, somewhat clumsy to operate by modern standards, and probably unsuitable for all but the simplest music.

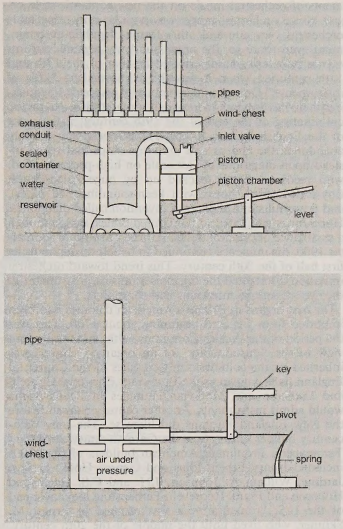

Figure 14: Blowing mechanism of the hydraulus.

From S. Sadie (ed.), *The New Grove Dictionary of Musical Instruments*, vol. 2, © Macmillan Press Limited 1984

The artistic history of the organ begins with the development of the chromatic keyboard (*i.e.*, having 12 keys per octave). By 1361 the cathedral organ at Halberstadt, Ger., had three chromatic keyboards and pedals; the keys, however, were much wider than those of the modern keyboard. The modern size of keys was fairly generally established by the end of the 15th century. Although the Halberstadt organ had three manuals, it had no stop mechanism. The main keyboard controlled a huge mixture stop, and the other keyboards controlled reduced groups of stops.

Ctesibius' slider arrangement was probably rediscovered some time in the early 15th century, and it became common soon after 1450. Reed stops began to appear at the same time, and by 1500 the organ had reached a stage in northern Germany in which all the important features of the modern organ were present. In the 16th century the organ began to develop an idiomatic repertoire distinct in style from that of instrumental ensembles, although written organ music of the Renaissance gives no clues as to how the different stops and keyboards were employed.

During the Middle Ages and the Renaissance, three diminutive forms of the organ were widely used. These were, first, the positive (in which category are included most chamber organs of the period), a small organ capable of being moved, usually by two men, either on carrying poles or on a cart. The second type, the portative, was smaller still, with only one set of pipes and a manual of very short compass. It was carried by the player, who worked the bellows with one hand and played the keys with the other. Such instruments were used in processions and possibly in concerted instrumental ensembles. Between the last two in size was the third type, the regal, which usually had only one reed stop, a regal, as previously described.

Portable organs

Since national styles of organ building vary widely and it is necessary to know something about them before the music of each nation can be performed intelligently, the more important styles must next be considered briefly. Of the basic medieval organ, prior to the development of national styles, little if any material survives, except in the old cathedral at Sion in Switzerland, where a large proportion of the seven-stop organ appears to date from about 1400. Although voiced on low wind pressure, the tone of the chorus is brilliant, colourful, and powerful.

Italy. Italy is mentioned first because its organs developed to their maturity soon after 1500 and remained relatively unaltered until about 1800. The Italian organ had one manual and usually only an octave of pedal keys, which had no pipes of its own (except an occasional independent 16-foot *contrabasso*) but was coupled permanently to the manual. The manual chorus (*ripieno*) had the peculiarity that there was no collective mixture; all the ranks were drawn by separate stops. Each rank broke back an octave as it reached the $1\frac{1}{2}$-inch pipe. In addition, there were flute stops of 4-foot, $2\frac{2}{3}$-foot, and 2-foot pitch and a register called the *fiffaro* or *voce umana* (not to be confused with the French *voix humaine* or German vox humana, which are regals), a principal rank found only in the treble and tuned sharp so that when it is played together with the *principale* one hears an audible beat. It was the forerunner of the similarly constructed voix céleste stop popular in the 19th-century romantic organ. The scale of the classic Italian *principale* was not much different from its counterpart in the north, but its mouth was narrower, its voicing more delicate, and there was a notable lack of chiff. Reeds were not found until late in the 16th century and were never considered essential.

Spain and Portugal. The Iberian organ followed the Italian tradition, but, later, many reeds were added, most notably the *trompetas reales* ("royal trumpets") and other horizontal (*en chamada*) reeds arrayed in fanlike projections from highly ornamental cases. These reeds were on extremely low wind pressure and achieved amazingly full sounds that filled the huge edifices.

Like their Italian counterparts, Spanish and Portuguese organs had only a few rudimentary pedals. The manuals, however, were divided, with keys up to middle C controlled by a draw knob to the left and keys up from C♯ by a draw knob to the right. This enabled the playing of a solo voice against an accompaniment on the same manual. A unique feature of Iberian churches was the presence of several separate and distinct instruments in one building, enabling interesting uses of antiphony, or contrasting masses of sound.

Germany. From 1500 to 1800 Germany led the world in organ building and the composition of organ music. The organ builders reached the peak of their achievement about 1700 in the work of Arp Schnitger. Schnitger made organs with four manuals, pedals, and as many as 60 speaking stops, but he made some instruments with fewer than 30 speaking stops that are capable of dealing with the whole pre-Romantic repertoire. His was the organ of the high Baroque; but his countrymen Andreas and Gottfried Silbermann were equally the masters of the slightly later, more sophisticated style of the mid-18th century.

The Schnitger organs

Seventeenth- and 18th-century German organs were usually constructed on *Werk*-principle lines: each department of the instrument, or *Werk*, was separately cased, the Hauptwerk (main manual) in front of and above the player, with the pedals at each side and the *Rückpositiv* (auxiliary manual) behind on the gallery railing. Each department, including the pedal, had its own principal chorus, complete up to at least one mixture. All departments were roughly equal in power but varied in pitch, having, respectively, a 16-foot, 8-foot, and 4-foot preponderance (and 32-foot and 2-foot as well in larger instruments). Each manual department had a set of flutes and mutations that could be combined in a variety of ways to provide accompaniment and melody or the balanced but contrasting tone qualities essential for duet and trio passages. Although the pedal department consisted mainly of its principal chorus, it could be coloured for solo and obbligato passages by 2-foot flute and reed stops. The reeds were not much louder than the flue stops, and the pedal 16-foot and 8-foot reeds were frequently drawn with the principal chorus for improved definition. When used in this way, they by no means caused the pedal to overwhelm the Hauptwerk. Such an instrument could deal with the

requirements of all 15th- through 18th-century organ music, although its limited supply of manual reeds placed it at some disadvantage in French music of the period.

France. As far as the manual departments are concerned, French organs differed little from the German type, but the principal choruses were generally larger in scale. The separate, large-scaled Tierce (1⅗-foot) was also universal, and there were many cornet stops. These mixture stops consisted of five pipes to each note: a stopped unison (8-foot) and large-scale open 4-foot, 2⅔-foot, 3-foot, and 1⅗-foot. They extended only from middle C upward and were largely melodic in use. They were never drawn with the principal chorus (Plein Jeu) but generally were used with the reed chorus (Grand Jeu). Apart from this, the Plein Jeu, Grand Jeu, and Jeux de Mutation were seldom or never intermixed in French music.

The pedal department of the French organ prior to 1700 was regarded largely as a sort of solo section that consisted usually of only 8- and 4-foot flutes and 8- and 4-foot trumpets. Only in the largest 18th-century French organs were 16-foot stops included, although there were often as many as three on the Grand Orgue (the manual analogous to the German Hauptwerk and the English Great Organ). When French organs had more than two manuals (Grand Orgue and Positif), the others (Récit and Écho) were usually of short compass; but if, as sometimes, there was a fifth manual, it was a Clavier de Bombardes, consisting of 16-, 8-, and 4-foot trumpets and a cornet. Unlike its German counterpart, the main case housed all divisions except the Positif, which was in its usual location on the gallery railing.

French use of reed pipes

French organs were notable for their reeds, and the highly stylized French music of the 17th and 18th centuries calls for their frequent use. Surviving specimens in good order are rare; but unaltered, late 18th-century, four-manual organs survive at Poitiers cathedral (by the noted builder François-Henri Clicquot) and at Saint-Maximin, Provence (by Jean-Esprit Isnard).

Great Britain. Few British organs before the Commonwealth (1649–60) had two manuals, and none had pedals. Mixtures and reeds seem to have been unknown, and mutations were restricted to a single 12th.

After 1660 a new school rapidly grew up, and, although the two principal builders had both been abroad during the Commonwealth (Bernard Smith in Germany or Holland and Renatus Harris in France), their British work owed little to foreign influence. Only the Great Organ had a complete diapason chorus, and the Choir, or Chayre, organ usually extended upward only to a single two-foot. Almost every organ had a cornet, and the reeds in common use were trumpet, vox humana, and cremona, or krummhorn, with half-length, cylindrical resonators. There were no pedals, but the manual compass almost invariably extended to the third G below middle C. If there was a third manual, it consisted of a short-compass echo department in which all the pipes were shut up in a box to produce the echo effect. In 1712 the builder Abraham Jordan first fitted the echo box with shutters that were controlled by a pedal at the console; this arrangement produced what Jordan described as the swelling organ, but it was not to reach its full development until 150 years later; no 18th-century organ music demands a swell box. There are hardly any surviving examples of British instruments of this period in original condition.

Developments after 1800. Because of the increasing interest in orchestral and operatic music, the organ fell out of favour during the 18th century, and by 1800 it survived only as an ecclesiastical drudge. From the middle of the 19th century, however, a revival took place under the leadership of two great builders, Aristide Cavaillé-Coll of France and Henry ("Father") Willis of England. In Britain during the first half of the 19th century, the introduction of pedals made it possible for the first time to play the organ music of J.S. Bach and his German contemporaries and predecessors. While retaining respectable vestiges of the classical chorus, Cavaillé-Coll and Willis developed the solo stops, especially reeds, and Willis, in particular, provided new aids to registration.

Organists found that they could play effective arrangements of orchestral music on the new romantic-style organ. Since orchestral music was popular and respectable orchestras very rare and other forms of public entertainment even more so, the organ suddenly regained an immense popularity hardly rivaled by that of the 17th and 18th centuries, when it was the acknowledged "king of instruments." Organ builders naturally responded by making their instruments increasingly orchestral in character, culminating at the end of the 19th century in the work of the English builder Robert Hope-Jones, who entirely abandoned the chorus and mutation stops and relied instead upon diapasons of vast scale on high-pressure wind, with reeds to match, backed up by huge-scaled flutes, tiny-scaled string stops (with keen-sounding flue pipes), and powerful stops of his own invention called diaphones. Hope-Jones emigrated to the United States, and, although a semblance of classical design returned to Britain soon after 1900, his influence continued to be felt throughout the first half of the 20th century. This trend toward orchestral imitation discredited the organ as a musical instrument in the eyes of serious musicians and composers.

First instruments in the colonies

The first organs in Britain's American colonies had been imported from England beginning about 1700. This was the period of the English Commonwealth, and the Puritan view of the "unsuitability" of an organ in church was inherited by the colonies. Only parishes of the Church of England (later known as the Protestant Episcopal Church) and Lutheran and Moravian churches in Pennsylvania would admit instruments. Another century elapsed before the New England Puritans did likewise. The only 18th-century builder of note was the German-American David Tannenberg. Prominent American builders of the 1800s included Henry Erben, Elias and George Hook, George Jardine, William A. Johnson, J.H. and C.S. Odell, and Hilborne and Frank Roosevelt. Perhaps the inevitable end of the U.S. "romantic" era was reached in Ernest M. Skinner, who lived until the middle of the 20th century. In Canada, Joseph Casavant built his first organ in Quebec province in 1837. Two of his sons visited France in 1878–79 and brought back to North America the Cavaillé-Coll tradition.

Albert Schweitzer, organist, philosopher, and later medical missionary, wrote a booklet, *Deutsche und französische Orgelbaukunst und Orgelkunst* ("The Art of German and French Organ Builders and Players"), in 1906 outlining the inadequacies of the 19th-century organ for the performance of the music of J.S. Bach and his contemporaries. It was not until 1926, however, with Karl Straube, that the revival of 18th-century and earlier styles of organ building began. Straube, organist at Bach's Tomas Church in Leipzig, noted editor of Baroque organ works, and leading exponent of the Romantic works of Max Reger, renounced the Romantic approach to the organ and called for a return to Baroque principles. Certain historically minded organ builders in Germany, soon followed in other European countries and in North America, heeded Straube's call by constructing instruments based tonally and structurally upon Baroque models and by restoring old but altered tracker-action organs to their original specifications. While even the best of such specialized organs may not accommodate large-scale works by Romantic and later composers, their musical qualities and sensitivity to the player's touch render them artistically superior to unwieldy all-purpose organs, some of which have more than 150 ranks.

The late 20th century has seen a decline in production of pipe organs, with several large manufacturers going out of business in the United States. However, small firms building highly refined tracker-action instruments have proliferated. Increasingly, their organs adopt tuning systems other than equal temperament, pitches higher or lower than usual, short-octave keyboards, and other retrospective features that allow performers to re-create organ music of the 16th through 18th centuries in ways that would have been familiar to composers of those times.

The reed organ. The term reed organ normally refers to a keyboard instrument in which sound is produced by free reeds. Accordions and concertinas are examples of small, hand-held reed organs. Free reeds are thin, flexible strips

Free reeds

of metal, usually brass, that are secured at one end over or under close-fitting openings in plates that are mounted over a wind-chest. Suction or wind pressure causes the free end of the reed to vibrate in and out of its aperture when its key is depressed to open a valve, or pallet, in the wind-chest. The pitch of each reed is determined by its length, though tuning can be accomplished by thinning or weighting the reed. No resonator is required to modify the tone quality, which is affected chiefly by the shape, thickness, resilience, and curvature of the reed.

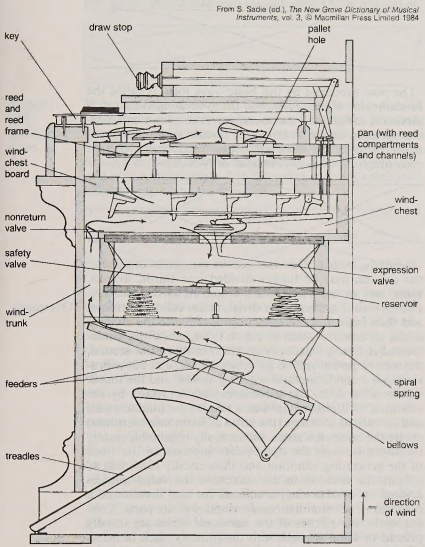

Figure 15: Reed organ operated with wind under pressure.

It is not known when the free reed was first introduced to Europe from Asia, where as early as 1100 BC free reeds were incorporated into mouth organs such as the Chinese *sheng*. The *sheng* itself was known in Europe by 1777, by which time free reeds had already appeared in experimental organs. The tuning stability, small size, and low cost of free reeds were quickly recognized as virtues, and by the early 19th century small organs using free reeds in place of or in addition to pipes and with bellows pumped by the player's feet were being manufactured in Europe and the United States. Occasionally free reed stops appeared as an adjunct to pianos and in mechanical instruments such as Johann Nepomuk Maelzel's panharmonicon, first exhibited in Vienna in 1804.

Because of their simplicity, portability, and ease of maintenance, by the mid-19th century reed organs had become popular domestic instruments, rivaling the piano in numbers though not in quality or quantity of repertoire. In churches and other institutions, especially less affluent ones in rural areas, reed organs with up to three manuals, a pedal keyboard, and five or more sets of reeds often served in place of costlier pipe organs. The versatile and expressive harmonium (a compact reed organ patented in 1842 by the Frenchman Alexandre-François Debain and later developed by others) attracted the efforts of major composers such as Antonín Dvořák and Cesar Franck.

The harmonium

While European reed organs generally operated with wind under pressure (supplied by feeder-bellows), a type that employed suction to sound the reeds was developed in the United States, notably in New England, where seraphines, lap organs, and melodeons (as some varieties were called) were patented and manufactured in great numbers after about 1830. In 1847, Emmons Hamlin, an employee of the George A. Prince melodeon factory in Buffalo, N.Y., greatly improved the tonal quality of free reeds by bending them in various ways; the Boston firm that Hamlin founded with Henry Mason in 1854 became an international leader in producing "cabinet organs" of modest size.

Although reed organs continued to be manufactured into the 20th century and were occasionally employed in ensemble music by serious composers such as Arnold Schoenberg and Kurt Weill, they suffered from defects such as sluggish response, cloying tone, and limited expressive capability. In the face of unrelenting competition from cheap upright pianos (which they often resembled in appearance) and, later, from electronic instruments, reed organ production declined in the second quarter of the century, though fine old examples in playable condition remain numerous. Production of small reed organs has continued in India, where they provide drone accompaniments for, for example, sitar music. (C.Cl./La.L.)

Wind instruments

GENERAL CONSIDERATIONS

Classification. Prominent in the music of all cultures since prehistoric times, wind instruments exhibit great diversity in structure and sonority. A system of classification of these instruments must reflect and categorize the relationships and the differences between the many varieties. The conventional division of the symphony orchestra into sections has simplified the grouping of wind instruments into woodwinds and brasses, but this is an inaccurate classification that generally does not apply outside of Western culture. The fact that some modern woodwinds, such as flutes and saxophones, are made of metal, while several ancestors of present-day brasses, such as the cornett and serpent, were typically made of wood, illustrates the unsuitability of a classification according to material.

The standard method of instrument classification was introduced in 1914 by Curt Sachs and Erich von Hornbostel. It is based on the acoustical principles of an instrument's sound, regardless of its stylistic or cultural context. In this system, all wind instruments—that is, all instruments in which air itself is the primary vibrating medium for the production of sound—are called aerophones, whether or not the air is enclosed in a tube.

Sachs-Hornbostel further classifies aerophones as free aerophones, edge instruments, reedpipes, and trumpet-type instruments according to their manner of tone production. Free aerophones, which include a variety of primitive instruments as well as such technologically sophisticated devices as reed stops in organs (see *Keyboard instruments: The organ* above), are distinguished from the other categories because the vibrating air is not contained by a tube. The bull-roarer exemplifies the primitive. A spatulate stone, bone, or board, sometimes carved in the shape of a fish, is tied through a small hole to a string, which in turn is attached to a stick; when the instrument is whirled around, it produces a sound by its disturbance of the air.

Free aerophones

The reeds of the mouth organ, accordion, reed organ, and the reed stops of the pipe organ, known as free reeds, are all considered free aerophones as well: the reed vibrates above or through a slot, setting the air into pulsations. The resulting pitch is determined by the thickness and length of the vibrating reed.

In edge instruments (or flutes), an airstream directed against a sharp edge sets an adjoining air column within a tube into regular pulsations, producing sound. Flutes are divided into so-called true flutes and whistle flutes (also called duct flutes or recorders). Like all aerophones, flutes may be simple or complex, depending on their construction, the transverse flute being simple, and panpipes, organs, and other multiple-tube instruments being more complex.

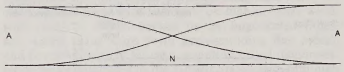
In true flutes, a ribbon-shaped column of air is produced

between the player's lips and directed against the edge of an aperture. The player blows against either the sharp rim at the upper, open end of the tube (end-blown), or against the rim of a hole in the side of the tube (side-blown). The Japanese *shakuhachi* is an end-blown flute, consisting of a wide bamboo tube with a notch at the top, four front finger holes, and one rear thumbhole. The modern transverse flute and piccolo are side-blown. In a further subcategory, globular flutes, the body of the flute pipe is vessel-shaped, not tubular. Such flutes, of various materials, are found in North and South America, Africa, China, and Oceania.

The player of a whistle flute, by contrast, blows through a mouthpiece. The air passes through a duct, or windway, between a plug in the mouthpiece and the flute wall; the duct directs the air against the sharp edge of another hole further down the body of the instrument. Because the airstream is shaped and directed by the duct rather than by the player's lips, whistle flutes are simpler to play than true flutes. The recorder, the ocarina, and the open flue stops of the organ are all whistle flutes.

Reedpipes

In the third category of aerophones, reedpipes, the column of air is activated by the vibrations between the two parts of a double reed or those between a single reed and the mouthpiece. In the Sachs-Hornbostel system, all double reeds are generically classified as oboes, and the single reeds as clarinets. Accordingly, the bassoon is an oboe, and the saxophone a clarinet.



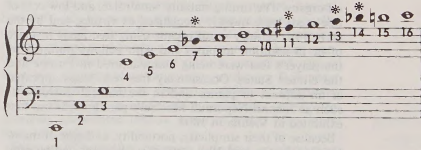
The fourth category, trumpet-type aerophones, includes instruments in which the vibration of the player's compressed lips sets the air column in motion. Depending on the shape of the bore, trumpet-type aerophones are either trumpets, whose bore is cylindrical, or horns, whose bore is conical, although in practice they are sometimes difficult to distinguish. (Some writers prefer to call horns those instruments known or believed to have descended from primitive instruments made from animal horns or tusks, terming the remaining lip-vibrated instruments trumpets.) Trumpet-type aerophones are further classified in two ways: (1) according to the position of the mouth hole—they are end-blown if it is located at the upper orifice of the tube and side-blown if pierced somewhere in the side—and (2) by the presence or absence of a mouthpiece. Finally, trumpet-type aerophones are classified according to construction designed to permit the playing of chromatic pitches. They are natural if not so constructed, such as the conch shell and the hoop-shaped baroque trumpet, and chromatic if built with finger holes, slides, or valves.

A possible fifth category, sometimes suggested as an addition to the Sachs-Hornbostel list, would be the human voice, which approximates the criteria for a double reed aerophone.

With the Sachs-Hornbostel classification well in mind, the common terminology can be used with the understanding that the term woodwinds refers to flutes and reed instruments and the term brasses to lip-vibrated aerophones.

The production of sound. Tubes used to produce a musical sound may be cylindrical, conical, or some combination of the two. They may also be straight or curved. Regardless of the material used, their interior surface must be smooth for best results. The relation of tube length to diameter varies widely but must remain within certain practical limits in order to produce musical pitches. The air contained within the tube is set into vibration by the breath, or in some cases a bellows, acting upon a sound-generating device. The pressure exerted against the molecules of air in the tube causes the particles to move forward along the tube until they bump into others, setting them in motion while the first bounce back. This process creates regular pulsations producing sound waves. Throughout the sounding length of the tube, the entire wave moves at the speed of sound. The air itself moves only slowly, and the phenomenon has been compared to the starting of a freight train, in which the first burst of energy from the engine jerks the car behind, which in turn passes the impulse of the car behind it, and so on throughout the length of the train. The impact of the cars also produces a reverse pressure as it moves along. Similarly, at the sounding length of the tube, the waves are reflected back upon themselves, creating a counter pressure that forms nodes and antinodes. The node results from interference between the forward and the reverse forces creating a static point; the antinode is the point of freest vibration in the sound wave. Antinodes always occur at the open ends of a tube, and it must be remembered that the end where the sound generates is also an open end, except in the clarinet types. In its simplest form, a node (N) is created at the exact middle between the two antinodes (A) at each end of the vibrating length.

Freight-train analogy



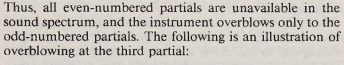
The note produced by this basic wave form is called the fundamental. If the pressure of the generating vibration is increased sufficiently, the sound waves divide in half, producing an antinode in the exact middle with consequent nodes between the three antinodes, producing a pattern consisting of A-N-A-N-A instead of A-N-A.

Overtones

Similarly, with further increase in the generating force, the column may be further divided into thirds, fourths, fifths, and so on. The process is known as overblowing. Pitches resulting from these divisions are called overtones, and their frequency increases in proportion to the division of the air column—that is, 1:2, 1:3, 1:4, etc. If the fundamental is C at a frequency of 128 vibrations per second, the second partial will be an octave higher, c at 256 vibrations per second; the third will be g at 384, and the fourth will be c′ at 512. The successive pitches created by the vibration of the air column as a whole (the fundamental) and its various divisions (the series of harmonic overtones) create the harmonic series, theoretically obtainable *in toto* on any tube with the appropriate increase in the force of the generating vibration and theoretically extending to infinity. In addition to the successive individual pitches created by overblowing, a column (or any division of a column) of air simultaneously vibrates in its parts. Consequently, the pitches of the harmonic series are usually present in some strength with the primary pitch heard as the fundamental. For this reason, the pitches of the harmonic series are known as partials and numbered in the order in which they appear. The following example shows the harmonic series for the fundamental pitch C. (Asterisked notes are noticeably out of tune with the tempered chromatic scale, which contains 12 equal semitones.)

The relative strength of the various partials, which is controlled largely by the shape of the tube and the type of generator, is responsible for the timbre or colour of the pitch. It is this feature that allows the ear to distinguish between the quality of various tones.

It is notable that each successive interval of the harmonic series grows smaller, the number of partials doubles in each octave, and diatonic pitches of the major (*i.e.*, whole and half steps) scale become available in the fourth octave. The series is particularly significant among the natural trumpet-type aerophones (*i.e.*, those lacking valves, finger holes, keys, or slides), for the pitches that could be played are limited to a range of 1 to about 16 notes from this



series without some device to alter the fundamental. The tubes of all trumpet-type aerophones are long in relation to their width and are differentiated according to whether the fundamental can be sounded. Instruments wide enough to sound the fundamental are called whole-tube instruments, those too narrow to do so are half-tube. The latter include those that can be overblown into the third and fourth octave, producing approximately 16 partials.

A pipe stopped at one end will have the static point of its air column there, consequently producing a node (N) at the closed end and an antinode (A) at the other.

Stopped and unstopped pipes

Because of the closed end, the column cannot be divided in half nor into any even-numbered multiples, for such divisions would require an antinode at the closed end. Thus, all even-numbered partials are unavailable in the sound spectrum, and the instrument overblows only to the odd-numbered partials. The following is an illustration of overblowing at the third partial:

The clarinet family and stopped flue pipes in the organ are the most commonly known instruments of this type.

Pulsating air within a tube in turn initiates pulses in the free air, creating sound waves roughly similar in a single dimension to the waves created on still water if a stone is dropped into it. Because free aerophones must create such eddies in the air directly, the capabilities of these instruments are extremely limited. Even organ reeds, which belong to this class, are capable of sophisticated music merely because of their number. Each reed produces only the pitch to which it is tuned, and the pipe, if present, does not determine pitch but serves only as a resonator for the reed.

Trumpet-type aerophones. As regards sound generation, trumpets and horns differ from other aerophones in their use of the so-called "lip reed," which is formed when the player's partially closed lips vibrate as they press against the rim of a mouthpiece or mouth hole (although the behaviour of the lips, strictly speaking, is not exactly comparable to the operation of a reed). When the lips vibrate, the resulting tremor in the flow of the breath is transmitted to the air in the tube, which resonates at the frequency that most closely matches that of the lips. The experienced player adjusts his embouchure to produce the desired frequency.

The mouthpiece, an important accessory to sound production in trumpet-type aerophones, is an adaptor used to widen the starting diameter of a bore otherwise too small to allow the lips to vibrate effectively. It has three internal elements—the cup; the throat, an opening at the base of the cup; and the backbore, which leads to the main tubing—the shape and relationship of which strongly influence an instrument's tone and technical capacity. Mouthpieces on Western orchestral trumpets have a hemispheric cup

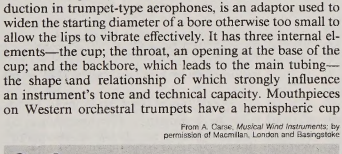

Figure 16: Mouthpieces of trumpet-type aerophones.

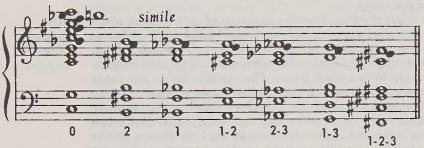
with shallow walls that meet the throat at a sharp angle; these effect a bright tone. Mouthpieces used with cornets and trombones are deeper, with rounded-off throats, and those for French horns are virtually funnel-shaped; these all produce a more mellow tone.

An instrument's bore also influences its tone, as reflected in the subtypes trumpet and horn in the Sachs-Hornbostel classification. Trumpets normally have narrow, cylindrical bores that expand in the final third of the tube's length and terminate in a small bell, which helps to radiate the sound and to bring the harmonics into tune. This bore configuration, in conjunction with a mouthpiece with a shallow cup, favours the production of high partials. Horns, on the other hand, have expanding bores through all or part of the tube's length and normally end in a large bell. Aided by a deep-cupped or funnel-shaped mouthpiece, they favour low partials and function most efficiently in a low range.

Pitch-changing devices

Ways of filling in the missing tones of the harmonic series on trumpet-type aerophones were known in the West as early as the 10th century when finger holes, which shorten the sounding length of the tube, were cut into instruments made from animal horns. The cornett, which was made from two halves of a hollowed-out block of wood that had been glued together and bound with leather, was similarly fitted with finger holes and was widely used in Europe from the end of the 15th through the 17th century. In the late 18th and 19th centuries, makers covered the holes of trumpets and horns with keys to enable them to play a complete chromatic scale; the keyed horn was invented in Bohemia around 1770, and keys were thereafter added to the trumpet and bugle.

Another solution to providing the missing tones was to increase the sounding length of the tube, thereby making the partials of different harmonic series available separately and producing a chromatic scale. As early as the 14th century, the term *sacabuche* (Spanish: "drawpipe," or "pull push") was used to refer to a lip-vibrated instrument, presumably with a single telescoping slide. Fifteenth-century Flemish paintings depict what appear to be slide trumpets, in which the player slid the entire instrument up and down along the long shank of the mouthpiece with one hand, steadying the mouth pipe with the other.



From this awkward beginning, it is easy to imagine bending the slide back upon itself, a less cumbersome alternative that appears to have been adopted in the mid-15th century. On so-called double slide instruments, such as the Renaissance sackbut and its successor, the modern trombone, two parallel inner tubes of the slide mechanism are attached at their upper ends to the body of the instrument by a cross stay. The mouthpiece is fit into the top of one tube, and the bell section fits on the other. The U-shaped slide moves along the two stationary tubes, lowering the fundamental by a half step with each lower slide position and making available the notes of seven harmonic series.

Crooks, detachable lengths of tubing, also were used to increase the sounding length and lower the pitch of trumpets, trombones, and horns. They are of two types: "terminal" crooks, which attach to the mouthpiece receiver, and "medial" crooks, which are inserted in a wider portion of an instrument's tubing. First mentioned in the mid-16th century, both types of crooks are clearly depicted in Praetorius' *Syntagma musicum* (1619). Praetorius' illustration of trombones, for example, features crooks inserted between the slide and bell sections. Terminal crooks were common on trumpets from the 17th through the 19th century. They were also used, singly and in combination, on the horn until the mid-18th century, when sliding medial crooks were added to the tubing inside the hoop of the German horn known as the *Inventionshorn*.

Hand stopping

In the early 18th century, horn players in Bohemia discovered that the gaps in the instrument's harmonic series could be filled by using the hand to partially stop the bell. When the hand was cupped to form an extension of the air column, the pitch of the note being played was lowered one-half step. Hand stopping, which became known throughout Europe in the 1750s thanks to the Bohemian hornist Anton Hampel, was later applied to the trumpet.

About 1815, either Heinrich Stölzel or Friedrich Blühmel, both of Berlin, invented the valved horn. When the valve was opened by depressing a key, it deflected the airstream into extra tubing, changing the effective length of the tube and lowering its pitch. The two valves of the original valved horns were used in combination: the first lowered the pitch one step; the second, one-half step; together they lowered the pitch one and a half steps. Later, a third valve, which lowered the pitch yet another step and a half, became a standard feature of such instruments. Used singly and in combination, these valves made the instrument completely chromatic above the second partial. The illustration below shows the harmonic series made available by the depression of different valves and combinations of valves; notes shown in black are slightly out of tune with the tempered scale.

Perhaps because the natural horn had more notes available than did 19th-century natural trumpets and also because the valve system, particularly on the early horns, affected the purity of tone, valved horns were accepted slowly. At first, valves were considered a convenient substitute for crooks—in effect, a means to modulate (change key) quickly—but band musicians were quick to develop virtuoso techniques of rapid chromatic playing.

Despite their convenience, valves are inherently defective in that they open a fixed amount of tubing. If the first valve on an instrument in C is depressed, lowering the pitch a whole step, the fundamental pitch of the instrument is changed from C to B♭. Using the second valve and its corresponding length of tubing (intended for a C instrument) to lower the instrument, now in B♭, one-half step requires slightly more tubing than needed to lower a C instrument one-half step. In many cases, the player can correct such discrepancies by adjusting his embouchure, decreasing slightly the speed of lip vibration to flatten the pitch without destroying its tone quality. The greater the amount of tubing, however, the worse the discrepancies in tuning. Most trumpets now have compensating slides that operate either manually or automatically to add length to the tubing on the first and third valves. For some large instruments, such as tubas, this device is impractical, and extra valves are added.

Flutes and reeds. Sound is generated by different methods in the aerophones designated as flutes and reeds in the Sachs-Hornbostel system. In flutes, the airstream is directed against a sharp edge; in reeds, the air column in the tube is caused to vibrate between two parts of a beating double reed or between a beating single reed and a mouthpiece.

Reeds and reed-making

Essential to sound production in reedpipes is the reed itself. Those used on most Western instruments are typically made from the stems of the large semitropical grass *Arundo donax*, commonly referred to as cane, grown on the Mediterranean coasts of France, Spain, and Italy. (Substitutes for cane—wood, whalebone, silver, and plastic—also have been tried.) Seasoned over a period of years, cane reeds may be purchased finished or be made by the player himself.

The double reed for an oboe or bassoon is made from a strip of cane about twice the length of the finished reed. The inner surface is gouged thin, shaped to be narrower at the ends, and notched in the middle. The reed is then soaked in water and folded in half at the notch. The free ends are bound with thread and, for oboes and English horns, mounted on a short, tapered metal tube called a staple. A bassoon reed is bound with thread and wire over a steel mandrel, which is later removed to leave a hollow rounded stem. To finish the reed, the halves are separated at the notch and the tips scraped to a feather edge on the outside. The form and degree of "scrape" applied to the tip of the reed has a profound influence on its behaviour and may vary a great deal from player to player. In playing, the double reed of the oboe and bassoon is held by the tension of the lips drawn in over the teeth. The opening between the two blades of the reed alternately opens and closes with the pressure of the breath to generate the pulsations in the tube.

The single reed for the clarinet is made from a slip cut from the stem of *Arundo donax*. After being trimmed, the reed is flattened on the inner side, while the end of the rounded outer side is scraped down to a feather edge. The thick end of the reed is attached, flat side down, to the mouthpiece by a metal ligature or length of twine. In playing, the thin end of the reed vibrates, alternately closing and opening the space between the reed and the mouthpiece. The vibration carries through the wedged-shaped tone chamber in the mouthpiece and into the air column in the tube.

The body of some folk instruments is itself a length of reed, made into an instrument by cutting and raising a rectangular tongue from the tube below a natural knot. The tongue is sometimes kept from closing down completely by inserting a hair at the base of the cut.

Because the tubes of flutes and reed instruments (in contrast to those of trumpet-type aerophones) are short in relation to their diameter, they are generally capable of sounding the fundamental and respond best to pitches low in the harmonic series. To play in the upper register, the player must overblow, breaking the air column up into parts, each of which vibrates at a frequency that is in direct proportion to the fundamental. Oboes, bassoons, and saxophones—all open tubes with conical bores—overblow at the octave; clarinets, whose cylindrical bore acts as a closed pipe, overblow at the 12th.

Overblowing

In overblowing, the player tightens his lips on the reed. Increasing lip pressure is not always sufficient by itself, however, and a variety of techniques and mechanisms have been developed to assist the player in making the notes of the upper register emerge clearly and instantaneously. For example, on flutes and bassoons, the first finger hole is positioned so that when it is opened on certain high pitches low partials are prevented from forming; opening a special key on the clarinet, saxophone, and modern oboe serves the same purpose. Overblowing is not a universal practice: the double and single reeds of some non-Western and early European reedpipes are inserted directly into the oral cavity or covered by a reed cap and hence, being uncontrolled by the lips, do not overblow.

Because of the acoustic characteristics of flutes and reeds,

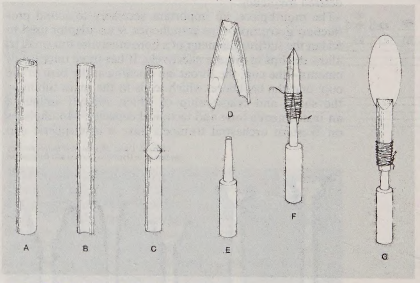

Figure 17: *Stages in the making of oboe reeds.*
(A) Cane is cut to desired length and (B) split in thirds, lengthwise, (C) nicked in the centre, and (D) folded over and cut in the desired shape. The folded cane is mounted on (E) the oboe's staple and (F) is tied, and (G) the tips of the reed are separated by a thin metal tongue.

only a few pitches are available on instruments lacking finger holes. Hence instruments with finger holes are known in most developed cultures, as are fingering systems. Typical of such systems in the West is the six-hole system, so named because the six finger holes of the Baroque transverse flute and oboe—there were no thumbholes—were controlled by the first, second, and third fingers of both hands. (The left hand normally took the higher position on the pipe, but this did not become standard until the mid-18th century.) Both instruments were pitched in D and sounded d (the D below middle C) when all six finger holes were covered. Lifting the fingers one by one, beginning with the lowest, shortened the sounding length of the instruments and produced e, f♯, g, a, b, and c♯—the remaining notes of the D-major scale; the octave (d′) was overblown.

Cross-fingering

On six-hole transverse flutes and oboes, chromatic pitches were obtained by closing one or more holes below an open one, a technique known as cross-fingering. For example, to produce f rather than f♯, the player uncovered the fifth hole with the second finger of his right hand while keeping the sixth hole (and the first through fourth holes) covered. (Because this arrangement of the fingers looked vaguely like the tines of a fork, some musicians call it a fork fingering.) With the six-hole configuration, however, no cross-fingering could produce e♭/d♯, because there was no hole to cover below the fundamental, d. Consequently, a seventh hole was bored between the sixth and the end of the transverse flute and oboe; it was covered by a closed key controlled by the fourth finger of the right hand. (A closed key covers the hole when at rest.)

In the late 18th century, additional keys were introduced to ease various difficulties of fingering and intonation. At first, open and closed keys were fitted to instruments through slots cut in rings or knobs of wood left after the body of the instrument was turned on a lathe; the key was secured in the slot with a metal pin. In the first quarter of the 19th century, as the number of keys increased, this type of mounting became increasingly inconvenient for builders. Brass saddles, which included the key mount, came to replace wooden knobs, first on bassoons and later on other woodwinds. Both these methods of affixing keys were eventually superseded by the use of metal pillars screwed directly into the wood, to which were attached the key and axle. In addition, 19th-century reformers like Theobald Böhm made other more radical changes in instrument construction (to be discussed below). Changes of the type Böhm championed, along with the constantly expanding key system, brought with them a transformation in tone quality, as the valves did to the brasses. Although some connoisseurs consider these changes regrettable, they have made possible technical dexterity in all keys.

SOCIAL ASPECTS OF WIND INSTRUMENTS

To understand the importance of wind instruments throughout the world, one must first appreciate the great diversity of social contexts in which they are used. Which types are played, who plays them, and why? This discussion will examine the function and symbolism of wind instruments in various world cultures. Next, some relations between cultures as revealed by the dissemination of wind instruments will be surveyed. Finally, the decorative aspects of wind instruments will be treated. The instruments discussed below as illustrations have been chosen to provide the widest possible sampling of a vast selection.

In primitive cultures. For nonliterate peoples, music often serves purposes other than entertainment or aesthetic enjoyment. Certain wind instruments are closely associated with the supernatural, and their sounds connote powerful magic. Australian Aborigines, for instance, identify the sound of a bull-roarer with the voices of supernatural beings; for the Plains Indians, the same sound signifies an awesome natural phenomenon, such as thunder. Wind instruments are often among a group's most important ritual objects, and in some cultures they are specially venerated. The Kamairua Indians of the Amazon rain forest keep their giant flutes (three to four feet long), wherein spirits are believed to dwell, in a special shrine where they are worshiped. The flutes and drums of New Guinea are similarly housed and worshiped.

Ritual use of wind instruments

Wind instruments in primitive cultures also serve nonreligious functions. In New Guinea, bamboo trumpets were once played to frighten an enemy during battle and to alert a village that the victorious warriors were coming home with the corpses of the foes. Conch-shell trumpets are used for signaling in the Pacific coastal regions of Colombia and in the Ecuadoran highlands. Trumpets also may be associated with the office of king or chief, as in West Africa, where their use is strictly controlled by tribal law.

A variety of wind instruments in primitive cultures are used for personal amusement, and some are known to accompany vocal performance and dance. For example, the didgeridoo of the Australian Aborigines, which is found across the northern coastal areas from west to east, supplies introductions, interludes, and conclusions, as well as accompaniments for the singing of songmen and their clapping sticks; it also provides intricate aural counterparts to the foot movements of dancers. The player's technique, which involves both blowing and singing into the instrument, is very elaborate.

It is common in primitive cultures for musical instruments to have symbolic significance. The form of an instrument or its decoration may relate to tribal myths, as do North Pacific coast whistles carved in the shapes of birds and African ivory horns stained with human blood. Wind instruments in particular often have sexual connotations. Among the Tucano Indians of Colombia, the number of tubes on a set of panpipes depends on the age of the male performer and the development of his sexual organ. Boys between five and nine years of age play instruments with only three pipes, while men's panpipes have eight or nine. Wind instruments are also made to resemble the male and female sexual organs. The phallic shape of flutes, which are played exclusively by men in many primitive cultures, is self-evident. Instruments reserved for women are often round or curved and may bear associations with the Moon or water. (Oceans respond to tides, tides to the Moon; the Moon marks the female menstrual cycle.) No symbolism is universal, however, and an instrument's sexual connotations may conflict: for example, a conch shell, which by its shape and derivation from a water animal is female, is generally made into a trumpet, usually considered a male instrument.

Symbolic associations of wind music

Not only the shapes but also the sounds of primitive instruments are often rich in symbolism. The sound of the flute, for example, is widely associated with love magic. Among the tribes of the northeast and Great Plains of North America, young men played the flute to serenade young women; in New Guinea, flutes and flute music are connected with rites of sexual initiation. In some cultures, instrument symbolism is highly developed. For the Tucano Indians of Colombia, instrument sounds constitute a symbolic taxonomy comprising three levels: whistling, vibration, and percussion. The whistling of a flute connotes sexual invitation, while vibration, represented by such instruments as the indigenous clarinet and the bull-roarer, symbolizes a warning or threat. Percussive sounds produced by drums and various rattles symbolize the uniting of male and female.

In Asia. In the literate cultures of Asia, wind instruments are used in a variety of social contexts, not least in religious ritual. In Taiwan, the transverse flute (*di*) and free-reed mouth organ (*sheng*) are played in celebrating Confucius' birthday; it is the only surviving music thought to resemble that of ancient Chinese court rituals. The Chinese-inspired ritual music of Japan's Shintō religion likewise employs the flute and mouth organ, along with the oboe (*hichiriki*). In Tibet, the low-pitched chanting of

Buddhist monks is accompanied by a variety of instruments, the most spectacular of which is the long copper *rag-dung*. These straight, conically bored natural horns vary in length from some 5 to 20 feet (1.5 to 6 metres) and are sometimes made in sections that can be telescoped to enhance portability; they provide drones for chanting. The only melodic instrument in Tibetan religious orchestras is the double reed *rgya-gling*, which is used to play preludes and interludes to the chants.

Wind instruments are used in many different ways in Asian classical and folk music (see below *The music of wind instruments*); thus, the distinctions between art and folk instruments are not always clear-cut. In China, for instance, transverse flutes may be played in modern folk ensembles as well as in ritual and local theatre orchestras. This diversity of use has affected manufacture: although flutes are still made in irregular temperaments for traditional music, many are now constructed in equal temperament for use in the concert hall. Folk instruments also have been brought into classical music traditions elsewhere. The *śahnāī* of India, a conical oboe with a metal bell and six to eight finger holes, was traditionally associated with outdoor performance and largely with folk music; it is now played on the concert stage, in mosques, and in temple compounds.

Military use of wind instruments

In western Europe. European society has long valued wind instruments, from their earliest use in rituals down to the present day. In the Carolingian era, signal horns became closely associated with the military and nobility. The oliphant, an end-blown horn made from an elephant tusk, is prominently mentioned in the medieval epic *Song of Roland*. Later, European armies used shawms and straight metal trumpets (*buisines*) to sound military calls and to rally troops in battle, following the practice of Islāmic military bands. Wind instruments may also have been incorporated into medieval liturgical services, although much of the early evidence supporting this is found in religious art and may refer less to ritual practice than to symbolic or allegorical meanings of the instruments depicted.

Wind bands consisting of shawms, trumpets, and trombones were associated in the Renaissance with the nobility, who sought to demonstrate wealth and power in the musical events they sponsored; court documents and pictorial sources testify to the wide use of winds in processions and other ceremonies. Collecting instruments also may have been considered a mark of wealth and prestige, since some nobles assembled enormous collections, in which winds figure prominently. The household inventory of Georg Raymund Fugger of Augsburg, for example, lists about 400 instruments, including 111 flutes. In England, 272 of 381 instruments in Henry VIII's collection were winds.

During the same period, groups of professional wind-instrument players were formed in municipalities across Europe. *Stadtpfeifer*, as these musicians were known in Germany, played for ceremonies, weddings, and sometimes with singers in performances of elaborately scored sacred polyphony. In France during the reign of Louis XIV, the Grande Écurie (an ensemble that provided music for royal occasions) cultivated wind instruments and contained within their group the finest players and wind-instrument makers. At a different level, amateur musicians included the famous English diarist Samuel Pepys, whose love of the recorder was matched only by his devotion to his viol and lute. As public concerts began, contemporaneously with Pepys, the middle classes became further involved in music-making. Among the amateurs of note was Frederick II the Great of Prussia, who hired the German musician and composer Johann Joachim Quantz to teach him the flute. Folk music was still supplied with its share of wind instruments, and in its own milieu many instruments of earlier times are still preserved.

With the passing of patronage from royal establishments to the public, art music found a broader base for support, while amateur music continued to thrive at its own level. The 20th century marks another high point in the cultivation of wind instruments; the quantity of instruments is greater than ever, and technical development has reached new heights, while never before have so many become competent performers.

Dissemination. When an instrument is introduced to a different geographic area, the new instrument that develops there generally retains some connection to its predecessor: a similar name or function, a shared physical characteristic, or an association with a particular social class. Instrument dissemination, then, reflects the relationships between cultures. The dissemination of the *zūrnā*, an oboe found throughout the Arab world, in Turkey, and in parts of Europe and Asia, is a useful illustration.

The *zūrnā* first became known in Islāmic areas, where it emerged from a synthesis of earlier types from Iran, Mesopotamia, Syria, and Anatolia. In its basic, four-piece form, with flared body, reed, staple, and pirouette (a disk or cylinder that partly covers the reed), it spread rapidly to lands conquered by the Arabs. It also was known by the 12th century in western Europe (shawm) and later in the Balkan region (*zurla*). With the spread of Islām, the *zūrnā* was introduced from the Middle East and Persia to India, Southeast Asia, and China. The Persian *surnāy* (or *surnā*), for instance, became the *sānāyī* of northern India and the *so-na* (*suona*) of China. The latter contrasts with the indigenous Han Chinese oboe (*guan*), which has a short cylindrical tube that does not overblow at the octave.

First used as a signaling instrument in military bands, the Arabs later employed the *zūrnā* for a variety of functions: to greet important persons, to mark the beginnings of pilgrimages, and to accompany other ceremonies. Some of these functions were spread along with the instrument. Thus, the *zūrnā* was heard at funerals in the Arab world, as well as in Armenia and Sri Lanka. Other extramusical associations suggest different cultural connections: the *sarunai* of Malaysia, for example, was used mainly for shadow puppet plays, as the *zūrnā* had been employed in the Turkish shadow theatre. Today the *zūrnā* survives as a folk instrument in Islāmic areas and other regions, including Greece, Cyprus, and Armenia. It is used mainly in festive village music and is played in small ensembles by members of the lowest social classes.

Craftsmanship. The high value placed upon musical instruments within a culture is generally reflected in their craftsmanship. Instruments of a primitive society, for example, may be decorated with symbolic designs; more technologically advanced cultures may provide elaborate inlay and elegant carving.

The Chinese *so-na*

The form of a wind instrument may itself be decorative. The symmetry of the *so-na*, a Chinese oboe whose conical shaft terminates in a bell section of brass, is reminiscent of a pagoda. The tube of the instrument is gracefully indented for each finger hole, leaving the impression of a series of diminishing concentric circles, which are capped by the small brass pirouette and a short reed. The related Arabic *surnāy* may be decorated with inlay. In Europe in the Middle Ages, the oliphant was highly prized not only for the ivory from which it was made but also for its sometimes elaborate carvings.

Similar, if less striking, attention to design is encountered in European woodwinds. The bulges that typify the profile of the Baroque oboe and recorder are at once utilitarian (they reinforce the joints of the instruments) and artistic. The addition of ivory rings at the joints added to their beauty. Among the more fantastic and ingenious specimens of woodwinds are certain flutes and clarinets of the late 18th and 19th centuries made as functional walking sticks.

Undecorated brass instruments with their graceful curves demand little additional garnishment; yet even these graceful instruments were frequently embellished with engraving on the rim of the bell or on the bell itself, particularly by the famous Nürnberg makers of the 17th and 18th centuries. Seams and joints in the brass tubing were often reinforced by ornate but functional metal tubes and rings (sleeves and pommels). The most elaborate and fantastic decorations, possibly inspired by the Chinese, emerged in the Renaissance, when unusual brass instruments were commissioned for ostentatious dramatic performances intended for royalty and their guests. Trumpets were made in the shape of dragons, the bell of these (and other) instruments being transformed into the dragon's head. At times a tongue was even inserted to vibrate when the instrument

was blown, and fishlike scales were painted on the outside. Such extravagances appeared sporadically in the following centuries, especially in late 19th-century Italy. Elaborate key mechanisms have inhibited decoration in woodwinds in the 20th century, and makers of brasses have generally been satisfied with the beauty of the functional design of their instruments.

THE HISTORY OF WESTERN WIND INSTRUMENTS

Contributions of Curt Sachs

In the study of musical instruments the name of Curt Sachs looms so large that, despite the studies made since his death in 1959, no one has yet achieved his eminence in the field of musical instruments. The origins of musical instruments extend to prehistoric times, and frequently only fantastic legends survive; yet, by combining information from anthropology, history, and linguistics, Sachs made discoveries, developed theories, and drew conclusions that have stimulated much research in and given purpose to the entire field. Much of the following material leans on his research and perception.

Early history. The sources of information are often nebulous. In a few instances, actual instruments have been preserved for thousands of years. Many depictions of instruments remain, but few give accurate detail. Legend and written records reveal other facts. Finally, among the instruments of contemporary primitive civilizations, those of some non-Western cultures, and those of folk cultures are some that have not changed basically in thousands of years. The study of what information is available reveals many facts and allows much plausible speculation when facts are obscure.

There are many conjectures concerning the origin of wind instruments, and, since they are found widely scattered over the face of the Earth, it is quite likely that the process of vibrating the lips against a hole in a branch, a bone, a shell, an animal horn, or a tusk may have been discovered independently in many early cultures. Their origin may, in fact, have transcended even the first lip buzzing. Many primitive cultures employ these same mediums as masks with which to disguise the voice in magical or religious rites; their use as musical instruments appears to have been an afterthought. Such megaphones are still used today in as widely dissimilar cultures as those of Switzerland and the Brazilian Indians. The conch shell, the most frequent of marine shells used to produce sound, probably began its service to music as a voice distorter, later to become an effective trumpet.

Trumpets. Bamboo, cane, and the limbs or trunks of trees form other materials for primitive trumpets. The Australian didgeridoo, for instance, can be made from either cane or, more frequently, a eucalyptus branch, often hollowed out by termites. From the New Kingdom of Egypt in the tomb of King Tutankhamen (d. *c.* 1350 BC) was found the earliest specimen of a silver trumpet. Later the *salpinx*, also a straight trumpet, was known in Greece. A beautiful specimen made of 13 fitted sections of ivory with a bronze bell (Museum of Fine Arts, Boston) is ascribed to the 5th century BC. The Roman equivalent, the tuba, was bronze and reached Rome from the Etruscans.

Another Roman trumpet was the *lituus*, a J-shaped instrument whose immediate origin was also Etruscan. Its inspiration, visible in its earliest examples, was a simple hollow cane with a cow horn for a bell. Similar instruments are also found in China, where the *cha chiao* adds a shallow and flat mouthpiece to the same basic design. Another long trumpet of Rome was the cornu, which was curved to a G-shape for portability and braced crosswise for carrying over the shoulder.

Horns. As ancient as the trumpet is the natural horn, which was derived from an animal horn or a tusk. With the multifarious species of horned animals, the African countries achieved a rich variety of shapes, sizes, and pitches. The earliest and the most progressive horns were end-blown, but many side-blown horns remain in use even today, particularly in Africa.

The shofar

The shofar deserves special mention, for it has served the Jewish religion since the beginning of historic times and is now retained for Rosh Hashana (New Year's) and Yom Kippur (Day of Atonement) in most congregations. The instrument is merely a goat's or ram's horn, flattened and bent in a steaming process. The various ritual blasts use the second and third partial only, and its mighty sound was considered efficacious in reaching the ear of Yahweh.

The Roman version of the animal horn was the *buccina*, which was originally an ox's horn, sometimes supplied with a mouthpiece. Although ostensibly the *buccina* was a shepherd's instrument, it had a bronze counterpart that was suitably decorated for use in the Roman army.

More impressive, however, were the *lurer* (singular *lur*), the early bronze horns of the Scandinavians. Conical and shaped in pairs, like the curves of mammoth tusks, they have a funnel-shaped mouthpiece and end in a flat studded disk. Although their origin was once thought to have been as early as 3000 BC, 1600 to 1000 BC now appears more likely. The line of development would appear to have passed from metal-studded animal horns to the impressive bronze pieces, many of which have been excavated in Denmark. The effective mouthpiece allowed production of tones to the 11th or 12th partial, but it appears unlikely that these unusual instruments had much influence on later European horns.

Flutes. Flutes were ubiquitous in antiquity. In early depictions they are sometimes confused with reedpipes. Their most primitive forms have already been mentioned. In early historical periods they were known in Sumer and Egypt, and in the latter country specimens have been found in tombs, excellently preserved through the centuries by the arid climate. The Egyptian flute is vertical, about a yard long and a half-inch wide, and is easily end-blown because of its narrow embouchure. Near the lower end there are two to six finger holes. The instruments still exist today and are known by the Persian name *nāy*. In Greece panpipes, undoubtedly derived from the more sophisticated Chinese instruments, were shepherds' instruments. A series of graduated closed-end tubes were bound like a raft and end-blown.

The idea of the hydraulos, a water organ, may have stemmed from the multitubed panpipe. Its main development appears to have been around Alexandria from the 3rd century BC. Air under hydraulic pressure activated the pipes as controlled by an elementary keyboard. The tone was reported to be loud and penetrating. Despite the invention of pneumatic power, the hydraulus lasted at least through the 5th century AD.

The ancient Egyptian clarinet

Reedpipes. Egypt also made clarinets, instruments composed of two canes with three sides of a rectangle cut obliquely in the upper end of the two single reeds. The term idioglottic is used to describe a reed cut from the tube itself. From four to six equidistant finger holes are cut in each cane, and blowing with the entire reed engulfed in the mouth cavity produces a pungent, tremulous sound. The slight deviation of pitch between the two tubes creates the beats that cause the tremolo. (The device was rediscovered and copied in organ pipes late in the 15th century in Germany.) Sachs noted a double clarinet on a relief dated 2700 BC in the Egyptian Museum in Cairo. The same instrument is known today as *zummārah* wherever Islāmic civilization flourished; and closely related instruments—the *arghūl* of the Middle East, which has one long drone pipe and one short fingered pipe, and the *launeddas* of Sardinia, which consists of three pipes—also preserve the same shrill, reedy sound that must have been characteristic four centuries ago.

The New Kingdom (1567–1085 BC) yields the Egyptian oboe, known only as *mat*, the generic name of pipes. Like the flute, the oboes were made of narrow cane but were about two feet long; and, like the clarinet, they were blown in pairs, the left playing a drone while the right fingered a melody. Such instruments with their rich, penetrating sound have been known through the ages under various names and shapes. Their effect has long been considered intoxicating. The Greek version of the double reed was the aulos. The two divergent narrow pipes activated by a large reed would create a loud, pungent sound highly prized by the Greeks. Probably no wind instrument has received as much praise over such an extended period of time.

Developments in the Middle Ages. Western society in the Middle Ages went through crises that created decisive

changes in music and musical instruments. Except for the *tibia,* which was the Roman equivalent of the aulos, Rome showed little interest in Greek instruments, preferring the more powerful brasses that could be heard in such spectacular events as those given at the Colosseum. So Greek music dissolved, and its instruments dispersed to the countryside. The invasions of migratory tribes began in AD 150, culminating in the fall of Rome in AD 476 and continuing long past that date. With Greek and Roman culture in decline, the migratory peoples might have established their own music; but they brought few musical instruments. The Christians, who controlled the Roman Empire after the conversion of the emperor Constantine (AD 312), had little love for the musical instruments associated with earlier persecutions. Folk instruments, of course, remained, and such documents as the Utrecht Psalter (*c.* 830; Utrecht, Library of the State University) contain drawings showing instruments, but there is little to indicate a flourishing musical culture. The great centres of learning in general as well as the cultivation of music and the playing of instruments remained in the Middle East.

Influence of Islām on medieval musical instruments

The most significant movement affecting the history of medieval musical instruments was the spread of Islām in the 7th and the first half of the 8th centuries, by which time it had arrived at its maximum expansion—west across Africa as far as southern Spain, south down the coast of eastern Africa to Madagascar, and east through Persia, northern India, and Indochina to Indonesia and the southernmost Philippine Islands. The Christians began pushing back the Muslims in the 9th and 10th centuries in Spain, Sicily, and Sardinia. In addition to this most obvious contact, the trade routes brought continuous Muslim products into the European cities engaged in Eastern commerce, especially Venice, Genoa, and Pisa; and from the late 11th to the early 13th centuries the Crusades took Christians to Muslim homelands, where they further absorbed Middle Eastern ideas and customs. Finally, a slower, less dramatic route existed across the Balkans and to the north, by which musical instruments drifted from the Middle East or Byzantium into the countries of northern Europe and on west to Iceland. Neither the Christians nor the Muslims attained their political or religious objectives in their conflicts, but the stimulation of the progressive civilization of the Muslims nevertheless had a profound effect in Europe.

In the 13th-century Spanish manuscript of the *Cantigas de Santa Maria,* illuminations depict Muslims in their own costumes playing their instruments next to Christians, who are playing closely related specimens. If the West had not had strength and some tradition, Western music today might not differ significantly from that of the Middle East. Instead, the West modified the instruments and developed them in special ways. The Eastern melody and drone, combined with rhythm, were retained through the period and, indeed, to this day in much of Western folk music. The development of polyphony forced changes in many musical instruments. With voice parts covering much the same general range, each instrument had to possess a distinctive colour and a power of penetration to delineate its musical part.

Among the earlier instruments, the animal horn remained, often decorated and even provided with holes to allow the production of melody but leaving little evidence that it contributed to cultured music. The trumpet in the mid-14th century was bent back upon itself in the shape of a very flat S, making it easier to hold and carry. The peculiar idiom of the trumpet limited it mostly to fanfares and signals, however; it was only occasionally joined with other wind instruments.

As with the trumpet, other important woodwind instruments of the Middle Ages did not appear until the Gothic period. The vertical flute, single and double, came from the Middle East and remains today in the Balkans. A single short pipe, always associated with the drum (tabor), still persists in the Basque regions of Spain and France. Too narrow to sound the fundamental, the pipe needs only two finger holes and a thumbhole to complete its scale, and it can thus be played with the left hand alone, freeing the right hand to beat the tabor and leaving the legs free to dance. The transverse flute moved from the Byzantine Empire to Germany in the late Middle Ages. Although associated with the fiddle during the Minnesinger period of the 12th and 13th centuries, it became linked with the drum and military music in the form of the fife.

A folk clarinet, often double, used a cow horn for a bell and occasionally a second cow horn to provide a wind chamber around the reed. Known as the hornpipe in England, the instrument is called by various names from Wales along the Mediterranean to India. It may also appear with the reeds enclosed in a calabash (*magudi* or *pungi* of India) or in sheep's bladder (bladder pipe).

Origin of the bagpipe

Ostensibly, the bagpipe appears to have been a development of the simpler enclosed reed instruments, but actually the bagpipe was known to Rome (Latin *utriculus*), where it was presumably a recent import from Asia in the 1st century AD. The bag was formed originally from the entire hide of a sheep or goat, with the chanter, the pipe with finger holes, fitted into a wooden stock at the neck. When drones are present, they emerge from stocks in the forelegs. A blowpipe is necessary to fill the bag with air, and an arm over the bag provides pressure to activate the pipes. The chanter has seven holes in front and a thumbhole behind.

The pneumatic organ appeared around the 2nd century AD as a portative variety—that is, an organ small enough to be carried. These organs consisted of one or more ranks of flue pipes controlled by a keyboard. To aid portability, the usual two octaves had only the essential chromatic notes. From the Gothic period, portatives were frequently found both in pictures of processions and in seated ensembles. Depictions show the player operating a bellows with his left hand while manipulating the keys with the second and third fingers of his right hand. Various references show the presence of organs of many sizes throughout the Middle Ages. By the 10th century the nonportable positive organ began its distinguished career as the earliest form of church organ.

The Renaissance. The major accomplishment of music in the Renaissance was the emancipation of instrumental from vocal music. As polyphony developed, the two- and three-part music of the 13th century expanded to a norm of four parts in the art music of the 15th century and to five or six parts by the middle of the 16th. Early in this vertical expansion the voice parts were differentiated in range, forming a texture extending to approximately three to three and a half octaves. Apart from the organ, no winds possessed a diatonic range of that size. Furthermore, as the voice parts spread, the penetrating and contrasting quality so advantageous for the crossing parts in medieval music became less desirable. The music of the time then demanded the building of instruments in different sizes for the various parts in order to secure a smooth blend throughout the texture. Such ensembles were called consorts. Wind instruments flourished. At no time in the history of music was the choice of available timbres greater, and within the 16th century as many instruments as possible were built in families. The common sizes, built a fifth apart, were called the treble, tenor, and bass, usually with corresponding pitches in winds of a, d, and G. Flutes and recorders were an octave higher. A descant and a great bass were introduced for music that exceeded the combined range of the standard instruments. Woodwinds, in general, were made in one piece in a plain design, and Venice appears to have been an early centre of wind-instrument manufacture.

The new concept of blending tone quality was applied to the flutes and recorders. Both were made with a relatively large cylindrical bore, which emphasized the low partials. As a result, the upper range was limited, but the effective octave and a half that remained was sufficient for Renaissance music. Since the transverse flute adapted less well to various sizes, it was more often used with other instruments.

Double-reed instruments

Double reeds were particularly numerous during the Renaissance, and in many species the reeds were capped. The best-known of these was the crumhorn (German *Krummhorn*), an instrument of narrow cylindrical bore whose unusual J shape complemented its pungent, buzzy

tone. The reed cap may have been inspired by bladder pipes or bagpipes in which the reed is activated without lip contact. The cap made it impossible for a player to exert lip pressure on the large reed within, so the instrument could not be overblown. Its seven finger holes, one thumbhole, and one upper key gave a range of only nine notes. Nevertheless, the crumhorn consort made an excellent ensemble, and some fine early sets of instruments still survive as testimony.

Other soft-toned capped double reeds, known largely from written descriptions and pictorial sources, are the Italian *cornamusa,* probably little more than a crumhorn without the nonfunctional curved area, and the *dolzaina,* appearing much the same as the *cornamusa.* A loud capped reed was the *schryari,* made in the three principal sizes. The outer shape was inverse conical, but, since no specimens remain, the contour of the bore is unknown.

Shawms were a particularly important family of loud double reeds, with related instruments spread across all Asia. Their wide conical bore, large double reed, and seven front finger holes provided them with a loud, reedy tone, reminiscent of Middle Eastern reed instruments of today. The player could rest his lips on a wooden pirouette into which the reed was inserted and activate the reed without contact in the wind chamber formed in his mouth. Nevertheless, the reed could be controlled if desired, and the instrument was overblown partly through the second octave. Shawms were made in progressive sizes from the small descant in a′ to the great bass in G or F, the latter attaining a length of 8 to 9 feet (about 2½ metres). The power of the shawms enabled them to consort with trombones and to carry well in the outdoor tower music of central European cities.

The more gentle curtal (German *Dulzian;* Italian *fagotto;* French *basson*) was a noncapped double reed with its conical bore doubled back within the same block and ending in a small bell. It was activated by a long, carefully trimmed double reed connected with the instrument proper by a short tube called the *bocal.* Six front finger holes, two thumbholes, and two keys gave it a range of two octaves and a second. First mentioned in 1540, its bass (sometimes called the double curtal in England and the *Choristfagott* in Germany) soon became the most important size, particularly at the beginning of the Baroque period, when it was needed for a bass whenever higher winds were scored. German church composers of the 17th century normally used the *Choristfagott* as a bass for violins and violas as well. The double reeds with doubled back cylindrical bores were an interesting development. The *sordone* (French *courtaut*) was such an instrument, its narrow bore terminating in a side vent near the *bocal.* Most extraordinary was the racket, whose narrow bore went through a cylinder of ivory or wood as many as nine times to make a double-bass instrument from a cylinder length of a few inches. The instrument plays an octave below notation and forms the lowest of the Renaissance winds. The Renaissance reeds that were not adaptable to outdoor music vanished early in the 17th century, except for the curtal. The shawm survived somewhat longer.

The cornett

Another important woodwind was the *cornetto* (an Italian name Anglicized as cornett; also known under its German name, *Zink*), the descendant of the medieval cow's horn with finger holes. The treble cornett in g was made from two pieces of wood, hollowed out and glued together to create a mildly conical tube, usually octagonal and most often curved in the shape of its prototype. A covering of leather, protecting the surface and sealing any leaks, was frequently decorated at the upper end. The cornett was made in larger sizes, but only the descant was widely used.

The trumpet maintained its usefulness as a ceremonial instrument and developed in the direction more fully described in the next section. The trombone blended nicely in consort with cornetts as the treble instrument or in the loud consort in the company of shawms.

The Baroque and Classical periods. Dramatic events in music around 1600 in Italy profoundly affected the music of Europe during the Baroque era. A group of literary men and musicians who called themselves the Camerata gathered in the home of Giovanni Bardi, Count di Vernio, in the last decade of the 16th century to experiment with a type of drama that would use music as an adjunct to poetry. The musical result was the negation of polyphony, the reduction of melody to a position subservient to the text, and the creation of a bass line with improvised accompanying harmony to support the drama in the singing voice, altogether a direct repudiation of the ideals of the Renaissance. A 17th-century Italian composer, Claudio Monteverdi, referred to the style as *seconda prattica* and within his lifetime developed it into a much finer medium than the experimental style he inherited.

The new style greatly affected instrumental practice. Those instruments that could not produce expressive sounds and that could not imitate the passions as represented by the skilled singers were relegated to the middle or lower register of the ensemble, where they could serve either as an inconspicuous background or as a contrasting support for the predominantly expressive melody. If the Renaissance was the era of woodwinds, the Baroque was the era of strings, and the violin family assumed a dominant position throughout both Baroque and Classical periods. Nevertheless, wind instruments were not overlooked, and before the end of the period they were altered in order to compete with the strings. In the meantime, the winds were useful for dance music and municipal music (*i.e.,* for town ceremonies). Particularly in Germany, the loud winds of the Renaissance continued to be used. They maintained their 16th-century functions of being played regularly from towers, and they were always available for music in churches and palaces.

By the early 1730s, however, when J.S. Bach and Handel were producing many of their great works, reaction set in against the presumed pretentiousness of the elaborate Baroque style, and a premium was placed on simplicity and clarity. The importance of the bass line diminished, and the counterpoint, reborn in the 18th-century style, was again abandoned. By mid-century the sentimental style of an ornamented simple melody over an uncomplicated texture of basic tonal harmony had taken over, and it was on this foundation that Haydn and Mozart based their composition of a mature Classical style. Wind instruments of Renaissance type were then preserved only in rural areas or as folk instruments; and the new winds, developed in the 18th century, challenged but never quite captured the supremacy of the strings.

The Baroque opera demanded the depiction of the grand and majestic; so, obviously, the trumpet was important. The instrument was now compactly folded once to reduce seven feet of tube to only a little over two feet of length. The normal keys of the period were D or C, a terminal crook lowering the D instrument when C was desired. The leading trumpeter played in the high or clarino range, which included the pitches of the fourth octave, where the tone was particularly magnificent and where the available diatonic notes permitted the playing of melodies, trills, and various ornaments. Other trumpets played successively lower pitches. The trombone (German *Posaune;* English sackbut; French *saquebute;* Spanish *sacabuche*) was used in opera and church orchestras. By the Baroque period it was made in three sizes—f alto, B♭ tenor, and F bass—sizes that remained in use in Germany through much of the 19th century. The treble cornett gained a new use in the Baroque. Since its range equaled that normally used by the violins in the 17th century, it could substitute for them or contrast them and also effectively contrast the soprano voice. Consequently, it was useful in Monteverdi's opera *Orfeo* (first performed 1607) and in many German church cantatas, as well as instrumental ensembles. Difficult to play, it was extremely treacherous, and to be played with sufficient control it needed not only a good musician but also one with luck. The names of the Renaissance wind instruments are familiar to many music lovers since the Baroque organ adapted so many stops imitating the colour of these instruments. The beating reed adapted in the Renaissance regal was brought into the organ proper and formed a variety of useful colours.

Brass in Baroque opera

Woodwind instruments were far too valuable for their individual tone colours to remain subservient to the ubiquitous violins; and in Paris the musician and instrument

builder Jean Hotteterre, his family and associates all skilled wood turners, redesigned first the oboe and later the recorder, transverse flute, and bassoon—all in the last half of the 17th century. With the advent of these instruments, Renaissance woodwinds gradually vanished. The new instruments were turned in short sections, peculiarly with a broken profile—that is, an unevenly expanding or contracting bore between sections—a feature not long retained.

The oboe. The oboe (French *hautbois*) was first to compete with the violin. The upper register, difficult and incomplete in the shawms, had to be developed. Hotteterre narrowed the bore of the treble shawm, reduced the size of the finger holes, and considerably narrowed the reed, which was attached to a staple and inserted directly into the top section as in the musette. With the pirouette abandoned, the more delicate reed could be carefully controlled by the player and pinched between the lips to produce fast enough vibrations for overblowing. Hotteterre also lowered the customary d′ pitch in descant to c′ by fitting a "butterfly" key at the end—*i.e.,* in two-winged shape to accommodate the little finger of either hand. The oboe was immediately successful; in fact, it became the most favoured woodwind in the 18th century. Its tone was rich and expressive, and its better players could imitate all subtleties and expressive characteristics of highly trained operatic sopranos. A tenor form and a rare bass were not cultivated in art music. After the Renaissance, families of instruments were not generally made, and expressive playing was largely in demand in the soprano range. The English horn, or the alto oboe, was adopted around 1720 but made no great impact. The instrument was curved as a horn in its early form and covered with leather. Bach called it oboe da caccia and used it occasionally for its dark, smooth tone colour.

Success of the oboe

The bassoon. The bassoon underwent far less radical changes in the hands of Hotteterre than the oboe. The former curtal was simply built in four sections and lengthened to produce B♭,. The date of the bassoon's introduction into the orchestra is uncertain since the double-reed instrument in the bass range was frequently taken for granted; but a French composer, Jean-Baptiste Lully, scored specifically for it in 1674. The standard bassoon for most of the 18th century had four keys, but six were common by the end of the century. The range was a remarkable three octaves, although the top b♭′ was available on few bassoons. As with the curtal, whose sound was mellow and obtrusive, the bassoon was praised for its tone and compared to the human voice, the ultimate in contemporaneous praise. Such comments testified to its success in playing expressively; and a considerable solo literature, rare among low-pitched instruments, bears further witness to its flexible melodic capabilities. Its service as a wind bass was indispensable. Some small bassoons, tenoroons and fagottini, were built in the century but remained obscure. More important was the contrabassoon, whose sporadic appearance in score probably reflected on its rarity more than its usefulness.

The flute. The Renaissance recorder blended well in consort but was weak in its upper register and needed modification to meet the demand for an expressive melodic style. The very nature of the instrument, with its lack of lip control, prevented much dynamic control; but the Baroque changes nevertheless went far toward producing an expressive instrument. It is to be remembered that throughout the Baroque period the Italian term *flauto* referred to the recorder; the cross flute was normally called transverso or *flauto traverso* and was so indicated on scores. Although many ambiguous cases exist, the recorder was the type of flute called for in much of Baroque music. The redesigned recorder was built in three sections with an inverse conical bore in the middle and foot. Although the full consort sizes and many others were made, the treble recorder (with a bottom written note of f′; *i.e.,* today's alto recorder) was the principal instrument used for solos and orchestral performance.

Developments in the recorder

The transverse flute was also built in three sections with an inverse conical bore; and this flute as well as the recorder spoke better in the upper register. The E♭ key, as mentioned earlier, was soon added to make the instrument completely chromatic throughout its range (d′ to b♭‴). Intonation on the flute was nevertheless difficult. The necessary cross-fingerings caused a somewhat muffled quality. Consequently, the flute sounded best and its technique was most facile in the key of D. Only rarely did Baroque composers of flute music venture far from the keys in one, two, or three sharps. To alleviate some of these problems and to adapt to the varying pitches at that time, after 1720 the middle section was often divided. Then the flute could be provided with from three to six different lengths for the upper of these sections (*corps de rechange*). In spite of these difficulties, the one-keyed flute had a lovely tone, softer than the modern flute. Keys were soon added to solve difficulties of intonation and tuning. By 1760 some London makers added keys for f′, g♯′, and b♭′, eliminating the usual cross-fingerings in the first octave. By the end of the 18th century, the flute was lengthened and the keys added for c′ and c♯′, thus matching the range of the oboe. The tone quality of the instrument changed little and its versatility improved.

The military fife, which retained the one-piece construction of the Renaissance, remained useful for its limited repertoire, and the piccolo in B♭ or C was only occasionally used.

The clarinet. One of the most significant contributions to Western art music in the 18th century was the addition of the clarinet. The various cane instruments with a single reed and stemming from antiquity still remained in the area around the Mediterranean as folk instruments. Furthermore, the bagpipe had adapted the single-reed pipe as its chanter. The chalumeau, one of these single-reed folk instruments, occasionally emerged into art music, when the two oboists of the orchestra would use chalumeaux to imitate the sound of trumpets. Johann Christoph Denner, the renowned 16th-century recorder maker from Nürnberg, saw the possibilities of the instrument. He made them of boxwood, gave them an attached reed, and doubled their length, achieving a chalumeau register, as it is still called, from f to b♭′. Using the back key as a speaker, the instrument overblows at the 12th, making a clarino register from c′ to f‴. Soon keys for b♭′, c♯″, and e♭″ were added, completing the classical clarinet. These extra keys also produced e, f♯, and a♭ in the so-called chalumeau register, providing a total usable range of three octaves and one note. The clarinet had then emerged. Again, those describing the instrument compared its virtues to the human voice, and the instrument was adopted wherever players were available. Compared to the instruments of today, the cylindrical bore was narrow and the reed smaller to fit the long, narrow mouthpiece. Furthermore, the mouthpiece was inserted so that the reed, attached with cord, was on the upper side of the instrument.

Early clarinets were made largely in C or B♭, sometimes with an A section to use on the B♭ instrument. Small F clarinets were available for use in bands; but, as with the other woodwinds of the time, a pair of treble clarinets were sufficient for the orchestra.

A more important auxiliary instrument than, say, the tenor oboe was the basset horn, which provided an extension of the bore to take the chalumeau range down to c. The untimely demise of the basset horn in the 19th century has been regretted by many, for modern experimentation has shown it to be vastly superior to the alto clarinet in E♭ commonly used in bands.

The basset horn

The French horn. Another major contribution in the 18th century was the emergence of the French horn as an orchestral instrument. Early in the century the tone of the horn was appropriate for its use in signaling during the hunt. By mid-century, the mouthpiece had been altered and the hand inserted in the bell to provide the warm, mellow quality in midrange that Classical composers found so useful. Consequently, much experimentation to increase its usefulness ensued, resulting in the crooks and in hand stopping. Even with its severe limitations, the horn of the Classical period became an essential colour.

The trumpet. After the mid-18th century, high melodic parts in the trumpet appeared less necessary to an aesthetic that spurned the majestic for a simpler style. Trumpets

were built in many keys, but for the most part trumpets in F replaced those in D and C; and the notes of the fourth octave, which were most difficult on the shorter instrument, were abandoned. In short, the complete clarino style disappeared along with those players of the privileged guild who had learned to master that treacherous range. The F trumpet remained standard in Europe through the 19th century.

The Romantic period. In the 19th century the pendulum swung from the restraint of the classic to the expressive. The aesthetic demanded an emphasis on the personal, on the dramatic, and on the passionate. Music responded with modulation to remote keys and required instruments in increased range, more facile technique, and wider dynamic contrast. Obviously, instruments had to be adjusted. Families of instruments again became important, and new tone colours were introduced.

The entire period has sometimes appropriately been called the age of mechanization. Around the first quarter of the century, the period of Beethoven's major orchestral works, more keys were added to existing woodwinds, and evidence from one passage in Beethoven's Ninth Symphony implies that the fourth horn player already had one valve on his instrument. Almost immediately afterward more drastic changes were necessary in order to fulfill the demands of the composers.

The central figure in the changes in woodwinds was a Munich flutist and instrument builder, Theobald Böhm. Profiting by the experiments of many others, Böhm devised the long axle to allow control of holes from some distance and then proceeded to redesign the flute on acoustic principles. Böhm made the holes in his flute as large as possible and changed all closed keys to open keys to allow full venting. He then placed all holes in an acoustically correct position, providing for comfort in fingering by using ring keys on the long axle to close holes that players could not reach easily. At this stage the Böhm conical flute of 1832 appeared. By 1847 Böhm had become convinced that only a cylindrical bore would solve certain problems in intonation, and by using covered finger holes he could make them even larger. The Böhm experiments changed the character of the flute considerably, producing more volume and a more brilliant tone; with his improvements, along with the subsequent minor changes, the flute became one of the most versatile instruments of the orchestra, performing superbly in all keys.

Böhm's innovations in instrument building

Similar changes were made about the mid-century in other woodwinds, the Böhm system (1843) adaptations to the clarinet finally conquering other key arrangements except in Germany. Charles Triébert and his son modified the oboe, finally adding some features from the Böhm flute to produce the "conservatory system." Certain improvements were made in the bassoon in 1825 by Carl Almanräder, a chamber musician of Biebrich. Since the improvements were accompanied by deficiencies in tone, the French preferred to develop the classic bassoon. Although the Heckel family (Johann Adam Heckel and Wilhelm, his son and successor), also of Biebrich, eventually corrected the faults, the difference between the French and the German bassoon still remains, the former having a reedier, more individual tone, the latter with its comparative richness blending better. First the Americans and finally the British accepted the German instrument.

The classic orchestra reached a certain perfection in balance between strings, woodwinds, and brass, which was distorted at the beginning of the 19th century by the addition of two horns and three trombones. From there on, the orchestra grew, and families of instruments again became important for additional colour and for balance. In his *Principles of Orchestration* (1913; written 1896–1908), the Russian composer Nikolay Rimsky-Korsakov developed the theory that the four basic woodwinds had a vast range of expression. At each end of the entire range were areas useful for their individual colour, and the instruments of smaller and larger sizes intensified those colour effects. This theory formed the basis of his orchestration and had profound effects on the art music of the early 20th century, even to the popular hotel dance bands of the 1930s in America.

The piccolo was accepted early, carrying upward and intensifying the brilliance of the top octave of the flute. It remained for the 20th century to exploit the low tones of the piccolo. By the end of the 19th century the alto flute, a weak instrument dynamically, joined the orchestra but was exploited most effectively by the French composers of the early 20th century—for example, Claude Debussy. The oboe developed no satisfactory descant, but the English horn, first used notably in Hector Berlioz's *Roman Carnival Overture* (1844), became increasingly useful for its peculiar dark and melancholy expression. A small clarinet in D (E♭ in wind bands) proved suitable for bright, strident effects, while the bass clarinet added a mysterious piquancy as an extension of the dark and colourful chalumeau register. The contrabassoon gained importance as the most effective wind double bass and the lowest instrument of the orchestra.

Woodwinds of the 19th-century orchestra

Little needs to be added about the trumpet and French horn. By mid-century, valves were established for horns and trumpets, but even through the early works of the 20th-century German composer Richard Strauss these were considered largely as a means for instant transposition of the instrument. At the same time, however, the full chromatic possibilities were exploited by such composers as César Franck and Peter Ilich Tchaikovsky.

Since 1590 a wooden cup-mouthpieced instrument, the serpent, had been built to support voices in French choirs; but by the mid-18th century it was serving as a double bass for the woodwind choir. The serpent and its derivatives, the Russian bassoon and the bass horn, were eventually replaced by the contrabassoon. The ophicleide, the bass of the keyed bugle, was prominent in the second quarter of the 19th century as a brass double bass.

The invention of the bass tuba by a German instrument builder named Johann Gottfried Moritz in 1835 provided a more reliable and more even brass bass. Tuned in F or E♭, its range was, respectively, B♭$_{1}$–e♭^{1} and C–f^{1}. Later a BB♭ (double B-flat) contrabass became available. The tuba was distinguished by a wide conical bore and a deep cup mouthpiece, both of which favoured the fundamental and lower partials. It was built in many sizes to provide a rich and mellow brass choir for the wind band, of which the cornet of similar proportions was the lead melodic instrument, in contrast to the more penetrating trumpet of the orchestra. The flügelhorn, slightly more conical than the cornet, is also an appropriate treble for the tuba family. The tubing of the various instruments could be and was bent in many different shapes. Some even had bells pointing backward in order to send the sound toward marching soldiers in a parade. When the bass instrument was bent into an over-the-shoulder model, it was called a helicon. Later, the American bandmaster John Philip Sousa established his own variation of the helicon, and it became known as the sousaphone.

Also noteworthy are the Wagner tubas, especially built for Richard Wagner's operas *Der Ring des Nibelungen.* Narrower in bore than the baritone horn, they are supplied with a funnel-shaped mouthpiece in order to form a tone intermediate between the French horn and the tuba. Built in tenor and bass ranges, the instruments fulfill their purpose admirably.

The 19th century gave rise to families of reed instruments. The Belgian instrument maker Adolphe Sax patented the saxophone in 1846, combining a wide conical bore with a large single reed and producing an instrument that overblows at the octave and covers a written range of b♭ to f‴. Sax's patent covered instruments in 14 different sizes, and others were added later. Intended for the military band, the saxophone has found only occasional use in the orchestra. It has been used most familiarly in America in jazz ensembles from the 1930s on.

The saxophone

The Chinese *sheng,* which had reached Europe in the late 18th century, inspired the invention of three distinct musical instruments in the West: the mouth organ, the accordion, and the reed organ. It is a mouth organ consisting of free-reed pipes vibrating under wind pressure from a globular wind chamber blown into by the player. The pitch is determined by the reed itself, which activates vibrations in the surrounding air.

The Western mouth organ, invented about 1825, has two reeds of the same pitch, one of which vibrates as the player exhales, the other, as he inhales. The slotted edge that the player puts in his mouth directs air to and from the reeds. Tones are eliminated by covering the slots, so that a skillful player can produce a single pleasant tone at a time. Although a few players have developed a skilled technique, the instrument is normally completely diatonic and is largely confined to folk and popular music.

Invented in 1822 by Friedrich Buschmann of Germany, one of the mouth-organ patenters, and operating on the same principle was the accordion, in which a bellows substitutes for the breath and buttons or keys open channels to free reeds. Melody is controlled by the right hand, the bass and accompanying chords, by the left. Although originally a diatonic instrument, by mid-century it became chromatic. Accordions with keyboard for the right hand have also become popular.

The reed organ dates from about 1810. It was a free-reed instrument with a foot-operated bellows providing wind pressure to vibrate reeds whose access was controlled by a keyboard. The instrument was provided with an assortment of Greek-derived trade names, of which the harmonium appears to be most prominent for those organs operating on the principle of pressure bellows. An instrument operating on sucker bellows was later developed and became especially popular in the United States; in fact, all such suction instruments are commonly known as American organs. In the 19th century the reed organ, mellow in tone and inexpensive, became an important instrument in homes and small churches.

The 20th century. The 20th century began with few radically new ideas in instruments. Many people were still debating the merits of Wagner and Brahms while Richard Strauss, the Impressionists, and the Russian nationalists were each continuing the exploitations of the tone colour and technical capacities of the expanded orchestra. Challenged by these works, instrument makers continued to make minor alterations to solve fingering problems or to produce even tone. For a time the standards of increased size and greater technical capacity were most important, but eventually such works as Arnold Schoenberg's *Pierrot Lunaire* (1912) and Anton von Webern's *Five Pieces for Orchestra* (1911–13) disturbed the overripe late Romanticism, and the emphasis on bigness evaporated. The entire aesthetic became disunified. In general, after the first quarter of the century, ensembles became smaller and an anti-Romantic if not a purely Classical trend was discernible. In instruments, two diverse directions became apparent: (1) a return to the historically accurate sounds for the music of the repertoire and (2) the application of electrical power to do everything from duplicating known tone colours with artificial amplification to the creation of entirely new instruments.

Revival of Baroque woodwinds

With the early music revival came the reproduction of early brasses and woodwinds. Around 1925 an English musician and instrument builder named Arnold Dolmetsch began making Baroque recorders, which had been in eclipse for more than 100 years and which again became one of the most widely played wind instruments. More recently, reproductions of other historical instruments became available, including crumhorns, shawms, *Rauschpfife*, Renaissance flutes and recorders, Baroque transverse flutes, Baroque oboes, and Baroque trombones. The Baroque trumpet was again made, although few trumpeters returned to the valveless eight-foot D trumpet of the period; with a discreet use of narrow bores, shallow mouthpieces, and valves, they obtained trumpets that give the range and character of the clarin trumpet.

As regards the second trend, there has been considerable interest in adapting electronic technology to wind instruments since the early 1970s. Synthesizer control devices that treat the sound of the wind instrument as input to be manipulated electronically have been used successfully, as have synthesizers with breath-operated control. Digital technology permits the "sampling" and manipulation of wind instrument acoustics—in effect, the digital equivalent of a tape playback system (see below *Electronic instruments*). (R.A.Wa./J.M.Bo.)

THE MUSIC OF WIND INSTRUMENTS

In western Europe. The diversity of wind instruments and their musical use in post-antiquity is reflected in medieval literature and art. From this evidence it can be inferred that wind instruments were grouped according to volume of tone—that is, as either loud or soft (*haut* or *bas*). Loud winds—trumpets, shawms, and bagpipes—accompanied outdoor processions and dancing; trumpets also were brought into church to play the sustained lower parts of primarily vocal motets and masses. Soft wind instruments, such as the recorder, transverse flute, cornett, and portative organ, were mostly played indoors and, together with bowed and plucked strings, likely performed instrumental arrangements of songs and motets.

Unmixed consorts in the Renaissance

During the Renaissance, wind instruments were grouped into unmixed consorts whose homogeneous sound derived from the texture of contemporaneous vocal ensembles. (A typical wind consort of the early 16th century comprised three sizes of the same instrument type, usually an alto, two tenors, and a bass; a century later, some winds were made in as many as eight sizes, which, however, were grouped into two different ensembles, one at four-foot, the other at eight-foot pitch.) In addition to polyphonic dance music, these consorts performed arrangements of secular songs such as those published in 1533 by Pierre Attaignant, which bear designations as appropriate for either transverse flutes or recorders. The preference for unmixed consorts was so strong by the late 16th century that even at large musical events involving many musicians, different groups played whole pieces or portions of them in alternation rather than at the same time.

The Baroque period. At certain centres, particularly Venice, it was the practice in the late 16th century to combine and contrast an instrumental consort (mainly winds) with voices in a type of religious composition called the sacred concerto. In the *Sacrae symphoniae* (1597 and 1615) of Giovanni Gabrieli, for example, an ensemble of three cornetts, two trombones, and tenor violin accompanies solo voices, alternates with and accompanies one or two choirs, or performs alone. Gabrieli adopted a similar approach in his instrumental music. His *Sonata pian' e forte* (1597), the first musical composition for which instrumentation is specified, employs two ensembles of equal size—three trombones and cornett; and three trombones and a viola da braccio—sometimes playing together, sometimes separately.

Large ensembles of singers and instrumentalists also were divided into forces of different size. In some sacred concerti of the early Baroque, a large group of supplementary instrumentalists, who doubled the choral parts, was contrasted with instrumental soloists, or concertino (violinists or virtuoso cornettists), who played in dialogue with the vocal soloists. This disposition of instruments, in conjunction with the antiphony perfected by Gabrieli, gave rise to the concerto grosso. Some concerti grossi, notably those of Arcangelo Corelli, employ a solo group made up of two soprano-range instruments and bass, a combination known as "trio sonata" texture that had wide currency in the Baroque era. (While Corelli's trio sonatas were written for strings, a bassoon might virtually double the bass line, and the repertoire as a whole contains works written for wind instruments in one or both of the upper parts.) By the late Baroque, concerti grossi had in effect become concerti for solo instruments. J.S. Bach's *Brandenburg Concertos, Nos. 1, 2, 4 and 5* (pre-1721), which involve extended virtuoso passages for winds, are outstanding examples of this transition.

Programmatic associations of Baroque winds

Before the mid-16th century, instrumentation depended less on tone quality or the composer's preference than on what instruments were available. Winds and strings were largely interchangeable. After that time, however, some wind instruments began to establish their autonomy. In the Florentine *intermedi* (staged musico-dramatic presentations generally based on pastoral or mythological themes), particular winds were associated with particular characters or situations, such as trombones with the netherworld. Many associations established in the *intermedi* were later retained in 17th-century opera, oratorio, and ballet. As members of the violin family displaced

winds as the preferred instruments of Baroque ensembles (both inside and outside the theatre), the theatrical uses of winds became more pronounced and composers increasingly sensitive to their extramusical associations. Also characteristic of Baroque opera and oratorio was the obbligato use of winds in a manner stylistically analogous to writing for solo voice.

The Classical period. The Classical technique of winds doubling strings emerged in scoring for opera orchestras in the mid-17th century and continued to be important through the next century in the compositions of Haydn and Mozart. (Most 18th-century orchestras included at least four winds, usually two oboes and two horns; by the 1770s, Mozart was writing for double flutes, oboes, and bassoons, a brass section of pairs of horns and trumpets, plus timpani and four-part strings.) In effect, this rendered winds less prominent in the texture of the Classical orchestra compared with the Baroque, in which the distinctive sonorities of winds had been used to highlight the different contrapuntal lines. In Classical orchestration, oboes and bassoons generally double the string parts, while brasses reinforce the harmony in relatively slow note values or play idiomatic fanfares and horn calls. Wind instruments did, however, retain their programmatic associations in church music and opera—"magical" instruments in Mozart's *The Magic Flute* (1791; *Die Zauberflöte*) include the flute and piccolo, the latter representing Papageno's reed pipes. They also were used for obbligato accompaniments. Sesto's aria "Parto, parto, ma tu ben mio" from Mozart's *La Clemenza di Tito* (1791; "The Clemency of Titus"), for example, features a basset clarinet obbligato.

In the late Classical period Beethoven's orchestration at first seems a continuation of the conservative Classical practice, with considerable doubling of parts. His use of winds, however, particularly in the symphonies, at times tends toward theatricality bordering on the operatic. Familiar examples are the "false" entrance of the horn before the recapitulation in the first movement of the *Eroica* (1804; *Symphony No. 3 in E Flat Major*), and the oboe solo in the first movement of the *Symphony No. 5 in C Minor* (1808). Beethoven's dramatically charged approach to wind scoring in nominally abstract music profoundly influenced later composers. In such late 19th-century works as Gustav Mahler's first three symphonies and the tone poems of Tchaikovsky and Rimsky-Korsakov, wind parts have strongly connoted extramusical significance.

Another use of winds in the Classical and later periods was in small ensemble music. French Baroque composer Jean-Baptiste Lully anticipated future developments with his marches, a tradition that continued either in the hands of later specialists (Anton Reicha's wind ensembles, John Philip Sousa's marches) or as exceptional works by great masters (the wind quintets of Mozart and Beethoven). Carrying forward Baroque practice, composers in the Classical era also wrote chamber works for mixed ensembles of winds with piano or strings, or wind concerti, such as those for clarinet and bassoon by Mozart. (J.M.Bo.)

The Romantic period. In the 19th century wind instruments underwent extensive improvements, which ultimately led to the expansion and diversification of the woodwind and brass sections of the orchestra. An early advocate of such enrichment was Berlioz, whose *Grand traité d'instrumentation et d'orchestration modernes* (1844; *A Treatise upon Modern Instrumentation and Orchestration*) dealt with the ranges, mechanical problems, and sound qualities of all wind instruments, including newly invented ones. Typical of Berlioz' own compositions, the *Te Deum,* Opus 22, calls for an expanded wind complement of four flutes, four oboes, four clarinets, four horns, four bassoons, alto saxhorn, two trumpets, two cornets, six trombones, and two tubas. Wagner augmented even these large forces in the service of the music drama, quadrupling in the *Ring* orchestra most of the woodwinds and scoring for eight horns (four of which doubled on tenor and bass Wagner tubas), a contrabass tuba, three trumpets and bass trumpet, one contrabass, and three tenor trombones. In the late 19th-century symphony and tone poem, as in opera, the large, variegated orchestra maintained close ties with programmatic or operatic impulses.

Berlioz' treatise on orchestration

Perhaps as a corollary of the expanding use of winds in the Romantic orchestra, the 19th century produced remarkably few concerti for solo winds and orchestra. There was a similar decrease in chamber music for winds. Among the few composers of music for solo winds with piano are Carl Maria von Weber, Robert Schumann, and Johannes Brahms. Brahms also wrote some outstanding chamber works for winds and strings, as did Franz Schubert.

The 20th century. Although the huge symphony orchestra was accommodated for a time in the early 20th century by such composers as Mahler and Igor Stravinsky, two important trends in instrumental music emerged between World Wars I and II. One of these was the ever-growing interest of composers in ensembles consisting predominantly of wind instruments. Stravinsky, for example, composed his *Symphonies of Wind Instruments* in 1920, *Concerto for Piano and Wind Instruments* in 1923–24, and *Symphony of Psalms* in 1930, the orchestration of the last being noteworthy for its lack of violins and violas. The other important trend was a relative increase in the proportion of new music for chamber ensembles, especially those with wind instruments. In this repertoire such composers as Debussy (*Syrinx,* 1912, for flute) and Stravinsky (*Three Pieces for Clarinet,* 1919) extended the level of technique and the range of special effects demanded of wind players. Experimentation continues to the present day, with the electronic amplification of winds and the development of new techniques, such as multiphonics, in which two or more pitches are sounded simultaneously on a single woodwind instrument. (E.J.E./J.M.Bo.)

Jazz. Throughout the 20th century, jazz has been one of the most vital sources of American wind music. The first jazz ensembles to feature solo winds—trumpet or cornet, clarinet, and trombone—were formed in New Orleans in the second decade of the 20th century. In this early style, the soloists either improvised simultaneously or adapted their playing to the musical texture, the clarinet ornamenting the trumpet lead, the trombone filling in the chord notes and outlining the bass notes. By the mid-1920s, however, Louis Armstrong, arguably the most important wind instrumentalist of early jazz, had developed a dramatic solo style that did not depend on ensemble interaction; this style became a model for later jazz soloists. The following decade was the principal era of the "big bands," the best-known being those led by Duke Ellington and Count Basie. During the 1930s and '40s the wind sections of such groups grew from 6 (three reeds, two trumpets, and trombone) to a standard of 13 (five reeds, four trumpets, and four trombones). After World War II, the big bands gradually were supplanted by smaller "bebop" groups, which almost invariably included trumpet and saxophone. The recorded performances of alto saxophonist Charlie Parker, whose improvisational ability is legendary, are still studied and greatly admired. Since the 1960s, jazz musicians, particularly trumpeter Miles Davis, have been among the instrumentalists who are experimenting with new sonorities and—with the aid of electronic technology—forging new links between jazz and the music of the American and European avant-garde. (J.M.Bo.)

Influence of Louis Armstrong

In folk traditions. Wind instruments play an important role in the folk music of many cultures. Most folk music for winds imitates vocal models, such as the folk music for harmonica played by both black and white Americans, the love songs for flute played by Native American men, and the bagpipe music of eastern Europe, which usually consists of richly ornamented versions of local folksongs. (Many kinds of bagpipes are found throughout eastern and western Europe. These vary from the very simple ones found in Hungary, Czechoslovakia, and Poland to the beautifully fashioned instruments with three and four pipes [drones] found in Scotland, Ireland, and the north of England.)

A few types of folk music are idiomatic to wind instruments. In Poland, perhaps because of the proliferation of instruments, including several basic types of flutes and bagpipes, folk music is dominated by instrumental tunes, most of them for dancing. In the Basque region of northern Spain and southwestern France, dances and pro-

cessions are often accompanied by a single musician who plays a three-holed flute with one hand and a six-stringed dulcimer with the other. In certain African instrumental ensembles, percussion instruments sometimes are joined by teams of flute or horn players, each of whom plays a single note whenever it occurs in the melody. The Mbuti of Zaire often use up to six flutes, each playing variations of a different ostinato pattern. (E.J.E./J.M.Bo.)

In Asia. Wind instruments occupy a prominent place in the concert and theatre music of several Asian cultures. In the many regional types of Chinese opera, for example, singing and action are accompanied by a small onstage orchestra. The orchestra of Peking opera, the most widely known type, consists of two sections: percussion, which plays preludes and punctuates the singing and action; and the string and wind ensemble, which accompanies the singing and plays interludes. Winds in the latter group include the *sheng* (mouth organ) and various types of transverse flutes, including the *di*, one of whose seven holes is covered with a reed membrane to produce a distinctive buzzing sound. Many virtuoso solo pieces have since the 1960s been written for the *di*, which, as a result, has become an important concert instrument in Hong Kong and the United States.

The nōkan

In Japan the side-blown flute (*nōkan*), used in the traditional music for nō drama, is the only melody instrument of the nō ensemble (*hayashi*), which also includes the shoulder drum, side drum, and floor drum played with sticks. The *hayashi* mostly plays dance accompaniments, although the flute is also used to mark off sections of the play and to evoke different moods. The *nōkan* is also used in the larger ensemble for Japanese Kabuki theatre. In the Japanese court orchestra, the basic melody instrument is the double-reed *hichiriki*, which frequently is joined by flutes, a mouth organ (*shō*), and percussion.

The instrumental ensembles of Southeast Asia typically include winds. The *pī* oboe, for example, is the only nonpercussive instrument in the *pī phāt* bands of Thailand, which are used in theatre music; the bamboo duct flute (*khlui*) is sometimes substituted for the *pī* in the *pī phāt* when reduced volume is desired and is also played in some other Thai ensembles. Perhaps the most distinctive instrument of Southeast Asia, the free-reed *khāēn* (related to the Chinese *sheng*), is played as a solo instrument or to accompany a singer. (J.M.Bo.)

Electronic instruments

EARLY DEVELOPMENTS IN ELECTRONIC INSTRUMENTS

Precursors of electronic instruments. Electricity was used in the design of musical instruments as early as 1761, when J.B. Delaborde of Paris invented an electric harpsichord. Experimental instruments incorporating solenoids, motors, and other electromechanical elements continued to be invented throughout the 19th century. One of the earliest instruments to generate musical tones by purely electric means was William Duddell's singing arc, in which the rate of pulsation of an exposed electric arc was determined by a resonant circuit consisting of an inductor and a capacitor. Demonstrated in London in 1899, Duddell's instrument was controlled by a keyboard, which enabled the player to change the arc's rate of pulsation, thereby producing distinct musical notes.

The largest, and perhaps most advanced, of early electric instruments was Thaddeus Cahill's Telharmonium. Completed in 1906, this instrument employed large rotary generators to produce alternating electric waveforms, telephone receivers equipped with horns to convert the electric waveforms into sound, and a network of wires to distribute "Telharmonic Music" to subscribers in New York City. Complex and impractical, the Telharmonium nevertheless anticipated electronic organs, synthesizers, and background music technology.

Early electronic instruments. The dawn of electronic technology was marked by the invention of the triode vacuum tube in 1906 by Lee De Forest. The triode gave musical instrument developers unprecedented ability to design circuits that would produce repetitive waveforms (oscillators) and circuits that would strengthen and articulate waveforms that had already been produced (amplifiers). In the time period between World Wars I and II, many new musical instruments using electronic technology were developed. These may be classified as follows:

Classification

1. Instruments that produce vibrations in familiar mechanical ways—the striking of strings with hammers, the bowing or plucking of strings, the activation of reeds—but with the conventional acoustic resonating agent, such as a sounding board, replaced by a pickup system, an amplifier, and a loudspeaker, which enable the performer to modify both the quality and the intensity of the tone. These instruments include electric pianos; electric organs employing vibrating reeds; electric violins, violas, cellos, and basses; and electric guitars, banjos, and mandolins.

2. Instruments that produce waveforms by electric or electronic means but use conventional performer interfaces such as keyboards and fingerboards to articulate the tones. The most successful of these was the Hammond organ, which implemented the same technical principles as the Telharmonium but used tiny rotary generators in conjunction with electronic amplification in place of large, high-power generators. The Hammond organ was placed on the market in 1935, and it remained a commercially important keyboard instrument for more than 40 years. Other, more experimental early electronic keyboard instruments used rotating electrostatic generators, rotating optical disks in conjunction with photoelectric cells, or vacuum-tube oscillators to produce sound.

3. Instruments that were designed for performance in the conventional sense but which implemented novel forms of performer interfaces. Of these, Leon Theremin's theremin (1920), Maurice Martenot's ondes martenot (1928), and Friedrich Trautwein's trautonium (1930) have been widely used. The theremin is played by the motion of the performer's hands in the space around a pair of metal antennas; the ondes martenot player uses the right hand to determine the tone's pitch on a special keyboard while the left hand manipulates a set of buttons and levers to articulate the tone; and the trautonium is played by simultaneously manipulating a fingerboard-like resistance element with one hand and a set of panel controls with the other hand. Composers of the stature of Richard Strauss, Paul Hindemith, Arthur Honegger, Darius Milhaud, Olivier Messiaen, André Jolivet, Edgard Varèse, and Bohuslav Martinů have written for one or more of these instruments.

4. Instruments that were not intended for conventional live performance but instead were designed to read an encoded score automatically. The first of these was the Coupleux-Givelet synthesizer, which the inventors introduced in 1929 at the Paris Exposition. This instrument used a player-piano-like paper roll to "play" electronic circuits that generated the tone waveforms. Unlike a player piano, however, the Coupleux-Givelet instrument provided for control of pitch, tone colour, and loudness, as well as note articulation. The principles of score encoding and sound control embodied in this instrument have become increasingly important to contemporary composers as electronic musical instrument technology has continued to develop.

THE TAPE RECORDER AS A MUSICAL TOOL

The next stage of development in electronic instruments dates from the discovery of magnetic tape recording techniques and their refinement after World War II. These techniques enable the composer to record any sounds whatever on tape and then to manipulate the tape to achieve desired effects. Sounds can be superimposed upon each other (mixed), altered in timbre by means of filters, or reverberated. Repeating sound-patterns can be created by means of tape loops. Tape splicing can be used to rearrange the attack (beginning portion) and decay (ending portion) of a sound or to combine portions of two or more sounds to form striking juxtapositions of sound with arbitrarily great length and complexity. By changing the speed of the tape, wide variations in the pitch and tempo of the recorded material can be effected; by playing the tape backward, a sound's evolution can be reversed. Thus, the composer can exercise precise control over every aspect of his original sound material.

Tape composition techniques

Although Hindemith, Ernst Toch, and others had experimented with it previously, the development of tape music began in earnest in 1948 with the work of Pierre Schaeffer and his associates at the Club d'Essai in Paris, under the auspices of Radio-diffusion et Télévision Française. They called their creations musique concrète—a term emphasizing their choice of a variety of natural sounds as raw material. These sounds were shaped, processed, and then put together (composed) to form a unified artistic whole. The *Symphonie pour un homme seul* ("Symphony for One Man Only"), composed by Schaeffer and his collaborator, Pierre Henry, is one of the landmarks of musique concrète, for it laid the technical and aesthetic foundations for much of the later tape music.

In 1951 a studio for *elektronische Musik* was founded at Cologne, W.Ger., by Herbert Eimert, Werner Meyer-Eppler, and others, under the auspices of the Northwest German Broadcasting Studio. While the composers associated with this studio used many of the same techniques of tape manipulation as did the French group, they favoured electronically generated rather than natural sound sources. In particular, they synthesized complex tones from sine waveforms, which are pure tones with no overtones. Certain compositions of Karlheinz Stockhausen, such as the *Gesang der Jünglinge* (*Song of Youth*), are illustrative of the resources available in the Cologne studio.

(Ca.G./R.A.M.)

POST-WORLD WAR II ELECTRONIC INSTRUMENTS

Advances in electronic technology during World War II were applied to electronic instrument design in the late 1940s and '50s. The Hammond Solovox, Constant Martin's Clavioline, and Georges Jenny's Ondioline are examples of commercially produced monophonic (capable of generating only one note at a time) electronic instruments. These instruments used small keyboards and were designed to mount immediately under the keyboard of a piano. They were capable of simulating a wide variety of traditional orchestral timbres, which the player selected by setting an array of tablet-shaped switches along the front of the instrument.

Also during this postwar period, electronic organs became one of the largest segments of the musical instrument industry. These multikeyboard, polyphonic (chord-playing) instruments were first modeled after traditional pipe organs, but they later evolved into a new class of musical instruments for domestic use. The electronic home organ offered a variety of timbres, which were oriented toward popular music, as well as such performance assists as automatic rhythm production, easily enabling it to replace the player piano in popularity.

Score-reading instruments

Instruments capable of reading and performing encoded scores were developed during the 1940s and '50s. Unlike commercial keyboard-controlled organs and related instruments, the score-reading instruments were large, experimentally oriented devices. One example, the Hanert Electrical Orchestra, built in 1944–45 by John Hanert at the Hammond Instrument Co. in Chicago, consisted of a roomful of electronic tone-generating equipment controlled by an elaborate, motor-driven scanner. The scanner, which was mounted on a carriage that rolled along a 60-foot table, read an encoded score that was drawn on cardboard cards that covered the table. Another, somewhat more advanced score-reading instrument was the RCA Electronic Music Synthesizer, designed by Harry Olson and Herbert Belar at RCA Laboratories at Princeton, N.J., U.S. The RCA synthesizer was capable of producing four musical tones simultaneously. Pitches, tone colours, vibrato intensities, envelope shapes, and portamento of the four tones were encoded in binary form on a perforated paper roll. The perforations, which the composer made with a special typewriter-like keyboard, specified the sounds' properties for every $1/30$ second, thus enabling the composer to produce musical changes faster and more precisely than traditional musicians are capable of playing. Two RCA synthesizers were built; the second (called the Mark II) was installed in 1959 at the Columbia-Princeton Electronic Music Center in New York City and was used extensively by Milton Babbitt and several other composers.

The development of tape music as a compositional medium, the advancement of the technology of score-reading music systems, and the commercial proliferation of electronic organs and other keyboard-controlled electronic instruments all set the stage for the appearance of the electronic music synthesizer in the 1960s. Other contributing factors were the advancement of electronic technology itself and the domination of popular music by the electric guitar and other amplified instruments.

THE ELECTRONIC MUSIC SYNTHESIZER

The word synthesize means to produce by combining separate elements. Thus, synthesized sound is sound that a musician builds from component elements. A synthesized sound may resemble a traditional acoustic musical timbre, or it may be completely novel and original. One characteristic is common to all synthesized music, however: the sound qualities themselves, as well as the relationships among the sounds, have been "designed," or "composed," by a musician. The notions that synthesized music is intended to imitate a more traditional entity and that synthesized music is generated by automated, mechanical means without control by a musician are generally not true.

A traditional musical instrument is a collection of acoustic elements whose interrelationships are fixed by the instrument builder. Thus, for instance, a violin consists of four strings (the vibrating elements) which are positioned over a fingerboard (playing surface) and coupled through the bridge to the instrument's body (acoustic resonator). The violinist brings the strings into contact with the fingerboard and a bow to cause the strings to vibrate; but he does not change the position of the strings relative to the bridge, the position of the bridge relative to the body, or the configuration of the body itself.

A synthesist, on the other hand, views his instrument as a collection of parts that he configures to produce the desired timbre and response. This is often called "programming," or "patching," and may be done before or during performance. The elements, or parts, that a synthesist works with depend on the design of the instruments that he is using. Generally, synthesizers include oscillators (to generate repetitive waveforms), mixers (to combine waveforms), filters (to increase the strength of some overtones while reducing the strength of others), and amplifiers (to shape the loudness contours of the sounds). Other sound-producing and -processing elements, which can exist as electronic circuits or as built-in computer programs, may also be available. To facilitate the musical control of these elements, a synthesizer may have any combination of a conventional keyboard; other manual control devices, such as wheels, sliders, or joysticks; electronic pattern generators; or a computer interface.

Synthesizer components

The appearance of high-quality, low-cost silicon transistors in the early 1960s enabled electronic instrument designers to incorporate all the basic synthesizer features in relatively small, convenient instruments. The Synket, built by the Italian engineer Paolo Ketoff in 1962, was designed for live performance of experimental music. It had three small, closely spaced, touch-sensitive keyboards, each of which controlled a single tone. Its foremost exponent was John Eaton, who concertized widely on his Synket throughout the 1960s and '70s, performing his own compositions.

The synthesizers of the Americans Donald Buchla and Robert Moog were introduced in 1964. These instruments differed primarily in the control interfaces they offered. The Buchla instruments did not feature keyboards with movable keys; instead, they had touch-sensitive contact pads that could be used to initiate sounds and sound patterns. Buchla's instruments were widely employed by experimental composers, especially Morton Subotnik, whose compositions *Silver Apples of the Moon* (1966), *The Wild Bull* (1967), and *Sidewinder* (1970) appeared on long-playing records.

Moog's instruments featured conventional keyboards as well as other control devices, which enabled them to be used more easily in the performance of traditional music. *Switched-on Bach,* the music of J.S. Bach transcribed for

Moog synthesizer and recorded by Walter Carlos and Benjamin Folkman in 1968, achieved a dramatic commercial success. In the years following the appearance of *Switched-on Bach,* many synthesizer recordings of traditional and popular music appeared, and synthesizer music was frequently heard in movie soundtracks and advertising commercials. Throughout the 1970s, commercial electronic-instrument manufacturers produced smaller, more convenient versions of Buchla's and Moog's designs, and these were widely used by keyboard musicians in the popular music idioms.

Analog and digital synthesizers

Most electronic music synthesizers that were designed before 1980 are called analog synthesizers, because their circuits directly produce electric waveforms that are analogous to the sound waveforms of acoustic instruments. This is in contrast to digital synthesizers and music systems, the circuits of which produce series of numbers that must then be converted to waveforms. The first digital music synthesis systems were general-purpose computers.

THE COMPUTER AS A MUSICAL TOOL

The direct synthesis of sound by computer was first described in 1961 by Max Mathews and coworkers at the Bell Telephone Laboratories, Murray Hill, N.J., U.S. Computer sound synthesis involves the description of a sound waveform as a sequence of numbers representing the instantaneous amplitudes of the wave over very small successive intervals of time. The waveform itself is then generated by the process of digital-to-analog conversion, in which first the numbers are converted to voltage steps in sequence and then the steps are smoothed to produce the final waveform.

Unlike the electronic music synthesizers of the 1960s and '70s, in which electronic circuits performed specific waveform generation and processing functions, computer-based music composition systems are capable of performing any function that can be described as a computational procedure, or algorithm. The algorithm is written by a composer or programmer as a series of instructions that are stored in digital media (*i.e.,* punched cards, magnetic tape, or magnetic disks) and "loaded" into the computer when the music is to be realized. The composer then also writes a score that specifies properties of the individual sound events that make up the composition.

A great variety of sound-synthesis and music-composition algorithms have been developed at research institutions around the world. Music V, created in 1967–68, is the most widely used sound-synthesis program to have been developed at Bell Laboratories. Music V consists of computer models of oscillator and amplifier modules, plus procedures for establishing interactions among the modules. Another widely used synthesis algorithm is Frequency Modulation (FM) Synthesis. Described by John Chowning of Stanford University (Palo Alto, Calif., U.S.) in 1973, FM produces a wide variety of complex timbres by rapidly varying the frequency of one waveform in proportion to the amplitude of another waveform.

FM Synthesis

As computer technology developed and computers became more powerful and less expensive during the 1970s and '80s, the flexibility and sound-production capability of computer-based music systems attracted an increasing proportion of experimental music composers. By the end of the 1980s, computer music systems surpassed tape studio techniques and analog synthesizers as the electronic composition medium of choice among modern and experimental music composers.

DIGITAL SYNTHESIZERS, THE MUSIC WORKSTATION, AND MIDI

Digital synthesizers. During the 1980s, commercial electronic instrument manufacturers introduced many performance-oriented keyboard instruments that used digital computer technology in combination with built-in sound-synthesis algorithms. One of the earliest and best-known of these was the Yamaha DX-7, which was based on the results of Chowning's research in FM Synthesis. Introduced in 1983, the DX-7 was polyphonic, had a five-octave touch-sensitive keyboard, and offered a wide choice of timbres, which the player could adjust or change to suit his requirements. Well over 100,000 DX-7s were sold, and Yamaha adapted their FM technology to a line of instruments ranging from portable, toylike keyboards to rack-mounted modules for studio and experimental use. Another important early digital synthesizer was the Casio CZ-101, a battery-powered four-voice keyboard instrument using simple algorithms that were modeled after the capabilities of analog synthesizers. The CZ-101 was introduced in 1984 at a price approximately one-quarter that of the DX-7 and achieved widespread popularity.

Sampling instruments; music workstations. A sound waveform from a microphone or tape recorder can be digitized, or converted to a sequence of numbers that is the digital representation of the waveform. Instruments that enable a musician to digitize a sound waveform and then process it and play it back under musical control are called sampling instruments. The first commercial sampling instrument was the Fairlight Computer Musical Instrument (CMI), developed in Sydney, Australia, during the late 1970s. The Fairlight CMI was a general-purpose computer with peripheral devices that allowed the musician to digitize sounds, store them, and then play them back from a keyboard. The instrument was sold with programs that enabled the musician both to synthesize sound "from scratch" and to manipulate digitized sound using techniques that were developed in tape studios.

The Fairlight CMI

In 1980 Roger Linn introduced the Linn Drum, an instrument containing digitized percussion sounds that could be played in patterns determined by the musician. In 1984 Raymond Kurzweil introduced the Kurzweil 250, a keyboard-controlled instrument containing digitally encoded representations of grand piano, strings, and many other orchestral timbres. Both the Linn and the Kurzweil instruments were intended for composition as well as for performance, since they contained digital memories into which the musician could enter a score.

By the end of the 1980s, many instrument manufacturers had combined the technologies of the digital computer, digital sound synthesis, and sampling (digital sound recording) into integrated composition and sound-processing systems called music workstations. The Synclavier series, manufactured by New England Digital Corp. since 1976, is representative of this class of instruments.

Musical Instrument Digital Interface. In 1983 several commercial instrument manufacturers agreed on a way of interconnecting instruments so that they could work together or in conjunction with a personal computer. The resultant specification, called Musical Instrument Digital Interface (MIDI), has become universally accepted by musicians and instrument builders. MIDI embodies the means for transmitting commands that tell which notes are being played, what timbre is desired, what nuances are being produced, and so forth. With a personal computer and the appropriate software (programs), MIDI-equipped instruments are capable of performing as a system similar to the larger music workstations. By the end of the 1980s, MIDI systems had become very popular with amateur as well as professional musicians. (R.A.M.)

ASSESSMENT

Electronic instruments have contributed to a tremendous expansion of musical resources. Their increasing sophistication has made available to the composer a palette of sounds ranging from pure tones at one extreme to the most complex sonic structures at the other. In addition, it has made possible the rhythmic organization of music to a degree of subtlety and complexity previously unattainable. One consequence of the use of electronic instruments has been the wide acceptance of a new definition of music as organized sound. Another consequence is the acceptance of the notion that the composer may communicate directly with an audience without the need for a performer as interpreter. Yet another consequence is the democratization of both experimental and traditional music composition through the availability of high-quality, reasonably priced instruments and computer software.

Some observers have felt that the elimination of the performer as interpreter, while it may enable the composer to realize perfectly his intentions, is nevertheless a serious

loss. Performance, it is argued, is a creative discipline complementary to that of composition itself, and varieties of interpretation add richness to the musical experience; moreover, the physical presence of the performer infuses drama into what would be otherwise a purely aural, intellectual, and, by implication, somewhat lifeless event. But in fact many compositions for electronic instruments may be performed live with virtuosity and drama. With contemporary electronic instrument technology, the composer is free to choose whether or not the creative contribution of a performer will serve his artistic goals.

(Ca.G./R.A.M.)

BIBLIOGRAPHY

General works. Comprehensive information on diverse musical instruments is found in such authoritative reference sources as DON MICHAEL RANDEL, *The New Harvard Dictionary of Music* (1986); *New Oxford History of Music*, 10 vol. (1954–90); STANLEY SADIE (ed.), *The New Grove Dictionary of Musical Instruments*, 3 vol. (1984); SIBYL MARCUSE, *Musical Instruments: A Comprehensive Dictionary*, new ed. (1975); and Q. DAVID BOWERS, *Encyclopedia of Automatic Musical Instruments* (1972).

History and evolution of musical instruments are studied in many well-illustrated works, including DONALD JAY GROUT and CLAUDE V. PALISCA, *A History of Western Music*, 4th ed. (1988); GIOVANNI COMOTTI, *Music in Greek and Roman Culture* (1989; originally published in Italian, 1979); SOLON MICHAELIDES, *The Music of Ancient Greece: An Encyclopaedia* (1978); DAVID MUNROW, *Instruments of the Middle Ages and Renaissance* (1976); SIBYL MARCUSE, *A Survey of Musical Instruments* (1975); ANTHONY BAINES (ed.), *Musical Instruments Through the Ages*, new ed. (1976); ANTHONY BAINES, *European and American Musical Instruments* (1966, reissued 1983); ALEXANDR BUCHNER, *Musical Instruments Through the Ages*, trans. from Czech (1956; reissued 1973 as *Musical Instruments: An Illustrated History*); ROBERT DONINGTON, *The Instruments of Music*, 3rd rev. ed. (1970); FRANCIS W. GALPIN, *A Textbook of European Musical Instruments: Their Origin, History, and Character* (1937, reissued 1976); KARL GEIRINGER, *Musical Instruments: Their History in Western Culture from the Stone Age to the Present Day*, trans. from German, 2nd ed. (1959, reissued 1965); CURT SACHS, *The History of Musical Instruments* (1940, reprinted 1968); and JEREMY MONTAGU, *The World of Medieval and Renaissance Musical Instruments* (1976), *The World of Baroque and Classical Musical Instruments* (1979), and *The World of Romantic & Modern Musical Instruments* (1981).

Physical properties of the instruments are addressed in REINHOLD BANEK and JON SCOVILLE, *Sound Designs: A Handbook of Musical Instrument Building* (1980); CHARLES FORD (ed.), *Making Musical Instruments: Strings and Keyboard* (1979); and DENNIS WARING, *Folk Instruments* (1979, reprinted 1990 as *Making Wood Folk Instruments*). Exhibitions and collections are the source of useful and well-illustrated information. See PHILLIP T. YOUNG, *The Look of Music: Rare Musical Instruments, 1500–1900* (1980); LAURENCE LIBIN, *American Musical Instruments in The Metropolitan Museum of Art* (1985); and JAMES COOVER, *Musical Instrument Collections: Catalogues and Cognate Literature* (1981).

Geographic and ethnic distribution of musical instruments is explored in DAVID RECK, *Music of the Whole Earth* (1977); ELIZABETH MAY (ed.), *Musics of Many Cultures: An Introduction* (1980); FRANCIS W. GALPIN, *The Music of the Sumerians and Their Immediate Successors, the Babylonians & Assyrians* (1937, reprinted 1970); NICHOLAS BESSARABOFF, *Ancient European Musical Instruments* (1941, reissued 1964); EMANUEL WINTERNITZ, *Musical Instruments of the Western World* (1967); FRANK HARRISON and JOAN RIMMER, *European Musical Instruments* (1964); JAAP KUNST, *Music in Java*, 3rd ed., rev. by E.L. HEINS, 2 vol. (1973; originally published in Dutch, 1934); HENRY GEORGE FARMER, *Studies in Oriental Musical Instruments*, 2 vol. (1931–39, reprinted in 1 vol., 1978); WILLIAM P. MALM, *Japanese Music and Musical Instruments* (1959, reissued 1990); S. BANDYOPADHYAYA, *Musical Instruments of India* (1980); MARIE-THÉRÈSE BRINCARD (ed.), *Sounding Forms: African Musical Instruments* (1989); PERCIVAL R. KIRBY, *The Musical Instruments of the Native Races of South Africa*, 2nd ed. (1965); MARGARET TROWELL and K.P. WACHSMANN, *Tribal Crafts of Uganda* (1953); WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia*, 2nd ed. (1977); BRUNO NETTL, *Music in Primitive Culture* (1956), and *Folk and Traditional Music of the Western Continents*, 3rd ed., rev. by VALERIE WOODRING GOERTZEN (1990); MARY REMNANT, *Musical Instruments of the West* (1978); and EMANUEL WINTERNITZ, *Musical Instruments and Their Symbolism in Western Art* (1967, reissued 1979).

The process of arranging music for particular instruments and combinations of instruments is discussed in EDMUND A. BOWLES, "Haut and Bas: The Grouping of Musical Instruments in the Middle Ages," *Musica Disciplina* 8:115–140 (1954); HOWARD MAYER BROWN, *Sixteenth-Century Instrumentation: The Music for the Florentine Intermedii* (1973); CLAUDE V. PALISCA, *Baroque Music*, 3rd ed. (1991), surveying the seminal period in the development of concerted music; ADAM CARSE, *The History of Orchestration* (1925, reissued 1964); HECTOR BERLIOZ, *Treatise on Instrumentation*, rev. and enlarged by RICHARD STRAUSS (1948; originally published in French, 1844); NICOLAS RIMSKY-KORSAKOW (NIKOLAY RIMSKY-KORSAKOV), *Principles of Orchestration*, trans. from Russian (1923, reissued 1964); CECIL FORSYTH, *Orchestration*, 2nd ed. (1935, reprinted 1982); MICHAEL HURD, *The Orchestra* (1980); MADEAU STEWART, *The Music Lover's Guide to the Instruments of the Orchestra* (1980); JOAN PEYSER (ed.), *The Orchestra: Origins and Transformations* (1986); and MARK C. GRIDLEY, *Jazz Styles: History & Analysis*, 4th ed. (1991).

Current developments and research in the field are reflected in the articles of such special periodicals as *The Galpin Society Journal* (annual); *Journal of the American Musical Instrument Society* (annual); *The Musical Quarterly*; *Early Music* (quarterly); *Ethnomusicology* (three times a year); and *Asian Music* (semiannual).

Percussion instruments. JAMES BLADES, *Percussion Instruments and Their History*, rev. ed. (1984), is a definitive work in the field, with numerous illustrations and bibliographies; MARGARET A. SCHATKIN, "Idiophones of the Ancient World," *Jahrbuch für Antike und Christentum* 21:147–172 (1978), surveys uses of percussion instruments in ceremonies of major cultures of antiquity; REGINALD SMITH BRINDLE, *Contemporary Percussion*, 2nd ed. (1991), offers information on how composers write for these instruments; JAMES HOLLAND, *Percussion* (1978), presents the history and development of orchestral percussion. For separate groups of instruments, see JOSEPH H. HOWARD, *Drums in the Americas* (1967), containing descriptions of the most popular drums from pre-Columbian times to the present; RICHARD ST. BARBE BAKER, *Africa Drums*, rev. ed. (1951), based on anthropological material on Kenya and Nigeria; C.R. DAY, *The Music and Musical Instruments of Southern India and the Deccan* (1891, reprinted 1974), still useful though dated; and WENDELL WESTCOTT, *Bells and Their Music* (1970), a brief survey of the cultural role of the bell from the Bronze Age. Good coverage of drums, membranes, and plates is provided in NEVILLE H. FLETCHER and THOMAS D. ROSSING, *The Physics of Musical Instruments* (1991). Many works cited in the general section of this bibliography, especially those concerned with ethnic instruments, offer considerable coverage of percussion instruments.

Stringed instruments. Historical surveys, together with information on sound production in different types of instruments, are found in MARTHA MAAS and JANE MCINTOSH SNYDER, *Stringed Instruments of Ancient Greece* (1989); HORTENSE PANUM, *The Stringed Instruments of the Middle Ages, Their Evolution and Development* (1939, reprinted 1971; originally published in Danish, 1915); OTTO ANDERSSON, *The Bowed-Harp: A Study in the History of Early Musical Instruments* (1930, reissued 1973; originally published in Swedish, 1923); WERNER BACHMANN, *The Origins of Bowing and the Development of Bowed Instruments Up to the Thirteenth Century* (1969; originally published in German, 2nd ed., 1966); and MARY REMNANT, *English Bowed Instruments from Anglo-Saxon to Tudor Times* (1986). The most important family among Western stringed instruments is described and analyzed in DAVID D. BOYDEN *et al.*, *The New Grove Violin Family* (1989; also published as *Violin Family*); and SHEILA M. NELSON, *The Violin and Viola* (1972). HENRY RASOF, *The Folk, Country, and Bluegrass Musician's Catalogue* (1982), provides good coverage of 11 stringed folk instruments. For separate instruments, see ROSLYN RENSCH, *Harps and Harpists* (1989), a history with analysis of the instrument design and schools of playing; JOAN RIMMER, *The Irish Harp*, 3rd ed. (1984); SUSAN PALMER and SAMUEL PALMER, *The Hurdy-Gurdy* (1980), a useful account of this little-studied instrument; PANDORA HOPKINS, *Aural Thinking in Norway: Performance and Communication with the Hardingfele* (1986), a thorough original study; R.H. VAN GULIK, *The Lore of the Chinese Lute: An Essay in Ch'in Ideology*, new rev. ed. (1969); JOHN HENRY FELIX, LESLIE NUNES, and PETER F. SENECAL, *The Ukulele: A Portuguese Gift to Hawaii* (1980); JAMES TYLER and PAUL SPARKS, *The Early Mandolin* (1989); WILLIAM R. CUMPIANO and JONATHAN D. NATELSON, *Guitarmaking, Tradition and Technology: A Complete Reference for the Design and Construction of the Steel-String Folk Guitar and the Classical Guitar* (1987); JOSÉ ROMANILLOS, *Antonio de Torres, Guitar Maker: His Life and Work* (1987); and DAVID RUSSELL YOUNG, *The Steel String Guitar: Construction & Repair*, updated ed. (1987).

Keyboard instruments. *Development of the keyboard, the clavichord, and the harpsichord:* FRANK HUBBARD, *Three Centuries of Harpsichord Making* (1965, reissued 1976), clarifies

the history of the instrument and the techniques of earlier harpsichord makers; RAYMOND RUSSELL, *The Harpsichord and Clavichord*, 2nd ed. (1973), offers a general history, less technical than Hubbard's, illustrated with excellent photographs; DONALD H. BOALCH, *Makers of the Harpsichord and Clavichord, 1440–1840*, 2nd ed. (1974), presents known data on all makers whose names have survived as well as the locations of their extant instruments; EDWIN M. RIPIN (ed.), *Keyboard Instruments: Studies in Keyboard Organology, 1500–1800*, 2nd rev. ed. (1977), collects articles on specialized topics, including Italian, Flemish, and English harpsichords, 15th-century instruments, and the *Geigenwerck*; FRANZ J. HIRT, *Stringed Keyboard Instruments, 1440–1880* (1968; originally published in German, 1955; reissued with parallel English and German text, 1981), is a splendid picture book with interesting but not always reliable supporting text; WOLFGANG ZUCKERMANN, *The Modern Harpsichord: Twentieth Century Instruments and Their Makers* (1969), remains a standard work, though it is unreliable for historical information and technical aspects of instrument design and building; WILLI APEL, "Early History of the Organ," *Speculum* 23(2):191–216 (April 1945), gives an excellent account, especially useful for the details on the evolution of the keyboard; EDWIN M. RIPIN *et al.*, *The New Grove Early Keyboard Instruments* (1989; also published as *Early Keyboard Instruments*), is a collection of previously published materials. See also HOWARD SCHOTT, *Playing the Harpsichord* (1971); and JOHN PAUL, *Modern Harpsichord Makers* (1981).

The piano: ROSAMOND E.M. HARDING, *The Piano-Forte: Its History Traced to the Great Exhibition of 1851*, 2nd ed. (1978), is a standard work in the field with excellent diagrams. ALFRED J. HIPKINS, *A Description and History of the Pianoforte and of the Older Keyboard Stringed Instruments* (1896, reprinted 1977), is a classic that has never been superseded as a brief account of the subject; ARTHUR LOESSER, *Men, Women and Pianos: A Social History* (1954, reprinted 1990), surveys all keyboard instruments, their music, and their place in society—the author's bias in favour of the modern piano makes the book less reliable for details on instruments before 1840; DIETER HILDEBRANDT, *Pianoforte, a Social History of the Piano* (1988; originally published in German, 1986), is a much later similar work, focusing on the cultural imagery of the 19th century; DANIEL SPILLANE, *History of the American Pianoforte: Its Technical Development, and the Trade* (1890, reissued 1969), remains a standard work on American piano building; WILLIAM BRAID WHITE, *Piano Tuning and Allied Arts*, 5th rev. ed. (1946, reprinted 1964), is the standard technician's manual in America; CYRIL EHRLICH, *The Piano: A History*, rev. ed. (1990), is valuable for later developments; DAVID WAINWRIGHT, *The Piano Makers* (1975), concentrates on British manufacturers. See also EDWIN M. GOOD, *Giraffes, Black Dragons, and Other Pianos: A Technological History from Cristofori to the Modern Concert Grand* (1982).

The organ: AUSTIN NILAND, *Introduction to the Organ* (1968), is, as its name implies, a good introduction to the subject from a British point of view; in a similar vein, very practical, but from a continental approach, is HANS KLOTZ, *The Organ Handbook* (1969; originally published in German, 7th ed., 1965). The classic work on the subject is EDWARD J. HOPKINS and EDWARD F. RIMBAULT, *The Organ, Its History and Construction*, 3rd ed. (1877, reprinted in 3 vol., 1987); less complete, but more general and contemporary coverage is given in WILLIAM LESLIE SUMNER, *The Organ*, 4th rev. ed. (1973, reprinted 1981). PETER WILLIAMS, *The European Organ, 1450–1850* (1966, reissued 1978), is a thorough history of continental organs. POUL-GERHARD ANDERSEN, *Organ Building and Design* (1969; originally published in Danish, 1956), emphasizes architecture and the organ's relation to it. National schools are discussed in CECIL CLUTTON and AUSTIN NILAND, *The British Organ*, 2nd rev. ed. (1982), post-revival; FENNER DOUGLASS, *The Language of the Classical French Organ* (1969); and WILLIAM HARRISON BARNES, *The Contemporary American Organ*, 9th ed. (1971), heavy on mechanics with drawings. ORPHA OCHSE, *The History of the Organ in the United States* (1975, reprinted 1988), is a comprehensive study of American builders; ROBERT F. GELLERMAN, *The American Reed Organ: Its History, How It Works, How to Rebuild It* (1973), cites the most important patents; WILLIAM H. ARMSTRONG, *Organs for America: The Life and Work of David Tannenberg* (1967), deals with the 18th-century German immigrant builders. A fascinating book on portatives, positives, and regals is MICHAEL I. WILSON, *The English Chamber Organ: History and Development, 1650–1850* (1968). PETER WILLIAMS, *A New History of the Organ from the Greeks to the Present Day* (1980), covers the development of the instrument in all countries and over 2,000 years. Other informative monographs include BARBARA OWEN, *The Organ in New England: An Account of Its Use and Manufacture to the End of the Nineteenth Century* (1979); ROBERT B. WHITING (comp.), *Estey Reed Organs on Parade: A Pictorial Review* (1981); and JOHN ALLEN FERGUSON, *Walter Holtkamp, American Organ Builder* (1979).

Wind instruments. ANTHONY BAINES, *Woodwind Instruments and Their History*, 3rd ed. (1967, reprinted 1977), remains an authoritative work in its field; ARTHUR H. BENADE, *Fundamentals of Musical Acoustics* (1976, reissued 1990), addresses the questions of sound production; and ADAM CARSE, *Musical Wind Instruments: A History of the Wind Instruments Used in European Orchestras and Wind-Bands from the Later Middle Ages Up to the Present Time* (1939, reprinted 1975), surveys the instruments by type. Good illustrations are presented in PHILLIP T. YOUNG, *Twenty-Five Hundred Historical Woodwind Instruments: An Inventory of the Major Collections* (1982); and JAMES M. BORDERS, *European and American Wind and Percussion Instruments: Catalogue of the Stearns Collection of Musical Instruments, University of Michigan* (1988). See also JEAN JENKINS (ed.), *International Directory of Musical Instrument Collections* (1977); and LYNDESAY G. LANGWILL, *An Index of Musical Wind-Instrument Makers*, 6th rev. ed. (1980).

Individual instruments are studied in F. GEOFFREY RENDALL, *The Clarinet: Some Notes Upon Its History and Construction*, 3rd ed., rev. by PHILIP BATE (1971); WILLIAM H. STUBBINS, *The Art of Clarinetistry: The Acoustical Mechanics of the Clarinet as a Basis for the Art of Music Performance*, 3rd rev. ed. (1974); PHILIP BATE, *The Oboe: An Outline of Its History, Development, and Construction*, 3rd ed. (1975); GUNTHER JOPPIG, *The Oboe and the Bassoon* (1988; originally published in German, 1981); LYNDESAY G. LANGWILL, *The Bassoon and Contrabassoon* (1965, reprinted 1975); WILLIAM WATERHOUSE, *The Proud Bassoon* (1983); WILL JANSEN, *The Bassoon: Its History, Construction, Makers, Players, and Music*, 5 vol. (1978); BARRA BOYDELL, *The Crumhorn and Other Renaissance Windcap Instruments: A Contribution to Renaissance Organology* (1982); THEOBALD BOEHM, *The Flute and Flute-Playing in Acoustical, Technical, and Artistic Aspects*, 2nd ed. (1922, reissued 1964; originally published in German, 1871); PHILIP BATE, *The Flute: A Study of Its History, Development, and Construction*, 2nd ed. (1979); NANCY TOFF, *The Development of the Modern Flute* (1979, reprinted 1986); RAYMOND MEYLAN, *The Flute* (1988; originally published in French, 1974); MICHAEL SEYFRIT (comp.), *Recorders, Fifes, and Simple System Transverse Flutes of One Key* (1982); EDGAR HUNT, *The Recorder and Its Music*, rev. ed. (1977); R. MORLEY-PEGGE, *The French Horn: Some Notes on the Evolution of the Instrument and of Its Technique*, 2nd ed. (1973); G.B. LANE, *The Trombone in the Middle Ages and the Renaissance* (1982); ROBIN GREGORY, *The Trombone: The Instrument and Its Music* (1973); PHILIP BATE, *The Trumpet and Trombone: An Outline of Their History, Development, and Construction*, new ed. (1978); and WERNER MENKE, *History of the Trumpet of Bach and Handel: A New Point of View and New Instruments*, trans. from German (1934, reissued 1985).

Electronic instruments. General surveys of the electronic music scene are THOMAS B. HOLMES, *Electronic and Experimental Music* (1985), with an extensive detailed discography; ANDY MACKAY, *Electronic Music* (1981); and PAUL GRIFFITHS, *A Guide to Electronic Music* (1979). Analog synthesizer technology is emphasized in ALLEN STRANGE, *Electronic Music: Systems, Techniques, and Controls*, 2nd ed. (1983). JOEL NAUMANN and JAMES D. WAGONER, *Analog Electronic Music Techniques: In Tape, Electronic, and Voltage-Controlled Synthesizer Studios* (1985), is a technical discussion of tape composition, analog synthesizers, and basic electronic composition techniques. CHARLES DODGE and THOMAS A. JERSE, *Computer Music: Synthesis, Composition, and Performance* (1985), is another technical overview. THOMAS H. WELLS, *The Technique of Electronic Music*, 2nd ed. (1981), discusses electronic music composition without reference to specific equipment. An important standard for compatibility in digital sound equipment is the subject of CRAIG ANDERTON, *MIDI for Musicians* (1986); and JEFF RONA, *MIDI, the Ins, Outs & Thrus* (1987). DETA S. DAVIS, *Computer Applications in Music: A Bibliography* (1988), offers a valuable reference source for independent research.

Mystery Religions

Mystery religions were secret cults of the Greco-Roman world that offered to individuals a way to feel religious experiences not provided by the official public religions. They originated in tribal ceremonies that were performed by primitive peoples in many parts of the world. But, whereas in these tribal communities almost every member of the clan or the village was initiated, initiation in Greece became a matter of personal choice. The mystery religions reached their peak of popularity in the first three centuries AD; at that time an individual could choose among many religions of this type. Their origin, however, goes back to the earlier centuries of Greek history.

Etymologically, the word mystery is derived from the Greek verb *myein* ("to close"), referring to the lips and the eyes. Mysteries were always secret cults into which a person had to be "initiated" (taken in). The initiate was called *mystēs*, the introducing person *mystagōgos* (leader of the *mystēs*). The leaders of the cults included the *hierophantēs* ("revealer of holy things") and the *dadouchos* ("torch-bearer"). The constitutive features of a mystery society were common meals, dances, and ceremonies, especially initiation rites. These common experiences strengthened the bonds of each cult.

HISTORY

Hellenic roots. *Dionysiac.* In every Greek city the god Dionysus was worshipped by fraternities and sororities and also by mixed communities. Dionysus was a god of fruitfulness and vegetation but especially of wine. The Dionysiac festivals provided an opportunity for stepping outside of the daily routine. The festivals included not only drinking wine and engaging in sexual activity but also participating in such significant features of Greek civilization as choral singing and mimes. In many cases, only the initiated could participate in the ceremonies. As almost every Greek did join in, initiation into the Dionysiac cult might be compared to tribal initiations. It seems that initiation into the Dionysiac Mysteries was accompanied by initiation into sexual life. The act of producing offspring, however, could never be wholly separated from the thought of death, so that the worshippers of Dionysus were aware of a mystic communion among the ancestors, the living generation, and the future members of the community.

Eleusinian. The most important sanctuary of Demeter (Ceres), the goddess of grain, and her daughter Kore (Persephone) was in the city of Eleusis in Attica, between Athens and Megara. Famous religious agricultural festivals—known as the Greater and the Lesser Eleusinian Mysteries—celebrating the sowing, sprouting, and reaping of the grain, were reenacted in this city. The cycle of the grain, pictured in the myth of Kore (Persephone), was thought to be parallel to the cycle of man. The myth, as told in the Homeric hymn to Demeter, tells how Hades (Pluto, or Pluton), god of the netherworld, wanted a wife and how he carried off Kore into the depths of the earth. Her mother, Demeter, through long days of searching, during which she came to Eleusis, refused to make the grain grow. Finally, Hades was bidden to send Kore back to earth. She came back to light as the grain maiden and gave birth to her son Plutus (Kore, "the maiden"; Pluton, "the rich one"; Plutus, "wealth," especially in grain). But, because Kore had eaten a pomegranate seed, a symbol of death and birth, she could not be completely released, and a compromise was reached by which she spent one-third of the year with her husband, the rest with her mother. Satisfied with this, Demeter caused grain to grow again and taught the Eleusinians her rites. The entire story of Demeter and Kore was elaborately reenacted in the Eleusinian ceremony. Just as in the myth Kore was carried away to marry Hades and to give birth to Plutus, so was grain thrown into the field and buried in the earth to bring forth new life. Just as grain came up out of the ground and was reaped to yield man's bread and to be used as seed, so was a girl taken from her parents and her virginity "killed" to bring forth new offspring. And when a man died, he was buried in the earth to partake mystically in the cyclic renewal of life. This was the message of Eleusis: out of every grave new life grows—for the initiates there are "good hopes" for a glorious immortality in the afterlife.

The myth of Kore

Although there were festivals of Demeter throughout Greece, the true Eleusinian Mysteries were celebrated at Eleusis only. At first, the cult of Demeter was local and initiation was tribal rather than personal. By participating in the mysteries, a man became a full member of the civic body. This was changed when Eleusis was annexed to the Athenian territory about 600 BC. Initiation lost its importance as a means of conferring civic status; it became a purely religious ceremony. Every Athenian was admitted to the Eleusinian Mysteries, and soon the mysteries were open to every Greek, so that the ceremonies received an "international" character. Whoever wished to be initiated, however, had to go to Eleusis. It was a day's journey from Athens, a longer distance from most of the other Greek cities. The mystery rite became no longer a tribal ceremony. Each person had to decide for himself whether or not he wanted to be initiated. This development was possible only because Athens had become a large city with a differentiated culture that gave the individual ample choice of a way of life, including religion.

Meaning of the Dionysiac and Eleusinian mysteries

Both Dionysiac and Eleusinian mysteries had a wide range of meaning. Their essence was not contained in any written record but only in the festivals themselves—the holy days of the community. Many participants appreciated only the superficial level of the ceremonies and considered them as an opportunity for having a good time—good company, good food, intoxication, and sometimes (in the Dionysiac cult) sexual pleasures. The ceremonies were open to a deeper understanding, however, that was not made explicit by any theology or by any set of creeds but by the religious action itself, which contained the meaning and conveyed it to the participants without the interposition of words. Therefore, it was not possible to disclose to the noninitiated the mysteries by words, but it was treachery to reveal the secret dances.

Secular mystery communities. A society of initiates could drop its religious connections and become merely a social club. But because secrecy, common meals, and common drinking were implied, the Greeks and Romans regarded such clubs as mystery societies; they did not differentiate between religious associations and private clubs.

The role of aristocratic clubs in Athenian politics was very important. In 415 BC the famous mystery scandal occurred. Several aristocratic societies conspired to overthrow the Athenian democracy. In order to pledge all members, a common crime was committed in which each member had to participate. One night the members of the social clubs took hammers and removed the genitals of the many Hermes statues in the city. Whoever would desert the common political cause would be denounced by his former friends for having committed a crime against religion, and many witnesses against him would be at hand. The people of Athens immediately understood that a conspiracy was developing. By a series of severe trials, the conspirators were traced and exiled. The speech of the orator Andocides, one of the conspirators, delivered in his defense in 400 or 399 BC, when the old affair was again taken up in a trial, still survives. The title of the oration is "On the Mysteries."

The secular mystery clubs continued throughout Greek and Roman history, and it was often difficult to distinguish them from religious associations. The Romans were especially distrustful of secret societies. This suspicion was justified in the case of Catiline, who led a conspiracy that attempted to overthrow the government in 63 BC. But Trajan, the Roman emperor from AD 98 to 117, did not allow the citizens of Nicomedia (modern İzmit, Turkey) to form a club that planned to provide a fire brigade, and he only reluctantly allowed the citizens of Amisus (modern Samsun, Turkey) to establish an association for charitable purposes.

Orphic. Besides community initiations, there were ceremonies for individual persons of deeper religious longing. Such persons were called Orphics after Orpheus, the Greek hero with superhuman musical skills who was supposedly the author of sacred writings; these writings were called the Orphic rhapsodies and they dealt with such subjects as purification and the afterlife. It is possible to reconstruct a common pattern for these initiations of individuals, although an Orphic "church" never existed, and the doctrines of the many small communities of individualists varied on a broad scale.

The Orphic sense of sin

Many Orphics seem to have had a strong feeling of sin and guilt. They believed that there was a divine part in man—his soul—but it was wrapped up in the body, and man's task was to liberate the soul from the body. This could be achieved by living an Orphic life, which included abstinence from meat, wine, and sexual intercourse. After death the soul would be judged. If a man had lived a righteous life, his soul would be sent to the meadows of the blessed in Elysium; but, if he had committed misdeeds, his soul would be punished in various ways and perhaps sent to hell. Following a period of reward or punishment, the soul would be incarnated in a new body. Only a soul that had lived a pious life three times could be liberated from the cycle.

Pythagoreans. The Orphic creeds were the basis of the Pythagorean brotherhood, which flourished in southern Italy beginning in the 6th century BC. The Pythagoreans were aristocratic fraternities that sometimes had a political scope. Their main achievements, however, lay in the fields of music, geometry, and astronomy. They discovered that these subjects could be explained by numbers and ratios. Combining Orphic eschatology (the study of the last things, especially death and afterlife) with their discoveries, they invested music, geometry, and astronomy with religious values. According to their doctrine, the original home of the soul was in the stars. From there it fell down to earth and associated with the body. Thus, man was a stranger on the earth, and he had to strive to liberate himself from the ties of the flesh and return to the soul's celestial home.

Platonists. The philosophy of Plato (*c.* 428–348 or 347 BC) by no means resulted from connections with a mystery cult. Yet Plato did take up many ideas from earlier Greek religion, especially from the Pythagorean brotherhood and from the Eleusinian communities, and often described his philosophy in terms derived from the mysteries. For example, the notion of searching and finding, so important in Eleusis, became an important notion in Plato's philosophy: the philosopher should never cease or relax in his quest for truth. A value was thus attached to the very act of searching. Later mystery religions, in their turn, borrowed freely from the rich imagery of Plato's dialogues and are thus deeply tinged with Platonism.

Plato's theory of the soul

In the *Timaeus,* which is an exposition of his theory of the universe, Plato also developed his theory of the soul. The earth is surrounded by the spheres of the seven planets; the eighth sphere is that of the fixed stars. Beyond the eighth sphere is the realm of the divine. The sphere of the fixed stars, moved by the divine, continuously turns to the right at an even speed. This clockwise rotation affects the spheres of the planets, although they have their proper movement, which runs to the left, or counterclockwise. The sphere of mortality begins with the planets. The original home of each soul is in one of the fixed stars. As a result of the movement of the spheres, the soul falls through the planetary spheres to earth, where it is united with the body. The soul must then try to liberate itself from the body and ascend to the fixed star from which it fell. In later generations this picture was vividly worked out. The soul, in the course of its fall through the planetary spheres, was thought to acquire the qualities of the planets: sloth from Saturn, combativeness from Mars, lust for power from Jupiter, voluptuousness from Venus, greed from Mercury. After death, when the soul returned to the fixed star, it discarded these qualities, just as the *mystēs,* in certain initiations, discarded his everyday garment before entering the sacred place.

Many other traditional religious images were taken over by Plato, including the music of the spheres, the migration of the soul, the soul's remembrance of its celestial origin, and the idea of rewards for the righteous and punishment for the wicked. Later mystery associations adopted these concepts, which Plato had expressed so beautifully, and were deeply influenced by Plato's explanations.

The Hellenistic period. When Alexander the Great conquered the Asiatic kingdoms as far east as the Indus River, the Greek world was extended immensely. The religious ideas in Greece itself and the western part of the Alexandrian Empire, however, changed very slowly, because the Greeks, now masters of the world, felt no need for change.

In the Messenian town of Andania mysteries were celebrated in honour of the goddesses Demeter and Kore. A long inscription of 92 BC gives elaborate directions for the conduct of the rites, although, naturally, it gives no details of what went on during initiation. The mysteries in honour of the Cabeiri (gods of fertility) on the island of Samothrace attracted great attention in this period. These gods were thought to be helpers of the seafarers, and initiation into their mysteries was looked upon as a general safeguard against all misfortune but particularly against shipwreck. The Dionysiac Mysteries, with their revels and merriment, continued throughout the whole of Greek history. Together with most of the elements of Greek civilization, this cult was transferred to Italy. In 186 BC a scandal about the Bacchanalia—the Latin name for the Hellenistic Dionysiac Mysteries—so upset the Romans that a decree of the Senate prohibited them throughout Italy, except in certain special cases. These mysteries were celebrated in a lower middle class milieu and involved gross sex parties and violence conducted under the cover of mystery secrecy.

Hellenistic Mysteries in the Greek Orient

The important developments in the mystery rites during the Hellenistic period took place in the Greek Orient, where elements from the Greek and Oriental religions were blended. Contact with Greek civilization completely changed life in the Orient, where the knowledge of writing had been confined to a few priests and scribes. Society first disintegrated after the conquest of Alexander and then developed along new lines. Changes in religion were inevitable, and some influence of Oriental traditions upon the Greeks was bound to follow. But the process was a slow one and became manifest only a few centuries later.

With regard to the institution of kingship, however, syncretism worked quickly. Ancient Near Eastern kingship was originally sacral. The Syrian and Egyptian inhabitants of the newly created Greek kingdoms inevitably regarded the Greco-Macedonian kings as semidivine beings. The

Greeks themselves soon submitted to this mixture of politics and religion. Such a mixture was perfectly natural to the Egyptians and Syrians, who did not perceive the structure of society as an abstraction, such as "the state" or "the nation," but saw the unity of the body politic in the person of the king. He was the symbol of the security and help that man derives from an orderly society. Mystery rituals, called royal mysteries, were developed especially in Egypt. According to traditional Egyptian religion, the ruling pharaoh was an incarnation of Horus (the sun-god), his mother or wife an incarnation of Isis (the heavenly queen), and his deceased father an incarnation of Osiris (the god of fertility). In Hellenistic times, Osiris was commonly known by the name Sarapis. These gods became equated with Greek gods: Isis with Demeter and Aphrodite; Horus with Apollo and Helios; Sarapis with Zeus, Dionysus, and Hades (Pluto). Both Greek and Egyptian myths were adopted for these divinities.

One of the suburbs of Alexandria, the newly constructed Greek capital of Egypt, was called Eleusis after the city of Demeter in Greece, and the Eleusinian Mysteries were instituted in a Greco-Egyptian adaptation. Dionysiac Mysteries were introduced on an even greater scale, so that the royal court was temporarily thrown into turmoil by the number of Bacchic ceremonies in which the king was considered to be a reincarnation of Dionysus. The Pythagorean concept of the migration of the soul was also taken over and was blended with the Egyptian belief in the reincarnation of the sun-god Horus in the reigning king.

The cult of rulers thus introduced ideas from the Greek Orient into Greek communities. But the mixture of religion and politics was a great obstacle for the propagation of the Greco-Oriental mysteries in the Mediterranean world. Even the numerous Greeks who lived in Egypt and Syria maintained the traditional Greek concept of the separation of god and man, and it was only after the political aspect of the mysteries was discarded that the religious elements could gain a life of their own. Inscriptions discovered on the Greek island of Delos demonstrate this well. The worship of Sarapis was introduced at Delos during the time the island was temporarily a naval base of the Greco-Egyptian kings. When the Egyptian influence on the island receded, the cult of Sarapis not only remained but reached new heights. The Romans later used Delos as a free port for the eastern part of the Mediterranean, and from there the worship of Sarapis and Isis spread to most of the harbours of the Greek world and to the cities in the Bay of Naples, whence it was brought by Italian merchants to Rome.

The combination of mystery elements with ruler worship is also evident in the kingdom of Commagene (eastern Turkey and northern Syria). Here, the kings assigned large funds to construct throughout the country gigantic sanctuaries, where festivals of the gods and the royal ancestors were celebrated annually on the kings' anniversary days. Long inscriptions discovered in the remains of these sanctuaries bear striking similarities to the language of the mysteries. The ceremonies, however, seem to have contained little true religion.

Roman imperial times. The great period of the mystery religions began when the Romans imposed peace upon the Mediterranean world. The Dionysiac, or Bacchic, societies flourished in the whole empire—in Greece proper, on the Greek islands, in Asia Minor, along the Danube River, and especially in Italy and at Rome. Hundreds of inscriptions attest to Bacchic Mysteries. In some circles, Orphic and Dionysiac ideas were blended, as in the community that met in the underground basilica near the Porta Maggiore (Major Gate) at Rome. There was also a blend of ideas in the community for which the Orphic hymns were written. The members of this community (probably in Asia Minor) assembled at night in a clubhouse and held their services by the light of torches. Their rite consisted of a bloodless sacrifice and included the use of incense, prayer, and hymns. In addition to the mystery cults that were familiar from earlier times, the national religions of the peoples of the Greek Orient in their Hellenized versions began to spread. A faintly exotic flavour surrounded these religions and made them particularly attractive to the Greeks and Romans. The most popular of the Oriental mysteries was the cult of Isis. It was already in vogue at Rome in the time of the emperor Augustus, at the beginning of the Christian era. The Emperor, who wanted to restore the genuine Roman religious traditions, disliked the Oriental influences. But men of reputation, such as Messalla, a general and patron of writers, were strongly inclined toward the Isis Mysteries. Isis, the goddess of love, was the patroness of many of the elegant Roman courtesans. The religion of Isis became widespread in Italy during the 1st and 2nd centuries AD. To a certain extent, the expansion of Judaism and Christianity over the Roman world coincided with the expansion of the Egyptian cults.

Mysteries from Asia Minor

Far less important was the influence of cults from Asia Minor. By 200 BC the Great Mother of the Gods (Magna Mater) and her consort Attis were introduced into the Roman pantheon and were considered as Roman gods. Their cult seems to have been encouraged especially under Emperor Claudius about AD 50. The Great Mother was characterized by her universal motherhood, especially over wild nature. The mysteries symbolized, through her relationship to Attis, the relations of Mother Earth to her children and were intended to impress upon the *mystēs* the subjective certainty of having been united in a special way with the goddess. There was a strong element of hope for an afterlife in this cult. The Persian god Mithra (Mithras), the god of light, was introduced much later, probably not before the 2nd century. The cult of Mithra was concerned with the origin of life from a sacred bull that was caught and then sacrificed by Mithra. According to Persian sources, the bull by its death gave birth to the sky, the planets, the earth, the animals, and the plants; thus Mithra became the creator of life. From Syria came the worship of several deities, of which Jupiter Heliopolitanus (the local god of Heliopolis; modern Ba'labakk, Lebanon) and Jupiter Dolichenus (the local god of Doliche in Commagene; modern Dülük, Turkey) were the most important. Adonis (a god of vegetation) of Byblos (in modern Lebanon) had long been familiar to the Greeks and was often considered to be closely related to Osiris; the myths and rituals of the two gods were similar. Adonis' female partner was Atargatis (Astarte), whom the Greeks identified with Aphrodite. At the time of Emperor Marcus Aurelius, in the latter half of the 2nd century AD, a pseudo-prophet named Alexander the Paphlagonian devised a great mystery spectacle centred around a holy snake called Glycon and had great success during his lifetime.

The height of Syrian influence was in the 3rd century AD when Sol, the Syrian sun god, was on the verge of becoming the chief god of the Roman Empire. He was introduced into Rome by the emperor Elagabalus (Heliogabalus) in about AD 220, and by about AD 240 Pythian Games (*i.e.*, festivals of the sun god Apollo Helios) were instituted in many cities of the empire. The emperor Aurelian (270–275) elevated Sol to the highest rank among the gods. Sanctuaries of Sol and the gods of other planets (*septizonium*) were constructed. Even the emperor Constantine the Great, some 50 years later, wavered between Sol and Christ. For some time his religious policy was devised so as to allow the coexistence of both religions. Finally, Christianity was accepted as the official religion.

The different mystery religions were not exclusive of one another, but they appealed to different sociological groups. The middle class of the Greek and Roman cities preferred the Dionysiac societies, the festivals of which were a cult of beauty and merriment. Isis was worshipped by lower middle class people in the seaports and trading towns. The followers of the Great Mother in Italy were principally craftsmen. Mithra was the god of soldiers and of imperial officials and freedmen. There were no special societies for slaves; but they were usually admitted to the societies, and, during the time of the festival, all men were considered equal.

BELIEFS AND PRACTICES

Common features in Roman imperial times. For the first three centuries of the Christian Era, the different mystery religions existed side-by-side in the Roman Empire. They had all developed out of local and national cults and later

Mysteries fostered by new social conditions in the Roman Empire

became cosmopolitan and international. The mystery religions would never have developed and expanded as they did, however, without the new social conditions brought about by the unification of the Mediterranean world by the Romans. In the large cities and seaports, men from the remotest parts of the empire flocked together. Many people were removed from their accustomed surroundings and suffered from loneliness. They longed for new acquaintances and for assimilation, and they needed the assurance that only the knowledge of belonging to a community can give. Economic and political conditions in the Roman Empire also accelerated the growth of the mysteries. Members of a mystery society helped one another. For a lawyer, a craftsman, or a contractor, membership in a club could be the road to success. Furthermore, there is less opportunity for private initiative in a society ruled by a monarch than in a democratic society. The individual who felt that his initiative was frustrated by the preponderance of the imperial structure might well turn to a community that offered him the hope of a better future. The mystery societies, thus, commonly satisfied both a taste for individualism and a longing for brotherhood. At least in principle, the members of the communities were considered equal: one man was the other man's brother, irrespective of his origin, social rank, or nationality.

Because membership in each of the mystery communities was a matter of personal choice, propaganda and missionary work were inevitable. In the religions of Isis and Mithra, missionary zeal was particularly obvious. The followers of Isis and Mithra considered Rome to be the centre of their worship, and the city was called *sacrosancta civitas* ("sacred city") in an Isis romance written in the 2nd century AD by the Latin author Apuleius.

Priesthood. The organization of the mystery religions was rather loose. The priests of Dionysus were wealthy laymen, as the priests in Greece always were. The Roman community of the Great Mother had a large group of priests (the *galli*), headed by a chief priest (the *Archigallus*). They were eunuchs who wore female garb, who kept their hair long and perfumed with ointment, and who celebrated the goddess' rites with wild music and dancing until their frenzied excitement found its culmination in self-scourging, self-laceration, or exhaustion. Besides the priests there were priestesses and many minor officials. The followers were organized according to their function in the ritual procession as bearers of the tree (*dendrophori*) or bearers of the reed (*cannophori*). The men who carried the statue in the rites of Jupiter Dolichenus were called the sedan-chair men (*lecticarii*).

The higher grades of the Isis Mysteries were reserved to persons born of the priest caste of Egypt. To be born into this caste was more important than talent or skill. This limited the quality of the priests and was a serious disadvantage in the community's competition with other religions. But a second way of advancement within the religious group was devised for men of Greek or Roman origin. In Egypt, there was a group of elevated laymen—the porters of the holy shrine (*pastophori*). They were inferior in rank to everyone of the priest caste; but in Greek and Roman countries the rank of the *pastophori* became a surrogate for the native priest caste of Egypt. The *pastophori* were, in fact, the religious leaders of the communities.

Rites and festivals. A period of preparation preceded the initiation in each of the mysteries. In the Isis religion, for example, a period of 11 days of fasting, including abstinence from meat, wine, and sexual activity, was required before the ceremony. The candidates were segregated from the common folk in special apartments in the holy precinct of the community centre; they were called "the chastely living ones" (*hagneuontes*).

In all the mystery religions the candidates swore an oath of secrecy; the oath of the Isis Mysteries is preserved on papyrus. Before initiation, a confession of sins was expected. The candidate sometimes told at length the story of the faults of his life up to the point of his baptism, which was commonly a part of the initiation ceremony, and the community of devotees listened to the confession. It was believed that the rite of baptism would wash away all the candidate's sins, and, from that point on, his life would be changed for the better, because he had enrolled himself in the service of the saviour god.

In the Mithraic ceremonies, there were seven degrees of initiations: Corax (Raven), Nymphus (Bridegroom), Miles (Soldier), Leo (Lion), Perses (Persian), Heliodromus (Courier of the Sun), and Pater (Father). Those in the lowest ranks, certainly the Corax, were the servants of the community during the sacred meal of bread and water that formed part of the rite.

Initiation ceremonies

The initiation ceremonies usually mimed death and resurrection. This was done in the most extravagant manner. In some ceremonies, candidates were buried or shut up in a sarcophagus; they were even symbolically deprived of their entrails and mummified (an animal's belly with entrails was prepared for the ceremony). Alternatively, the candidates were symbolically drowned or decapitated. In imitation of the Orphic myth of Dionysus Zagreus, a rite was held in which the heart of a victim, supposedly a human child, was roasted and distributed among the participants to be eaten.

The baptism could be either by water or by fire, and the rites often included actions that had an exotic flavour. Sulfur torches were used during the baptism ceremony; they were dipped into water and then—contrary to the expectations of the observers—burned when drawn out of the water. In a dark room a script would suddenly become visible on a wall that had been prepared accordingly. Instructions still exist for producing a nimbus effect—the appearance of light around the head of a priest. The priest's head was shaved and prepared with a protective ointment; then a circular metal receptacle for alcohol was fixed on his head; it was set aflame in a dark room and would shine for some seconds. In the Dionysus and Isis mysteries, the initiation was sometimes accomplished by a "sacred marriage," a sacral copulation. Two cases are known in which a priest speaking from the statue of the god ordered a credulous woman to come to the temple and be the god's concubine, the part of the god being enacted by the priest.

The initiation ceremonies were usually accompanied by music and dance and often included a large cast of actors. In the Dionysiac societies, especially elaborate provisions were made for mimic representations. The names of the sacred roles varied from place to place; among the roles were: Dionysus and Ariadne (a vegetation goddess and wife of Dionysus), Palaemon (a marine deity), Aphrodite (the goddess of love and beauty), Proteurhythmos (the inventor of elegant rhythm), the "foster-father of Dionysus," Kore, Demeter, Asclepius (the god of medicine), Pan (the god of flocks and shepherds), Curetes (long-haired youths), nymphs (minor nature goddesses), shepherds, sileni and satyrs (creatures of the wild, part man and part beast), maenads (female attendants who shared in the nocturnal orgiastic rites of Dionysus), the "guardian of the grotto," and centaurs (a race of beings half man and half horse).

The ceremonies always contained a prayer for the welfare of the emperor and for the good fortune of the whole Roman Empire. In fact, the amalgamation of religion and politics was sometimes so close that the designation "imperial mysteries" is used. The pattern of imperial mystery ceremonies could vary widely. This was especially true of the Dionysiac rites. In the clubs of the upper middle class and wealthy, for example, the festivals were chiefly social events. But the members of these communities were grateful for the security and peace and for the opportunity to make a good living that the emperor guaranteed to them. They felt loyalty toward the Roman Empire and expressed this by ceremonies of the imperial mysteries.

Dionysus was the patron god of the important international society of actors, and their reunions were celebrated in the mode of Dionysiac Mysteries. When an emperor travelled in the empire, responsibility for dignified receptions of him was handed over to the society of actors. Because his route was known beforehand, a voyage of the emperor was turned into a series of pompous festivals that were organized in a manner closely resembling mystery ceremonies.

The meetings of the mystery clubs were often named af-

ter the common meal. The Dionysiac meetings were called *stibas* ("straw") because the participants ate their dinner sitting on straw. The meals of the followers of Sarapis and Attis were called *klinē* ("couch"), because the diners lay on couches.

Festivals connected with agriculture

Seasonal festivals. The religions of Dionysus and Demeter and of Isis and the Great Mother had something of an ecclesiastical year. The seasonal festivals were inherited from old tribal ceremonies that had been closely associated with the sowing and reaping of corn and with the production of wine. The dates varied greatly according to the geographical conditions and the emphasis of the seasonal rites in the country in which the mysteries had originated. Dionysiac festivals were held in all four seasons; vintage and tasting of the new wine were the most important occasions. But the religion of Dionysus was closely associated with that of Demeter, and, thus, sowing and reaping were also celebrated in Dionysiac festivals. In the religion of the Great Mother, a hilarious spring festival celebrating the renewal of life was enacted in Rome.

The festivals of the Isis religion were connected with the three Egyptian seasons caused by the cycle of the Nile River (inundation, sowing, and reaping). About July 19, when the whole country was almost desiccated by the heat and the drought, the high waters of the new flood miraculously arrived from Ethiopia. On that day, just before sunrise, Sirius (the Dog Star, or the star of Isis) would make its first appearance of the season on the horizon. This was the sacred New Year's Day for the Egyptians, and the festival of the Nile flood was their greatest festival. There were, in addition, the festivals of sowing and reaping. But because the Egyptian year was a solar year of 365 days without intercalation (leap years), the seasonal festivals that were fixed upon a particular date were retarded by one day every four years and complete confusion resulted. The Romans fixed the calendar of Egypt by introducing an intercalary day every fourth year. In Roman times, important Isis festivals were held on December 25, January 6, and March 5. The March festival, as it was celebrated in Corinth, is described at length in Apuleius' *Metamorphoses,* or *The Golden Ass.* It was a spring festival that celebrated the beginning of the seafaring season. A ship was carried on a cart (*carrus navalis*) through the city. It was followed by a procession of choruses, candidates, *mystai* in bright clothes wearing masks, and priests carrying the insignia of the goddess. The ship was let into the sea, and the participants returned to the temple, where initiation ceremonies, banquets, and dances were held.

In the religion of Sol, the festivals were determined by astronomy. The greatest festival was held on December 24–25, at the time of the winter solstice. Because from this date the length of the day began to increase, it was regarded as the day of the rebirth of the god and of the renovation of life.

Literature. The mystery communities had religious hymns, but almost nothing of them has been preserved. The initial words of some hymns from the Sta. Prisca Mithraeum in Rome are known, and some Isiac poems exist. More important is a text of 40 sentences in which the goddess Isis reveals herself; it was found at four different and geographically distant places and was probably exhibited in every Isis sanctuary. Narratives of the miracles wrought by the gods were preserved in many temple libraries; examples of these narratives, on papyrus and on stone, have been found. According to a recent theory, the literary genre of the romance was developed from these narratives. The last part of the *Metamorphoses* of Apuleius is an Isis text and narrates in detail the initiation into the Egyptian mysteries.

Hermetic writings and *Chaldean Oracles*

Hermes Trismegistos, the Greek name for the Egyptian god Thoth, was the reputed author of treatises that have been preserved. Thoth was the scribe of the gods, the inventor of writing, and the patron of all the arts dependent upon writing; he was sometimes thought of as an attendant of Isis and sometimes as the repository of all wisdom. These treatises are not exactly mystery texts, but they are works of revelation on occult subjects and on theology. Because the pagan mysteries had no official creed, each congregation of initiates was free to construct a theology of its own and to change it again. The Hermetic writings were attempts to provide a theology for a particular community. Although no authorized interpretation could exist for a doctrine that was in constant fluctuation and although none of the Hermetic treatises could claim to be the correct interpretation of the pagan mysteries, nevertheless, the texts give an instructive picture of spiritual life in mystery communities.

There are some contemporary texts that shed light on the mystery communities. Plutarch, the Greek biographer, wrote the philosophical treatise "About Isis and Osiris," which gives an interpretation of the Isis Mysteries. Arnobius, a 3rd-century Christian apologist, described an interesting semiphilosophical, semireligious mystery community known as the *viri novi* ("the new men"). Arnobius seems to have lived among them in North Africa for a time before his conversion to Christianity. They had a religious doctrine of the soul, with marked affinities to the teachings of the Neoplatonic thinkers Plotinus and Porphyry.

Only fragments are preserved of the *Chaldean Oracles,* a theosophical text in verse that was composed by Julianus the Theurgist and his son late in the 2nd century AD and had great influence on the Neoplatonists. The work combined Platonic elements with Persian or Babylonian creeds and was regarded by the later Neoplatonists as their basic religious book, something of a heathen bible. The doctrine of the *Chaldean Oracles* was associated with esoteric fire rituals. Julianus and his followers were called theurgists—*i.e.,* men who could perform divine operations. Their religion was partly one of meditation about the hidden and wondrous magical processes within the cosmos.

Theology. The creeds of the mystery religions were never worked out to the same extent that the Christian creeds were. Nevertheless, the doctrines of the mysteries may be called a theology. One of the central subjects in mystery writings was cosmogony—the theory of the origin or creation of the world. In the Hermetic treatises, in the *Chaldean Oracles,* and in the little known writings of Mithraism, the cosmogony was modelled after Plato's *Timaeus,* and it always dealt with the creation of the soul and with the soul's subsequent fate.

The myth of the soul

The theological doctrine of the soul and the myth about its celestial home, its fall, and its redemption were inseparable. The sequence is beautifully told in the "Hymn of the Soul," preserved in the *Acts of Thomas,* an apocryphal account of the journeys and death of the apostle. The hero of the hymn, who represents the soul of man, is born in the Eastern (the yonder) Kingdom; immediately after his birth, he is sent by his parents on a pilgrimage into the world with instructions to take a pearl from the mouth of a dragon in the sea. Instead of wearing his heavenly garment, he dresses in earthly clothes, eats earthly food, and forgets his task. Then his parents send a letter to rouse him. As soon as he has read the letter, he awakes and remembers his task, takes the pearl, and begins the homeward journey. On the way, his brother (the Redeemer) comes to accompany him and leads him back home to his father's palace in the east. This myth is a figurative representation of the theological doctrine of the soul's fall and its return to heaven.

Many of the questions that were the subject of later Christian theological discussions were already eagerly debated in the mystery religions. In a Hermetic treatise, for example, the existence of God was proved from the evident order of the world. This argument, which had first been formulated by Zoroaster, a 7th-century Iranian prophet, was expressed in the form of questions: Who could have created the heavens and the stars, the sun and the moon, except God? Who could have made wind, water, fire, and earth (the elements), the seasons of the year, the crops, the animals, and man, except God?

Passionate debates were held about the question of whether man was subject to blind fate. The Stoics (proponents of a Greek and Roman school of philosophy holding that men should be free from passion and calmly accept all occurrences as unavoidable) had adopted the doctrine that all events are determined by the stars. Thus, for many Greeks and Romans astrology became the only

sensible method of studying man's life and fortune. But for others the idea that man could achieve nothing by his own will was frightening, and they wanted to be liberated from this fear; the mystery religions promised to liberate them. The theology of the mystery religions admitted that the stars ruled the world and especially that the planets had evil influences. But the highest god of the religion (for example, Sarapis in the Isis Mysteries) stood far above the stars and was their master. A man who decided to become a servant of this god stepped out of the circle of determination and entered into the sphere of liberty. The god could suspend determination, because he ruled over the stars; he could unravel the threads of the Moirai (the three spinners of fate); he could save his servant from illness and prolong his life, even against the will of fate. In the Isis Mysteries there was a theology of grace foreshadowing Christian doctrine.

In many of the mystery cults, there was a marked tendency toward henotheism—the worship of one god without denying the existence of other gods. Thus, Isis was the essence of all pagan goddesses; Sarapis was the name uniting the gods Zeus, Pluto, Dionysus, Asclepius, Helios, and even the Jewish god YHWH (Yahweh). In the religion of Sol, an elaborate syncretistic theology was developed to show that all known gods of all nations were nothing but provisional names for the sun god.

RELIGIOUS ART AND ICONOGRAPHY

Much of Greco-Roman art was executed for use in the mystery communities. The Dionysiac monuments are by far superior to all others in artistic quality. This is to be expected, because the worship of Dionysus often took the form of a worship of beauty. Nevertheless, the other communities also produced a great number of art objects.

Architecture. The mystery religions developed different types of edifices for their purposes. Every Greek city had temples and precincts of Dionysus. The Isis Mysteries adopted the Greek temples, frequently adding a cupola. Many Isis temples were modest in size, but the temple at Pergamum (modern Bergama, Turkey) was a great basilica with a vaulted roof and strong towers, in the fashion of the best Roman architecture. The Isis temple that the emperor Domitian erected on the Campus Martius (the Field of Mars) in Rome at the end of the 1st century AD was a stately building, and the Temple of Sarapis (the Sarapeum) at Alexandria was a huge construction. The subterranean basilica near Porta Maggiore in Rome (used by an Orphic or Pythagorean society) was a strong and magnificent structure hidden in a large garden. The Mithraic sanctuaries were artificial caves illuminated from above by light shafts. They were built for communities of 50 to 100 persons.

Isis temples

The buildings were designed to be functional for the religious ceremonies. The Mithraeum under the church of S. Clemente at Rome contained a system of underground galleries for initiation ceremonies. Beneath the temple of the Egyptian gods at Pergamum, subterranean passages existed for the use of the priests. One of the paths led into the huge, hollow statue of the god, so that the priest could speak from the mouth of the statue. By another secret way, an officiant could climb the huge corner towers of the temple to make announcements from there. The Sarapeum at Alexandria was directed toward the east; on a certain day of the year, at a certain time, sunbeams directly struck the head of the god's statue. This same temple was so arranged that those waiting to be initiated could hire rooms in an adjacent building during the time of preparation before the ceremony.

Because the use of water was such an important element in most of the mystery rites, the location of the temples was often determined by the availability of water; Mithraic sanctuaries were always erected on the spot at which a fountain had its source. In the temples of Isis, a cistern for holy water was required; in Delos and in a house at Pompeii in Italy, a system of water basins could imitate the flood of the Nile. The Dionysiac temple at Corinth had an underground system of tubes and barrels that could be operated by buttons from the outside. The priest showed the worshippers of the god a barrel filled with water. They left the temple together, and the door was sealed from without. By pressing the buttons, the water was let out of the barrel, and wine was poured in. The following day, when the seal was removed, the spectator witnessed the Dionysiac miracle of water turned into wine.

On the ground floor of the Mithraic sanctuaries at Ostia, mosaic pavements showed the seven grades of the initiation and their symbols together with the ladder of the seven steps that led to religious salvation. In initiation ceremonies the mosaic was perhaps used to indicate the place where the different participants were to take their places.

Statuary. A great many statues were exhibited in the temples and shrines of the mystery gods. They were usually executed in the traditional Greek style. In the sanctuary of Isis and Sarapis at Thessalonica (modern Thessaloníki), in northern Greece, there were statues of a whole series of Greek goddesses, each of whom was identified with Isis in one way or another to show that the Egyptian goddess was the essence and synthesis of Greek religion. In the 4th century BC the sculptor Bryaxis created a famous colossal statue of Sarapis in the temple at Alexandria. It represented the god—as a combination of the Greek gods Zeus (the father of the gods), Hades, and Dionysus—seated upon a throne, with Cerberus, the three-headed monster, beside him. An interesting statuette found at Cyrene (modern Shaḥḥāt, Libya) shows a female initiate of Isis. The woman is wrapped from feet to waist like a mummy; but the upper part of her body is free, and she is wearing the crown of Isis on her head. The statue thus showed how an initiate would first die and subsequently resurrect in triumph during the ceremony. Many terracotta statues of Isis and her son Horus have survived from Roman Egypt; they are similar to the later statues of the Christian Madonna and Child. Syrian statues of Jupiter Heliopolitanus represent the god in a rigid attitude, like a pillar. In the base of some of these statues are holes, into which sticks could be inserted for the purpose of carrying the statue in procession. In Mithraic sanctuaries a great number of statues, especially of the gods of the planets, were exhibited. Statues of the Mithraic time god were also frequent; they were often hollow and were constructed so that they could spit fire.

Reliefs. The Dionysiac reliefs are numerous. They show symbols of the religion, such as the shepherd's staff, the winnow (an ancient device for separating chaff from grain), and the phallus; they depict the gay life of satyrs and maenads, shepherds and shepherdesses; and they represent the "golden age" of the gods with tame and wild animals enjoying a peace that the god had instituted. A great silver dish dating from about the 4th century AD and found at Mildenhall, England, shows the swift and elegant dance of the maenads. Dionysiac sarcophagi represented Bacchic revels and the pastime of the Erotes and Psyches in afterlife. Many reliefs of the Isis Mysteries also survive. They display the mystical cista (a receptacle for carrying sacred objects) with the snake of Horus, the priest carrying holy water in a procession, female attendants with a ladle, and a man in a dog's mask, who represents Anubis (the guardian god). Other Isiac reliefs show Isis riding on a dog, symbolic of her position as goddess of Sirius (the Dog Star).

The "golden age" of the gods

In Mithraic caverns there was always a relief depicting the god sacrificing the bull. Representations of the sacramental meal were also frequent; a relief recently discovered in Konjic, Bosnia and Herzegovina, shows a banquet at which the initiates are wearing masks, among them a lion, a raven, a soldier, and a Persian. Two reliefs—at Rome (now at Modena, Italy) and at Housesteads, England (the best preserved fort along Hadrian's Wall)—depict the creation of the world out of an initial egg; in this case, Orphic and Mithraic ideas were amalgamated. Other episodes of Mithraic mythology that were commonly displayed include the birth of Mithra from a rock with the shepherds who welcome him and his dealings with the sun god.

The stucco reliefs in the subterranean basilica near Porta Maggiore are of outstanding quality. In the central episode, Sappho—an early Greek poetess who supposedly killed herself in a "lover's leap" from the island of Leucas into the Ionian Sea—is shown leaping toward Apollo, the

god of the sun; this symbolized the soul's transcendence into more favourable existence. Many of the reliefs in the basilica allegorize episodes from Greek mythology in the fashion of the Pythagoreans, who found a hidden religious or philosophical meaning behind the mythical tales of the Greek tradition.

Painting. There are few paintings from the temples of the mystery religions that have been preserved; nevertheless, some of these deserve comment. The superb Dionysiac frescoes of the Villa of the Mysteries (Villa dei Misteri) at Pompeii show the initiation of a girl into the Bacchic Mysteries: in one fresco she is lifting the cover of a sacred casket; in a second scene three followers of Dionysus are practicing lecanomancy (divination by the inspection of a bowl filled with water); in a third scene the girl is unveiling an erect phallus and because of this she is being flagellated; finally, she is seen dancing in happy bliss. A number of Isiac frescoes, preserved in the temple of Isis at Pompeii, show the sacred dance of the initiates, the presentation of an urn filled with the ritual holy water to the initiates, the coffin of Osiris and his resurrection, and episodes from the cycle of Io, a Greek heroine equated with Isis. Isiac frescoes dating from the time of the emperor Caligula in the 1st century AD are also found in the ruins on the Palatine at Rome. In the Mithraeum under Sta. Prisca in Rome, two layers of frescoes were found that show the procession of the initiates toward ritual sacrifice of a bull, called Suovetaurilia, and the sacred meal of the sun god and Mithra. Sometimes a fresco replaced the relief of the sacrifice of the bull. The initiation ceremonies are shown in the Mithraic sanctuary at Capua (in western Italy); the candidate, accompanied by the *mystagōgos,* is blindfolded, kneels down, and lies prostrate. At Rome, in the tomb of Vincentius and Vibia, who worshipped the god Sabazius (a Thracian form of Dionysus), frescoes show how Vibia was carried away by Death, as Kore had been carried away by Hades, how she was judged and acquitted, and how she was introduced by a "good angel" to the sacred meal of the blessed.

Mosaics. A mosaic at Antioch represents the Phoenix—the solar bird who died and resurrected from its own ashes and who was its own father and son at the same time—with sunrays encircling its head. A Dionysus mosaic at Cologne, Germany, depicts in several panels the life of satyrs and maenads and also Bacchic symbols such as the winnow (an implement of purification) and the oyster (which has to be liberated from the shell as the soul from the body). The room evidently was used for banquets and Dionysiac merrymaking.

MYSTERY RELIGIONS AND CHRISTIANITY

Similarities between mysteries and Christianity

Christianity originated during the time of the Roman Empire, which was also the time at which the mysteries reached their height of popularity. This was by no means an accident. The Christian theologian Origen wrote in the 3rd century that it was part of the divine plan that Christ was born under the emperor Augustus: the whole Mediterranean world was united by the Romans, and the conditions for missionary work were more favourable than ever before. The simultaneousness of the propagation of the mystery religions and of Christianity and the striking similarities between them, however, demand some explanation of their relationship. The hypothesis of a mutual dependence has been proposed by scholars—especially a dependence of Christianity upon the mysteries—but such theories have been discarded. The similarities must rather be explained by parallel developments from similar origins. In both cases, national religions of a ritualistic type were transformed, and the transformation followed similar lines: from national to ecumenical religion, from ritualistic ceremonies and taboos to spiritual doctrines set down in books, from the idea of inherited tradition to the idea of revelation. The parallel development was fostered by the new conditions prevailing in the Roman Empire, in which the old political units were dissolved, and the whole civilized world was ruled by one monarch. People were free to move from one country to another and became cosmopolitan. The ideas of Greek philosophy penetrated everywhere in this society. Thus, under identical conditions, new forms of religious communities sprang from similar roots. The mystery religions and Christianity had many similar features—*e.g.,* a time of preparation before initiation and periods of fasting; baptism and banquets; vigils and early-morning ceremonies; pilgrimages and new names for the initiates. The purity demanded in the worship of Sol and in the Chaldean fire rites was similar to Christian standards. The first Christian communities resembled the mystery communities in big cities and seaports by providing social security and the feeling of brotherhood. In the Christian congregations of the first two centuries, the variety of rites and creeds was almost as great as in the mystery communities; few of the early Christian congregations could have been called orthodox according to later standards. The date of Christmas was purposely fixed on December 25 to push into the background the great festival of the sun god, and Epiphany on January 6 to supplant an Egyptian festival of the same day. The Easter ceremonies rivalled the pagan spring festivals. The religious art of the Christians continued the pagan art of the preceding generations. The Christian representations of the Madonna and child are clearly the continuation of the representations of Isis and her son suckling her breast. The statue of the Good Shepherd carrying his lost sheep and the pastoral themes on Christian sarcophagi were also taken over from pagan craftsmanship.

In theology the differences between early Christians, Gnostics (members—often Christian—of dualistic sects of the 2nd century AD), and pagan Hermetists were slight. In the large Gnostic library discovered at Naj'Ḥammādī, in upper Egypt, in 1945, Hermetic writings were found side-by-side with Christian Gnostic texts. The doctrine of the soul taught in Gnostic communities was almost identical to that taught in the mysteries: the soul emanated from the Father, fell into the body, and had to return to its former home. The Greeks interpreted the national religions of the Greek Orient chiefly in terms of Plato's philosophical and religious concepts. Interpretation in Platonic concepts was also the means by which the Judeo-Christian set of creeds was thoroughly assimilated to Greek ideas by the early Christian thinkers Clement of Alexandria and Origen. Thus, the religions had a common conceptual framework. The doctrinal similarity is exemplified in the case of the pagan writer and philosopher Synesius. The people of Cyrene selected him as the most able man of the city to be their bishop, and he was able to accept the election without sacrificing his intellectual honesty. In his pagan period he wrote hymns that closely follow the fire theology of the *Chaldean Oracles,* later he wrote hymns to Christ. The doctrine is almost identical.

The similarity of the religious vocabulary is also great. Greek life was characterized by such things as democratic institutions, seafaring, gymnasium and athletic games, theatre, and philosophy. The mystery religions adopted many expressions from these domains: they spoke of the assembly (*ekklēsia*) of the *mystai;* the voyage of life; the ship, the anchor, and the port of religion; and the wreath of the initiate; life was a stage and man the actor. The Christians took over the entire terminology; but many pagan words were strangely twisted in order to fit into the Christian world: the service of the state (*leitourgia*) became the ritual, or liturgy, of the church; the decree of the assembly and the opinions of the philosophers (*dogma*) became the fixed doctrine of Christianity; the correct opinion (*orthē doxa*) about things became orthodoxy.

Differences between mysteries and Christianity

There are also great differences between Christianity and the mysteries. Mystery religions, as a rule, can be traced back to tribal origins, Christianity to a historical person. The holy stories of the mysteries were myths; the Gospels of the New Testament, however, relate historical events. The books that the mystery communities used in Roman times cannot possibly be compared to the New Testament. The essential features of Christianity were fixed once and for all in this book; the mystery doctrines, however, always remained in a much greater state of fluidity. The theology of the mysteries was developed to a far lesser degree than the Christian theology. There are no parallels in Christianity to the sexual rites in the Dionysiac and Isiac religion, with the exception of a few aberrant Gnostic communities.

The cult of rulers in the manner of the imperial mysteries was impossible in Jewish and Christian worship.

The mysteries declined quickly when the emperor Constantine raised Christianity to the status of the state religion. After a short period of toleration, the pagan religions were prohibited. The property of the pagan gods was confiscated, and the temples were destroyed. The precious metal used to coin Constantine's gold pieces was taken from heathen temple treasuries. To show the beginning of a new era, the capital of the empire was transferred to the new Christian city of Constantinople. The centres of pagan resistance were Rome, where the old aristocracy clung to the mysteries, and Alexandria, where the pagan Neoplatonist philosophers expounded the mystery doctrines. When Julian the Apostate, Roman emperor from AD 361 to 363, tried to reestablish pagan worship, he found allies at Rome and Alexandria. After his death, the pagan opposition to Christianity continued for one more generation. The Roman aristocrats multiplied their efforts to maintain the piety of the mysteries, and the pagan philosophers tried to refine their theology by oversubtle interpretations. In 391, however, the Sarapeum at Alexandria was demolished, and in 394 the opposition of the Roman aristocracy was crushed in battle at the Frigidus River (now called the Vipacco River in Italy and the Vipava in Slovenia).

Only remnants of the mystery doctrines, amalgamated with Platonism, were transmitted by a few philosophers and individualists to the religious thinkers of the Byzantine Empire. The mystery religions exerted some influence on the thinkers of the Middle Ages and the philosophers of the Italian Renaissance.

BIBLIOGRAPHY. General texts include JAMES GEORGE FRAZER, *The Golden Bough*, 3rd ed., 12 vol. (1911–15, reprinted 1990), also available in an abridged ed., *The New Golden Bough* (1959, reissued 1972), a famous and influential treatise on ancient religion, especially on Adonis, Attis, Osiris, Dionysus, and Demeter; JOHN FERGUSON, *An Illustrated Encyclopaedia of Mysticism and the Mystery Religions* (1976, reissued as *Encyclopedia of Mysticism and Mystery Religions*, 1982); JOSCELYN GODWIN, *Mystery Religions in the Ancient World* (1981), an illustrated, popular overview; and WALTER BURKERT, *Ancient Mystery Cults* (1987), with an extensive bibliography.

The Greek mysteries are explored in ERWIN ROHDE, *Psyche: The Cult of Souls and Belief in Immortality Among the Greeks* (1925, reprinted 1987; originally published in German, 8th ed., 1921), by the first author to understand the religion of Dionysus; LOUIS RICHARD FARNELL, *The Cults of the Greek States*, 5 vol. (1896–1909, reissued 1971), a careful and conscientious collection and interpretation of the sources for Demeter and Dionysus; JANE ELLEN HARRISON, *Prolegomena to the Study of Greek Religion*, 3rd ed. (1922, reprinted with a new introduction, 1991), containing original accounts about Demeter, Dionysus, and Orpheus; MARTIN P. NILSSON, *A History of Greek Religion*, 2nd ed., trans. from Swedish (1949, reprinted 1980), an excellent handbook; E.R. DODDS, *The Greeks and the Irrational* (1951, reissued 1973), relevant especially for Dionysiac and Orphic religion; and WALTER BURKERT, *Greek Religion* (1985), which includes a discussion of mysteries.

Mysteries in the Roman Empire are considered by FRANZ CUMONT, *The Oriental Religions in Roman Paganism* (1911, reissued 1956; originally published in French, 2nd ed. rev., 1909), an excellent general account; A.D. NOCK, *Conversion: The Old and the New in Religion from Alexander the Great to Augustine of Hippo* (1933, reprinted 1988), a well-written and original study of the relation of Oriental cults and Christianity, and *Early Gentile Christianity and Its Hellenistic Background* (1964), a learned collection of articles; MARTIN P. NILSSON, *The Dionysiac Mysteries of the Hellenistic and Roman Age* (1957, reprinted 1985), a clear and scholarly survey of the religion of Dionysus in later times; REINHOLD MERKELBACH, *Roman und Mysterium in der Antike* (1962), on the ancient romances as mystery texts, and *Isisfeste in griechischrömischer Zeit* (1963), on the Isis festivals and their relationship to Christian festivals; and RAMSAY MACMULLEN, *Paganism in the Roman Empire* (1981). Myth and Mythology

Myth is a collective term denoting a symbolic narrative in religion, as distinguished from symbolic behaviour (cult, ritual) and symbolic places or objects (temples, icons). Myths are specific accounts of gods or superhuman beings involved in extraordinary events or circumstances in a time that is unspecified but which is understood as existing apart from ordinary human experience.

As with all religious symbolism, there is no attempt to justify mythic narratives or even to render them plausible. Every myth presents itself as an authoritative, factual account, no matter how much the narrated events are at variance with natural law or ordinary experience. By extension from this primary religious meaning, the word myth may also be used more loosely to refer to an ideological belief when that belief is the object of a quasi-religious faith; an example would be the Marxist eschatological myth of the withering away of the state.

While the outline of myths from a past period or from a society other than one's own can usually be seen quite clearly, to recognize the myths that are dominant in one's own time and society is always difficult. This is hardly surprising, because a myth has its authority not by proving itself but by presenting itself. In this sense the authority of a myth indeed "goes without saying," and the myth can be outlined in detail only when its authority is no longer unquestioned but has been rejected or overcome in some manner by another, more comprehensive myth.

The word myth derives from the Greek *mythos,* which has a range of meanings from "word," through "saying" and "story," to "fiction"; the unquestioned validity of *mythos* can be contrasted with *logos,* the word whose validity or truth can be argued and demonstrated. Because myths narrate fantastic events with no attempt at proof, it is sometimes assumed that they are simply stories with no factual basis, and the word has become a synonym for falsehood or, at best, misconception. In the study of religion, however, it is important to distinguish between myths and stories that are merely untrue.

The term mythology denotes both the study of myth and the body of myths belonging to a particular religious tradition. The first part of this article discusses the nature, study, functions, cultural impact, and types of myth, taking into account the various approaches to the subject offered by modern branches of knowledge. In the second part, the specialized topic of the role of animals and plants in myth is examined in some detail. The mythologies of specific cultures, such as Germanic, Greek, and Roman, are covered in the article EUROPEAN RELIGIONS, ANCIENT.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 811, and the *Index.*

The nature, functions, and types of myth

Myth has existed in every society. Indeed, it would seem to be a basic constituent of human culture. Because the variety is so great, it is difficult to generalize about the nature of myths. But it is clear that in their general characteristics and in their details a people's myths reflect, express, and explore the people's self-image. The study of myth is thus of central importance in the study both of individual societies and of human culture as a whole.

RELATION OF MYTHS TO OTHER NARRATIVE FORMS

In Western culture there are a number of literary or narrative genres that scholars have related in different ways to myths. Examples are fables, fairy tales, folktales, sagas, epics, legends, and etiologic tales (which refer to causes or explain why a thing is the way it is). Another form of tale, the parable, differs from myth in its purpose and character. Even in the West, however, there is no agreed definition of any of these genres, and some scholars question whether multiplying categories of narrative is helpful

at all, as opposed to working with a very general concept such as the traditional tale. Non-Western cultures apply classifications that are different both from the Western categories and from one another. Most, however, make a basic distinction between "true" and "fictitious" narratives, with "true" ones corresponding to what in the West would be called myths.

If it is accepted that the category of traditional tale should be subdivided, one way of doing so is to regard the various subdivisions as comparable to bands of colour in a spectrum. Within this figurative spectrum, there will be similarities and analogies between myth and folktale or between myth and legend or between fairy tale and folktale. In the section that follows, it is assumed that useful distinctions can be drawn between different categories. It should, however, be remembered throughout that these classifications are far from rigid and that, in many cases, a given tale might be plausibly assigned to more than one category.

Fables. The word fable derives from the Latin word *fabula,* which originally meant about the same as the Greek *mythos;* like *mythos,* it came to mean a fictitious or untrue story. Myths, in contrast, are not presented as fictitious or untrue.

Instructional value of fables

Fables, like some myths, feature personified animals or natural objects as characters. Unlike myths, however, fables almost always end with an explicit moral message, and this highlights the characteristic feature of fables—namely, that they are instructive tales that teach morals about human social behaviour. Myths, by contrast, tend to lack this directly didactic aspect, and the sacred narratives that they embody are often hard to translate into direct prescriptions for action in everyday human terms. Another difference between fables and myths relates to a feature of the narratives that they present. The context of a typical fable will be unspecific as to time and space; *e.g.,* "A fox and a goose met at a pool." A typical myth, on the other hand, will be likely to identify by name the god or hero concerned in a given exploit and to specify details of geography and genealogy; *e.g.,* "Oedipus was the son of Laius, the king of Thebes."

Fairy tales. The term fairy tale, if taken literally, should refer only to stories about fairies, a class of supernatural and sometimes malevolent beings—often believed to be of diminutive size—who were thought by people in medieval and postmedieval Europe to inhabit a kingdom of their own; a literary expression of this belief can be found in Shakespeare's *A Midsummer Night's Dream.* The term fairy tale, however, is normally used to refer to a much wider class of narrative, namely stories (directed above all at an audience of children) about an individual, almost always young, who confronts strange or magical events: examples are "Jack and the Beanstalk," "Cinderella," and "Snow White and the Seven Dwarfs." The modern concept of the fairy tale seems not to be found earlier than the 18th century in Europe, but the narratives themselves have earlier analogues much farther afield, notably in the Indian *Kathā-saritsāgara* (*The Ocean of Story*) and in *The Thousand and One Nights.*

Like myths, fairy tales present extraordinary beings and events. Unlike myths—but like fables—fairy tales tend to be placed in a setting that is geographically and temporally vague and might begin with the words "Once upon a time there was a handsome prince . . ." A myth about a prince, by contrast, would be likely to name him and to specify his lineage, since such details might be of collective importance (for example, with reference to issues of property inheritance or the relative status of different families) to the social group among which the myth was told.

Folktales. There is much disagreement among scholars as to how to define the folktale; consequently, there is disagreement about the relation between folktale and myth. One view of the problem is that of the American folklorist Stith Thompson, who regarded myths as one type of folktale; according to this approach, the particular characteristic of myth is that its narratives deal with sacred events that happened "in the beginning." Other scholars either consider folktale a subdivision of myth or regard the two categories as distinct but overlapping. The latter view is taken by the British classicist Geoffrey S. Kirk, who in *Myth: Its Meaning and Functions in Ancient and Other Cultures* (1970) uses the term myth to denote stories with an underlying purpose beyond that of simple story-telling and the term folktale to denote stories that reflect simple social situations and play on ordinary fears and desires. Examples of folktale motifs are encounters between ordinary, often humble, human beings and supernatural adversaries such as witches, giants, or ogres; contests to win a bride; and attempts to overcome a wicked stepmother or jealous sisters. But these typical folktale themes occur also in stories normally classified as myths, and there must always be a strong element of arbitrariness in assigning a motif to a particular category.

A different and important aspect of the problem of defining a folktale relates to the historical origin of the concept. As with the notion of folklore, the notion of folktale has its roots in the late 18th century. From that period until the middle of the 19th century, many European thinkers of a nationalist persuasion argued that stories told by ordinary people constituted a continuous tradition reaching back into the nation's past. Thus, stories such as the *Märchen* ("Tales") collected by the Grimm brothers in Germany are folktales because they were told by the people rather than by an aristocratic elite. This definition of folktale introduces a new criterion for distinguishing between myth and folktale—namely, what class of person tells the story—but it by no means removes all the problems of classification. Just as the distinction between folk and aristocracy cannot be transferred from medieval Europe to tribal Africa or classical Greece without risk of distortion, so the importing of a distinction between myth and folktale on the later European model is extremely problematic.

Sagas and epics. The word saga is often used in a generalized and loose way to refer to any extended narrative re-creation of historical events. A distinction is thus sometimes drawn between myths (set in a semidivine world) and sagas (more realistic and more firmly grounded in a specific historical setting). This rather vague use of saga is best avoided, however, since the word can more usefully retain the precise connotation of its original context. The word saga is Old Norse and means "what is said." The sagas are a group of medieval Icelandic prose narratives; the principal sagas date from the 13th century and relate the deeds of Icelandic heroes who lived during the 10th and 11th centuries. If the word saga is restricted to this Icelandic context, at least one of the possible terminological confusions over words for traditional tales is avoided.

Origin of sagas

While saga in its original sense is a narrative type confined to a particular time and place, epics are found worldwide. Examples can be found in the ancient world (the *Iliad* and *Odyssey* of Homer), in medieval Europe (the *Nibelungenlied*), and in modern times (the Serbo-Croatian epic poetry recorded in the 1930s). Among the many non-European examples are the Indian *Mahābhārata* and the Tibetan Gesar epic. Epic is similar to saga in that both narrative forms look back to an age of heroic endeavour, but it differs from saga in that epics are almost always composed in poetry (with a few exceptions such as Kazakh epic and the Turkish *Book of Dede Korkut*). The relation between epic and myth is not easy to pin down, but it is in general true that epics characteristically incorporate mythical events and persons. An example is the ancient Mesopotamian epic of Gilgamesh, which includes, among many mythical episodes, an account of the meeting between the hero Gilgamesh and Utnapishtim, the only man to have attained immortality and sole survivor (with his wife) of the flood sent by the gods. Myth is thus a prime source of the material on which epic draws.

Legends. In common usage the word legend usually characterizes a traditional tale thought to have a historical basis, as in the legends of King Arthur or Robin Hood. In this view, a distinction may be drawn between myth (which refers to the supernatural and the sacred) and legend (which is grounded in historical fact). Thus, some writers on the *Iliad* would distinguish between the legendary aspects (*e.g.,* heroes performing actions possible for ordinary humans) and the mythical aspects (*e.g.,* episodes involving the gods). But the distinction between

myth and legend must be used with care. In particular, because of the assumed link between legend and historical fact, there may be a tendency to refer to narratives that correspond to one's own beliefs as legends, while exactly comparable stories from other traditions may be classified as myths; hence a Christian might refer to stories about the miraculous deeds of a saint as legends, while similar stories about a pagan healer might be called myths. As in other cases, it must be remembered that the boundaries between terms for traditional narratives are fluid, and that different writers employ them in quite different ways.

Parables. The term myth is not normally applied to narratives that have as their explicit purpose the illustration of a doctrine or standard of conduct. Instead, the term parable, or illustrative tale, is used. Familiar examples of such narratives are the parables of the New Testament. Parables have a considerable role also in Ṣūfism (Islāmic mysticism), rabbinic (Jewish biblical interpretive) literature, Ḥasidism (Jewish pietism), and Zen Buddhism. That parables are essentially non-mythological is clear because the point made by the parable is known or supposed to be known from another source. Parables have a more subservient function than myths. They may clarify something to an individual or a group but do not take on the revelatory character of myth.

Etiologic tales. Etiologic tales are very close to myth, and some scholars regard them as a particular type of myth rather than as a separate category. In modern usage the term etiology is used to refer to the description or assignment of causes (Greek *aitia*). Accordingly, an etiologic tale explains the origin of a custom, state of affairs, or natural feature in the human or divine world. Many tales explain the origin of a particular rock or mountain. Others explain iconographic features, such as the Hindu narrative ascribing the blue neck of the god Śiva to a poison he drank in primordial times. The etiologic theme often seems to be added to a mythical narrative as an afterthought. In other words, the etiology is not the distinctive characteristic of myth.

APPROACHES TO THE STUDY OF MYTH AND MYTHOLOGY

The importance of studying myth to provide a key to a human society is a matter of historical record. In the middle of the 19th century, for instance, a newly appointed British governor of New Zealand, Sir George Grey, was confronted by the problem of how to come to terms with the Maori, who were hostile to the British. He learned their language, but that proved insufficient for an understanding of the way in which they reasoned and argued. In order to be able to conduct negotiations satisfactorily, he found it necessary to study the Maori's mythology, to which they made frequent reference. Other government officials and Christian missionaries of the 19th and 20th centuries made similar efforts to understand the mythologies of nations or tribes so as to facilitate communication. Such studies were more than a means to an end, whether efficient administration or conversion; they amounted to the discovery that myths present a model or charter for man's behaviour and that the world of myth provides guidance for crucial elements in human existence—war and peace, life and death, truth and falsehood, good and evil. In addition to such practically motivated attempts to understand myth, theorists and scholars from many disciplines have interested themselves in the study of the subject. A close study of myth has developed in the West, especially since the 18th century. Much of its material has come from the study of the Greek and Roman classics, from which it has also derived some of its methods of interpretation.

Myths as a model of human behaviour

The growth of philosophy in ancient Greece furthered allegorical interpretations of myth—*i.e.*, finding other or supposedly deeper meanings hidden below the surface of mythical texts. Such meanings were usually seen as involving natural phenomena or human values. Related to this was a tendency toward rationalism, especially when those who studied myths employed false etymologies. Rationalism in this context connotes the scrutiny of myths in such a way as to make sense of the statements contained in them without taking literally their references to gods, monsters, or the supernatural. Thus, the ancient writer Palaiphatos interpreted the story of Europa (carried off to Crete on the back of a handsome bull, which was actually Zeus in disguise) as that of a woman abducted by a Cretan called Tauros, the Greek word for bull; and Skylla, the bestial and cannibalistic creature who attacked Odysseus' ship according to Homer's *Odyssey*, was by the same process of rationalizing interpreted as simply the name of a pirate ship. Of special and long-lasting influence in the history of the interpretation of myth was Euhemerism (named after Euhemerus, a Greek writer who flourished about 300 BC), according to which certain gods were originally great people venerated because of their benefactions to mankind.

Influence of Euhemerism

The early Church Fathers adopted an attitude of modified Euhemerism, according to which classical mythology was to be explained in terms of mere men who had been raised to superhuman, demonic status because of their deeds. By this means, Christians were able to incorporate myths from the culturally authoritative pagan past into a Christian framework while defusing their religious significance—the gods became ordinary humans. The Middle Ages did not develop new theoretical perspectives on myth, nor, despite some elaborate works of historical and etymological erudition, did the Renaissance. In both periods, interpretations in terms of allegory and Euhemerism tended to predominate.

In early 18th-century Italy, Giambattista Vico, a thinker now considered the forerunner of all writers on ethnology, or the study of culture in human societies, built on traditional scholarship—especially in law and philosophy—to make the first clear case for the role of man's creative imagination in the formation of distinct myths at successive cultural stages. His work, which was most notably expressed in his *Scienza nuova* (1725; *The New Science of Giambattista Vico*), had no influence in his own century. Instead, the notion that pagan myths were distortions of the biblical revelation (first expressed in the Renaissance) continued to find favour. Nevertheless, Enlightenment philosophy, reports from voyages of discovery, and missionary reports (especially the Jesuits' accounts of North American Indians) contributed to scholarship and fostered greater objectivity. Bernhard Le Bovier de Fontenelle, a French scholar, compared Greek and American Indian myths and suggested that there was a universal human predisposition toward mythology. In *De l'origine des fables* (1724; "On the Origin of Fables") he attributed the absurdities (as he saw them) of myths to the fact that the stories grew up among an earlier, more primitive human society. About 1800 the Romantics' growing fascination with language, the postulation of an Indo-European language family, the study of Sanskrit, and the growth of comparative studies, especially in history and philology, were all part of a trend that included the study of myth.

The relevance of Indo-European studies to an understanding of Greek and Roman mythology was carried to an extreme in the work of Friedrich Max Müller, a German Orientalist who moved to Britain and undertook important research on comparative linguistics. In his view, expressed in such works as *Comparative Mythology* (1856), the mythology of the original Indo-European peoples had consisted of allegorical stories about the workings of nature, in particular such features as the sky, the Sun, and the dawn. In the course of time, though, these original meanings had been lost (through, in Müller's notorious phrasing, a "disease of language"), so that the myths no longer told in a "rationally intelligible" way of phenomena in the natural world but instead appeared to describe the "irrational" activities of gods, heroes, nymphs, and others. For instance, one Greek myth related the pursuit of the nymph Daphne by the god Phoebus Apollo. Since—in Müller's interpretation of the evidence of comparative linguistics—"Daphne" originally meant "dawn," and "Phoibos" meant "morning sun," the original story was rationally intelligible as "the dawn is put to flight by the morning sun." One of the problems with this view is, of course, that it fails to account for the fact that the Greeks continued to tell this and similar stories long after their supposed meanings had been forgotten; and they did so,

Müller's study of myth and linguistics

moreover, in the manifest belief that the stories referred, not to nature, but precisely to gods, heroes, and other mythical beings.

Interest in myth was greatly stimulated in Germany by Friedrich von Schelling's philosophy of mythology, which argued that myth was a form of expression, characteristic of a particular stage in human development, through which men imagine the Absolute (for Schelling an all-embracing unity in which all differences are reconciled). Scholarly interest in myth has continued into the 20th century. Many scholars have adopted a psychological approach because of interest aroused by the theories of Sigmund Freud. Subsequently, new approaches in sociology and anthropology have continued to encourage the study of myth.

Allegorical. An example of an allegorical interpretation would be that given by an ancient commentator for the *Iliad,* book 20, verse 67. Referring to an episode in which the gods fight each other, the commentator cites critics who have explained the hostilities between the gods allegorically as an opposition between elements—dry against wet, hot against cold, light against heavy. Thus, the gods Apollo, Helios, and Hephaestus represent fire, and the god Poseidon and the river Scamander represent water. Similarly, the goddess Athena is interpreted as wisdom/sense, the god Ares as the absence of that quality, the goddess Aphrodite as desire, and the god Hermes as reason. An allegorical interpretation of a myth could be said to posit a one-to-one correspondence between mythical "clothing" and the ideas being so clothed. This approach tends to limit the meaning of a myth, whereas that meaning may in reality be multiple, operating on several levels.

Romantic. In the late 18th century artists and intellectuals came increasingly to emphasize the role of the emotions in human life and, correspondingly, to play down the importance of reason (which had been regarded as supremely important by thinkers of the Enlightenment). Those involved in the new movement were known as Romantics. The Romantic movement had profound implications for the study of myth. Myths—both the stories from Greek and Roman antiquity and contemporary folktales—were regarded by the Romantics as repositories of experience far more vital and powerful than those obtainable from what was felt to be the artificial art and poetry of the aristocratic civilization of contemporary Europe.

Myths as natural expressions of human experience

This new attitude is illustrated in a work of the German critic and philosopher Johann Gottfried von Herder entitled "Auszug aus einem Briefwechsel über Ossian und die Lieder alter Völker" (1773; "Extract from a Correspondence on Ossian and the Songs of Ancient Peoples"). Ossian is the name of an Irish warrior-poet whose Gaelic songs were supposedly translated and presented to the world by James Macpherson in the 1760s. Although largely the work of Macpherson himself, these songs made a colossal impact when they were published. Herder believed that the more "savage," that is, the more "alive" and "freedom-loving" a people (*ein Volk*) was, the more alive and free its songs would be. In opposition to the culture of the educated, Herder exalted the *Kultur des Volkes* ("culture of the people"). In 1769 Herder abandoned his job as a schoolteacher and took a boat from Riga, on the Baltic, to Nantes, on the Atlantic coast of France. In *Journal meiner Reise im Jahre 1769* (1769; *Journal of My Travels in the Year 1769*), a description of the experience, he wrote:

> In everything [on board ship] there is experience to illuminate the original era of the myths. *Then* [*i.e.,* in antiquity] every man, ignorant of nature, listened for signs and *had* to listen for them . . . . *Then,* Jupiter's lightning was terrifying—as indeed it *is* [*i.e.,* now] on the Ocean . . . . There are a thousand new and more natural explanations of mythology . . . if one reads, say, Orpheus, Homer, Pindar . . . on board ship.

In other words, for Herder ancient myths were the natural expressions of the concerns that would have confronted the ancients; and those concerns were the very ones that, according to Herder, still confronted the *Volk—e.g.,* ordinary sailors—in Herder's own day.

Comparative. Since the Romantic movement, all study of myth has been comparative, although comparative attempts were made earlier. The prevalence of the comparative approach has meant that since the 19th century even the most specialized studies have made generalizations about more than one tradition or at the very least have had to take comparative works by others into account. Indeed, for there to be any philosophical inquiry into the nature and function of myth at all, there must exist a body of data about myths across a range of societies. Such data would not exist without a comparative approach.

Folkloric. The classic folklore approach is that of Wilhelm Mannhardt, a German scholar, who attempted to collect data on the "lower mythology," which he considered to be more or less homogeneous in ancient and popular peasant traditions and basic to all formation of myth. Mannhardt saw sufficient analogies and similarities between the ancient and modern data to permit use of the latter in interpreting the former. Like Herder, he saw the source of mythology in the traditions passed on among the *Volk.* He collected information not only about popular stories but also about popular customs. He interpreted ancient Greek rituals by relating them to customs of the agricultural peoples of northern Europe, proposing this link in his book *Antike Wald- und Feldkulte* (1877; "Ancient Wood and Field Cults"). Other people who examined myth from the folklore standpoint included Sir James Frazer, the British anthropologist, the brothers Grimm (Jacob, who influenced Mannhardt, and Wilhelm), who are well-known for their collections of folklore, and Stith Thompson, who is notable for his classification of folk literature, particularly his massive *Motif-Index of Folk-Literature* (1955). The Grimms shared Herder's passion for the poetry and stories of the *Volk.* Their importance stems in part from the academic diligence and meticulousness that they brought to the recording and study of popular tradition. In addition to their collection of *Märchen* ("Tales"), they published volumes of *Deutsche Sagen* ("German Legends"). These were tales that purported to record actual events and that were ostensibly set in a specific place and period, as opposed to the "once-upon-a-time-in-the-forest" setting characteristic of the *Märchen.* Collecting and classifying mythological themes have remained the principal activities of the folklore approach.

Myth as a folk tradition

Functionalist. One of the leading exponents of the functionalist approach to myth was the French sociologist Marcel Mauss, who used the phrase "total social facts" in reference to religious symbols and myths and their irreducibility in terms of other functions. In his *Essai sur le don* (1925; *The Gift*), Mauss referred to a system of gift giving to be found in traditional, preindustrial societies. Observing that there was a mass of complex data on the subject, Mauss continued: in these "early" societies, social phenomena

> are not discrete; each phenomenon contains all the threads of which the social fabric is composed. In these *total* social phenomena, as we propose to call them, all kinds of institutions find simultaneous expression: religious, legal, moral, and economic.

In his introduction to the English edition Edward Evans-Pritchard commented on that passage:

> "Total" is the key word of the *Essay.* The exchanges of archaic societies which he examines are total social movements or activities. They are at the same time economic, juridical, moral, aesthetic, religious, mythological . . . phenomena. . . . . Their meaning can therefore only be grasped if they are viewed as a complex concrete reality.

Functionalism is primarily associated with the anthropologists Bronisław Malinowski and A.R. Radcliffe-Brown, however. Both ask not what the origin of any given social behaviour may be but how it contributes to maintaining the system of which it is a part. In this view, in all types of society, every aspect of life—every custom, belief, or idea—makes its own special contribution to the continued effective working of the whole society. Functionalism has had a wide appeal to anthropologists in Britain and the United States, especially as an interpretation of myth as integrated with other aspects of society and as supporting existing social relationships.

Structuralist. Structuralist approaches to myth are based on the analogy of myth to language. Just as a lan-

guage is composed of significant oppositions (*e.g.,* between phonemes, the constituent sounds of the language), so myths are formed out of significant oppositions between certain terms and categories. Structuralist analysis aims at uncovering what it sees as the logic of myth. It is argued that supposedly primitive thought is logically consistent but that the terms of this logic are not those with which modern Western culture is familiar. Instead they are terms related to items of the everyday world in which the "primitive" culture exists. This logic is usually based on empirical categories (*e.g.,* raw/cooked, upstream/downstream, bush/village) or empirical objects (*e.g.,* buffalo, river, gold, eagle). Some structuralists, such as the French anthropologist Claude Lévi-Strauss, have emphasized the presence of the same logical patterns in myths throughout the world.

The logic of myth

In earlier anthropology, "primitive mentality" was characterized by the inability to make distinctions, by a sense of "mystic participation" or identity between man, his cosmos, and all other beings. Beginning with complex kinship systems and later exploring other taxonomies, structuralists argue to the opposite conclusion: the supposedly primitive man is, if anything, obsessed with the making of distinctions; his taxonomies reveal a complexity and sophistication that rival those of modern man.

Formalist. In contrast to the structuralists' search for the underlying structure of myths, the 20th-century Russian folklorist Vladimir Propp investigated folktales by dividing the surface of their narratives into a number of basic elements. These elements correspond to different types of action that, in Propp's analysis, always occur in the same sequence. Examples of the types of action isolated by Propp are "An interdiction is addressed to the hero"; "The interdiction is violated"; "The false hero or villain is exposed"; and "The hero is married and ascends the throne."

An important development of Propp's approach was made in the late 20th century by the German historian of religion Walter Burkert. Burkert detected certain recurrent patterns in the actions described in Greek myths, and he related these patterns (and their counterparts in Greek ritual) to basic biologic or cultural "programs of action." An example of this relation is given in Burkert's *Structure and History in Greek Mythology and Ritual* (1979). Burkert shows how certain Greek myths have a recurring pattern that he calls "the girl's tragedy." According to this pattern, a girl first leaves home; after a period of seclusion, she is raped by a god; there follows a time of tribulation, during which she is threatened by parents or relatives; eventually, having given birth to a baby boy, the girl is rescued, and the boy's glorious future is assured. The reason for the frequency and persistence of this pattern is, in Burkert's view, the fact that it reflects a basic biologic sequence or "program of action"; puberty, defloration, pregnancy, delivery. Another pattern Burkert explains in a similar way is found in myths about the driving out of the scapegoat. This pattern, Burkert argues, stems from a real situation that must often have occurred in early human or primate history; a group of men, or a group of apes, when pursued by carnivores, were able to save themselves through the sacrifice of one member of the group. The persistence of these patterns through time is explained, according to Burkert, by the fact that they are grounded in basic human needs—above all, the need to survive.

FUNCTIONS OF MYTH AND MYTHOLOGY

Explanation. The most obvious function of myths is the explanation of facts, whether natural or cultural. One North American Indian (Abnaki [Wabanaki]) myth, for example, explains the origin of corn (maize): a lonely man meets a beautiful woman with long, fair hair; she promises to remain with him if he follows her instructions; she tells him in detail how to make a fire and, after he has done so, she orders him to drag her over the burned ground; as a result of these actions, he will see her silken hair (viz., the cornstalk) reappear, and thereafter he will have corn seeds for his use. Henceforth, whenever Abnaki Indians see corn (the woman's hair), they know that she remembers them. Obviously, a myth such as this one functions as an explanation, but the narrative form distinguishes it from a straightforward answer to an intellectual question about causes. The function of explanation and the narrative form go together, since the imaginative power of the myth lends credibility to the explanation and crystallizes it into a memorable and enduring form. Hence myths play an important part in many traditional systems of education.

Justification or validation. Many myths explain ritual and cultic customs. According to myths from the island of Ceram (in Indonesia), in the beginning life was not complete, or not yet "human": vegetation and animals did not exist, and there was neither death nor sexuality. In a mysterious manner Hainuwele, a girl with extraordinary gift-bestowing powers, appeared. The people killed her at the end of their great annual celebration, and her dismembered body was planted in the earth. Among the species that sprang up after this act of planting were tubers—the staple diet of the people telling the myth. With a certain circularity frequent in mythology, the myth validates the very cultic celebration mentioned in the myth. The cult can be understood as a commemoration of those first events. Hence, the myth can be said to validate life itself together with the cultic celebration. Comparable myths are told in a number of societies where the main means of food production is the cultivation of root crops; the myths reflect the fact that tubers must be cut up and buried in the earth for propagation to take place.

Cultic or ritual validation

Ritual sacrifices are typical of traditional peasant cultures. In most cases such customs are related to mythical events. Among important themes are the necessity of death (*e.g.,* the grain "dies" and is buried, only to yield a subsequent harvest), a society's cyclic renewal of itself (*e.g.,* New Year's celebrations), and the significance of women and sexuality. New Year's celebrations, often accompanied by a temporary abandonment of all rules, may be related to or justified by mythical themes concerning a return to chaos and a return of the dead.

In every mythological tradition one myth or cluster of myths tends to be central. The subject of the central mythology is often cosmogony (origin of the cosmos). In many of those ceremonies that each society has developed as a symbol of what is necessary to its well-being, references are made to the beginning of the world. Examples include the enthronements of kings, which in some traditions (as in Fiji or ancient India) are associated with a creation or re-creation of the world. Analogously, in ancient Mesopotamia the creation epic *Enuma elish,* which was read each New Year at Babylon, celebrated the progress of the cosmos from initial anarchy to government by the kingship of Marduk; hence the authority of earthly rulers, and of earthly monarchy in general, was implicitly supported and justified.

Ruling families in ancient civilizations frequently justified their position by invoking myths—for example, that they had divine origins. Examples are known from Imperial China, pharaonic Egypt, the Hittite Empire, Polynesia, the Inca Empire, and India. Elites have also based their claims to privilege on myths. The French historian of ancient religion Georges Dumézil was the pioneer in suggesting that the priestly, warrior, and producing classes in ancient Indo-European societies regarded themselves as having been ordained to particular tasks by virtue of their mythological origins. And in every known cultural tradition there exists some mythological foundation that is referred to when defending marriage and funerary customs.

Description. Inasmuch as myths deal with the origin of the world, the end of the world, or a paradisiacal state, they are capable of describing what people can never "see for themselves" however rational and observant they are. It may be that the educational value of myths is even more bound up with the descriptions they provide than with the explanations. In traditional, preindustrial societies myths form perhaps the most important available model of instruction, since no separate philosophical system of inquiry exists.

Instruction through myths

Healing, renewal, and inspiration. Creation myths play a significant role in healing the sick; they are recited (*e.g.,* among the Navajo Indians of North America) when an individual's world—that is to say, his life—is in jeopardy.

Thus, healing through recitation of a cosmogony is one example of the use of myth as a magical incantation. Another example is the case of Icelandic poets, who, in singing of the episode in old Norse mythology in which the god Odin wins for gods and men the "mead of song" (a drink containing the power of poetic inspiration), can be said to be celebrating the origins of their own art and hence renewing it.

The poetic aspect of myths in archaic and primitive traditions is considerable. Societies in which artistic endeavour is not yet specialized tend to rely on mythical themes and images as a source of all self-expression. Mythology has also exerted an aesthetic influence in more modern societies. An example is the prevalence of themes from Greek and Roman classical mythology in Western painting, sculpture, and literature.

MYTH IN CULTURE

Myth and psychology. One of the most celebrated writers about myth from a psychological standpoint was Sigmund Freud. In his *Die Traumdeutung* (1899; *The Interpretation of Dreams*) he posited a phenomenon called the Oedipus complex, that is, the male child's repressed desire for his mother and a corresponding wish to supplant his father. (The equivalent for girls was the Electra complex.) According to Freud, this phenomenon was detectable in dreams and myths, fairy tales, folktales—even jokes. Later, in *Totem und Tabu* (1913; *Totem and Taboo*), Freud suggested that myth was the distorted wish-dreams of entire peoples. More than that, however, he saw the Oedipus complex as a memory of a real episode that had occurred in what he termed the "primal horde," when sons oppressed by their father had revolted, had driven out or killed him, and had taken his wives for themselves. That subsequent generations refrained from doing so was, Freud suggested, due to a collective bad conscience. The relevance of Freud's investigations to the study of myth lies in his view that the formation of mythic concepts does not depend on cultural history. Instead, Freud's analysis of the psyche posited an independent, trans-historical mechanism, based on a highly personal biologic conception of man. His anthropological theories have since been refuted (*e.g.,* totemic [symbolic animal] sacrifice as the earliest ritual custom, which he related to the first parricide), but his analysis is still regarded with interest by some reputable social scientists. Criticism, however, has been leveled against the explanation of myths in terms of only one theme and in terms of the "repression" of conscious ideas.

Freud's creation of a trans-historical method

Another theorist preoccupied with psychological aspects of myth was the Swiss psychoanalyst Carl Jung, who, like Freud, was stimulated by a theory that no longer has much support—*i.e.,* the theory of Lucien Lévy-Bruhl, a French philosopher, associating myth with prelogical mentality. This, according to Lévy-Bruhl, was a type of thought that had been common to archaic mankind, that was still common to primitives, and in which people supposedly experienced some form of "mystical participation" with the objects of their thought, rather than a separation of subject and object. Jung's theory of the "collective unconscious," which bears a certain resemblance to Lévy-Bruhl's theory, enabled him to regard the foundation of mythical images as positive and creative, in contrast with Freud's more negative view of mythology. Jung evolved a theory of archetypes. Broadly similar images and symbols occur in myths, fairy tales, and dreams because the human psyche has an inbuilt tendency to dwell on certain inherited motifs (archetypes), the basic pattern of which persists, however much details may vary. But critics of Jung have hesitated to accept his theory of archetypes as an account of mythology. Among objections raised, two may be mentioned. First, the archetypal symbols identified by Jung are static, representing personal types that conflate aspects of the personality: they do not help to illuminate—in the way that the analyses of Propp and Burkert do—the patterns of action that myths narrate. Second, Jungian analysis is essentially aimed at relating myth to the individual psyche, whereas myth is above all a social phenomenon, embedded in society and requiring explanation with reference to social structures and social functions.

Myth and science. Attention has sometimes focused on changes occurring in the way the real world is apprehended by different peoples and how these changes in "reality" are reflected in myths. This reality changes continually throughout history, and these changes have especially occupied philosophers and historians of science, for a sense of reality in a culture is basic to any scientific pursuit by that culture, beginning with the earliest philosophical inquiries into the nature of the world. Though it would perhaps be going too far to identify the images and concepts that make up a culture's scientific sense of reality with myth, parallels between science and myth, as well as the presence of a mythological dimension to science, are generally reckoned to exist.

The function of models in physics, biology, medicine, and other sciences resembles that of myths as paradigms, or patterns, of the human world. In medicine, for instance, the human body is sometimes likened to a machine or the human brain to a computer, and such models are easily understood. Once a model has gained acceptance, it is difficult to replace, and in this respect it resembles myth, while at the same time, just as in myth, there may be a great variety of interpretations. In the 17th century it was assumed that the universe could be explained entirely in terms of minute corpuscles, their motion and interaction, and that no entities of any other sort existed. To the extent that many models in the history of science have partaken of this somewhat absolutist character, science can be said to resemble myth. There are, however, important differences. Despite the relative infrequency with which models in science have been replaced, replacement does occur, and a strong awareness of the limitations of models has developed in modern science. In contrast, a myth is not as a rule regarded by the community in which it functions as open to replacement, although an outside observer might record changes and even the substitution of a new myth for an old one. Moreover, in spite of the broad cultural impact of theories and models such as those of Newton and Einstein, it is in general true to say that models in science have their principal value for the scientists concerned. Hence, they function most strongly for a relatively small segment of society, even though, for instance, a medical theory held in academic circles in one century can filter down into folk medicine in the next. As a rule, myth has a much wider impact.

Scientific models as paradigms

Modern science did not evolve in its entirety as a rebellion against myth, nor at its birth did it suddenly throw off the shackles of myth. In ancient Greece the naturalists of Ionia (western Asia Minor), long regarded as the originators of science, developed views of the universe that were in fact very close to the creation myths of their time. Those who laid the foundations of modern science, such as Nicholas of Cusa, Johannes Kepler, Sir Isaac Newton, and Gottfried Leibniz, were absorbed by metaphysical problems of which the traditional, indeed mythological, character is evident. Among these problems were the nature of infinity and the question of the omnipotence of God. The influence of mythological views is seen in the English physician William Harvey's association of the circulation of the blood with the planetary movements and Darwin's explanation of woman's menstrual cycles by the tides of the ocean.

Several thinkers (*e.g.,* the theologian Paul Tillich and the philosopher Karl Jaspers) have argued convincingly for a mythological dimension to all science. Myth, in this view, is that which is taken for granted when thought begins. It is at the same time the limit reached in the course of scientific analysis, when it is found that no further progress in definition can be made after certain fundamental principles have been reached. In recent scientific researches, especially in astronomy and biology, questions of teleology (final ends) have gained in importance, as distinct from earlier concerns with questions of origin. These recent concerns stimulate discussion about the limits of what can be scientifically explained, and they reveal anew a mythological dimension to human knowledge.

Myth and religion. The place of myth in various religious traditions differs.

Ritual and other practices. The idea that the principal

function of a myth is to provide a justification for a ritual was adopted without any great attempt to make a case for it. At the beginning of the 20th century many scholars thought of myths in their earliest forms as accounts of social customs and values. According to Sir James Frazer, myths and rituals together provided evidence for man's earliest preoccupation, namely, fertility. Human society developed in stages—from the magical through the religious to the scientific—and myths and rituals (which survived even into the scientific stage) bore witness to archaic modes of thought that were otherwise difficult to reconstruct. As for the relationship between myth and ritual, Frazer argued that myths were intended to explain otherwise unintelligible rituals. Thus, in *Adonis, Attis, Osiris* (1906) he stated that the mythical story of Attis' self-castration was designed to explain the fact that the priests of Attis' cult castrated themselves at his festival.

The Myth and Ritual school

In a much more articulate way, biblical scholars stressed the necessity to look for the situation in life and custom (the "Sitz im Leben") that mythical texts originally possessed. A number of scholars, mainly in Britain and the Scandinavian countries and usually referred to as the Myth and Ritual school (of which the best-known member is the British biblical scholar S.H. Hooke), have concentrated on the ritual purposes of myths. Their work has centred on the philological study of the ancient Middle East both before and since the rise of Islām and has focused almost exclusively on rituals connected with sacred kingship and New Year's celebrations. Of particular importance was the discovery that the creation epic *Enuma elish* was recited at the Babylonian New Year's festival: the myth was, it was argued, expressing in language that which the ritual was enacting through action. Classical scholars have subsequently investigated the relations between myth and ritual in ancient Greece. Particularly influential has been the study of sacrifice by Walter Burkert entitled *Homo Necans: The Anthropology of Ancient Greek Sacrificial Ritual and Myth* (1983).

Connections between myths and cult behaviour certainly exist, but there is no solid ground for the suggestion, following Frazer, that, in general, ritual came first and myth was then formulated as a subsequent explanation. If it is only the subsequent myth that has made the sense of the earlier ritual explicit, the meaning of the ritual may remain a riddle. There is in fact no unanimous opinion about which originated first. Modern scholars are inclined to turn away from the question of temporal priority and to concentrate instead on the diversity of the relationship between myth and ritual. While it is clear that some myths are linked to rituals, so that it makes sense to say that the myth is expressing in the language of narrative that which the ritual expresses through the symbolism of action, in the case of other myths no such ritual exists.

The content of important myths concerning the origin of the world usually reflects the dominant cultural form of a tradition. The myths of hunter-gatherer societies tell of the origin of game animals and hunting customs; agricultural civilizations tend to give weight to agricultural practices in their myths; pastoral cultures to pastoral practices; and so on. Thus, many myths present models of acts and organizations central to the society's way of life and relate these to primordial times. Myths in specific traditions deal with matters such as harvest customs, initiation ceremonies, and the customs of secret societies.

Religious symbolism and iconography. Sacred objects are found in all religious traditions, and sacred images in most. They are the material counterparts of myth inasmuch as they represent sacred realities of figures, as myths do in narrative form. Representing does not entail faithful copying of natural or human forms, and in this respect religious symbolism is again like myth in that both depict the extraordinary rather than the ordinary. Many symbolic representations have their sources in myths. Representations in human form, especially "natural" human form, are rare. The sculptures of divine figures in classical Greece (by sculptors such as Phidias and Praxiteles) are the exception. Usually the degree of representation occurring in cult practices and the depiction of mythical themes has been considerably less humanistic. An example is the way geometric and animal figures abound in the history of religions. Another example is the use of sacred masks, as in the mysteries of Dionysus, an ecstatic cult in the Aegean world of classical antiquity, and the indigenous traditions of Australia, America, prehistoric Europe, and elsewhere.

Sacred texts. The Old Testament is usually regarded as embodying much material that anthropologists would regard as containing mythical themes in just the same way as the practices of the ancient Greeks, Chinese, or Abnaki Indians are bound up with myths. Yet the religion of Israel was in many respects critical of myths (in the sense of noncanonical, approved narratives). Similarly, it rejected any representation of God in natural forms. Anti-mythological tendencies exist in the religions that have their roots in Israel. The New Testament of Christianity in some instances derogates myths by describing them as "godless" and "silly." Islām's emphasis on the transcendence of God, as attested in the Qur'ān, similarly allows little room for mythological stories. The activities of the supernatural beings known as *jinn,* however, are acknowledged even by official Islām, besides being prominent in popular belief (as in *The Thousand and One Nights*); and other mythological themes, for example motifs relating to the end of time (eschatology), also figure in Islāmic religion, above all in its Shī'ite form. Orthodox Shī'ite Muslims believe in the existence of 12 *imāms,* semidivine descendants of the Prophet Muḥammad through his son-in-law 'Alī. Toward the end of time, according to the beliefs of Shī'ism, the 12th *imām* will return to bring truth and justice to mankind.

Biblical and Qur'ānic criticism of myth

Other traditions with sacred scriptures are more tolerant of myth, for example Hinduism and Buddhism. Running through certain central texts of the Hindu sacred tradition is the theme of the contrast between the One and the Many. Thus, the philosophical poem known as the *Bhagavadgītā* contrasts the person who sees Infinity within the ordinary finite world with the person who merely sees the diversity of appearances. Yet this ascetic and abstract view by no means excludes a rich and extraordinarily diverse mythology, which is reflected in the tremendous variety of Indian religious statuary and which mirrors the religious complexity of Indian society. A justification for the coexistence of an ideal of unity with a pluralistic reality is found in the *Rigveda,* where it is written that although God is One the sages give him many names. Buddhism also finds room for exuberant mythology as well as for the plainer truths of sacred doctrine. Buddhism embraces not only the teachings of the Buddha about the pursuit of the path to Enlightenment and Nirvāṇa but also the exotic mythical figures of Yamantaka, who wears a necklace of skulls, and the grossly fat god of wealth Jambhala.

Myth and the arts. *Oral traditions and written literature.* Myths in ancient civilizations are known only by virtue of the fact that they became part of a written tradition. In the case of Greece, virtually all myths are "literature" in the form in which they have survived, the oldest source being the works ascribed to the Greek poets Homer and Hesiod (usually dated, in written form, to the 8th century BC). Literary forms such as the epic have frequently served as vehicles for transmitting myths inasmuch as they present an authoritative account. The Homeric epics were both an example and an exploration of heroic values, and the poems became the basis of education in classical Greece. The great epics of India (*Mahābhārata* and *Rāmāyaṇa*) came to function as encyclopaedias of knowledge and provided models for all human existence.

Visual arts. In principle, the sort of relationship that exists between myth and literature exists also with respect to the other arts. In the case of architecture and sculpture, archaeological discoveries confirm the primacy of mythical representations. Among the earliest known three-dimensional objects built by man are prehistoric megalithic and sepulchral structures. Mythological details cannot actually be discerned, but it is generally believed that such structures express mythological concerns and that mythical images dictated the shape. An especially intriguing example is the stone circle at Stonehenge in southern England. Axes of this construction are aligned with significant risings and settings of the Sun and Moon, but the idea that

Mythological aspects of architecture

the circle was built for a religious purpose must remain likely rather than certain.

Grave monuments of rulers are among the most important remains of ancient civilizations (*e.g.,* the Egyptian pyramids; and the sepulchral structures of Chinese rulers since the Chou period, *c.* 1111–255 BC). There is worldwide evidence that in archaic cultures man considered the points of the compass to have mythological affiliations (*e.g.,* the West and death or the East and a new beginning). Mythological views even influenced building activity. One architectural feature that can have mythological significance is the column. In a number of popular traditions the sky is believed to be supported by one or more columns. The relatively strict separation between religious and civil architecture that modern man is perhaps inclined to take for granted has not existed in most cultures and periods and perhaps is not universal even in modern times.

Even when art ceases to represent mythological matters outright, it is still usually far from representational. That art has ceased to represent mythology is challenged by some theorists, who argue that what seems to be abandonment of mythological forms is really only a change in mythology. The opposing arguments are analogous to the favourable or unfavourable attitudes toward myth that religions have developed.

Myth as a source of the drama and the dance

Performing arts. Myth is one of the principal roots of drama. This is particularly obvious in the earliest Western drama, the tragedies of classical Greece, not only because of the many mythological subjects treated and the plays' performance at the festival of Dionysus but also because of the playwrights' mythlike presentation of events and facts. An example of such presentation is the story pattern, notably the way retribution follows transgression. Another feature of Greek drama that is relevant to the subject of myth is the fact that the role of the chorus was taken by a group of ordinary citizens. In Greek tragedy the heroic past was presented and explored by a chorus of nonheroic individuals; hence the meaning of the inherited myths was examined by a collectivity that can be seen as standing for the wider collectivity (more than 10,000 in number) that constituted the audience at the plays. In its songs the chorus frequently had recourse to expressions of a proverbial kind, using the distilled wisdom of the community to account for the strange and often disturbing events represented in the plays. The origins of drama are obscure, but Theodor Gaster, an American historian of religion, has suggested that in the ancient eastern Mediterranean world the interrelationship of myth and ritual created drama. Elsewhere, dramatic presentations (as in Japanese Nō plays and the Javanese *wayang*) are similarly rooted in myth.

Dance has been a medium for the expression of mythological themes throughout the world and in all periods for which there is evidence. Especially common are dances aimed at ensuring the continuity of fertility or the success of hunting, at curing the sick, or at achieving shamanistic trance states. An aspect of the decay of ritual in the modern West is the tendency for dance to lose its close and direct connection with the life of the community. A further consequence is that the role of dance in embodying and exploring a community's myths has often been overlooked, and dance may have become further removed from myth than any other form of art in the Western world. There are important and significant exceptions, however. One of the most notable is the work of the American choreographer Martha Graham, who frequently used mythical themes—often drawn from Greek antiquity—as the inspiration for her ballets.

Music. Myth and music are linked in many cultures and in various ways. For example, numerous stories ascribe the origins of music to a figure, usually divine, who lived in the mythical past. Thus, in ancient Greece the lyre was said to have been invented by the god Hermes, who handed it on to his brother Apollo as part of a bargain. From then on Apollo played the lyre at the banquets of the gods, while the Muses sang to his accompaniment. An ancient Chinese myth tells of the discovery of the "foundation tone," which, in addition to being a musical note of specific pitch, also had political implications, since each dynasty was thought to have its own "proper pitch." The foundation tone was produced when Ling Lun, a scholar, went to the western mountain area of China and cut a bamboo pipe in such a way that it produced the correct sound.

Throughout the world music is played at religious ceremonies to increase the efficacy and appeal of prayers, hymns, and invocations to divinities. The power of music to charm the gods is movingly expressed in the Greek story of Orpheus. This mythical figure goes to the underworld to try to have his dead wife, Eurydice, restored to life. By means of his lyre playing and singing he is able to win over even the god of death, so that Eurydice is allowed to leave the underworld. The continuing potency of the myth (including its tragic conclusion—Orpheus is forbidden to look back at his wife but does so and thus loses her again) is shown by the fact that it has been retold in Europe by numerous composers of opera since the early 17th century.

Lévi-Strauss's view of myth and music

That a particularly close connection exists between myth and music has been argued by Claude Lévi-Strauss. In an analysis of the myths of certain South American Indians (*Le Cru et le cuit,* 1964; *The Raw and the Cooked*) he explains that his procedure is "to treat the sequences of each myth, and the myths themselves in respect of their reciprocal interrelations, like the instrumental parts of a musical work and to study them as one studies a symphony." His treatment is divided into such subsections as "The 'Good Manners' Sonata," "Fugue of the Five Senses," and "The Opossum's Cantata." In *Myth and Meaning* (1978) Lévi-Strauss returned to the link between myth and music, which had proved difficult for his readers to understand. To make his point clearer Lévi-Strauss took the example of a theme from an opera by Richard Wagner. Each time the theme is repeated its overall meaning grows clearer, as each instance is superimposed on the others in the series, so that it becomes possible to see what the different occurrences of the theme have in common. Analogously, the meaning of a myth is found not simply by reading its narrative in sequence, but by superimposing upon one another similar mythical events from one narrative and boiling down each resulting "bundle" to a common denominator. It is the relationship between these bundles that constitutes the logic of the myth.

The use of music for religious ends has declined in modern Western societies, but mythical themes (*e.g.* in opera and oratorio) are still used with genuine artistic effect. The repertoires of late 20th-century opera companies may include, for example, Giacomo Puccini's *Turandot,* about a princess who asks her suitors three riddles and beheads them if they fail to answer correctly and a prince who will die if his name is discovered; Richard Strauss's *Die Frau ohne Schatten* ("The Woman Without a Shadow"), about a princess who must gain a shadow or her husband will be turned to stone; and Wagner's *Tannhäuser, Lohengrin, Der Ring des Nibelungen,* and *Parsifal,* all loosely based on tales from medieval Germanic mythology.

Myth and history. Myth and history represent alternative ways of looking at the past. Defining history is hardly easier than defining myth, but a historical approach necessarily involves both establishing a chronological framework for events and comparing and contrasting rival traditions in order to produce a coherent account. The latter process, in particular, requires the presence of writing in order that conflicting versions of the past may be recorded and evaluated. Where writing is absent, or where literacy is restricted, traditions embedded in myths through oral transmission may constitute the principal sources of authority for the past. Hence, myths may be cited when a situation in the present is materially affected by what version of the past is accepted. For instance, if a dispute arises among the Iatmul of Papua New Guinea over the rights of different clans to possess land, the contending parties take part in oral contests involving the recitation of long lists of mythological names and other details from the myths. Since each clan's view of the mythic past has implications for the ownership of estates by persons living in the present, victory in these contests is a matter of direct practical importance to the participants.

Myth, history, and tradition

Even in societies where literacy is widespread and where

a considerable body of professional historians is at work, it may still be the case that a majority of the population form their views of the past on the basis of inherited mythlike traditions. Examples from the 20th century in Europe would be the polarized communities (Protestant and Roman Catholic) of Northern Ireland, or pro- and anti-Communist sympathizers in Greece. In the former case, the two communities have different and irreconcilable pictures of the events related to the partition of Ireland. In the latter case, the course of the civil war (after the end of World War II) is viewed quite differently by the two groups. These rival traditions may be described as mythlike because they are narratives with a strong validating function—the function of justifying current enmities and current loyalties—and they are believed with a quasi-religious faith against which objective historical testing is all but powerless.

Finally, similarities to myths may be present even in the work of those who are justifiably described as historians. A clear instance of this is the ancient Greek writer Herodotus, the so-called "father of history." He had the radically original idea of writing an account of the struggle between the Greek world and its "barbarian" neighbours during the Persian Wars, an account that combined and evaluated a range of disparate and often conflicting pieces of information. On these grounds he should certainly be described as a historian. Yet, his work is full of themes and story patterns that also occur in Greek myths—for example, transgression against the gods leads to retribution; again, people who live at the margins of the Greek world are imagined as having customs that are the exact inverse of their Greek equivalents. In the work of Herodotus there is no incompatibility between myth and history; both historical events and the patterns into which such happenings are perceived as falling form part of his overall enterprise: namely, to conduct an inquiry (the meaning of the Greek word *historia*) into the past. As with the distinction between myth and science, then, that between myth and history is by no means a straightforward one.

MAJOR TYPES OF MYTH

Myths of origin. Cosmogony and creation myth are used as synonyms, yet properly speaking, cosmogony is a preferable term because it refers to the origin of the world in a neutral fashion, whereas "creation myth" implies a creator and something created, an implication unsuited to a number of myths that, for example, speak of the origin of the world as a growth or emanation, rather than an act. Even the term origin should be used with caution for cosmogonic events (as well as for other myths purporting to describe the beginning of things), because the origin of the world hardly ever seems the focal point of a mythological narrative—as a mythological narrative is not a matter of inquiry into the first cause of things. Instead, cosmogonic myths are concerned with origins in the sense of the foundation or validity of the world as it is. Creation stories in both primitive and advanced cultures frequently speak of the act of creation as a fashioning of the earth out of raw material that was already present. In African cosmogonies, especially, the earth is preexistent. A creation out of nothing occurs as a theme much less frequently, for all that such creation myths are more satisfying to the philosophical mind. Philosophical questions, however, are less important in the justificatory systems set up by myth.

Water, though important everywhere as a source of life and image of endless potentiality, has a special role in Asia and North America, where the creator (often an animal) is assisted by another figure, who dives for earth in the primordial ocean. The earth-diver helper sometimes develops into an opponent, or Satan-like character, in other areas—*e.g.*, those touched by Zoroastrianism, an ancient Persian dualistic religion. Though hardly an explanation in the ordinary sense of the word, the theme accounts for the fact that evil is constitutive of the cosmos without holding the creator responsible for it. Other widely diffused motifs are: the cosmogonic egg, found in the Pacific world, parts of Europe and southern Asia (*e.g.*, in Hinduism); the world parents (usually in the image of sky and earth); and creation through sacrifice or through a primordial battle. Creation through the word of the creator also occurs outside the Old Testament account (in Polynesia).

Cosmogony sets the pattern for everything else in most traditions; other myths are related to it or derived from it. Because man's inhabitable world, the cosmos, is the crucial issue, no matter how various the contents may be and how different from one period to another, cosmogony probably is the clearest expression of man's basic mythological propensity. All cosmogonic accounts have certain formal features in common. They speak of irreconcilable opposites (*e.g.*, heaven and earth, darkness and light) and, at the same time, of events or things totally outside the common range of perception and reason (*e.g.*, a "time" in which heaven and earth were not yet separated and darkness and light intermingled). In other words, the basic ingredients of man's world and orientation are presupposed yet are realized, constituted, or brought about anew in the narration. The narrative can arrive at such a reconstitution only by transcending the limits of ordinary perception and reason.

Common features in cosmogonic and creation myths

The origin of man is usually linked immediately to the cosmogony. Man, for instance, is placed on the earth by God, or in some other way his origin is from heaven. Nevertheless, it is only in mythologies influenced by philosophical reflections that the place of man becomes the conspicuous centre of the cosmogony (*e.g.*, Pythagoreanism, a Greek mystical philosophical system; Orphism, a Greek mystical religious movement; Gnosticism, a Christian dualistic and esoteric movement; and Tantrism, a Hindu and Buddhist esoteric meditation system). Man is sometimes said to have ascended from the depths of the earth (as with the Zuni, an American Indian people) or from a certain rock or tree of cultic significance. These images are often related to the idea of a realm of ancestors as the origin of newborn children. Man is also said to be fashioned from the dust of the ground (as in Genesis) or from a mixture of clay and blood (as in the Babylonian creation myth). In all cases, however, man has a particular place (because of his duties to the gods, because of his limitations, or even because of his gifts), even though—especially in many hunters' civilizations (*e.g.*, the African San peoples and many North American Indian tribes)—the harmony of man and other forms of nature is emphasized.

In most cosmogonic traditions the final or culminating act is the creation of man. The condition of the cosmos prior to man's arrival is viewed as separate and distinct from the alterations that result from the beginning of the human cultural world. Creation is thus seen as a process of periods or stages, frequently in a three-stage model. The first stage consists of the world of gods or primordial beings; the second stage is the world of the ancestors of man; and the third stage is the world of man. The three stages are sometimes seen as interrelated; for example, the gods may be the creators of man or the ancestors of man, or ancestors may undergo a transformation to become men.

Among innumerable tales of origin, one of the most common types is related to the origins of institutions. Certain initiation ceremonies or ritual acts are said to have originated in the beginning, in mythical times, this primeval moment of inception constituting their validity.

Myths of eschatology and destruction. Myths of eschatology deal with "the end." The end is conceived of as the opposite of the cosmogony; it means first and foremost the origin of death but also, in a wider sense, the end of the world. Special forms of eschatology are prevalent in messianism (belief in a future salvation figure) and millenarianism (belief in a 1,000-year reign of the elect).

Myths about the origin of death, for which an added explanation has to be found in the sense that death is not seen as automatically the end of life, are probably as widely diffused as creation stories. One of the most common types of such myths speaks of a primordial time in which death did not exist and explains that it arose as the result of an error, as a punishment, or simply because the creator decided the earth would get too crowded otherwise. One example of a myth about the origin of death may be regarded as characteristic; it occurs, with variations, in many parts of the world. Among the Zulus the story is told that the supreme being Unkulunkulu instructed the

The origin of death

chameleon to take a message to mankind, saying that they would be immortal. But the chameleon moved slowly, since he stopped to have something to eat (or, according to a variant, basked in the sun and fell asleep). In due course the supreme being changed his mind and sent a lizard to men, telling them that they would die. The lizard arrived and delivered his message. When the chameleon eventually arrived, his message conflicted with what mankind had already been told by the lizard. The chameleon was not believed, and men were mortal from then on.

Expectations of a cataclysmic end of the world are also expressed by myths. A universal conflagration with a final battle and defeat of the gods is part of Germanic mythology and has parallels in other examples of Indo-European eschatological imagery. In many "primitive" religions specific expectations about the end of the world do occur, but until recently they have not received much scholarly attention. An example of such a belief about the end of the world is found among the Pawnee Indians. In their view, there will come a time when everything will disappear and the star of death will govern the world. The Moon will turn red, the Sun will be extinguished, and men will be turned into stars flying along the route to heaven now taken by the dead.

Messianic and millenarian myths. The hope of a new world surges up from time to time in many civilizations. Many such religious movements have flourished in the 20th century in Melanesia, Africa, South America, and Siberia. Christian elements are usually detectable, but the basic element in virtually all cases is indigenous. These cults and movements centre on prophetic leaders, often emphasize the return of the dead at the renewal to come, and are convinced of a catastrophic end of the present world. In many cases, the culture hero is expected to return and lead believers in battle against the evil forces. In the history of Judaism and Christianity, as in many primitive millenarian and messianic movements, there is an expectation of a new heaven and a new earth.

Myths of culture heroes and soteriological myths. A great many nonliterate traditions have myths about a culture hero (most notably one who brings new techniques or technology to mankind—*e.g.,* Prometheus, who supplies fire to mankind in Greek mythology). A culture hero is generally not the person responsible for the creation but the one who completes the world and makes it fit for human life; in short, he creates culture. Another example of a culture hero is Maui in Polynesia, who brought islands to the surface from the bottom of the sea, captured and harnessed the Sun, lifted the sky to allow man more room, and, like Prometheus, gave fire to mankind.

The bringer of culture is often also the bringer of health. Thus, the culture hero of the Woodlands and Plains Indians in North America is at the same time related to the foundation of the medicine society. A comparable figure occurs in many traditions of classical antiquity or the Mediterranean basin generally as the "good son"—*e.g.,* Horus, the son of the god Osiris in Egypt, or the figure of the king in the Psalms. Health and (spiritual) salvation are synonymous, and this is implied in the Greek word *sōtēr,* which can mean both "saviour" and "preserver from ill health." Related to soteriological myths in many cases is the hope for a final and total salvation in which the "good" powers will triumph, such as through Saoshyant, the saviour in Zoroastrianism. In fact, Zoroastrianism shared with the Judeo-Christian tradition the notion of a Last Judgment followed by the ultimate salvation of the world. According to Zoroastrian belief, as the end approached heroes from the past would come to life and help in the struggle of good against evil. Saviours, the Saoshyants, would work toward the triumph of virtue and the spreading of heavenly light over all creation.

Myths of time and eternity. The apparent regularity of the heavenly bodies long impressed every society. The sky was seized as the very image of transcendence, and what seemed to be the orderly course of Sun, Moon, and stars suggested a time that transcended man's—in short, eternity. Many myths and mythological images concern themselves with the relationship between eternity and time on earth. The number four for the number of world ages figures most frequently. The Zoroastrians of ancient Persia knew of a complete world age of 12,000 years, divided into four periods of 3,000 each, at the end of which Ormazd (Wise Lord) would conquer Ahriman (Destructive Spirit). Similarly, the Book of Daniel (in the Old Testament) mentions four kingdoms—of gold, silver, bronze, and a mixture of iron and clay, respectively—after which God will establish an everlasting kingdom. The notion of four world ages, sometimes associated with metals, occurs also in the works of classical writers and in later speculative writings on human history. Judaism developed the view of a 1,000-year period between the four world ages and the everlasting kingdom (hence the words millennium and millenarian). Although other numbers occur (three, six, seven, 12, and 72), four is dominant. In ancient Mexico this world was held to be preceded by four other worlds. India, in both Hindu and Buddhist texts, has developed the most complex system of world ages and worlds that arise and come to an end. Here, too, the number four is important—*e.g.,* the four ages (*yugas*) of decreasing length and increasing evil. Many writings, often with large numbers, reflect exact astronomical observations and calculations. Some mythologies—*e.g.,* those of the Maya in Central America—have developed sophisticated views interrelating time and space. Mythological accounts of repetitions of worlds after their destruction occur not only in India but also elsewhere, such as in Orphism and in the Stoic philosophy that flourished in classical antiquity.

The ages of the world

Myths of providence and destiny. In attitudes to the idea of a link between human activity and the stars, the most familiar example of which is probably astrology, there is a broad range of mythical motifs between astrological calculations (in the sense of an attempt at an intellectualized account of what is happening) and devotional self-surrender. There are many occasions at which a man may be filled with doubt about his own fate or the fate of his community. In some myths divine supremacy is marked by a god's mastery over fate. Marduk, the patron god of Babylon, acquires the "tablets of fate" in his primordial battle preceding the creation. There is no doubt about Zeus's supremacy in the Greek poet Hesiod's genealogical account of the gods, yet in the works of Homer, Zeus is powerless to defy fate and save the life of his son Sarpedon. Mythological views of providence, destiny, or fate are given precise shades of meaning vis-à-vis dominant views in a tradition concerning justice and divine law, the philosophical problem of determinism, the theological problems of theodicy (justification of a good god with observable facts of evil), and predestination. An important difference in mythological accounts of providence exists between those traditions that speak of the creation of the world as a result of God's will (as in Judaism, Christianity, and Islām) and those that attribute worldly phenomena to causation by a lesser being (as Buddhism does).

Myths of rebirth and renewal. Myths of archaic traditions generally imply a conception of the world, nature, and man in terms of cyclic time. According to Australian Aboriginal myth, man is reincarnated into profane life at the moment of his birth. At his initiation he reenters sacred time, and through his burial ceremony he returns to his original "spirit" state. Similar beliefs are held by many tribal peoples, and their myths are expressed in terms of cosmic cycles. Special myths are narrated in many places in preparation for initiation procedures. In agricultural societies, in addition to the themes of cosmic renewal, renewal through birth, and rebirth through initiation ceremonies at the attainment of manhood and womanhood, the theme of seasonal renewal is of great importance. The cyclic concept of time in all these traditions is present in many of the great religious and philosophical systems, such as Brahmanism (a Hindu system), Buddhism, and Platonism, and to some extent it is at variance with the idea of linear time typical of Judaism, Christianity, and Islām. But no culture, not even that of Jews, Christians, or Muslims, completely disregards the cyclic patterns of the seasons, work, festivities, or existence. Such patterns seem to be engraved on man's perception of the world.

Cyclic time

Myths of memory and forgetting. Some of the North American medicine men claim to remember their prena-

tal existence. Such memory, according to their mythology, is lost in ordinary people. Similar myths of memory and forgetting are related to the hierarchy that exists in all archaic societies. The fundamental knowledge of the world, transcending ordinary consciousness, is not equally attainable by everyone. Myths of memory can take the form of collective nostalgia. In South America the Yaruros, whose material existence was so simple that they lacked the skills of the agricultural and pastoral life, were one of the many tribes that in the face of modern Western cultural expansion gave up the struggle for their own social and cultural identity, becoming assimilated into a more complex society. As the Yaruros ceased to struggle for the preservation of their tribal identity, they expressed a yearning to return to the Great Mother ruling the land of the dead and awaiting them in her paradise. Mythologies of memory and forgetting have a role in many traditions. They are of great significance in traditions where the idea of rebirth or reincarnation exists. Some people have claimed to remember previous existences, and a few (among them the Buddha) the very first. The veil of *māyā* ("illusion") in many Indian stories prevents a man from remembering his true origin and goal. In Gnosticism there is talk of a similar forgetfulness, which must be resisted. In ancient Greek myth, Mnemosyne (Memory), the mother of the Muses, is said to know everything, past, present, and future. She is the Memory that is the basis of all life and creativity. Forgetting the true order and origin of things is often tantamount to death (as in the case of Lethe, the river of death in Greek mythology, which destroys memory). Anamnesis, "commemoration" or "recollection," is one of the crucial parts of the Christian celebration of the Communion. Through the anamnesis, the passion and death of the Lord is "applied" to the congregation. In philosophy, the imagery of forgetting and remembering occurs in the thought of Śaṅkara, a medieval Indian philosopher, and of Plato in connection with the paramount calling of the thinker and the difficulty of living up to that calling.

Myths of high beings and celestial gods. Supreme celestial deities occur in many mythologies, with various qualities and attributes, in many shapes, and with great diversity in cultic significance. A cardinal distinction exists between the supreme being in many archaic or polytheistic traditions and the God of the great monotheistic systems (Judaism, Christianity, and Islām). Even though certain qualities seem alike in many cases (*e.g.,* transcendence, omniscience), the God of the latter arose historically in a reaction to polytheistic views and practices and demonstrates his supremacy accordingly, whereas the more archaic types of supreme beings nowhere show that aggressive aspect in their mythologies. The exalted status of archaic supreme beings and celestial gods does not necessarily involve exclusion of other supreme beings. Outstanding examples are Vishnu, Śiva, and the great goddess in Hindu literature, who are each described as supreme yet do not reduce the "reality" of the others. "Supremacy" is not as unambiguous and general a term as it seems, and in Hinduism it refers first and foremost to the *perfection* (*i.e.,* the idea that a deity is supremely perfect) of a deity in himself.

Distinction between high gods and one unique God

The sky seen as a sacred entity is an all but universal belief. It is often related to or identical with the highest divinity. Nevertheless, supreme beings are always more than what can be explained from celestial phenomena alone, for they are often called creators of the world, founders of the order of the world, and protectors of law; and they are praised for their eternity and goodness. Often, the supreme being that created the world does not—or has ceased to—receive attention in the cult, although he may still be invoked in moments of great crisis. In a good many ancient agricultural societies, the idea of a great goddess prevailed instead of a male creator-god. The great goddess (as in the ancient Middle East and India) is venerated principally because of her omnipotence, especially her power over life. The sky god-creator sometimes cedes to a divinity who is also related to the sky but apparently is experienced more concretely because of his activity. Such a divinity (especially in pastoral cultures) can be a god of atmospheric phenomena (storm, rain, thunder, or lightning), whose power for the good of the people is extolled. In spite of his power, however, he is one of several gods, and in some cases (Yahweh in ancient Israel and Allāh in Islām) one such god retains the full creative function of early creator gods, and in him all "true" divinity is concentrated. In addition, a divinity related to the Sun rather than the heavens can assume preeminence; this has happened in some ancient imperial traditions (*e.g.,* Egypt, Inca Empire). Among sky gods who remained important in the mythologies of ancient civilizations are Zeus in Greece, Jupiter in Rome, and T'ien in China.

Myths concerning founders of religions and other religious figures. Although the founders of great religions (Confucius, Zoroaster, the Buddha, Moses, Jesus, Mani, Muḥammad) are generally conceded to have had actual existence, information about them is couched in legendary terms that have many mythological features. The same is true of many other religious figures (prophets, saints, or gurus [Hindu spiritual teachers]). Those traditions that have preserved the memory of their founders have, as a rule, carefully emphasized the elements that function most mythologically, in the sense that they state categorically realities that could not be known in any ordinary fashion or that raise the founder above ordinary historical conditions. Examples are the account of Jesus' prayer in Gethsemane, which no one heard according to the text itself, his statement that he was before Abraham, and his prophecies. Buddhist texts state that the Buddha not merely surpassed all yogis in knowledge of previous existences but, in fact, had conquered time. Well known too are his predictions concerning the course and decline of Buddhism and (in Mahāyāna texts) his promises as to the future spiritual attainments of the bodhisattvas. Other examples are Muḥammad's eschatological teachings in the Qur'ān and those of Zoroaster.

Mythological features in records of historical figures

Myths of kings and ascetics. Genuine myths concerning kings are found only in traditions that know a form of sacred kingship. Temple records from ancient Babylon mention offerings to kings who were considered divine. Hymns addressed to them make references to the king's union with a goddess—*i.e.,* the mythological motif of the "sacred marriage." One of the epithets for the king in ancient Egypt was "endowed with life" or "imparting life." The twofold meaning of the epithet is significant and can serve to make the mythology of sacred kingship understandable in other places as well, because the function of the king is in fact double. He mediates between the divine world and the world of man, representing each to the other. Hence, in Egypt a sacrifice by an individual was understood as offered to the king and at the same time by the king. The king's role of mediator and protector brings royal mythologies close to myths of culture heroes. Solemn procedures in which kings become divinities occur relatively late in history. An early and most conspicuous case of such an apotheosis (becoming divine) is that of Alexander the Great, who was called a god in his lifetime. Later, apotheosis took place for Roman emperors, although there are no cases of an emperor being accorded divine honours in his lifetime. A great many legends have accumulated around the figures of kings (*e.g.,* around King Aśoka of India and King Arthur in Britain). Stories about the Holy Roman emperor Frederick I Barbarossa and Charlemagne have a somewhat eschatological mythical flavour, because they are said to dwell each in his mountain (in the Kyffhäuser and the Untersberg, respectively) until they appear again to act as saviours in a crisis.

Most narratives about great ascetics, as well as other saints, could be regarded as legends rather than myths. There are, however, instances of saints or ascetics who are presented as a more than worldly model, so that a case can be made for the mythological function of their legends (*e.g.,* al-Ḥallāj in Islām and St. Francis in Christianity). In the case of traditions that have asceticism as an integral part, certain figures and the legends around them do indeed function as exemplars.

Myths of transformation. Countless stories exist concerning the origin of peculiar rocks, properties of animals, plants, stars, or other features in the world. In addition to such etiologic tales there are several myths that speak

of cosmic changes brought about at the end of primordial times. An altogether different and extensive mythology exists concerning initiation rites and other "rites of passage" that involve transformation of man's being.

Cosmic transformation may concern an original world, without proper human means of existence and without death, that was transformed through a certain event (*e.g.,* the death of Hainuwele, a type of primal being known as a dema, or ancestral, deity) into the world known to mankind, a truly inhabitable world with vegetation, animals, and other features that had not existed before.

On a wider scale are myths that could be appendages to cosmogonic myths but that have not turned into mere etiologies. Many myths akin to the type of the dema deity (like Hainuwele) and to the culture-hero type (like Prometheus) account for events—such as the invention of agriculture, domestication of animals, and the use of fire—that have transformed the world for the benefit of man. Many others are just as closely related to cosmogonic accounts but tell of "setbacks" in primordial times. In agricultural societies, for example, myths have been collected that ascribe the unevenness of land or the formation of mountains to an ancient mishap or evil force.

Realization of the contents of myths

In rites of passage (*e.g.,* rites accompanying birth, attainment of maturity, marriage, death) the contents of myths are acted out. In each case the intention behind the rites is that man's mode of being be affected, indeed transformed. Through the birth ceremony the child "becomes" a person, and through initiation an adolescent "becomes" an adult, a member of a sodality, or a warrior. There is a great variety of customs in different communities and traditions, but everywhere these rites dramatize graphically the cosmic processes and realities expressed in language in myths. In many traditions the myths of the community are conveyed to the novice at the time of his initiation. Even in the major world religions rites of passage are still performed, as evidenced in such ceremonies as circumcision, Baptism, weddings, and mortuary rites. In all instances, the rites derive their meaning from the core of the tradition, and for that reason man's existence is regarded as transformed. In some cases the transformation derived from the dominant myth is far-reaching. The initiated shaman is able to transcend the ordinary human condition and overcome dangers that would cause the death of a noninitiate. Through his initiation he is believed to have gone through death and thus conquered it. In certain Hermetic (an occult magical tradition) and Gnostic texts the certainty of attaining divine being is clearly expressed.

MYTH IN MODERN SOCIETY

Secularization of myth and mythology. Deciding the extent to which there has actually been any secularization of myth involves a problem of definition. If myth is seen as the product of a past era, it is difficult to determine at what actual moment that era ended. Thus, it is virtually impossible to state precisely when a certain mythical theme becomes a mere literary theme or to determine in general when myths are no longer being created. It is more fruitful to recognize that symbols, myths, and rituals are all subject to change over time. Nor is secularization an irreversible process. It is instead a process that takes place time and again. Secularization movements and movements toward "mythification" of a phenomenon, narrative, or idea are aspects of the same historical processes. There have also been many types of secularization; the one brought about in Western society since the Middle Ages is only a single example. Another instance was the development in archaic and classical Greece (sometimes referred to—with great oversimplification—as a movement "from myth to reason") whereby fundamental questions about the nature of the universe came increasingly to receive answers in terms of philosophical, as opposed to mythical, reasoning.

On the other hand, although the secularization of modern times is not a unique phenomenon, it is a new and complex type, to which many factors have contributed. Scientific, particularly astronomical, discoveries of the late medieval and Renaissance periods were accompanied by a new trust in cosmic laws and an increasingly abstract notion of God. More or less Euhemeristic historical accounts that were common in the Middle Ages and were a symptom of a certain secularization process themselves gave way to history writing, focusing on psychological, social, and economic facts. In philosophy, naturalism of various sorts opposed notions of transcendence that earlier systems had taken for granted. The most common tendency in modern society has been to regard the characters and events in mythical accounts as not real or as by-products of realities that are not transcendent but rather immanent.

Secularization with mythification

This secularization in modern society, like earlier secularization processes, is accompanied by a process whereby new myths are formed (see below *Political and social uses of myth*).

Demythologization of major religious traditions. Demythologization should be distinguished from secularization. Every living mythology must come to terms with the world in which it is transmitted and to that extent inevitably goes through processes of secularization. Demythologization, however, refers to the conscious efforts people make to purify a religious tradition of its mythological elements. The term demythologization (*Entmythologisierung*) was coined by Rudolf Bultmann, a German theologian and New Testament scholar. In the strict sense of the word, demythologizing efforts have been limited to theological discussions in 20th-century Christianity.

Even after secularization has taken place a certain mythological residue may persist. Edward B. Tylor, one of the founders of anthropology as an academic discipline in the 19th century, coined the use of the word survival for customs and beliefs that continued to be adhered to long after the context in which they had had their meaning had ceased to exist. Because such customs and beliefs may be regarded as mere superstitions, the word survival usually has a slightly derogatory overtone. There are many survivals of myth in this sense. The myth of "the noble savage," well-known from the 18th-century writer Jean-Jacques Rousseau, can be understood as a survival of a paradisiacal mythology: Western man expecting to find evidence of paradise on earth.

The secularization process in modern times has affected symbolic behaviour (cult, ritual, liturgy) and symbolic objects (sacred places) more than myth, however. Nevertheless, commonly accepted forms of mythology in modern society do not permeate all parts of society or fulfill all needs. (In all likelihood, no society has ever been perfectly homogeneous in its myths.) At the same time there exist profound mythological needs in modern society, and some are filled by myths borrowed from submerged or alien traditions. Modern society's neglect of cosmic symbolism (which in contrast was widespread in archaic tradition) has provoked certain reactions, such as the continuing interest in astrology, which may even be seen as an attempt to present a coherent account of the cosmos. And the huge scientific advances of the 20th century have given rise to a literature, science fiction, that resembles myth, even down to an eschatological element.

Political and social uses of myth. In the industrialized Western society of the 20th century, myths and related types of tales continue to be told. Urban folklorists collect stories that have much in common with the tales collected by the Grimm brothers, except that in the modern narratives the lone traveler is likely to be threatened, not by a werewolf, but by a phantom hitchhiker, and the location of his danger may be a freeway rather than a forest. Computer games use sophisticated technology to represent quests involving dragons to be slain and princesses to be saved and married. The myth of Superman, the superhuman hero who saves the world and preserves "the American way," is a notable image embodying modern Americans' confidence in the moral values that their culture espouses. Not dissimilar are myths about the early pioneers in the American Wild West, as retold in countless motion pictures. Such stories often reinforce stereotypical attitudes about the moral superiority of the settlers to the native Indians, although sometimes such attitudes are called into question in other movies that attempt to demythologize the Wild West.

A particular illustration of the power that myths continue to exert was provided as late as the 1940s by the belief

in the existence of an Aryan racial group, separate from and superior to the Semitic group. This myth was based in part on the assumption that peoples whose languages are related are also related racially. The fact that this assumption is spurious did not prevent the Aryan myth from gaining wide acceptance in Europe from the 18th century onward, and it was eventually to provide a supposed intellectual justification for the persecution of the Semitic Jews by their Aryan Germanic "superiors" during the period of Nazi domination. This episode suggests that, in politics, a myth will take hold if it serves the interests and focuses the aspirations of a particular group; the truth or falsity of the myth is irrelevant. In a sense, of course, this function is merely an extension of its more general role in religion, where a myth, as well as addressing questions such as a society's place in the cosmos, may serve to justify a particular kind of governmental organization.

Myths and ideologies

Although politics is often regarded as having taken over the role once played by religion or myth in Western society, the situation is more complex than such a generalization would imply. Just as myth has always had a strong social and political element, so political movements and theories have mythical dimensions. For instance, a mythological component has always been important in keeping political units together, from villages to nations. Recently, however, this mythical dimension has gained prominence with the rise of competing mythlike ideologies such as capitalism and communism; the word ideology might indeed be replaced, in much contemporary discussion about politics, by the term mythology. Finally, crucial terms in modern sociopolitical discussion, such as freedom and equality, although they have a long and complex philosophical history, are often posited in a manner analogous to the function of myth presenting its own authority.

Animals and plants in myth

Relationships between man, animals, and plants

Animals and plants have played important roles in the oral traditions and the recorded myths of the peoples of the world, both ancient and modern. This section of the article is concerned with the variety of relationships noted between man and animals and plants in myths and popular folk traditions and in so-called primitive and popular systems of classification.

Man has always been intrigued by the problem of boundaries: what distinguishes him from another man; what marks off his culture from another; what the dividing lines are between man and plants, man and animals, or man and his gods. At times he has maintained a rigid sense of separation and viewed the breaking of distinctions as transgression. At other times he has sought to cross the boundaries in order to gain power or knowledge. In some myths, he has glorified an age when distinct categories had not yet come into existence, and he has yearned for a return to this paradisiacal condition. In other traditions, he has viewed with horror the monsters that result when different spheres of being are mixed.

According to a view prevalent in many traditional societies, man was formed by the gods. His history is given in the myths of the primordial establishment of things, and his solemn responsibility, along with every other living thing, is to fit himself within this given world. This does not mean that people living in such traditional societies lack distinctions. Among the African Lele, for example, animals are distinguished from man by their lack of manners, their immense fecundity, and by their sticking to their own sphere and avoiding contact with humans. Animals that violate this third characteristic are understood to be human-animals, the product of sorcery or metempsychosis (transmigration of souls).

Man's relationship to nature and the divine

The Great Chain of Being that dominated Western thought throughout the Middle Ages made man both the highest of the animals and the lowest of the gods. Man's body was like that of the animals: corporeal, sensate, and mortal. Man's spirit or intellect resembled the gods: incorporeal, rational, and immortal. The great surge of ethnological and biologic data and theories from the 16th century on tended to undermine this point of view. New forms of men were encountered (*e.g.*, the "savage") who seemed to their first describers closely akin to the brute; new biologies were proposed that placed man wholly within the animal kingdom, merely as one species among many, and postulated man's descent from animals. More recently, psychology and ethology have emphasized the irrational (or brutish) elements in man and suggested close analogies between animal and human behaviour. Since the 18th century man has been defined in a new, nonbiological way: as a cultural being rather than as the inhabitant of a natural realm. There have been many forms of this dichotomy: man is the only being who has a language, uses symbols, employs tools, freely plays, is self-conscious, or possesses a history. Man, in short, creates himself as a cultural being in distinction to the animal or plant, which is created by its environment or heredity. These questions of man's identity and the way he resembles or differs from other sentient beings may be found in every culture and during every age.

Man is a creature who tends to draw boundaries, both conceptually and practically. Not only does his being demand that he find a position in a complex system of relationships but also his social life and his biologic survival depend on the making of distinctions. To speak with the gods, have relations with another human, take possession of another's territory, or eat this or that plant or animal involves man in a host of decisions upon which his existence depends. One of his chief resources for answering such questions is that of the myths and legends mapping the world in which he dwells.

Myths and legends concerning animals and plants employ a wide variety of motifs but express a limited number of relationships. Man, animals, and plants may stand in a relationship of (1) opposition or difference, (2) descent, (3) mixture, (4) transformation, (5) identity, or (6) similarity. These are determined by and expressive of the total worldview of a people. The hunter, for example, has a different understanding of the animal from that of the agriculturalist or pastoralist; the tuber planter has a different view of plants from that of the cultivator of grains. Even within these broad categories sharp differences occur. The Kalahari San of southern Africa, who, alone, naked, and crawling on the ground, blends in with his environment in order to kill an animal for food, reveals a way of looking at man's relation to nature different from that of the Masai tribesman of eastern Africa, who, costumed and walking upright as part of a line of chanting hunters in order to slay a lion as a symbol of his manhood, stands forth visibly as the ruler of the world through which he moves. The Cretan bull dancer of ancient Mediterranean culture, playing with the animal by somersaulting over his back, expresses a conception of man's relation to this powerful animal and the forces of fecundity and death that it symbolizes different from that of the Spanish bullfighter who slays the beast.

RELATIONSHIPS OF OPPOSITION OR DIFFERENCE

The fundamental religious boundary is that between the sacred and the profane, the sacred being conceived of as a sphere of power superior to or opposed to the mundane. That which is sacred may be either creatively or chaotically powerful. If the former, it is primarily expressed in creation myths; if the latter, in demonic traditions.

Cosmogonies. The notion of a creator deity in animal or plant form is comparatively rare. There are stories of animals, birds, or insects creating the world and of creators with animal attributes or animal companions, but these are isolated traditions. Even in the widespread motif of the birth of the world from a cosmic egg there is rarely the notion of a bird laying or incubating the egg (the most notable exception is the world egg laid by a beautiful bird in the beginning of the *Kalevala,* the national epic of Finland). There are, however, a number of cosmogonic (origin of the world) motifs that employ a fundamental animal or plant symbolism: the cosmic tree that supports and nourishes the world; the earth surrounded by a serpent or supported on a turtle or on some other animal's back; the features of the present world created by the actions of some primeval animal—*e.g.,* lakes and rivers caused by

the digging of an animal or hills raised by the flapping wings of a bird. Sacrificial motifs abound, such as the world being formed from the cut-up parts of an animal or restored by its primordial sacrifice.

Animals in opposition to creation

A number of important traditions associated with animals occur in dualistic creation accounts in which animals oppose creation, acting as a foil to the creator, or creation is accomplished by combat between the creator and animal monsters representative of chaos who must be slain or bound before the world can be established. The widely distributed earth-diver myth is the most familiar example of dualistic creation (see above *Myths of origin*).

Other oppositions occur with respect to the creation of man (see below *Relationships of descent*). Perhaps the most frequent myth of the origin of death is that of the "perverted message" or "two messengers." In one, an animal is sent with a message from the creator that man is immortal, but the animal alters the message to state that man must die. In the other, two animals are sent, one with the word that man is immortal, one with the message that man will die. A mishap occurs to the first, and only the fatal message reaches man.

Union of disparate features expressing a creative totality

In some traditions, there is a union of disparate features or opposites in a given mythic being. This does not express a chaotic hybrid but rather a creative totality (the "coincidence of opposites"). Though most frequently expressed by androgyny (having both male and female characteristics), either in traditions of an androgynous creator or first man, the theme is present in some animal and plant traditions as well (*e.g.,* the emergence of man from the androgynous *rīvās* plant in Iranian mythology). Although it occurs in cosmogonic settings (*e.g.,* the tree that unites heaven and earth), motifs of the reconciliation of animal and plant opposites more usually occur in paradisiacal imagery that promises the harmonious mingling of realms (*e.g.,* the "peaceable kingdom" of Isaiah 11:6–8 or Virgil's Eclogue IV).

Animal and plant deities. Belief in sacred plants or animals is widespread. Common to all of these is the notion that the plant or animal is a manifestation of the sacred and thus possesses the dual attributes of beneficence (in healing, hunting, or agricultural magic) or danger (as expressed in taboos against their destruction or consumption). More rarely, gods are believed to have animal (theriomorphic) or plant (phytomorphic) forms. Influenced by ancient Greek disparagement of contemporary Egyptian religion and Judeo-Christian antipathy to "idolatry," Western scholars have tended to speak of such traditions as "animal worship," although it is usually not the animal itself but rather the sacred power revealed by the animal that is being revered. Other deities possess animal or plant attributes or are incarnations associated with particular animals or plants. Here the animals or plants possess a symbolic function. Certain qualities are associated with certain species (*e.g.,* wisdom with the owl, strength with the lion, immortality with the eagle, inspiration with the grape), and the god's possession of these qualities is indicated by his being identified with the appropriate animal or plant. In other traditions, natural phenomena are associated with the actions of certain species (*e.g.,* wind as a bird, lightning as a snake), and the god who controls such phenomena is identified with the species. At times, the animal or plant achieves a divine identity of its own—*e.g.,* the thunderbird or the earthquake monster.

Western attitudes toward animals and plants as manifestations of the sacred

Hunting and agricultural deities. In the traditions of archaic hunting peoples there is frequently a figure whom scholars term the master of the animals or the protector of game. He is the ruler of the forest, of all animal species, or of only one particular species (usually a large game animal—*e.g.,* the northern master of the caribou). The master controls all game animals (frequently by penning them up). He dispenses a certain number to man as food and can be invoked by a shaman when he withholds game. He guides the hunter and, in some traditions, avenges the spirits of slain animals, whose souls return to his enclosures when they die. He is sometimes pictured in human form, on occasion having animal attributes or riding an animal; in other traditions, he is a giant animal or can assume animal form.

In a related complex, a deity in animal form demonstrates to man the art of hunting, serving as the first victim (a motif found in some of the American Indian bear mother or buffalo woman tales). Or the deity appears among men as an animal who must be slain and eaten so that he may return to his heavenly home (*e.g.,* the Ainu Iyomante feast in Japan).

A similar pattern is found among archaic agricultural peoples. An ancestral (*dema*) goddess, at times in plant form, produces food asexually from her body. She is slain by the tribe, and from the dismembered portions of her body crops appear.

The archaic pattern of the *dema* deity needs to be distinguished from the widespread tradition among technically more sophisticated agricultural peoples of the bountiful mother earth or the god or goddess of vegetation or special crops. In the latter case, the deity, frequently depicted or associated with the appropriate animal and vegetative characteristics, is the principle of inexhaustible vitality. The god frequently has a human consort who participates in a sacred marriage in order to gain fecundity for man (this happens in ancient Mesopotamian religions, for instance).

The functions of the culture hero

Culture heroes. The master of the animals or corn mother is frequently found in association with animal culture heroes. An animal or trickster who can assume animal form secures for man the various attributes of culture (acting either in consort with or opposition to the gods). These traditions are found in etiologic stories about how man first learned to hunt, discovered tobacco, and accomplished other things. The most frequent motif is that of the animal who stole fire from the gods for man. Frequently, such traditions lie behind etiologies of specific animal or plant characteristics; *e.g.,* the bat is black and blind because it stole fire and was singed by the flames and blinded by the smoke. In other tales, the animals oppose the acquisition of culture by man and must be overcome by a human culture hero.

A closely related theme is the myth of a life-giving tree or other healing magical plant, growing in paradise or some other inaccessible place, to which the culture hero must travel in order to gain a boon for mankind. He is frequently assisted by or has to overcome supernatural animals. This is an especially widespread type of myth, with numerous instances found throughout the world.

Demonic plants and animals. Opposed to these positive conceptions of the creative powers of plants and animals is the notion that their sacred power is chaotic or demonic. Rather than aiding man, they are destructive. The most common examples are monstrous plants and animals, which figure especially in heroic quests as guardians of boons or threats to be overcome; mythical animals associated with destructive natural phenomena, such as the earthquake monster or the monster who according to some traditions causes eclipses by devouring the Sun or Moon; and personifications of evil powers such as death or disease (*e.g.,* the hound of hell) or chaos beasts (such as dragons) whose release marks the end of the world or who will be slain in a final battle by a saviour deity. A universal phenomenon is the association of certain species of animals with sorcerers and witches. The most frequent form of this belief is that of the familiar—an animal whose soul is bound up with that of the sorcerer, whose form the sorcerer can assume, and who may be commanded to serve his evil master.

Dragons and familiars

Some species (*e.g.,* animals such as the serpent and various narcotic plants) exhibit the ambivalence of the sacred—they are conceived as being both beneficent and dangerous. This reflects a crucial aspect of the sacred—that it is a region of power. As was stated above this power is ambivalent—*i.e.,* it can act for mankind's benefit or detriment—and is perceived therefore as the location either of creativity or of chaos.

RELATIONSHIPS OF DESCENT

One of the major ways man has of organizing his world is through genealogy or relations of descent. In theogonies, or tales of the origin of gods (*e.g.,* that by Hesiod), or in legendary lists of human offspring (such as the genealogies

in the Old Testament), relations of descent and the association of characteristics, territories, and spheres of influence with descendants provide a means of mapping the cosmos and the human world. In traditions concerning animals and plants, relations of descent are most prominent in myths of the origin of man and in totemic (animal-clan relational) materials. Central to both is the figure of the plant or animal ancestor.

Creation of man from plants or animals. A widespread motif, especially among archaic peoples, concerns man's supposed descent from plants or animals. These descent traditions usually name a particular species as man's ancestor, and the tribe frequently takes its name from the plant or animal.

In some myths, an asexual mode of creation is implied; a child, for example, appears from the bud of a tree or from a split fruit, or man is a featherless bird sent from the sky. Even the motif of the birth of man from an egg is predominantly an asexual motif inasmuch as no preliminary coition is mentioned. Other traditions, particularly agricultural ones, see man as the product of the mating of a plant or animal species. In some myths, fabrication rather than descent is emphasized. Man is fashioned from a plant or animal by the gods, or his parts are modeled after other species. In these descent traditions, the primal man who results is usually the progenitor of a particular people. Other peoples are created from different or less favourable species. These traditions persist in folkloric accounts of the birth of individuals from plants or animals. Such myths express a close relationship between man and the animal and plant world. Man does not represent a new type of being but rather a new manifestation or form.

The widely distributed notion of animal or plant ancestors places considerable emphasis on transformation (see below *Relationships of transformation*). The ancestral myths describe a primeval time of creation (or successive creations) followed by a decisive alteration in the conditions of life in the shift from the ancestral to the present human mode of being. Compared with the "fixed" characteristics of the present period, the ancestral era is represented as having been one of flux, lacking definite boundaries. In it animals, plants, and men are much the same: they can speak with each other, have sexual relations with each other, and engage in other relationships. The ancestors are polymorphic (many formed) and are frequently depicted as emerging from the ground. In such cases their movement toward the surface is represented as an increasing differentiation, away from compound hybrids and toward forms somewhat resembling present species. But even on the surface, the ancestors remain relatively fluid; some resemble plants, others animals or men, and all have shared characteristics and the power to change their form at will.

The ancestral era

The ancestors are depicted as primordially powerful beings, but due to a variety of causes their world becomes transformed, and the present order of things comes into existence. Human culture and the decisive features of the world as man now knows it are established during the transformation: man's labour, sexuality, and death are due to some action of the ancestors; the topography of the land is the "tracks" left by the ancestors; men, animals, and plants are depicted as having received their present form after the ancestral age.

Totemism. The relations to an animal or plant ancestor are frequently associated with the complex phenomenon of totemism. Totemism is primarily a social relationship. It expresses the belief that there is a connection between a group of persons, on the one hand, and a species of animal or plant, on the other. The relationship to the totem (animal or plant symbol) occurs in a variety of forms; associated phenomena (*e.g.*, exogamy, or marriage outside the clan, and taboos against killing the totem species) may or may not be present. The myths associated with such traditions narrate the origin of a social group and the discovery of its totem. It was commonly believed in the 19th century that there was a stage in the development of human thought that could be called "totemic," a stage at which primitive peoples perceived a mystical connection between particular social groups and the animals or plants that were their totems. Totemism apparently covered a bewilderingly wide range of phenomena: the list of totems among the Nuer, for instance, includes lion, waterbuck, tortoise, papyrus, rafters, and certain diseases. Utilitarian explanations for the choices of totems—"good to eat," "useful," etc.—do not fit the ethnographic data, and to say that the totems are chosen because they have some special mystical significance is merely to rephrase the problem, without identifying why only certain items have mystical significance. In *Le Totémisme aujourd'hui* (1962; *Totemism*) Lévi-Strauss advocated a different approach. He suggested that totemism, far from being a special stage in human development, was merely an instance of the use, within so-called primitive systems of classification, of objects and categories from the world of everyday experience to divide and order that experience.

A phenomenon that has, at times, been confused with the social relations of totemism is that of the individual guardian. It involves a relationship between a particular person and a particular species, usually revealed to the individual in a vision, such as in the vision quests among the North American Plains Indians. These guardians become a source of knowledge and good fortune for the individual. To these traditions, other folkloric motifs may be related, such as the birth of various individuals from intercourse between humans and animals or plants; the animal wife; animal nurses; or the ability of certain persons to understand or converse with animals or plants.

Hierarchy. The fluidity of boundaries characteristic of relations of descent raises important questions as to the status of man or of culture in relation to nature. Are animals and plants more like men than not? Is the human world superior to or inferior to the natural sphere? Such questions lie behind a variety of motifs associated with descent traditions: that the first men were undeveloped, amorphous, or resembled animals; that animals resisted the creation of man; and that the primordial man is the ruler of the natural world. The characteristic fluidity of the descent traditions persists in traditions such as the wild man and in relations of transformation and identity (see below).

The status of man and culture in relation to nature

RELATIONSHIPS OF MIXTURE

For some societies boundaries and the maintenance of distinctions guarantee the continued existence of the cosmos as an integrated totality. There are rituals that periodically reenact the original process whereby the cosmos was divided up and established in its present form. In such cases a new beginning, for example New Year's celebrations as carried out in modern Western society, re-create the original beginnings of things as they are today. Other rituals foster remembrance of the decisive deeds of the ancestors in fixing the present state of things; ritualized social structures (such as the caste structure of India) maintain a complex system of distinctions; and religious ideologies (such as astrology) foster the notion of spheres of power that control all members of a class, be they gods, planets, animals, plants, minerals, or men. In such societies, to be real is to affirm and repeat the structures of the cosmos. Each being is called upon to dwell in a limited world in which everything has its given place and role to fulfill. To be sacred is to remain in place. To break out, to cross boundaries, is to open the world to the threat of chaos, to commit transgression. Associated with this worldview is the notion that the mixing of realms is the result of evil influence and leads to monsters, hybrids, and uncleanliness. An alternative view in the history of religions sees positive sacred power to be gained from the violation of the given boundaries of the world. Each being, in such a view, is called upon to challenge its limits; to break them and to create new possibilities for existence, to achieve freedom. Associated with this view is either the necessity for a periodic loosening of restraint or the celebration of gods or sacred persons who have achieved freedom. Religiously expressed, for the one view, the sacred is the ordinary, that which remains in place; for the other, the sacred is the extraordinary, that which is not restricted to its allotted place.

These two points of view—*i.e.*, that power comes from

conformity to class or freedom from class—may be illustrated by the widespread category of taboo. Research in the second half of the 20th century has led to the conclusion that taboo is primarily a taxonomic (classificatory) system.

Proscriptions against crossing boundaries

Those things that are forbidden involve the crossing of boundaries or are beings that fall between classes. Thus, one may not with impunity enter other spheres (*e.g.,* the realms of the gods) or touch sacred objects, transport an object from one realm to another, cross sexual or class lines, or have relations with a being not of one's class. Many food taboos have been shown to reflect taxonomic anomalies. An animal such as the bat is tabooed because it has fur like a mammal but flies like a bird; it has wings like a bird but has fur rather than feathers—and therefore is neither mammal nor bird and must be shunned. On the other hand, the consumption of forbidden foods or engaging in forbidden sexual practices (including homosexuality and bestiality) is part of the ritual of transcendence in many cultures. If an individual can survive the crossing of boundaries, he will obtain extraordinary sacred power (*e.g.,* adherents of Tantrism, a system of esoteric practices performed in both Buddhism and Hinduism, who violate both eating and sexual taboos; the Jewish magicians mentioned in the Old Testament Book of Isaiah, chapter 65, who eat the forbidden swine and say ". . . do not come near me, for I am holy").

From the earliest times man has shown a readiness to be fascinated by monsters. Monsters are chaos beasts, lurking at the interstices of order, be they conceived as mythical creatures who preceded creation, survivals from an archaic era, creatures who dwell in dangerous lands remote from human habitation, or beings who appear in nightmares. Though the forms and types of monsters are numberless, a single principle holds good for the majority of them: a monster is out of place, conforming to no class or violating existing classes. This is most frequently expressed by the monster's having hybrid form (the result of a mixture of species, attributes, sexes, and other categories), being the result of a transformation, or having dislocated or superfluous parts. Because modes of locomotion and other bodily characteristics are prime modes of classification, the superfluity or lack of organs removes the monster from the ordinary taxonomic divisions. The dragon, for example—perhaps the most widespread monster in myth and folklore—is born through a mixture of species: it is a serpent born asexually from a rooster's egg incubated in manure; by the transformation of an animal; or by the joint generation of a man or worm and a metal. Its form is a compound of species: the body of a serpent or crocodile with the scales of a fish; feet, wings, and occasionally the head of a bird; the forelimbs and occasionally the head of a lion; or, in another dominant type, the ears of an ox, the feet of a tiger, the claws of an eagle, the horns of a deer, the head of a camel, the eyes of a demon, the neck of a snake, the belly of a mollusk, and the scales of a fish. In other types of dragons, organs or attributes of the snake, lizard, fish, mollusk, toad, elephant, horse, pig, ram, deer, eagle, falcon, octopus, or whale predominate. In many traditions, the dragon has the power to transform itself at will. Its possession of superfluous organs is most frequently expressed by its being many headed, and it has both subterranean and aerial characteristics and habits.

Generation of the dragon

The most common hybrid monster generally mixes differing species—*e.g.,* the Centaur (horse-man), the Minotaur (bull-man), Echidna (snake-woman), Pegasus (horse-bird), Sphinx (woman-lion-bird), Siren (bird-woman), and Empusa (animal-metal) of Greek mythology and the griffin (lion-eagle), mermaid (woman-fish), vegetable lamb (plant-animal), barnacle goose (mollusk-bird), and mandrake (plant-man). In other instances, the characteristics are juxtapositions of different species—*e.g.,* the tree that bears human heads as fruit; horses born from eggs; flesh-eating mares; milk-producing birds.

The most extreme form of the fluidity that is characteristic of monsters is the Protean figure who can change into any form or combination of forms at will. In all of these monstrous forms, the central notion appears to be the danger associated with beings that are out of place or are fluid. But some contemporary anthropologists have argued the opposite conclusion; *i.e.,* rather than being threats to the classificatory system, monsters, through their startling combinations and juxtapositions, force men to think more clearly about and distinguish more sharply between the different boundaries of their world. In this interpretation, the monsters are ultimately supportive of order rather than a destructive threat to it.

RELATIONSHIPS OF TRANSFORMATION

One of the largest groups of animal and plant traditions in folklore and religious material is that of transformation. Familiar stories—such as Beauty and the Beast; the transformation of a man into an ass in the *Metamorphoses* by Apulcius, a Roman writer of the 2nd century AD; the frog king or the swan maiden, as well as such well-known traditions as that of the werewolf, the vampire, or leopard man—testify to the wide dissemination of this theme. Every permutation and combination exists: man into mammal, bird, fish, insect, reptile, amphibian, or plant; animal into man or plant; animal into another species of animal; or plant into animal. There are also partial transformations resulting in hybrid forms as well as alternating transformations—*e.g.,* animal, man, or tree by day and the reverse at night. Another great series of transformations concerns the dead, who either transmigrate into or return in animal and plant forms.

The power to compel another to change form, or to cross boundaries oneself at will, may be judged good or evil depending on the assessment of order in the worldview of the particular culture. In the majority of instances of transformation of another, the transformation is considered to be the result of evil magical powers, and most tales conclude with the disenchantment of the subject, his release from the evil power, and his return to his original form. Many of the instances of self-transformation are for the positive purpose of transcendence.

Several of the motifs present in the folklore of transformation suggest cultic procedures (*e.g.,* transformation into an animal by putting on its skin). Cultic practices probably lie behind and lend credibility to many such tales.

Ritualized moments of transition

In many societies, ritual change involves a transition period in which boundaries are broken and chaos rules, only to be overcome as order is restored. This is common in festivals in which the social order is temporarily suspended or reversed (as in the ancient Roman Saturnalia and the carnival celebrated in many Roman Catholic countries) and in rites of passage (such as initiation). Animal and plant transformations play a significant role in such ceremonies, both as negative symbols of chaos (*e.g.,* return of the dead in animal form to mingle with the living; ritualized combats against the primordial dragon) and as positive symbols of the breaking through of bounds and the release of the forces of life (*e.g.,* the presence in many of these ceremonies of young males dressed as animals who engage in sacred sexual intercourse). Prominent in such Saturnalian traditions are deities such as the Greek god Dionysus, who can assume vegetable, animal, or human forms at will, who is a god of sudden, dramatic epiphanies (manifestations) and license, and whose devotees, through orgiastic rituals, participate in his freedom to break all bounds in order to recover the boundless vitality and fecundity of primordial chaos. A new life for the cosmos, society, and the individual is supposedly obtained through the abolition of the order of the old.

Initiation ceremonies make use of transformations to a somewhat different end. The initiant receives new birth by the dying of his old self after a series of ordeals. Antagonists, frequently in masked animal form, torment him, and his "death" and rebirth are analogous to the hero's successful fight against monsters. Alternatively, the culmination of initiation is frequently the narration of the myths of the ancestors and the vision of them. Masked men, in mixed animal and plant forms, appear to the initiant to remind him of his true origin as opposed to his biologic origin as a product of his parents. (Other ritual uses of masks achieve the same effect: the ritual transformation of the "actor" into the sacred animal, plant, or deity.)

Frequently, although the nomenclature for plants and animals is learned by a child from birth, the logic of the

system is revealed only at initiation, at which point the initiant, as an adult, becomes responsible for the proper observance of all the boundaries required by his society (*e.g.,* among the Senufo of Africa, 58 figurines are presented to the initiant in a carefully prescribed order that provides an inventory of the basic classes of animals, men and human activities, and social distinctions).

The role of the shaman

Within many cultures there are religious specialists in the breaking of bounds. Perhaps the most widespread example is that of the shaman who is deemed able to journey at will to heaven or the underworld, mingling with both the gods and the dead. His journey occurs through magical flight (frequently in the form of a bird) with animal psychopomps (soul conductors) or guardians or by ascending the sacred tree that connects heaven and earth. The shaman may transform himself into an animal and know how to converse with animals. Another similar phenomenon is the existence of leopard societies in Africa. In these a practitioner is believed to be able to transform himself into an animal frequently considered to be his incarnate "second self."

RELATIONSHIPS OF IDENTITY

Works on the supposedly primitive mentality published in the 19th and early 20th century usually presumed that primitive man could not distinguish between plants, animals, and men. This "hazy vision," as it was often called, was believed to lie at the root of religious phenomena such as animism (belief that inanimate objects and natural phenomena have souls) and totemism. More recent studies have demonstrated the presence of complex taxonomies among peoples sometimes described as "primitive," although they do not usually employ the criteria of a modern biologist. Relations of identity, when compared with the other forms of relationship already described, are comparatively rare, occurring most frequently in traditions about the soul. Relations of similarity are more common, usually in literary settings, such as plant or animal fables. The most common expression of identity relates the soul of man to that of animals or plants.

Soul-stuff. Although man tends to associate the soul with personal survival or continuity after death, there is an equally ancient view that emphasizes the continuity of life. This view, to which the Dutch anthropologist Albertus Christiaan Kruyt gave the term soul-stuff (a term he contrasted with the postmortem soul), is chiefly found among the rice cultivators of the Indonesian culture area, although it is also witnessed elsewhere. Central to this belief is the circulation of vitality throughout different levels of existence. The soul-stuff is created by the deity as an indestructible reservoir of life. It is eternally reborn—either by returning to its creator, who will redistribute it, or by transmigrating into an embryonic human, animal, or plant. Whatever form it assumes, the same "stuff" is common to all beings.

Death, or postmortem, soul. The majority of traditions concerns the postmortem soul, which leaves the body or comes into existence only after death. A number of motifs reflecting different assessments of the nature of life and death occur. The soul may assume an animal or plant form or there may be animal psychopomps, most frequently a winged creature such as a bird or butterfly. The soul may transmigrate into or be reincarnated as an animal or plant. These traditions need to be distinguished from those concerning spirits of the dead who reappear in animal form. Related to these are traditions about the separable soul, which is capable of removing itself or being removed from a person while still living. This most usually occurs in sleep. While detached it may be placed in or assume the form of an animal or, more rarely, a plant. In general, where the notion of soul-stuff predominates, relations of identity are prevalent; where the notion of a death soul is present, the traditions are more closely akin to relations of transformation (see above).

Psychic interrelations

Plural souls. A more complex pattern, of wide distribution, is that of the plurality of souls. Man's vitality and personality are viewed as the result of a complex set of psychic interrelations. A classic example is that of the Apapocuva-Guaraní of Brazil, as described by the anthropologist Curt Nimuendajú: a gentle vegetable soul comes, fully formed, from the dwelling place of the gods and joins with the infant at the moment of birth. To this is joined, shortly after birth, a vigorous animal soul. The type of animal decisively influences the recipient's personality: a gentle person has received a butterfly's soul; a cruel and violent man, that of a jaguar. Upon death, the vegetable soul enters paradise; the animal soul becomes a fierce ghost that plagues the living. The plurality of souls provides a complex taxonomy accounting for and relating the distinctive character traits of plants, animals, and men.

The alter ego, or life index. Other religious and folkloric traditions view the life of man as bound up with that of a plant or animal: if one is destroyed the other dies as well. In some traditions, this is confined to the familiar or guardian of a witch or shaman; in others, it is an individual relationship possible for any man. An example of the latter relationship is nagualism, a phenomenon found among the Indians of Guatemala and Honduras in Central America. Nagualism is the belief that there exists a nagual—an object or, more often, an animal—that stands in a parallel relationship to a person. If a man's nagual suffers harm or death, the man suffers harm or death as well. According to one story, during the initial hostile encounters between the Indians and the Spaniards, the Indians' naguals fought on their side against the invaders. When the nagual of the Indian chief—which was in the form of a bird—was speared and killed by the Spanish general, the Indian chief died at the same moment.

Nagualism relates the life of each individual to the life of an animal or other object. More rarely, there is a relation between an entire tribe and a particular plant or animal. In some societies, a ritual of identification is performed, usually at birth (*e.g.,* planting a tree or burying the placenta at the roots of a tree). In others, an individual has a vision or undertakes a vision quest to identify his alter ego.

RELATIONSHIPS OF SIMILARITY

Relations of similarity between human beings and plants or animals usually depend upon the perception of an attribute or aggregate of attributes that they have in common. This process is apparent in colloquial expressions such as when someone is called a "cool cat," a "bitch," a "clumsy ox," a "greedy pig," or "foxy." A similar process appears to lie behind many of the so-called totemic names or theriophoric or phytophoric personal names (*e.g.,* Swift Deer, Bold Eagle) and is concealed in a number of familiar Western names (*e.g.,* Leo, "the lion"; Deborah, "the bee"; and Jonah, "the dove"). The reverse process, the giving of human names to plants or animals, also depends in a majority of instances on the discernment of character similarities. Care must be used, however, in the interpretation of proper names. Every plant or animal name does not necessarily reveal the perception of similarity. For example, the Seminole Indians combine a character name with a shape and animal name in an arbitrary fashion that appears to pay no attention to their meaning, resulting in unusual combinations such as that of a well-known Seminole medicine man whose name translates as "crazy, spherical puma."

Function of fables

The same process is at work in the universal literary form of plant and animal fables. The fable depends for its point upon the association made by the reader or listener between himself and one of a limited number of characteristics possessed by each animal or plant. More complex forms, verging on allegories, such as the beast epic and the debates between various plants and animals as to which are superior, also exist. The popular *Physiologus* ("Naturalist"), a Greek work from the 2nd century AD, and the medieval bestiary traditions draw morals particularly from monstrous or wondrous animals and plants. Both the fable and the bestiary traditions contributed to the formation of the stereotyped bird, beast, and flower emblems that figure in heraldry and religious iconography.

The process of discovering similarities of personality between plants and animals, on the one hand, and human beings, on the other, also plays a significant role in certain archaic sciences. Physiognomy, which claims to find correspondences between bodily features and psycholog-

ical characteristics, often makes use of such supposed similarities. The earliest Western systematic treatise, the Aristotelian *Physiognomonica,* maintains that people with facial characteristics resembling certain animals have the temperaments ascribed to those animals (*e.g.,* persons who have noses with slight notches resemble the crow and are impudent just as the crow is). These views persist in popular figures of speech, such as "bulldog jaw." The same structure underlies the use of plants and animals in archaic healing practices, alchemy, and astrological tables in which animals, plants, and minerals, as well as human personality traits, are associated with the birth signs of the zodiac or planets.

Names

A name is a word or group of words used to refer to an individual entity (real or imaginary); the name singles out this entity by directly pointing to it, not by specifying it as a member of a class. For instance, it is possible to refer to the same entity, in this case a river, in two distinct ways: (1) "The Colorado is a beautiful river," and (2) "The river that flows through Austin is beautiful." Because there is only one river that flows through Austin, Texas, the subject of sentence 2 is unambiguously identified, and the reference of the sentence is fully individual. The subject of sentence 2, however, is not a name but rather a nominal (noun) phrase that specifies one member of the whole class of rivers by indicating a unique property of it. The word Colorado in sentence 1, on the other hand, is a name, because it directly points to the specific river. The fact that there is more than one river called Colorado, and that more specific information is sometimes needed to identify the one being discussed (*e.g.,* "I prefer the Texan Colorado to the California one"), does not change the status of "Colorado" as a name, because each of the two rivers is referred to in the way required by the definition.

The article is divided into the following sections:

NAMES AND APPELLATIVES

A general appellative (*i.e.,* a common noun) capable of being used in reference to a whole class of entities can also be used with an individual reference. For instance, if an inhabitant of Austin, Texas, says, "Let's go swimming today, not in the pool but in the river," there is no doubt that the word river has a unique, individual reference to one single river, namely, the Colorado. This fact, however, does not make a name out of it; "river" is here a common noun, but its reference is specified by the extralinguistic context of the situation in which the sentence was said. Some names seem to belong more to the category of appellatives than to the category of names like Colorado in "the Colorado River." For example, names like Big River, Red River, Stony Brook, and Cedar Hill may have their origin in a specific use of a general noun. If a sentence like "After five days of marching, we had to cross a river, the big one, not one of the smaller ones" is used very often, the name Big River may result. Such names are more frequently given as directly descriptive names. The similarity of names of this type with expressions like those exemplified in sentence 2 above is deceptive. There is, after all, more than one big river, so that the specification "the big river" is not complete. The full identification of one single river as the reference is given by the context. Therefore, apart from certain special expressions (like "the big one, not one of the smaller ones"), names like Big River, Red River, and so on have the same status as names like Colorado.

In some languages, a name is differentiated from an appellative (common noun) by formal means. The difference is sometimes indicated by the script; *e.g.,* languages using alphabets such as the Latin, Greek, Cyrillic, Armenian, and Georgian use a capital letter at the beginning of a name. (But, on the contrary, in German all nouns, not only names, are written with an initial capital.) There are examples of a purely grammatical differentiation of names as well, such as the usual absence of the articles "a" or "an" in English; *e.g.,* "Yesterday I saw an archer practicing his art" and "Yesterday I saw (Bill) Archer practicing his art."

Formal means for marking names

The distinction between names and appellatives (common nouns) is generally clear: names are used in individual reference, appellatives can be used in reference to all members of a class or to any number of them (*e.g.,* river, hill, man, girl, car, table, virtue, and so on). Nevertheless, there are some borderline cases. For instance, a nation can be conceived as an individualized entity, so that "Americans," "Englishmen," and "Spaniards" are names; on the other hand, it is clear that other groups of people are not conceived in this way, so that expressions like "soldiers," "sailors," and "clergy" are not names. It is difficult to decide on the status of expressions like the "Baptists," "Adventists," and "spiritists." In a similar way, if all vehicles produced by Henry Ford are Fords and if one can buy an individual Ford as well, is "Ford" a name? It probably is, or approaches that status; but names of this type frequently lose the character of names and develop into common nouns. Expressions like "the Roman Catholic Church," "the Ministry of Education" (of a specific state) also have a dubious position as to their status as real names. The uncertainty in this respect is indicated by the vacillation in the use of capital letters in various languages. This overlapping has a long history and is reflected in modern terminology. The Greeks used the term noun (*onoma*) for both the common noun and the name; when they wished to make a distinction, they specified the name as a proper noun (*onoma kyrion*). It is in this tradition that the term proper noun, or proper name, is used for a name, and noun, general noun, or common noun, for an appellative.

THE SCIENCE OF ONOMASTICS

Categories of names. The science that studies names in all their aspects is called onomastics (or onomatology—an obsolete word). The subject of this science is broad because almost everything can have a name and because the study of names theoretically encompasses all languages, all geographical and cultural regions, and all historical epochs. For practical purposes, some divisions of the subject are necessary; *e.g.,* by language (as the study of Kiowa or Provençal names) or by geographical, historical, or similar partitions (the study of the names in India, of the Levant at the time of the Crusades, and so forth). Another division (usually combined with the preceding ones) is given by the character of the names themselves; in a very broad categorization, names of persons, or personal names, are discerned on the one hand, and names of places, or place-names, on the other. In the most precise terminology, a set of personal names is called anthroponymy and their study is called anthroponomastics. A set of place-names is called toponymy, and their study is called toponomastics. In a looser usage, however, the term onomastics is used for personal names and their study, and the term toponymy is used for place-names and their study. The term toponymy itself can be understood in two ways, even in the exact terminology: either it is taken in the broadest possible way as including inhabited places, buildings, roads, countries, mountains, rivers, lakes, oceans, stars, and so on, or it is restricted to inhabited places (cities, towns, villages, hamlets). If the latter alternative is the understanding of the term toponymy, then the uninhabited places (*e.g.,* fields, small parts of forests) are called microtoponymy; names of streets, roads, and the like are

Divisions within onomastics

called hodonymy; names of bodies of water, hydronymy; names of mountains, oronymy. Additional terms are not generally used (though one occasionally hears words like chrematonymy—names of things).

In any case, different categories of names frequently must be studied together, because there are transitions. For instance, many place-names are derived from personal names (*e.g.,* Washington), many names of planets and stars are derived from the names of mythological characters (*e.g.,* Venus, Mars, Alpha Centauri), and many personal names are derived from place-names, names of nations, and other such names (*e.g.,* Austerlitz, Napoleon's battlefield; French; Scott). There is also a division of names into primary and secondary ones. Neptune is primarily the name of a Roman god; transferred to the name of a planet, it is a secondary name.

Forms of personal names. There are many subdivisions and terms within the category of personal names. Originally, one name was given to a person at an early period of life—in Europe (and later in America), normally at Baptism. This is called either simply the name, the baptismal or Christian name, or the forename; in the United States and Canada it is usually called the first or given name. Because many people received the same name (given name), they were differentiated by surnames (for example, John Redhead, John Hunter, John Scott). Many of these surnames became fixed and hereditary in individual families. These are called either surnames or family names, and in the United States and Canada they are frequently known as last names. Thus the basic pattern is given name + family name, together called the name or the personal name. There are exceptions concerning this sequence. Among the Chinese and Hungarians, for example, the family name precedes the given name: Mao Tse-tung, Nagy István. The Hungarians usually switch the order when they write English; thus, Nagy István becomes István (or Stephen) Nagy. The Chinese, however, maintain the order of family name first.

Surnames and family names

There are variations in the basic pattern. In the United States and Canada the usual practice is to insert another name (frequently expressed in writing only by the initial letter) between the given and the family name. This is the second, or middle, name. It may be the original family name of a married woman inserted between her first name and the last name of her husband, the maiden name of one's mother, as well as other names. In Europe, such a second name is less common and is usually acquired at Baptism (or, eventually, at Confirmation). In most European countries, the first baptismal name is the important one, and the second one (third, and so forth) can be omitted. In German usage, however, the baptismal name immediately preceding the family name is the most important one. For example, if one of the baptismal names in Johann Sebastian Bach or Johann Wolfgang von Goethe is to be omitted, it would be Johann. (But in a sequence like Johann Nepomucenus Nestroy, the shorter form is Johann Nestroy, because Nepomucenus is only an attribute discerning one of the numerous saints who had the name Johann.) British usage varies in this respect, but sometimes follows the German pattern—*e.g.,* W. Sidney Allen.

In a few areas, particularly among East Slavs, the so-called patronymic (*i.e.,* a name derived from the given name of the father) is inserted between the given and the family name. In Russian, if the father's name is Ivan Krylov, then the son's name, for example, will be Pyotr (given) Ivanovich (patronymic) Krylov (family), and the daughter's name will be, for example, Varvara Ivanovna Krylova. The usual form of address in Russian—among acquaintances, neighbours, colleagues at work, and inclusive superiors—is by the given name and the patronymic. In Iceland the given name is used with the patronymic, the use of family names being discouraged. In Spain the family name of an individual consists of the family names of father and mother, the first being the most important one.

The terms maiden name and girl's name are sometimes used for the original family name of a married woman. Nickname is used in reference to surnames (which have not developed into family names), mainly of the jocose type—*e.g.,* a thickish Mr. John Smith is called Fatty. A surname, also called a byname or to-name (obsolete), can be used to differentiate persons with the same family names if they belong to different families and if given names are not used among them. In a village, there may be several families with the name Jones; if they are not called or referred to by first names, they may be known as Jones at the Pond, Jones the Redhead, and so forth. Hypocoristic forms of names are those that are used in familiar, friendly, or intimate situations (usually shortened or otherwise modified)—*e.g.,* Tom for Thomas, Jim for James. Some of these forms are also used as given names, particularly in the United States.

THE NAMING PROCESS

One of the most important elements of the naming process concerns the meaning and associations of the name. In this case the term meaning is radically different from that in the case of common nouns, in which the "meaning" is their ability to be used in reference to a class of entities, to denote or designate them. As was noted above, the absence of this ability to refer to a class of entities is typical of a name. If the meaning of a typical common noun, such as automobile, is considered, it can be seen that it denotes a certain type of vehicle. On the other hand, if the word automobile itself is considered, one can see that it consists of a Greek element, *auto* "self," and a Latin one, *mobilis* "movable," so that the sum of the meanings of the constituent parts of the word suggests a gloss like "self-movable," "self-mover." The meaning of a name involves that which the constituent parts suggest. In this sense, the meaning of a name like Red River is obvious. To get a meaning of a name like Philip, however, one must go back to its original Greek version, Philippos, which means "lover of horses." This meaning of names frequently gets lost, however. There are several causes for this, one being that the name may be accepted into another language, as were the Indian place-names in America (*e.g.,* Oshkosh, Chicago, Kankakee), and the Greek and other names transferred to Europe and America via Christianity. In addition, names may cease to be understood as a result of language change; *e.g.,* the place-name Birmingham was understandable in Old English as "habitation of Biorma's people," and the originally Germanic name Gerard was once understood as "strong spear" (*Ger-hardo*). Names also changed by shortening (*e.g.,* Los Angeles, from El Pueblo de la Reyna de los Angeles, "Town of the Queen of the Angels," the town named in honour of the Virgin Mary) and by scribal error (*e.g.,* Pria in France, a misread medieval abbreviation of Pradaria, "meadow"). Another cause of the loss of meaning in names is that the meaning simply fades out by constant use of the word as a name. No one thinks of the meaning "ford for oxen" when speaking about Oxford, and no one realizes a discrepancy if Mr. White has a dark complexion. Finally, it sometimes happens that a name has no particular meaning from the beginning. For instance, the place-name Tonolo and the family name Bréal were created from random sequences of sounds.

Loss of original meaning of names

Choice of personal names. Names that have no meaning (above all not for the person who chooses the name) still can have associations. Although "Mary" and "John" may have no specific meaning, they were the names of important persons in the Christian religion and therefore have been used very frequently. An association may be so strong that it overwhelms the meaning of a name, even a disagreeable meaning; *e.g.,* the association with the cult of St. Demetrios made the name Demetrios one of the most popular in the Greek Orthodox Church, though its meaning is "belonging to [the pagan goddess] Demeter." On the other hand, such an association may more or less completely fade out and be combined with or replaced by other associations, such as a national tradition (Patrick in Ireland, Yves in Brittany, István in Hungary, Ivan in Russia) or with a family tradition (Louis in the Bourbon family, Wilhelm among the Hohenzollerns, Henry in the Ford family). On a less elevated level, there is the example of a rich uncle making a given name more than eligible. A name can be associated, correctly or not, with various

prestige factors, or its choice may be influenced simply by fashion. Another source of names, often extraordinary ones, was the occasional habit in Roman Catholic countries of giving a child the name of the patron saint whose day of celebration coincides with the child's day of birth (or Baptism); many names like Hyacinthus X, or Narcissus Y, were produced in this way.

"Good" and "bad" names

In the majority of cases, children are given "good," likable, and propitious names. In some cultures (*e.g.,* in some parts of sub-Saharan Africa, formerly in China, and sporadically in ancient Greece), however, the children are (or were) sometimes given "bad" names with meanings like "ugly," "disagreeable," or "crippled." The purpose of such names, which are called apotropaic names, is to make the child undesirable to demons.

The choosing of a given name is a highly private and individual matter. All the circumstances just mentioned can be motives for the choice, in addition to many other personal reasons, such as a consideration for the relatives' names or a simple liking of the phonetic shape of a given name. This wish to give a likable name may go so far that a sequence of sounds is chosen that sounds pleasant to the person who makes the choice but that has no relation to the existing stock of names or to the words of the language; *e.g.,* "Golly" was invented as a name of a girl and has no "meaning" or associations. This phenomenon is relatively common in the United States.

Choice of place-names. Place-names are less personal, less intimate, and a matter of public concern. The usual pattern is that the national Ministry of the Interior (or its equivalent) keeps an official list of place-names, particularly of place-names that form administrative units, together with lists of districts, counties, and the like. This function may also be performed by the ministry or agency that supervises the postal service. Bodies endowed with authority provide or choose new place-names if there is a need to create them on a greater scale—*e.g.,* the U.S. Board on Geographic Names.

International cooperation (performed above all by the Universal Postal Union) is necessary because names of identical places may vary from language to language. Particularly difficult are place-names originally written in scripts other than the Latin (Roman) one (the official script of the Universal Postal Union), such as Arabic, Chinese, Cyrillic, and the Indic writing systems. But, even within the Latin script, there are two basic types of difficulties. First, one place can have different names (or modifications of a name) in various languages—*e.g.,* French Nice and Italian Nizza; German München, English and French Munich, and Italian Monaco. A very difficult situation arises when a place is generally better known by its international name than by its original one; *e.g.,* Dublin is Baile Átha Cliath in Irish. Confusion may also be caused by names that are translated; *e.g.,* the Rocky Mountains are in German Felsengebirge and in Russian Skalistye Gory. There are also names with the same written form but with varying pronunciations; *e.g.,* for Paris, the accent, pronunciation of vowels, and pronunciation of consonants change from French to German to English.

The second difficulty involves the actual printing of all the letters with diacritical marks that are necessary for different alphabets of the Latin script. Because many printing firms lack the various marks, some possibly confusing omissions or modifications can hardly be avoided; *e.g.,* the dot over the *I* in Turkish İstanbul and the bar through the *l* in Polish Kołobrzeg are frequently omitted. International cooperation is also necessary and is developing in connection with the choice of place-names in outer space, particularly on the surface of the Moon.

HISTORICAL AND CROSS-CULTURAL DEVELOPMENT OF NAMES

Legal aspects of naming. While place-names are considered a public matter, personal names also seem to be getting more regimented by various laws and regulations. The United Kingdom and the United States are practically the only countries that adhere to the principle of Roman law that a person has the right to use and change his name as he pleases, except for fraudulent purposes. The first important regulation concerning given names was the decision of the Council of Trent (1563), which specified that the Roman Catholic priest administering Baptism should make certain that children are given names of Catholic saints; if the parents were to insist on another name, the priest should administer Baptism in that name but add the name of a saint as the second baptismal name. This regulation, still a valid part of Canon Law, was directed against the Protestant custom (spreading at that time) of giving children names of important persons from the Old Testament otherwise unconnected with Christianity (*e.g.,* Abraham, Samuel, Rachel). In this respect the regulation was successful in Catholic countries, but it did not succeed in stopping the use of given (baptismal) names like Cesare in Italy (from Latin Caesar).

Naming regulations of the Council of Trent

The next important law was passed in France. The French Revolution first gave complete freedom in naming; the result was some very fanciful given names like Mort aux Aristocrates, Racine de la Liberté, or even Café Billard. To stop this, a law was passed in 1803 that restricted given names to "names of persons known from ancient history" and "names used in various calendars." Again, the law was successful in its main intention; in addition, it prevented the spread of controversial given names such as Marat and Robespierre and of literary names such as Aramis, d'Artagnan, and Romeo. Very reasonably, the law never was interpreted too narrowly, so that feminine given names such as Jeanette and Henriette, for example, have been admitted, though they were not legal because no calendar contains them. This law is still valid in France.

Similar laws were passed, at various times, in eastern European countries and in certain neighbouring central Asian states, where the given name can be chosen only from names known and established as such, the exact formulation varying from country to country. One of the results of this legislation is that the repertoire of Russian given names today is more or less exactly the same as that of the pre-Soviet period, when the Orthodox Church was paramount. Catholic names are commonplace in Lithuania, whereas Muslim and other names are used in Uzbekistan and Tajikistan, sometimes without any ecclesiastical association whatsoever. In the Caucasus there are given names such as Soslan and Dzerassa, drawn from Caucasian mythology.

In regard to family names, the most important regulation was made at the Council of Trent (1563); it was decreed that every parish must keep complete registers of Baptisms, with the names of the child and those of his parents and grandparents. This had been done before but not so systematically. The new practice (soon followed in Protestant parishes) helped to establish the family names. There is not much legislation concerning family names, because two basic assumptions are made: that the bride will accept the bridegroom's family name by marriage and that their children will automatically have the family name of the parents.

Parish registers

Combined names—as under the German law permitting the bride to add her original family name to her new one in a hyphenated form (Inka Schmidt, when married to Karl Neumann, may become Inka Neumann-Schmidt) or the practice in outstanding British families of combining the family names of the married couple in a hyphenated form (Beatrix Curzon and Frederic Cholmondeley become Beatrix and Frederic Cholmondeley-Curzon)—are rare.

In the majority of cases, the law is concerned with family names mainly in cases of divorce, adoption, and illegitimacy. After a divorce, the wife is usually eventually allowed to reassume her maiden name and in Germany, for example, can be forced to do so if she is judged to be the guilty party and her former husband so desires. In adoption procedures, either the family name of the adopting persons is accepted or a hyphenated form is created. A child born out of wedlock usually receives the family name of its mother.

In many parts of Europe, legislation or habit have changed the basic assumptions concerning the family name, and a different situation has developed. When a Czech woman, Anna Klímová, for example, marries a Josef Novák, both may retain their original family names, or the wife may

become Anna Nováková or, more remarkably, the husband may become Josef Klíma, accepting the wife's family name. This must be decided by mutual agreement, and their children's names also are agreed upon in this way. The purported reason for this legislation is the full equality of women. (There is, however, one loophole in the system, namely, the Russian patronymic: this is automatically derived from the father's name, whereas equality understood in this way would demand a choice between the father's or the mother's name.) In Spain the married woman normally retains her maiden name.

Personal names. *European patterns of naming.* The development of personal names was complicated. In the old Indo-European system, a person had one name, which could be one of two types: a compound or a noncompound substantive. Noncompound names may originally have been given to inferior members of the tribe and their children. The compound names frequently associated the bearer with a god (they are called theophoric names) or attested to his virtues, abilities, skills, possessions, and so forth. The association of the meanings of the parts of the compound was sometimes only loose, as is particularly observable in German anthroponymy (see below). Examples of compound names include the Sanskrit Viṣṇuputra "son of Vishnu," Devadatta "given by god," Devarāja "godking." From Iran come the Avestan name Hōrmizāfrid "benediction of Ahura Mazdā" and the Old Persian name Mithradates "given by Mithra" (two Iranian gods).

Compound and noncompound names

Among Greek names there are also many theophoric names, such as Herodotos "given by Hera," Isidoros "given by Isis" (modern Isidore), or Theodoros (modern Theodore) and Dorotheos (modern only in the feminine form, Dorothy), both "given by god." There are many other similar Greek names; *e.g.,* Astyanax "lord of the city," Pericles "very famous," and Demosthenes "strength of the people." Plato "broad (in shoulders)" is a noncompound Greek name.

The compound names of the Celts include Vercingetorix "great king of warriors," Orgetorix "king of killers," Rextugenos "son of justice." Noncompound Celtic names included, for example, Artos "bear" and Galba "big." Examples of Germanic compound names include Heriberhto "army + resplendent" (modern Herbert), Huguberhto "resplendent by thought" (modern Hubert), Godofrido "divine peace" (modern Gottfried and Geoffrey), Frideriko "peace + powerful" (modern Frederic and Friedrich), and Theodobaldo "people + valiant." Among the noncompound Germanic names is Karl (or Charles), in the Latin form Carolus, meaning "man."

Typical Slavic compound names are Vladimir "governs the world," Vladislav "rule + glory," and Miroslav "world + glory."

The Latin system of personal names was quite different and probably developed under Etruscan influence. In the earliest times the Romans seemingly had only one name; *e.g.,* Romulus, Remus, Manius. From the beginning of historical times, however, the Roman personal name consisted of a praenomen (given name, forename) and a nomen (or *nomen gentile*). Only intimates used the praenomen, and its choice was restricted to fewer than 20 names, among them Gaius, Gnaeus, Marcus, Quintus, Publius, Tiberius, and Titus. The nomen that followed was hereditary in each gens (a related group of families, like the Scottish clan); examples include Antonius, Aurelius, Claudius, Cornelius, Fabius, Horatius, Julius, Lucius, Maccius, Tullius, and some others. Because the choice of both the praenomen and the nomen was restricted, the patrician families and later all families started using a hereditary name, called a cognomen.

These cognomina developed from original surnames; *e.g.,* Cicero "bean," Pictor "painter," Plautus "flat foot," Tacitus "silent." Thus the Roman name eventually consisted of three parts: Marcus Tullius Cicero, Gaius Julius Caesar. In addition, a person might acquire an individual surname, called an agnomen: Publius Cornelius Scipio Africanus was so named because of his successful war in Africa.

This system of naming was used during the whole republican period and later in the empire. Toward the end of the empire, however, the naming pattern began to change and subsequently was lost. One reason was that more persons used names lacking any real relation to themselves. For instance, a slave (and then his children) used the praenomen and the nomen of the master who set him free; *e.g.,* had Marcus Tullius Cicero freed a Syrian slave, the name of the latter might have been Marcus Tullius Syrus.

The number of freed slaves grew constantly, particularly after the victory of the Christian religion. Also, a free inhabitant of the empire who was granted Roman citizenship acquired the praenomen and nomen of the magistrate who made him a citizen, and in AD 212, when all free noncitizens were given citizenship by the emperor Caracalla, hundreds of thousands of persons prefixed Marcus Aurelius to their names, whether Greek, Syrian, African, or any other. In this way, Roman names lost their significance.

Another change was introduced by the Christians, who belonged to social classes that were not particularly concerned with the habits of the Roman higher class and who preferred names connected with their own religion; *e.g.,* from its founders (Petrus, Paulus, Joannes, Maria, Timotheus) or from the new martyrs, frequently persons with simple Latin or Greek surname-like names such as Stephanos "wreath" (modern Stephen), Laurentius "laurel" (modern Lawrence), and Sidonius "coming from Sidon [in Phoenicia]" (modern Sidney). Simple names like these were sometimes called *signum.* The Christians, however, soon started creating their own names; *e.g.,* Benedictus "blessed," Desiderius "desiring [salvation]," Renatus "reborn [by Baptism]," (modern René).

Christian names

With the spread of Christianity, this stock of names spread into territories that did not belong to the Roman Empire, but the diffusion was slow. In both the Germanic and the Slavic sphere (half of which came under the influence of the Eastern Church), the use of many of the original non-Christian names was continued, partly by tradition and partly because some of the bearers of these names became saints themselves. In this way, the repertory of given names was set, in general, somewhere around the 12th century. A notable addition to it was the influx of Old Testament names brought by the Reformation (Adlai, Benjamin, and so on). Certain names have left no trace of their ephemeral existence—*e.g.,* Puritan names such as Humility, Be Faithful, Kill Sin; French revolutionary names; and Russian postrevolutionary names such as Mels (an acronym containing the initial letters of Marx, Engels, Lenin, and Stalin). American fanciful given names for girls, such as Claretta, Elizene, Gwyned, and Marilla, are also relatively insignificant in impact, though the group is growing.

Christian and non-Christian given names

Family names. Family names came into use in the later Middle Ages (beginning roughly in the 11th century); the process was completed by the end of the 16th century. The use of family names seems to have originated in aristocratic families and in big cities, where they developed from original individual surnames when the latter became hereditary. Whereas a surname varies from father to son, and can even be changed within the life span of a person, a hereditary surname that develops into a family name better preserves the continuation of the family, be it for prestige or for the easier handling of official property records and other matters. Family names frequently developed (via surnames) from hypocoristic forms of given names; *e.g.,* from Henry came Harry, Harris, Hal, Halkin; from Gilbert came Gibbs, Gibbons, Gibbin, Gipps, Gilbye, Gilpin; and from Gregory there developed Gregg, Grigg, Greggs, Griggs, Greig. Other sources of family names are original nicknames—Biggs, Little, Grant (grand, large), Greathead, Cruikshank, Beaver, Hogg, Partridge; occupations—Archer, Clark, Clerk, Clarkson (son of a clerk), Bond, Bonds, Bound, Bundy (bondman); and place-names—Wallace (man from Wales), Allington, Murray, Hardes, Whitney (places in England), Fields, Holmes, Brookes, Woods (from microtoponyms).

A great number of family names come from patronymic surnames; in English, they are usually formed by the suffixation of "-son." Patronymic surnames can be formed from the father's given name or from any of its variants. Therefore, there is not only the form Richardson, but

also Dickson, Dixon, Dickinson; and Henryson, Harrison, Henderson; Gilbertson, Gibson; and Gregson, Grigson. Some English patronymics, particularly in old families, are formed with a prefixed "Fitz-" (*e.g.,* Fitzgerald), which goes back to Norman French *fits* "son." In contradistinction to English, the Scottish patronymics are formed by a prefixed "Mac" or "Mc" (McGregor), the Irish with "O" (O'Brien) or "Mc" or "Mac," and the Welsh with "P-" (Powell "son of Howel"). In Modern Greek, patronymics are formed by suffixation; *e.g.,* Dimitriopoulos "son of Dimitrios."

French family names

The development of family names is similar in all of Europe. For example, French names such as Jaquet, Jacquot, Jacotot, Jacotin, Cottet, Cottin, Cotin, Jacquin, Jacquinet, Jacquinot, Jacquart, Jacquier all derive from Jacques; Davignon, Decaen, Derennes, and Beauvais developed from the place-names Avignon, Caen, and so forth; Breton, Lebreton, Lenormand come from the names of districts; Clerk, Leclerc, Duclerc, Auclerk, Clergue (*cf.* English Clark), Boucher, Boulanger, Masson designate professions ("butcher," "baker," "mason"); and Roux, Leroux, Rousset, Rousseau, Lerouge, Roujon are all variants of "red" (*i.e.,* red hair). Roughly the same scheme exists everywhere in Europe. Some family names can be traced to nicknames that must have their origin in incidents and attitudes that cannot be understood now; *e.g.,* Czech family names such as Nejezchleba "Don't eat bread!" and Skočdopole "Jump into the field!"

The development is slighty different among Jews. While living in ghettos, they used only given names. After the end of the 18th and the beginning of the 19th century, they chose or were given family names. Many of these names (which vary in the individual languages) are derived from religious vocations: Cantor, Canterini, Kantorowicz (lower priest); Kohn, Cohen, Cahen, Kaan, Kahane (priest); Levi, Halévy, Löwy (name of the tribe of priests). Many are derived from place-names—Morpurgo (Marburg)—or from nicknames—Hirsch ("deer" in German). Frequently, particularly in Austria, the Jews were given derisory family names, such as Eberstark "strong as boar," Rosenduft "fragrance of roses," and Hitzig "hot," from Itzick, a mocking form of Isaac.

The only outstanding exception to this European pattern of naming occurs with the names of kings, who use one of their given names. Some royal families have what could be called family names; *e.g.,* the Hohenzollerns (more correctly, Hohenzollers) of Prussia. The British royal family accepted the name Windsor only in 1917 (this was changed to Mountbatten-Windsor for the future members of the family who will not enjoy princely status). The pope of the Roman Catholic Church abandons his personal name after his election and chooses a single name, sometimes associated with his intentions; *e.g.,* Pope Paul VI chose the name Paulus because of St. Paul's missionary activities and travels.

Other patterns of naming. Names and naming practices in other cultural areas show a strong similarity in the basic trends. Among the ancient Assyrian and Babylonian names are theophoric designations such as Ashurbanipal, meaning "Ashur [a god] created son," and Nabukudurriusur (Nebuchadrezzar of the Bible), translated as "Nabu [a god] protected the estate." The Phoenician (Carthaginian) name Hannibal means "grace of Baal" (a god).

Theophoric names

The Hebrew Yehonatan, Yonatan (*i.e.,* Jonathan) means "God gave"; Rafa'el (Rafael) is translated as "God cured." There are also nontheophoric names such as Laban (from Hebrew *lavan* "white"). The Aramaic surname of the fisherman Simon, Kepha, meaning "stone," became famous in the New Testament as Petros (Peter), the Greek translation of the name (*petra* "rock, stone").

The more complicated structure of Arabic society brought an independent development similar to the European one. Given names such as Muḥammad, Ibrāhīm (= Abraham), Manṣur "victor," ʿAlī "exalted," ʿAbd Allāh "slave of Allāh" are differentiated by surnames such as Ibn ʿAbbās "son of ʿAbbās," al-Baghdādī "from Baghdad," al-Ghazālī "the spinner." The Caucasian (*e.g.,* Ossetic) personal name consists of a given name preceded by the name of the tribe (gens) in the genitive plural; the name of the father may be inserted, thus giving Gaglojty Soslany fyrt Nafi "Nafi, son of Soslan, of [the gens of] Gaglo." Chinese society has had the institution of hereditary family names since the 4th century BC, but the number of these names has been reduced to some 200. Examples include Chan, Mao, and Lu. The choice of the given name was formerly much freer, but legislation seems to have restricted it. In a similar way, there are not more than 300 Korean family names, but only three of them—Kim, Pak, and Yi—belong to the great majority of families in Korea. The given name is chosen, but its choice is limited by the practice that one of the two syllables of the name should be identical within a family for a generation; the whole given name should have an auspicious meaning.

By the 20th century, the originally European pattern of given name + family name had been introduced practically everywhere. Black Africa (*e.g.,* among the Yoruba) now has the "normal" pattern of personal names, but both the given and the family names are of vernacular stock. There are given names such as Olúsolá "god [non-Christian] made greatness," Òṣunbùnmi "Òṣun [a river] gave me," and Adeyẹmi "crown befits me," and family names like Ajólore "who [is] a kind doer." Among the American Indians there are, surprisingly, practically no theophoric names. Instead, the Indians used names related to the totem, to animals indicated by omens or dreams, and to successful incidents in life. Those North American Indians who did not accept English names now use the English translation of their names as last names (which sometimes are not hereditary); *e.g.,* John Sleeping Owl, Mary Little Bear.

Types of place-names

Place-names. *Descriptive and commemorative place-names.* If the "meanings" of place-names and the motives for their choice are examined, several broad types may be discerned. Descriptive names indicate a characteristic feature of the entity; *e.g.,* Rocky Mountains, North Sea, Newcastle. The chosen feature is sometimes only illusory or observed by chance, as in the case of the Pacific Ocean (only a small part of it was calm, or pacific, when seen and named). Honorific and commemorative names are another broad category. Examples include Constantinople (formerly called Byzantium, renamed Konstantinoupolis "city of Constantine" because that emperor made it the capital of the Roman Empire); Aphrodisias "[the town of] Aphrodite" (in Asia Minor), changed into Stauropolis "city of the cross" with the advent of Christianity; Cartagena, transferred to Colombia (South America) in commemoration of Cartagena in Spain (Cartagena in Spain was in turn developed from Latin Carthago Nova, a translation of the name given to the town by the Phoenician settlers in commemoration of Carthage, the Phoenician rival of Rome); Nieuw-Amsterdam, commemorative of the Dutch capital, changed to New York (honorific for the Duke of York). Among the numerous benedictory, wishful names are the Russian Vladivostok "govern the East!" (founded and named by Russians as their main base on the Pacific coast), Cape of Good Hope (a renaming of a more descriptive Cape of Tempests), and Greek Pontus Euxinus (now the Black Sea) "hospitable sea" (a renaming of Pontus Axeinos "inhospitable sea"). In most cases, however, place-names do not have a "meaning" at all, particularly not for the general user.

Place-names reflecting historical influences. Place-names are frequently accepted into the language of a new population. The toponymy of the United States illustrates this well. Spanish names are numerous in the South and Southwest; *e.g.,* Florida, San Antonio, Santa Fe, and San Diego, all of which are Spanish names of Roman Catholic saints or holidays. French names occur frequently in the Southeast and the central United States (*e.g.,* La Nouvelle Orléans, changed into New Orleans; Baton Rouge; St. Louis; Louisiana); Dutch names are found in the East (Haarlem changed into Harlem); Indian names are interspersed everywhere; and, finally, English names are superimposed over all the rest. An examination of all these names, which are now used by a mostly English-speaking population, could not fail to yield some information about the colonization of the United States, even if the history were not known.

In the same way, the place-names of Britain reflect its

history. Above all, there are Celtic names—*e.g.,* Eboracum (named for a tree), partly translated as Eoforwic, which changed into York. Roman names are also numerous; *e.g.,* Castra "military camp," changed into Chester, and Lindum Colonia "Colony Lindum" (which itself is Celtic, *linne* + *dunom* "town at the lake") is now Lincoln. There are, in addition, Anglo-Saxon names (*e.g.,* Whittingham "habitation of Hwita's people"), Scandinavian names (*e.g.,* Badby, in which *-by* is the Scandinavian element instead of English *-bury* "castle"), and Norman names (*e.g.,* Richmond, from a personal name consisting of *rīkī* "rich, powerful" + *mond* "world").

Changes in place-names

Any country's toponymy consists of various layers. In France there are Celtic names such as Lucodunos "shining town" that became Latinized into Lugdunum and changed into the modern form Lyon; Greek names such as Agathe (Tyche) "good (luck)," which has become Agde; Roman names such as Forum Julii "marketplace of Julius," modern Fréjus; and old Germanic names such as Clarbec "clear brook" (*klar* + *Bach* in German). Most important is the fact that place-names can be used as a source of information themselves, even if other forms of evidence are lacking; for instance, because Moskva (= Moscow) is a Finnish name (Finnish *kva* "water") and because other Finnish toponyms are present in Russia, the prehistoric presence of Finnish tribes in that location can be presumed. Names of rivers are particularly important for this purpose, because they are very conservative and usually are taken over by a new population. A considerable number of river names in western and central Europe show remarkable similarity (*e.g.,* Esera in Spain, Isère in France, Yser in Belgium, Isar in Bavaria, Jizera in the Czech Republic) and are the only evidence of a pre-Celtic Indo-European population of those regions.

In a similar way, names are also indicative of cultural and political trends. Singapore (Sanskrit Siṃhapura "castle of lions"), for example, testifies to the cultural influence of India in the area. Particularly significant in this respect are deliberate changes of names caused by changes in political power, ideology, and so forth. Changes such as Nieuw-Amsterdam becoming New York, or Léopoldville (named after the king of Belgium who acquired the Congo) becoming Kinshasa, are very common. Some cases of renaming do not lack humour: La Roche-sur-Yon in France was rebuilt by Napoleon and renamed Napoléon-Vendée, which was changed to Bourbon-Vendée under the Restoration; during the 100 days of Napoleon's return from Elba and in the subsequent second Restoration, the cycle was repeated once more, and only the Third Republic restored the old name. Renaming also shows examples of cynicism: Lyon, which had rebelled against the revolutionary covenant, was punished by systematic demolition and a massacre of its inhabitants; the ruins of the city were renamed Commune-Affranchie "Liberated Commune." Changes of place-names are sometimes made systematically; when the territory called Alto Adige in Italian and Südtirol (South Tirol) in German became part of Italy after World War I, for instance, a systematic effort was made to give or to return to these territories the Italian character in both place-names and personal names. The Russian Revolution brought a change of names that were reminiscent of the old regime and ideology; *e.g.,* St. Petersburg (changed into a more Slavic Petrograd by the tsar during the war) became Leningrad (and then St. Petersburg again in 1991); Tsaritsyn (from *tsar* "emperor") became Stalingrad (and then Volgograd in the late 1950s); and Yekaterinodar (from Yekaterina [= Catherine], an empress) became Krasnodar (from *krasny* "red"). However, most of the pre-Revolution names were reinstated after the collapse of the Soviet Union in 1991.

BIBLIOGRAPHY. General studies on names and naming are ERNST PULGRAM, *Theory of Names* (1954), treating theoretical problems such as the distinction between names and common nouns; and LESLIE DUNKLING, *The Guinness Book of Names,* 6th ed. (1993), providing information on many types of names, particularly personal names and place-names.

Treatments dealing specifically with personal names include L.G. PINE, *The Story of Surnames* (1965), readable and well informed; and RICHARD D. ALFORD, *Naming and Identity: A Cross-Cultural Study of Personal Naming Practices* (1988), a technical study. Other informative texts are C. L'ESTRANGE EWEN, *A History of Surnames of the British Isles* (1931, reprinted 1968), containing rich information and a bibliography; H.L. MENCKEN, *The American Language: An Inquiry Into the Development of English in the United States: Supplement II* (1948), a survey of American naming—some of the text is also available as part of a briefer form of the original 4th edition, abridged by RAVEN I. MCDAVID, JR. (1963, reprinted 1977); ELSDON C. SMITH, *American Surnames* (1969, reissued 1986), a historical survey; LESLIE DUNKLING, *First Names First* (1977, reprinted 1982); UNA STANNARD, *Mrs Man* (1977), dealing with the history of married women's names; J.N. HOOK, *Family Names* (1982), on American surnames; and DIETZ BERING, *The Stigma of Names: Antisemitism in German Daily Life, 1812–1933* (1992; originally published in German, 1987), on the relationship between Jewish acculturation attempts and bureaucratic requirements for permanent surnames rather than patronymics.

Dictionaries of personal names are CHARLES WAREING BARDSLEY, *A Dictionary of English and Welsh Surnames: With Special American Instances,* ed. by A. BARDSLEY (1901, reissued 1980); ELSDON C. SMITH, *New Dictionary of American Family Names* (1973, reissued 1988); E.G. WITHYCOMBE (compiler), *The Oxford Dictionary of English Christian Names,* 3rd ed. (1977, reissued 1988), indicating the provenience of names listed; BENZION C. KAGANOFF, *A Dictionary of Jewish Names and Their History* (1977); GEORGE R. STEWART, *American Given Names: Their Origin and History in the Context of the English Language* (1979); LESLIE DUNKLING and WILLIAM GOSLING, *The Facts on File Dictionary of First Names,* rev. ed. (1984); EDWARD MACLYSAGHT, *The Surnames of Ireland,* 6th ed. (1985), with a general history; PATRICK HANKS and FLAVIA HODGES, *A Dictionary of Surnames* (1988), a scholarly work examining the origin and history of nearly 70,000 European surnames, and *A Dictionary of First Names* (1990), looking at some 4,500 names; GEORGE F. JONES, *German-American Names* (1990), covering some 12,700 names; JULIA CRESSWELL, *Bloomsbury Dictionary of First Names* (1990), dealing mainly with names of English, Celtic, and Welsh derivation; and P.H. REANEY, *A Dictionary of English Surnames,* 3rd ed. with corrections and additions by R.M. WILSON (1991).

Studies of place-names include P.W. JOYCE, *Origin and History of Irish Names of Places,* 3 vol. (1869–1913), partly antiquated but still of great value; GEORGE R. STEWART, *Names on the Globe* (1975), on the theory of place-naming around the world, and *Names on the Land,* 4th ed. (1982), a readable and instructive study of the origin of U.S. place-names; and W.F.H. NICOLAISEN, *Scottish Place-Names* (1976, reissued 1986).

Dictionaries of place-names are EILERT EKWALL, *The Concise Oxford Dictionary of English Place-Names,* 4th ed. (1960, reissued 1987), including the origin of place-names; KELSIE B. HARDER (ed.), *Illustrated Dictionary of Place Names: United States and Canada* (1976, reprinted 1985); and ADRIAN ROOM, *Place-Names of the World: A Dictionary of Their Origins and Backgrounds,* rev. ed. (1987).

The journal of the American Name Society, *Names* (quarterly), publishes articles and research materials in the field of onomatology. Its June 1984 special issue, vol. 32, no. 2, contains a symposium on names and the law.

Annotated bibliographies include EDWIN D. LAWSON (compiler), *Personal Names and Naming* (1987); and RICHARD B. SEALOCK, MARGARET M. SEALOCK, and MARGARET S. POWELL, *Bibliography of Place-Name Literature: United States and Canada,* 3rd ed. (1982).

(L.Zg.)

Nanking (Nanjing)

Nanking (Wade-Giles romanization: Nan-ching; Pinyin: Nanjing), capital of Kiangsu Province in central eastern China, is a port on the Yangtze River and a major industrial and commercial centre. Rich in history, it served seven times as the capital of regional empires, twice as the seat of revolutionary governments, once (during World War II) as the site of a puppet regime, and twice as the capital of a united China (the second time from 1928 to 1937). The name Nanking ("Southern Capital") was introduced in 1421 during the Ming dynasty (1368–1644).

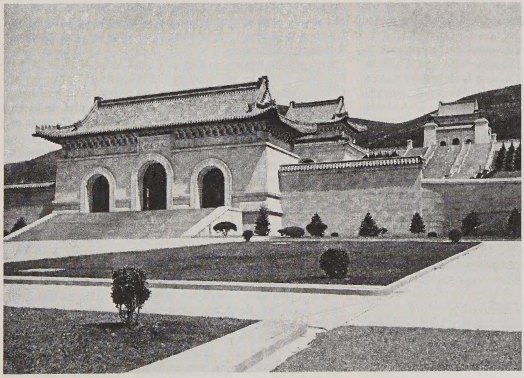
Physical and human geography

THE LANDSCAPE



The city site. Nanking is situated on the southeastern bank of the Yangtze, some 160 miles (260 kilometres) from Shanghai (215 miles by water, 193 miles by rail). The city proper comprises the area encircled by a gigantic wall constructed during the Ming period and adjacent suburbs. The city wall—of which about two-thirds is still standing—is 21 miles long, has an average height of 40 feet (12 metres), and contains 13 gates. The municipality (*shih*) of Nanking includes territory extending to the border of Anhwei Province on the north, west, and south and to the borders of Yang-chou and Cheng-chiang municipalities on the east. Included in the municipality, which has an area of about 2,516 square miles (6,516 square kilometres), are counties on either side of the Yangtze and both urban and rural districts. The city wall

Climate. The four seasons are clearly distinguishable. The hot summer months are from July to September, while winter lasts from December until March. Spring and autumn are both mild and pleasant. January and July mean temperatures are about 37° F (3° C) and 82° F (28° C), respectively. The average annual rainfall is 39 inches (990 millimetres), the bulk of it falling between June and August.

The city layout. The city of Nanking, encircled by hills and rivers, resembles a gourd, with its tip pointing northwest, toward suburban Hsia-kuan, on the south bank of the Yangtze. Hsia-kuan and P'u-k'ou, which is opposite it on the north bank, house the harbour facilities of the huge Nanking River Port. On the west and south Nanking is bordered by the Ch'in-huai River, which runs along the outside of the city wall and is a tributary of the Yangtze. On the east are the foothills of the Tzu-chin ("Purple-Gold") Mountains, and at the city's southern tip is Chin-liang ("Quite-Cool") Mountain. Outside of the city wall to the northeast is the extensive Hsüan-wu Hu ("Mystic Martial Lake"), containing five islets linked by embankments, and on the other side of the Ch'in-huai to the southwest is Mo-ch'ou Hu ("Lake of No Sorrow"); both lake areas are city parks. The skyline suggests spaciousness and grandeur. Blue-glazed tiles adorning the old city gates, parklike scenery along the boulevards, lotus blossoms and tea pavilions on the lakes, and temples half hidden in the green hills are all characteristic sights in Nanking.

The city comprises four districts. The north district, from I-chiang Men (a city gate) to the Ku Lou (Drum Tower; built in 1382), traversed by Chung-shan Avenue as its axis, contains such landmarks as Pei-chi Ko ("North Pole Pavilion") and Chi-ming Ssu ("Cockcrow Temple"), as well as government offices, Nanking University (founded in The city's four districts

Ewing Galloway

Sun Yat-sen Mausoleum at Nanking.

1902), and modern residential quarters. The central district, surrounding Hsin Chieh-k'ou ("New Crossroads"), is the business centre of the city, and to the south is situated the populous old city—traditionally famous for entertainment. The east district, a centre of culture, contains the ruins of the former Ming palace as well as the Nanking Museum, with its exhibits on Chinese history, and scientific institutions.

Forming an integral part of the life of the city are its immediate outskirts. To the south is the Yü-hua T'ai ("Terrace of the Rain of Flowers"), noted for its five-colour pebbles and a Communist martyrs' memorial. In the eastern outskirts, on the magnificent forested Tzu-chin range, are the Ming emperor Hung-wu's mausoleum, its approach noted for pairs of large stone animals; the blue-tile-roofed mausoleum of Sun Yat-sen; the Ling-ko Ssu ("Temple of the Valley of Spirits") and the nearby 200-foot-high pagoda; and the Tzu-chin Mountains Astronomical Observatory. Other scenic spots include Yen-tzu Chi ("Swallow's Bluff") in the north and Ch'i-hsia Shan ("Abode of Clouds Mountain") farther to the northeast. Two industrial districts extend northeastward and southwestward from the city.

THE PEOPLE

Despite much industrial growth, the city of Nanking retains a traditional feature—the existence of a substantial rural population within the boundaries of the municipality. The people speak Mandarin with a marked local accent. The city has small communities of Christians, Buddhists, and Muslims.

THE ECONOMY

Agriculture. Much of the land in the municipality's rural districts is under cultivation; the major agricultural products are rice, wheat, peanuts (groundnuts), and fruits and vegetables. In and around the many lakes and ponds *pai-ho* (lily bulbs), water chestnuts, lotus roots, and other aquatic plants are grown. Both freshwater fishery and pig farming are important. Along the canals and creeks, farmers raise large flocks of ducks; the Nanking duck, preserved in salt and pressed, is one of China's food delicacies.

Industry. Before 1949, Nanking was noted chiefly for its traditional handicraft products, such as satins, velvets, and brocades. The city's major industrial expansion has taken place since then, and Nanking has become an important industrial centre. Major manufactures include automobiles, petrochemicals, electronics, machinery, textiles, consumer goods, pharmaceuticals, and high-technology products. Industrial parks, economic development zones, foreign investment, and international joint ventures play major roles in the economy. Nanking is an important commercial port in the Yangtze River delta, second only to Shanghai, and serves as a hub for trade between the north and south.

Major industries

Transportation. Nanking's major avenue of commerce is the Yangtze, which connects the city with the Yangtze delta and with central China. Nanking is linked by rail to Shanghai and to major Chinese cities to the north. Another railroad leading south extends to T'ung-ling in Anhwei province; a loop line through the eastern suburbs links it with the Shanghai-Nanking line. In 1968 the rail ferry between P'u-k'ou and Hsia-kuan was replaced by the Yangtze bridge, more than 20,000 feet in length, with a double-track railroad on its lower deck and a four-lane highway on the upper deck.

Buses, taxis, automobiles, and bicycles are the city's primary means of transport. Highways link Nanking to Shanghai and other cities in Kiangsu, Chekiang, and Anhwei provinces. Nanking Lu-k'ou International Airport, which opened in 1997 and is located in a southern suburb, has flights to domestic and overseas destinations.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Nanking's municipal government is part of the hierarchical structure of the Chinese government that extends from the national organization, through the provincial apparatus, to the municipal and, ultimately, neighbourhood levels. Paralleling this structure is that of the Chinese Communist Party (CCP). As in all of China, real power in Nanking is held by the local CCP, but local government institutions perform various formal functions. The Nanking Municipal People's Congress, the formal governmental decision-making body, follows the guidance of the local CCP in issuing administrative orders, collecting taxes, determining the budget, and implementing economic plans. Under the direction of the local CCP, a standing committee of the Municipal People's Congress recommends policy decisions and oversees the operation of municipal government. Executive authority is formally assigned to the Nanking People's Government, the officers of which are elected by the congress. The local government consists of a mayor, vice mayors, and numerous bureaus in charge of public security, the judicial system, and other civil, economic, social, and cultural affairs.

Administratively, the city is divided into districts (*ch'ü*). Below the district, police substations supervise the population, while subdistrict or neighbourhood offices handle civil affairs in their areas. Residents' committees help mediate disputes, carry out literacy campaigns, and promote sanitation, welfare, and family planning.

Health. Nanking made great progress in public health and medicine during the Nationalist period. Health conditions have continued to improve under the Communist government, which has placed great emphasis on public health education. There are many general and specialized hospitals in Nanking, and clinics and health stations are maintained by neighbourhood associations, factories, and schools. Nanking is also a noted centre for training doctors in traditional Chinese medicine.

Education. Nanking inherited from Nationalist days an excellent school system that in 1949 included 300 primary and middle schools and some of the best universities and colleges in China. Since the 1950s there has been a considerable increase in the number of primary, middle, and technical secondary schools.

In addition, much attention has been given to adult education, and many spare-time schools, university extensions, and other institutions that provide training in technical fields have been established. Nanking University and Nanking Institute of Technology are among the leading institutions of higher education in the country, and colleges of hydraulic engineering, aeronautical engineering, and meteorology are also of national significance.

Adult and higher education

CULTURAL LIFE

Nanking's long history as a cultural centre is reflected in its many surviving monuments and buildings of historical significance. The Nanking Museum, Museum of the Heavenly Kingdom of Great Peace (Taiping Museum), and the Kiangsu Provincial Museum are all housed in buildings constructed in traditional Chinese style. Among the city's numerous research agencies and scientific societies is the Kiangsu Academy of Science, a branch of the Chinese Academy of Sciences.

Some of the leading artists of China have worked in the Kiangsu College of Traditional Painting. Troupes of Peking opera and various Kiangsu operas give performances of both traditional theatrical pieces and modern plays in the city. Sports grounds are found in all parts of Nanking and its suburbs. The well-equipped Wu-t'ai Shan Stadium, in the centre of the city, is used for major sports events. The public at large, however, finds its recreation in the many beautiful parks and resorts.

History

THE EARLY EMPIRES

Nanking's recorded history dates to the Spring and Autumn (770–476 BC) and the Warring States (475–221 BC) periods, when a castle near Yü-hua T'ai was constructed by the Yüeh state in 472 BC. After the Yüeh territory was taken over by the Ch'u state, another castle under the name of Chin-ling was built on Chin-liang Mountain to control the traffic between the Yangtze and the Ch'in-huai. Under the Ch'in (221–206 BC) and Han (206 BC–AD 220) dynasties, Nanking was successively under the jurisdiction of Mo-ling County (*hsien*) and Tan-yan County.

Nanking—under the name of Chien-yeh—emerged as the political and cultural centre of Southeast China during the period of the Three Kingdoms, when Sun Chien and his son Sun Ch'üan made it the capital of the kingdom of Wu from 229 to 280. In 317 the Eastern Chin dynasty (317–420), fleeing foreign invaders in North China, again chose the city as a capital. Renamed Chien-k'ang, Nanking became a haven for northern families in exile. After the fall of the Eastern Chin, Nanking, under four successive dynasties—Liu-Sung (420–479); Southern Ch'i (479–502); Southern Liang (502–557); and Southern Ch'en (557–589)—was the seat of government of the regional empires south of the Yangtze.

These regimes were dominated by military men whose rivalries weakened the government. But in Nanking progress was made in areas other than politics, and its population grew to 1,000,000 during the Southern Liang. Bountiful harvests, coupled with tea, silk, papermaking, and pottery industries, supported a booming economy. Culturally, the Six Dynasties—as the dynasties that ruled from 220 to 589 are called—produced a galaxy of scholars, poets, artists, and philosophers. The works of Wang Hsi-chih and Ku K'ai-chih set the canons of calligraphy and painting, respectively. The publication of *Wen hsüan* ("Literary Selections") and of *Wen-hsin tiao-lung* (a classic in literary criticism), the evolution of what has come to be known as the Six Dynasties essay style (a blending of poetry and prose), and the formal recognition and systematization by Shen-yüeh (a 6th-century courtier) of the four tones of the Chinese language were achievements of this period. In philosophy, the so-called *ch'ing-t'an* ("pure discourse") movement, spiritually akin to a form of Taoism, found many adherents who held themselves aloof from politics. Hundreds of Buddhist temples were built. Voluminous Buddhist scriptures were edited and transcribed, and thousands, including the emperor Wu Ti, founder of the Southern Liang dynasty, took monastic vows.

The Six Dynasties

From 581 to 1368, under the successive unified empires of the Sui, T'ang, Sung, and Yüan dynasties, Nanking reverted to the status of a prefectural city. Various names were given the city: Chiang-chou and Tan-yang under the Sui; Chiang-chou, Chin-ling, and Pai-hsia in early T'ang; Sheng-chou in late T'ang; and Chin-ling again under the Five Dynasties in the 10th century; Chien-k'ang under the Sung; and Chi-ch'ing under the Yüan. When the Southern T'ang briefly maintained a regional regime in the city from 937 to 975, Nanking enjoyed much intellectual creativity (the ruler Hou-chu himself being a poet of consummate skill) and was the scene of new construction, notably the octagonal stone pagoda of the Ch'i-hsia Temple and the crosstown channel of the Ch'in-huai Ho. Another period of prominence occurred during the Southern Sung dynasty (1127–1279), when Yüeh Fei used the city as his base for resistance against the Juchen in North China.

In 1368 the emperor Hung-wu, founder of the Ming dynasty, made Nanking the capital of a united China. Naming the city Ying-t'ien-fu ("Responding to Heaven"), he built a grand Imperial palace and the city wall. In addition, earth ramparts were prepared to form the basis for a larger outer wall. In 1421, however, Hung-wu's son, the Yung-lo emperor, moved the capital to Peking. The city became a subsidiary capital and was renamed Nanking.

The growth of trade and industry, however, brought new wealth to Nanking, especially to Hsia-kuan. Weaving, pottery, printing, and brocade making were the leading industries. Oceangoing vessels used by Cheng Ho in his famous 15th-century expeditions to the South Seas were built in the shipyards to the northwest of the city. An Imperial college—the Kuo-tzu chien—attracted students from throughout the empire, as well as from Japan, Korea, Okinawa, and Thailand. The scholars of this college helped compile the *Yung-lo ta-tien* ("Yung-lo Emperor's Encyclopaedia"); its printing plant issued fine editions of many classics, as well as such works as *Pen-ts'ao kang-mu* ("Great Pharmacopoeia") by Li Shih-chen and *Yüan-shih* ("History of the Yüan Dynasty") by Sung Lien.

In the Ch'ing (Manchu) dynasty (1644–1911/12), Nanking, renamed Chiang-ning, became the government seat of the viceroy of Kiang-nan (who governed the provinces of Kiangsu, Kiangsi, and Anhwei). In 1842 the treaty ending the Opium War was signed there. A decade later, in 1853, the city was taken by the Taiping revolutionary forces under the leadership of Hung Hsiu-ch'üan. As the capital of T'ai-p'ing T'ien-kuo (Heavenly Kingdom of Great Peace), Nanking became a commune practicing universal brotherhood, equality of the sexes, and communal ownership of property. Numerous palaces for Hung and his lieutenants were built. When the Taipings were overthrown in 1864, there was widespread destruction of public buildings, of temples, and of the city wall by Ch'ing troops, and the city was left nearly prostrate.

The Taiping capital

THE MODERN CITY

Recovery took decades. Although foreign trade was sanctioned by the treaties of Tientsin concluded with France in 1858, it did not begin until 1899. By that time, modern industry and communication had reached the city. In 1908 the Shanghai-Nanking railroad was opened, followed four years later by a railroad from the port city of Tientsin in Hopeh province to P'u-k'ou. Such economic growth, however, was overshadowed by the revolution of 1911. After the uprising had begun upstream at Wu-ch'ang in Hupeh province, the revolutionary leaders proclaimed Nanking the seat of the provisional government of the Republic of China, and the democratic constitution of 1912 was adopted there before the first president, Yüan Shih-k'ai, moved the capital to Peking.

Under the infant Republic of China, Nanking was governed by warlords for more than a decade. Sun Yat-sen, leader of the Kuomintang (Nationalist Party), embittered by politicians' intrigues centred in Peking, vowed to make Nanking the Nationalist capital. Accordingly, when his follower Chiang Kai-shek achieved unified control of the country in 1928, the Nationalist government made Nanking once more the capital of a united China. Progress was made in developing communications, industries, and natural resources. Physically, too, the city acquired a new look; modern boulevards and government buildings were constructed; new railroad stations and airfields were built; and the Sun Yat-sen Mausoleum was erected.

Such achievements were, however, cut short by the war against Japan. Nanking fell in 1937. In the sack of the city that followed, between 100,000 and 300,000 civilians were slaughtered. The city was then ruled by puppet governments until Japan's defeat in 1945. From 1946 to 1949 Nanking resumed its status as the capital of Chiang Kai-shek's Nationalist government, but Chinese Communist forces took the city in 1949. When the People's Republic of China was proclaimed on Oct. 1, 1949, Nanking was once again abandoned in favour of Peking as the national capital. In 1952 it was made the provincial capital of Kiangsu. Nanking was transformed into a modern industrialized city. Lives were lost and hardships suffered during the Great Leap Forward (1958–60) and the Cultural Revolution (1966–76). During the latter, many cultural and historical relics were damaged. Since then the city has generally prospered and has become a major tourist destination.

Naples

Naples (Italian: Napoli) lies on the west coast of the Italian Peninsula, 120 miles (190 kilometres) southeast of Rome, in the fertile region of Campania. On its celebrated bay—flanked to the west by the smaller Gulf of Pozzuoli and to the southeast by the more extended indentation of the Gulf of Salerno—the city is situated between two areas of volcanic activity: Mount Vesuvius to the east and the Campi Flegrei (Phlegraean Fields) to the northwest. The most recent eruption of Vesuvius occurred in 1944. In 1980 an earthquake damaged Naples and its outlying towns, and since then Pozzuoli to the west has been seriously afflicted by bradyseism (a phenomenon involving a fall or rise of land).

Naples is located near the midpoint of the arc of hills that, commencing in the north at the promontory of Posillipo and terminating in the south with the Sorrentine peninsula, form the central focus of the Bay of Naples. To the south of the bay's entrance to the Tyrrhenian Sea, the island of Capri forms a partial breakwater, visible from the city in clear weather and at times of impending storm but increasingly screened by polluted air from the industrial zone developed, since World War II, between central Naples and the Vesuvian slopes. Pollution also afflicts the waters of the port, obliging the more scrupulous practitioners of the immemorial Neapolitan fishing industry to withdraw ever farther from their native shore.

While Naples' importance as the principal port of southern Italy is at last in decline, the city remains the centre of the nation's meridional commerce and culture, beset by inveterate difficulties, and distinguished by an adroit and original spirit that retains many suggestions of the classical past and of assimilated historical experience. Of all the cities of southern Italy with Greek origins, Naples presents the most striking example of a lively continuity. It is also perhaps the last great metropolis of western Europe whose monuments, albeit often in decay, may still be seen in their popular context, without distractions of tourism or self-conscious commercialism.

Since World War II, during which Naples suffered severe bombardment, modernization has increasingly altered the city's setting and character; and a measure of long-deferred but often speculative prosperity is reflected in new suburbs now proliferating in once-rural surroundings. However, Naples remains arcane and compelling, a city whose richness requires from the visitor time, accessibility, and some knowledge of the Neapolitan past.

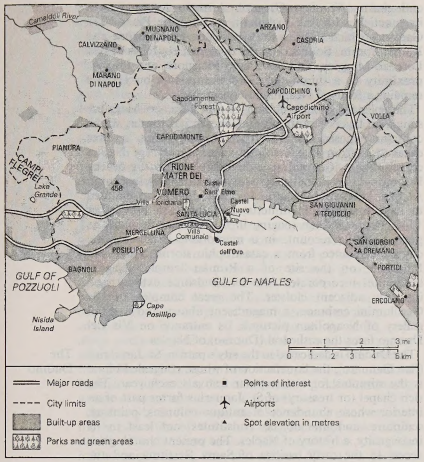
Physical and human geography

THE LANDSCAPE

Description and climate. Generations of observers have described Naples as a vast popular theatre, a designation applying as much to the city's aspect of a tiered arena as to its animated street life. It may also be characterized as an immense *presepio,* in evocation of the populous scene of the traditional Neapolitan Christmas crèche—the expansive natural setting being countered, within the town itself, by a congested vitality. In the shadow of Vesuvius, within the sweep of the bay, the Neapolitan decor is still predominantly one of moldering palaces in red or ochre and ancient churches in stone or stucco. Although the narrow old streets, teeming and traffic-ridden, clamber up hillsides topped by new constructions, few buildings in central Naples as yet rise more than 10 stories. Three fortified castles—two of them on the seafront and one on a central eminence—still define the city's heart. At the picturesque, pale Castel dell'Ovo, the shoreline divides into two natural crescents.



The blond, volcanic tuff, or tufa, of the region is much used in construction, as is the dark Vesuvian lava that paves the older streets. Magisterial use was also made, in past centuries, of the dark southern stone *piperno,* seen at its most imposing at the Castel Nuovo. The city's aspect of southern colours interspersed with evergreen groves of ilex, palm, camellia, and umbrella pine reflects a climate in which balconies are in use most of the year. High temperatures in July and August often exceed 90° F (32° C), while the damp, chilly winter is alleviated by many brilliant days. Winter temperatures rarely fall to freezing, and the snow occasionally appearing on Vesuvius is seldom seen in the town itself. The south wind, the sand-laden sirocco, intermittently brings a burdensome humidity, terminating in rain. Temperatures

Layout and architecture. Suburban Naples incorporates the headland of Posillipo, which joins the city at the yachting port of Mergellina—signaled by the church of Santa Maria del Parto. The nearby church of Santa Maria di Piedigrotta, centre of a now-diminished popular festival, is steeply overlooked by a small park encompassing the entrance to the Roman grotto called the Crypta Neapolitana. This poignant place also contains the Roman columbarium known as the Tomb of Virgil, and the sepulchre of the Romantic poet Giacomo Leopardi, who died at Naples in 1837.

From Mergellina, the seaside sweep of Via Francesco Caracciolo is flanked by the long, public park called Villa Comunale, sheltering the Zoological Station and the Aquarium (the oldest in Europe), both founded in 1872. Along the inland border of the park runs the Riviera di Chiaia, marking what was once the shoreline. (The name Chiaia probably derives from *ghiaia,* denoting a shingle.) Still for the most part lined with handsome old palazzi, the Riviera di Chiaia was a favourite residential area for foreign visitors in the 18th and 19th centuries. The Neoclassical Villa Pignatelli, constructed for Sir Ferdinand Acton in the 1820s, is now, with its period furnishings, a museum. Recessed in contiguous streets, the churches of Santa Maria in Portico and the Ascensione a Chiaia contain works of the prolific 17th- and 18th-century Neapolitan painters.

Above this busy littoral, the panoramic Corso Vittorio Emanuele unfurls northeastward around the lower slopes of the town, toward the labyrinthine zone of Rione Mater Dei. Higher still, the prosperous Vomero district is served, like other upper areas of the city, by spiraling roads and a funicular railway. Among the modern blocks of the Vomero, the early 19th-century Villa Floridiana—housing the national museum Duca di Martina, with a fine collection of European and Oriental porcelain and ceramics—is easily distinguished in its extensive park.

Piazza della Vittoria—whose titular church commemorates the Battle of Lepanto (1571)—closes the sweep of Villa Comunale and leads inland to the fashionable shops of Piazza dei Martiri, Via Chiaia, and Via dei Mille. The

Naples and surrounding area.

waterfront road, becoming Via Partenope, passes along the ancient quarter of Santa Lucia—much altered since the late 19th century by land reclamation and monotonous construction and bordered on the seafront by some of the city's best hotels. Beneath the spur of the Pizzofalcone quarter—the remaining fragment of the defunct volcano Echia and once the site of a villa of the Roman general Lucius Licinius Lucullus—a brief causeway leads to the seagirt Castel dell'Ovo, its ancient origins incorporated in a medieval fortress. On the bay's second crescent, the eastbound road passes below the long, red flank of the Royal Palace and arrives at the foot of the mighty Castel Nuovo, which, with its round towers, dominates the main port on the one hand and, on the other, the large Piazza del Municipio.

The Castel Nuovo

The Castel Nuovo, so called to distinguish it from the older Castel dell'Ovo, was founded in 1279 by Charles I of Naples (Charles of Anjou). One of many Neapolitan landmarks to bear interchangeable names, it is known locally as the Maschio Angioino, in reference to Charles' Angevin origins and from the southern Italian convention that a show of power is necessarily male. There, in the 14th century, the brilliant court of King Robert welcomed Petrarch and Boccaccio, and Giotto was summoned to execute frescoes (now lost). The castle was embellished by Alfonso V of Aragon (Alfonso I of Naples), whose triumphal entry into Naples in 1443 supplies the theme of magnificent Renaissance sculptures over the west entrance. The castle, containing important late medieval and Renaissance decoration, now houses municipal bodies and an institute of Neapolitan history with an important library. At the west end of Piazza del Municipio, the Naples city hall incorporates, in a handsome structure of the 1820s, a 16th-century church.

The waterfront road continues past docklands, skirting on its inner side the popular church of Santa Maria del Carmine. The nearby Piazza del Mercato, a lively scene of morning markets, was also, in past centuries, a place of execution. Bombardment of the port of Naples during World War II obliterated much of the character of this section of shoreline, and the road itself diverges in the industrial zone of San Giovanni a Teduccio (a name that possibly recalls that of Theodosius). Visible history resumes in the approach to Portici and the Vesuvian shore.

Inland above Piazza del Municipio, the San Martino Hill is surmounted by a former Carthusian monastery—now an important museum of paintings and objects concerned with the history of Naples—and by the massive abutment of Castel Sant'Elmo. Both are of Angevin origins. The castle, founded in 1329 by Robert of Anjou, was recreated in the 16th century, under the Spanish viceroys, in the form of a six-pointed star. Within the complex of the former San Martino monastery, the church itself is rich in paintings and marble decoration of the Neapolitan Baroque. From the adjoining museum, one passes to a terraced garden with an incomparable panorama of Naples and the bay.

South of Piazza del Municipio, beyond the Castel Nuovo, stands the red complex of the Royal Palace, whose northeast wing, set in a small park, houses the great collections of the National Library of Naples. The main facade of the Royal Palace grandly faces, southwest across the vast Piazza del Plebiscito, the basilica of San Francesco di Paola, which—erected in royal thanksgiving for the restoration of Bourbon rule (1815)—is modeled on the Pantheon of Rome. The palace, created by Domenico Fontana early in the 17th century, now houses government offices and a notable picture gallery. Above San Francesco di Paola to the southwest, the rise of Monte di Dio is crowned by two important churches: the 17th-century Santa Maria degli Angeli and the 18th-century Nunziatella.

Adjacent to the palace on the north is the San Carlo opera house, which has heard and inspired many of the great artists of bel canto. Although the prodigious musical creativity of 18th-century Naples has no modern parallel, the San Carlo remains an important element of Europe's musical life. Across the busy intersection from the San Carlo, the late 19th-century arcades of the cruciform Galleria Umberto I serve, under their glass cupola, as an ornate meeting place; the arcades were familiar ground to Allied servicemen in the closing phase of World War II—a dramatic period recalled in such writings as John Horne Burns's *The Gallery* (1947), Norman Lewis' *Naples '44* (1978), and the macabre *La pelle* (1949; *The Skin*, by the politically volatile Curzio Malaparte, while early postwar disaffection is portrayed in Raffaele La Capria's *Un giorno d'impazienza* (1952; *A Day of Impatience*). Immediately south, on Piazza Trieste e Trento, the 17th-century church of San Ferdinando has traditionally given the *Stabat Mater* of Giovanni Battista Pergolesi—composed in 1736 for this confraternity—during Easter Week.

Via Toledo

From Piazza Trieste e Trento, the teeming thoroughfare of Via Toledo—named for the Spanish viceroy Don Pedro di Toledo, who laid it out in 1536—passes north into the dense centre of Naples. Its innumerable shops interspersed with grand churches, Via Toledo is banked with 17th- and 18th-century palazzi whose former magnificence has been turned to commercial or municipal use or—as in the case of the mighty Palazzo Maddaloni—has been allowed to lapse into residential decay. On the slope above Via Toledo,

Lee de Wys, Inc./F. Damm

The Bay of Naples with the view south toward Mount Vesuvius.

steep alleys climb toward San Martino through a zone that, preserving its labyrinthine 17th-century structure, is still known as the Spanish Quarter. The lower line of Via Toledo is interrupted at Piazza Carità by structures built during the Fascist and postwar eras.

Debouching into the Neoclassical hemicycle of Piazza Dante, Via Toledo resumes its route under other names, skirting the western flank of the National Archaeological Museum in its ascent toward Capodimonte.

Piazza Dante forms part of the western boundary to the district that, lying along three principal *decumani* (streets of orientation) of the Greek and Roman town, has comprised the city's heart since ancient times. Beyond the picturesque Alba Gate this district is introduced, at the western extreme of Via Tribunali, by the historic Naples Conservatory of Music and its great adjoining Gothic church of San Pietro a Maiella. Via Tribunali, the *decumanus maior* of Greco-Roman Naples, extends east for approximately one mile, terminating at the law courts near the old Capuana Gate. At its western end, the Renaissance Pontano Chapel (in decay) recalls the humanist Giovanni Pontano, who lived in Naples under Aragonese rule, while the older origins of the contiguous Baroque church of Santa Maria Maggiore are apparent in a Romanesque campanile.

Parallel to Via Tribunali, the upper, briefer Via Anticaglia conserves, within subsequent structures, evident remains of Roman public buildings. The lower parallel—the street that, bearing interim names, becomes Via San Biagio dei Librai—delineates the so-called Spaccanápoli ("Split of Naples"), a designation more loosely applied to all of this ancient centre.

From Piazza del Municipio, Spaccanápoli is approached along the north-northwest trajectory formed by Via Medina and Via Monteoliveto—a route that passes, to the east of Via Monteoliveto, the recessed Renaissance and Baroque complex of Santa Maria la Nova; and, to the west, in a small square, the church of Monteoliveto, or Sant'Anna dei Lombardi, supreme in Naples for its abundance and quality of Renaissance sculpture. From Via Monteoliveto, the short slope called Calata Trinità Maggiore rises to Piazza del Gesù Nuovo, a principal means of access to Spaccanápoli.

Overlooked from the west by Palazzo Pignatelli (where the painter Edgar Degas resided while in Naples) and with the 18th-century ornate Neapolitan obelisk Guglia dell'Immacolata at its centre, this square is dominated by the church of Gesù Nuovo, its gem-cut facade masking a sumptuous Baroque interior. Opposite rises the medieval complex of Santa Chiara, erected for the Franciscan order in the 14th century. The vast church, transformed internally in the 18th century and now restored (following tragic bombardment in 1943) to its original Gothic form, houses a damaged splendour of royal tombs and early frescoes. At its rear the large cloister decorated in 18th-century majolica tiles is one of the loveliest in Naples.

Santa Chiara

From this square the line of Spaccanápoli runs due east. The profusion of important monuments there, the mingling of eras, and the exuberance of the human setting are of inexhaustible fascination. Near the Gesù Nuovo, Palazzo Filomarino houses the Italian Institute for Historical Studies, founded by the philosopher Benedetto Croce. (Another celebrated Neapolitan philosopher, Giambattista Vico, was born, two centuries before Croce, in a house also preserved in this street.) Flanked by great palazzi, the basilica of San Domenico Maggiore, its Gothic form merged into the structures of later centuries, is a treasury of painting and sculpture. In 1272–74, St. Thomas Aquinas taught in the adjoining monastery. Where the intersecting Via Mezzocannone turns south toward the University of Naples, the church of Sant'Angelo a Nilo contains a lofty tomb sculptured by Donatello and Michelozzo. The nearby Renaissance Palazzo Santangelo was a stronghold of the once-mighty Carafa family.

In the upward transverse of Via San Gregorio Armeno, the church of this name exemplifies the Neapolitan Rococo. In this street, in slotlike shops, figures are made for the innumerable Neapolitan family crèches—culminating each Christmas in a scene of indescribable liveliness and charm. Via San Gregorio Armeno terminates, at its junction with Via Tribunali, in the little Piazza San Gaetano, which overlies the site of the Greek agora and Roman forum. Bounded by the two great churches of San Lorenzo Maggiore and San Paolo Maggiore, and in close proximity to a third—the Gerolomini—this busy space remains a focus of Neapolitan continuity.

The splendid Gothic church of San Lorenzo Maggiore stands on layers of antiquities. Beneath its cloister, which contains exposed remains from Roman times, a large excavation from the Greek and Roman eras of Naples constitutes—with antiquities discovered below the nearby Duomo—a considerable segment of the ancient city centre. At San Lorenzo Maggiore, in 1334, Boccaccio claimed to have first seen Fiammetta; and there, in November 1345, Petrarch, then lodging in the adjacent monastery, prayed—as he recounts in a memorable letter—for the city's deliverance from a catastrophic storm. San Paolo Maggiore, on the site of a Roman temple, features antiquities incorporated into its handsome exterior and into the adjacent cloister. The great complex of the Gerolomini embraces a magnificent library and a small gallery of Neapolitan pictures. Its entrance on Via del Duomo faces the cathedral (Duomo) of Naples.

The Duomo

The Duomo is dedicated to the city's patron, St. Januarius (San Gennaro), the liquefaction of whose congealed blood is the stimulus for two popular festivals each year. The rich chapel (or treasury) of St. Januarius forms part of an interior whose abundance of antique columns, painting, sculpture, and fine objects constitutes, not least in its incongruity, a history of Naples. The present church gives access to the early basilica of Santa Restituta and the adjoining baptistery, with 5th-century mosaics, of San Giovanni in Fonte. Near the upper (southern) flank of the cathedral, the 14th-century church of Santa Maria Donnaregina is, in its interior decoration, among the most interesting and beautiful medieval monuments of Naples, while the nearby Santi Apostoli, on the site of a Roman temple, provides a prodigious display of 17th-century Neapolitan painting.

To the east, the formidable Castel Capuano—site of law courts since the 16th century—rises near the round towers of the Capuana Gate, which in turn overshadow the Renaissance church of Santa Caterina a Formiello. Renaissance also is the decoration, by Giuliano da Maiano, of the exterior arch of this Aragonese city gate. Beyond the Capuana Gate, the northwest-southeast diagonal of Via Carbonara follows the line of demolished city walls. Marked, on its upper slope, by the monumental church of San Giovanni a Carbonara—containing the statuary tomb of King Ladislas and other capital late Gothic and early Renaissance works—Via Carbonara descends, with a change of name, to Piazza Garibaldi and the railway station.

Toward the end of the 19th century, precipitate change was wrought, from Piazza del Municipio to the railway station, by the slum clearance, or *risanamento,* that, following a calamitous epidemic of cholera in 1884, drove the straight, ugly Corso Umberto I (also called the Rettifilo) through that historic quarter. The stolid Rettifilo conceals, in small recesses, many historic buildings—beginning with the church of San Pietro Martire and concluding, at Piazza Garibaldi, with that of San Pietro ad Aram and its paleo-Christian crypt. Near Piazza Garibaldi, the Aragonese Nolana Gate is an enclave of busy markets.

Museums. Naples possesses two of the world's great museums, both founded under Bourbon rule. The National Archaeological Museum houses unsurpassed collections of Greco-Roman antiquities, comprising many of the finest works—in marble, bronze, mosaic, fresco, and ceramic—from Herculaneum, Pompeii, and other Campanian sites and the Farnese marbles, a Bourbon inheritance. The museum also possesses significant Egyptian antiquities. Overlooking Naples on the north from its handsome park, the National Museum and Gallery of Capodimonte contains, together with important tapestries and porcelain, a splendid collection of paintings, including masterworks by Simone Martini, Masaccio, Botticelli, Colantonio, Lotto, Parmigianino, Correggio, Titian, El Greco, and

Pieter Bruegel the Elder, and fine examples of the Neapolitan 17th- and 18th-century painters. Following the earthquake of 1980, works by Caravaggio and Titian were removed to Capodimonte from their traditional settings in the city.

In addition to museums already noted, the civic Filangieri Museum houses, in a Renaissance building on Via del Duomo, a collection of paintings and objects, many of them related to Neapolitan history. At the nearby State Archives, documents of great historic importance are installed in the former Benedictine monastery of SS. Severo and Sossio—a vast complex including, in the Platano cloister, celebrated frescoes by Antonio Solario.

THE PEOPLE

Travelers in Italy accustomed to grand public squares where visitors may at leisure observe the monuments and manners of the town are often puzzled by Naples' apparent lack of such focal points—not because great piazzas do not exist there, but because they are often used as mere traffic arteries and because the city's life is not so much concentrated in such places as diffused around them. The city's heart will rather be discovered in the small, populous enclaves—animated in the mornings, dormant by afternoon, revived at evening—which, each with distinctive character, make up the town's traditional districts. Intimacy with such a city is necessarily gradual, requiring a state of mind amounting to a revelation.

Naples, which, following the 18th-century discoveries of the buried cities of Vesuvius, long remained essential to cultivated travel, now serves visitors mainly as a wayside halt to neighbouring sites and resorts. Already in decline, tourism at Naples was sharply reduced by the effects of World War II, which left the city a shambles, and by the cessation of regular sea travel, which no longer brought visitors to the port of Naples. Many of the city's monuments were, moreover, embedded in what modern travelers often viewed as uninviting squalor; and random street crime—making it unsafe to carry items of value—compounded the disadvantages. A new touristic emphasis on brevity, velocity, and large numbers imposed, in turn, requirements that Naples could not meet—the city's riches of ancient continuity and of a slowly unfolding charm being unsuited to a hasty or systematic approach.

Decline in tourism

Bypassed by the foreign influx, Naples has thus preserved much authenticity and some skepticism toward modern tenets. Goethe's generalization that Neapolitans "wish even their work to be a recreation" is still valid, however incompatible with economic and administrative realities. While Goethe himself could not resist the northern cliché that Neapolitans are childlike, the tolerant penetration of motive, the graceful absence of envy, belligerence, or nationalism, and above all the civilizing Neapolitan sense of mortality, seem indicative, rather, of a long transmitted comprehension in human affairs.

Intellectual life in Naples, which is mainly centred around scholars concerned with the classical and Neapolitan past, is marked by high distinction and strong animosities and generates an important and varied literature. Despite the growth of a middle class and a notable advance in the status of women, emphatic divisions persist between prosperous and poor, while, in all classes, history has fatally extinguished—with rare exceptions—the flame of civic spirit. Government corruption and neglect are intensified by bureaucratic confusion and by the violent interventions of the Camorra, an illicit Neapolitan association analogous to the Sicilian Mafia. Nevertheless, with infinite adaptation, a sense of identity is maintained. Many festivals have fallen victim to traffic, and the old Neapolitan songs—now electronically diffused—have no successors. But fervour and fireworks still greet saints and soccer players alike. The ironic Neapolitan dialect holds its own. Individuality and family loyalty remain strong, as does a capacity not only for pleasure but for joy.

THE ECONOMY

Industry. Naples is the industrial centre of southern Italy. Under the Bourbons the city had an early start in manufacturing, with foundation of the porcelain factory at the royal palace of Capodimonte in 1740 and the development of silk and other textile production soon thereafter. The textile industry has remained important. Other traditional industries of continuing importance are food processing and winemaking. The first steel mill opened at the end of the 19th century, but the industry did not add significantly to national production until the 1970s. Among the newer industries in the region are electronics manufacturing, petroleum refining, and automobile assembly. The tourist industry continues to be important to the regional economy.

Early economic development

Industrial development was aided considerably after World War II by the concerted action of state planning and fiscal agencies and of companies either owned or controlled by the national government. Local enterprise was associated with the programs. The region's infrastructure was upgraded extensively and its energy production expanded. Nevertheless, Naples and the whole of southern Italy lags well behind the north.

Transportation. In 1818 the first steamboat on the Mediterranean was launched at the royal shipyards in Naples. Remodeling of the ancient harbour and its early medieval additions—now mostly filled in—was begun in 1826. Port facilities were badly damaged during World War II, but the subsequent reconstruction and modernization of its facilities have kept Naples one of the chief Mediterranean ports.

In 1839 Italy's first railway traversed the five miles from Naples to the royal residence of Portici. The first funicular railway on the peninsula was opened to the heights of Vomero in 1880. Naples developed into an important railway centre, being the main junction between Rome and southern Italy. Since World War II the city also has become a major junction point for road and air travel.

History

THE EARLY PERIOD

Naples was founded about 600 BC as Neapolis ("New City"), close to the more ancient Palaepolis, which had itself absorbed the name of the siren Parthenope. Both towns originated as Greek settlements, extensions almost certainly of Greek colonies established, during the 7th and 6th centuries BC, on the nearby island of Pithecusa (now Ischia) and at Cumae on the adjacent mainland, where remarkable Greek ruins may be visited today. Ancient Neapolis, as Gibbon says, "long cherished the language and manners of a Grecian colony; and the choice of Virgil had ennobled this elegant retreat, which attracted the lovers of repose and study from the noise, the smoke, and the laborious opulence of Rome." Horace (here paraphrased by Gibbon), Virgil, and the Neapolitan poet Statius are among numerous classical writers who attest the Hellenism of Naples. The Greek language was preserved throughout the city's first millennium, surviving submission, in the 4th century BC, to the dominion of Rome.

Greek origins

Under the empire, Naples and its environs served as a centre of Greek culture and erudition and as a pleasure resort for a succession of emperors and wealthy Romans, whose coastal villas extended from Misenum on the Gulf of Pozzuoli (the ancient Puteoli) to the Sorrentine peninsula. The amenity of these dwellings, depicted in recovered Vesuvian frescoes, is confirmed in such remains as Tiberius' Villa Jovis on Capri, the villa of Oplontis at Torre Annunziata, and the ruins of Villa Pausilypon, which gave its Greek name—meaning "a pause from care"—to the headland of Posillipo. Near Herculaneum, the buried private establishment known as the Villa of the Papyri yielded, in the mid-18th century, a treasure of antique sculpture and a group of papyrus scrolls presumed to belong to an ancient library. These scrolls, many of them deciphered, are conserved in the National Library at Naples. The villa was never uncovered, and its 18th-century tunnels of approach were reopened only in 1987. A floor plan drawn up in the 18th century was the basis for the J. Paul Getty Museum at Malibu, Calif., U.S.

In Roman times Naples was adorned with temples and baths and with arenas similar to those surviving at Pozzuoli and Pompeii. Principal Roman roads connected the

city to the capital, and aqueducts supplied fresh water. The gulfs of Naples and Pozzuoli were linked by galleries pierced through the yellow tufa of lower Posillipo. Of these, an evocative example may be visited at Mergellina, at the Crypta Neapolitana, beside the Roman tumulus long venerated as the Tomb of Virgil, in tribute to the Mantuan poet who celebrated the Neapolitan ambience in the sixth book of his *Aeneid* and composed the *Georgics* there between 37 and 30 BC.

Eruption of Vesuvius in AD 79

In AD 79 the great eruption of Vesuvius buried the seaside towns of Pompeii, Herculaneum, and Stabiae, engulfing also many villas confidently constructed on the slopes of a mountain that had not erupted for more than seven centuries. A contemporary account of this event survives in two letters addressed to the historian Tacitus by Pliny the Younger, who describes the doomed attempt of his uncle, the polymathic elder Pliny, to rescue survivors by sea. More than 16 centuries later, in 1738, systematic excavation of the buried towns was inaugurated at Herculaneum, under the aegis of the Neapolitan Bourbons—initiating discoveries that would profoundly influence Western aesthetic and scientific concepts and transform our knowledge of the ancient world.

Early tribulations of Christians at Naples are exemplified in the martyrdom of the city's patron, St. Januarius. The Catacombs of St. Januarius, on the Capodimonte slope, antedate in their earliest section the saint's legendary decapitation in AD 305 and are extremely interesting historically and for paleo-Christian decoration. Other early Christian sites include the baptistery incorporated in the Duomo, the ancient apse at the nearby church of San Giorgio Maggiore, and the Catacombs of San Gaudioso below the great church of Santa Maria della Sanità in one of the city's most colourful districts.

During the decline of the Roman Empire, Naples suffered with all the Italian Peninsula, and, having espoused the Gothic cause, drew, in 536, the vengeance of the Roman commander Belisarius. In the division of the late empire the city remained, with some vacillation, under the Exarchate of Ravenna until the 8th century when, rebelling against the Eastern emperors, Naples established a form of republican government that secured embattled independence for more than three centuries. Succumbing at last to the Lombard power established at Capua and Benevento, Naples saw the Lombards dispossessed, in turn, by the Norman conquests that swept southern Italy in the 12th century. While including Naples in that turbulent subjugation, Norman—and, subsequently, Swabian—dominion elevated the metropolis to a regional and cultural capital, a position Naples would retain under diverse rulers until the 19th century. Although maintaining his court at Palermo, the Holy Roman emperor Frederick II fortified Naples, founded the university there in 1224, and nurtured, in a rebellious ambience, the city's intellectual life.

NAPLES FROM THE ANGEVINS TO THE RISORGIMENTO

Renewal of the city's importance

In 1266 establishment of the Angevin dynasty in Naples renewed the city's importance—formidably proclaimed by erection of the Castel Nuovo and the Sant'Elmo fortress. The Angevin kings and their Aragonese successors attracted to Naples great figures of Italian thought and literature and the northern architects and artists whose genius survives in many Gothic and Renaissance monuments. Under Alfonso V of Aragon—a monarch, in the words of the historian Jacob Burckhardt, "brilliant in his whole existence"—culture at Naples transcended warfare. In 1453 fugitives from the fall of Constantinople brought an infusion of Byzantine arts. The growth of Neapolitan political power is implicit in the visit of Lorenzo de'Medici, ruler of Florence, to the court of Ferdinand (Ferrante) I in 1479–80.

In 1503 Naples entered the possession of the Spanish Habsburgs, whose viceroys presided with autocratic severity for more than two centuries. Great churches, convents, and private palaces from this period testify to a concentration of power against which an oppressed populace might periodically but ineffectually rebel—as in the ill-fated revolt led by Masaniello (Tomaso Aniello) in 1647–48. This harsh viceregal power was terminated by Austrian conquest (1707). And, in 1734, Naples became, under the Spanish Bourbons, the capital of a large independent southern kingdom, Don Carlos (the future Charles III of Spain) assuming the old and all but impenetrable title of "king of the Two Sicilies."

Naples now burgeoned as a potent European capital, its implacable divisions of wealth and poverty thrown in relief by 18th-century illumination. It is significant that, despite the importance of preceding Neapolitan artists, it was only with the 18th century that Naples developed its own school of painting. Scholars and statesmen from that era—such as Giambattista Vico, Pietro Giannone, Bernardo Tanucci, Ferdinando Galiani, and Gaetano Filangieri—are of universal rather than exclusively Neapolitan distinction. Another period of prolific construction is commemorated in Bourbon public edifices—including the royal palaces of Portici and Caserta—and in private mansions. The Vesuvian littoral again became a site of busy communities and of the elegant Ville Vesuviane, today mostly in disrepair. The excavations at Herculaneum and Pompeii attracted foreign visitors, while, in a climate of Neoclassicism and incipient Romanticism, artists, writers, and scholars arrived to experience the Neapolitan ambience. Depictions of the city and its surroundings—and of its presiding volcano, somewhat slighted by earlier painters—now found their way around the world.

Ferdinand IV and Maria Carolina

At the court of Ferdinand IV (Ferdinand I of the Two Sicilies) and his masterful queen, Maria Carolina, the cultivated British envoy Sir William Hamilton forged an Anglo-Neapolitan bond that lingers today. Maria Carolina's repressive tendencies were traumatically intensified by the execution in 1793 of her sister Marie Antoinette, queen of France. With the irruption of Napoleon into Italy (1798), the royal family withdrew in panic to Palermo aboard Admiral Horatio Nelson's British ships. The Neapolitan educated classes proclaimed a republic, while the Neapolitan poor, the *lazzaroni*, abandoned by their sovereign, remained vigorously if incomprehensibly monarchist. The nobly conceived Parthenopean Republic collapsed in a welter of blood. A punitive return by the Bourbons and the execution or exile of the republicans make the year 1799 a tragic epoch in the Neapolitan story.

In 1805 the court fled anew to Palermo, and, until 1815, the Kingdom of Naples was ruled, with legislative reforms, by Napoleon's brother Joseph Bonaparte and, subsequently, by Joachim Murat. Following the fall of Napoleon, the Bourbons reentered Naples with Austrian assistance. However, the weakness and corruption of succeeding Bourbon monarchs and their ruthless suppression of progressive ideas set the scene for Giuseppe Garibaldi's triumphant entry into the city in 1860 and for absorption of Naples into the Kingdom of Italy.

THE MODERN CITY

Deprived of territorial power, the city of Naples has, since the late 19th century, increasingly sought survival in an elusive and temperamentally incompatible degree of industrialization and in the ingenuity of its citizens, whose gifts for improvisation have been called forth no less by modern bureaucratic riddles than by the indifference of past monarchies. The cholera epidemic of 1884 aroused a transient spirit of reform, reflected in slum clearance, modernization of water and transport systems, and other public works. (A striking contemporary account of the epidemic and its context may be found in *Il ventre di Napoli*, by the journalist Matilde Serao. In 1973, during a brief reappearance of cholera in the city, this book, reissued, was found all too apposite.) The optimism of the *risanamento* was blighted by the onset of World War I.

The rise of fascism in Italy, compounded by the Great Depression of the 1930s, darkened the interval between the wars—from which, at Naples, the philosopher Benedetto Croce and other enlightened figures stand forth in defense of humanity and reason. While Naples shared with all Italy the degradation of fascism, few Italian cities suffered so heavily in World War II or made so painful and incomplete a recovery. Concerted restoration of decaying monuments was only inaugurated, in any appreciable degree, in the 1980s. That the city survived the postwar period

without complete economic and social collapse can be attributed almost exclusively to the vitality and philosophy of its populace and to the Neapolitan ability to combine strong passions with a resilient endurance.

BIBLIOGRAPHY

General: SIR WILLIAM HAMILTON, *Campi Phlegraei* (1776), offers illustrated observations on the area of volcanic activity that influences the environment of Naples. Other relevant historic writings include JOHANN WOLFGANG VON GOETHE, *Italian Journey, 1786–1788*, trans. from German by W.H. AUDEN and ELIZABETH MAYER (1962, reprinted 1982), a travel diary, completed in 1816–17, with celebrated chapters on Naples; and NORMAN DOUGLAS, *Siren Land* (1911, reprinted 1982), an illuminating discussion of the ancient Neapolitan setting, Capri, and Sorrento. DESMOND SEWARD (ed.), *Naples, a Travellers' Companion* (1984), is an anthology of writings on Naples by authors from the 13th to the mid-19th century. PETER GUNN, *The Companion Guide to Southern Italy* (1969); and H.V. MORTON, *A Traveller in Southern Italy* (1969, reprinted 1987), are descriptive guidebooks. Essential information is collected in the detailed guidebook *Napoli e dintorni*, 5th ed. (1976). Social conditions, the poor, and especially children are the topic of MARIA CARMELA BARBIERO (ed.), *Gli eredi della povertà: stabilità e mutamento nel sottoproletariato nepoletano* (1981); JUDITH CHUBB, *Patronage, Power, and Poverty in Southern Italy: A Tale of Two Cities* (1982); and THOMAS BELMONTE, *The Broken Fountain* (1979). For an analysis of political developments, see P.A. ALLUM, *Politics and Society in Post-War Naples* (1973).

History: A fundamental encyclopaedic work, dealing authoritatively with every aspect of Neapolitan history, is *Storia di Napoli*, 11 vol. in 14 (1967–78), published by the Società Editrice Storia di Napoli; it is complemented by "Napoli Nobilissima," a series of brief scholarly monographs on every aspect of Neapolitan history, which periodically is bound into volumes. JOHN H. D'ARMS, *Romans on the Bay of Naples: A Social and Cultural Study of the Villas and Their Owners from 150 B.C. to A.D. 400* (1970), traces the life and culture through the analysis of the remains of important constructions; MARTIN FREDERIKSEN, *Campania* (1984), is a history of the region beginning with antiquity. GIOVANNI PUGLIESE CARRATELLI *et al., Megale Hellas: storia e civiltà della Magna Grecia* (1983), provides a comprehensive scholarly history of Greek civilization in southern Italy. Urban Naples and its administration in the Greek and Roman periods are examined in BARTOLOMMEO CAPASSO, *Napoli graeco-romana* (1905, reprinted 1978).

Works on later historical periods include GINO DORIA, *Storia di una capitale: Napoli dalle origini al 1860*, 6th rev. ed. (1975), covering the period up to the absorption of Naples into the Kingdom of Italy; JERRY H. BENTLEY, *Politics and Culture in Renaissance Naples* (1987); VINCENZO CUOCO, *Saggio storico sulla rivoluzione napoletana del 1799*, new ed. (1929, reissued 1980), on the Parthenopean Republic and the revolution; BENEDETTO CROCE, *La rivoluzione napoletana del 1799*, 8th ed. Napoleon

Napoleon Bonaparte (original Italian, Napoleone Buonaparte), a French general, was first consul and then emperor of the French and carried out many reforms that left a lasting mark on the institutions of France and of much of western Europe. But his driving passion was the military expansion of French dominion, and, though at his fall he left France smaller than it had been at the outbreak of the Revolution in 1789, he was almost unanimously revered during his lifetime and until the end of the Second Empire under his nephew Napoleon III as one of history's great heroes.

Napoleon was born at Ajaccio on the island of Corsica on August 15, 1769, shortly after the cession of Corsica to France by the Genoese. He was the fourth, and second surviving, child of Carlo Buonaparte, a lawyer, and his wife, Letizia Ramolino. His father's family, of ancient Tuscan nobility, had emigrated to Corsica in the 16th century.

Carlo Buonaparte had married the beautiful and strong-willed Letizia when she was only 14 years old; they eventually had eight children to bring up in very difficult times. The French occupation of their native country was resisted by a number of Corsicans led by Pasquale Paoli. Carlo Buonaparte joined Paoli's party, but when Paoli had to flee, Buonaparte came to terms with the French. Winning the protection of the governor of Corsica, he was appointed assessor for the judicial district of Ajaccio in 1771. In 1778 he obtained the admission of his two eldest sons, Joseph and Napoleon, to the Collège d'Autun.

Early years and education in France

A Corsican by birth, heredity, and childhood associations, Napoleon continued for some time after his arrival in Continental France to regard himself a foreigner; yet from the age of nine he was educated in France as other Frenchmen were. While the tendency to see in Napoleon a reincarnation of some 14th-century Italian *condottiere* is an overemphasis on one aspect of his character, he did, in fact, share neither the traditions nor the prejudices of his new country: remaining a Corsican in temperament, he was first and foremost, through both his education and his reading, a man of the 18th century.

Napoleon was educated at three schools: briefly at Autun, for five years at the military college of Brienne, and finally for one year at the military academy in Paris. It was during Napoleon's year in Paris that his father died of a stomach cancer in February 1785, leaving his family in straitened circumstances. Napoleon, although not the eldest son, assumed the position of head of the family before he was 16. In September he graduated from the military academy, ranking 42nd in a class of 58.

He was made second lieutenant of artillery in the regiment of La Fère, a kind of training school for young artillery officers. Garrisoned at Valence, Napoleon continued his education, reading much, in particular works on strategy and tactics. He also wrote *Lettres sur la Corse,* in which he reveals his feeling for his native island. He went back to Corsica in September 1786 and did not rejoin his regiment until June 1788. By that time the agitation that was to culminate in the French Revolution had already begun. A reader of Voltaire and of Rousseau, Napoleon believed that a political change was imperative, but as a career officer he seems not to have seen any need for radical social reforms.

THE REVOLUTIONARY PERIOD

The Jacobin years. When in 1789 the National Assembly, which had convened to establish a constitutional monarchy, allowed Paoli to return to Corsica, Napoleon asked for leave and in September joined Paoli's group. But Paoli had no sympathy for the young man, whose father had deserted his cause and whom he considered to be a foreigner. Disappointed, Napoleon returned to France; and in April 1791 he was appointed first lieutenant to the 4th regiment of artillery, garrisoned at Valence. He at once joined the Jacobin club, a debating society initially favouring a constitutional monarchy, and soon became its president, making speeches against nobles, monks, and bishops. In September 1791 he got leave to go back to Corsica again for three months. Elected lieutenant colonel in the national guard, he soon fell out with Paoli, its commander in chief. When he failed to return to France, he was listed as a deserter in January 1792. But in April France declared war against Austria and his offense was forgiven.

Apparently through patronage, Napoleon was promoted to the rank of captain but did not rejoin his regiment. Instead he returned to Corsica in October 1792, where Paoli was exercising dictatorial powers and preparing to separate Corsica from France. Napoleon, however, joined the Corsican Jacobins, who opposed Paoli's policy. When civil war broke out in Corsica in April 1793, Paoli had the Buonaparte family condemned to "perpetual execration and infamy," whereupon they all fled to France.

Napoleon Bonaparte, as he may henceforth be called (though the family did not drop the spelling Buonaparte until after 1796), rejoined his regiment at Nice in June 1793. In his *Souper de Beaucaire,* written at this time, he argued vigorously for united action by all republicans rallied round the Jacobins, who were becoming progressively more radical, and the National Convention, the revolutionary assembly that in the preceding fall had abolished the monarchy. At the end of August 1793, the National Convention's troops had taken Marseille but were halted before Toulon, where the royalists had called in British forces. With the commander of the National Convention's artillery wounded, Bonaparte got the post through the commissioner to the army, Antoine Saliceti, who was a Corsican deputy and a friend of Napoleon's family. Bonaparte was promoted to major in September and adjutant

Capture of Toulon

general in October. He received a bayonet wound on December 16, but on the next day the British troops, harassed by his artillery, evacuated Toulon. On December 22 Bonaparte, aged 24, was promoted to brigadier general in recognition of his decisive part in the capture of the town.

Augustin de Robespierre, the commissioner to the army, wrote to his brother Maximilien, by then virtual head of the government and one of the leading figures of the Reign of Terror, praising the "transcendent merit" of the young republican officer. In February 1794 Bonaparte was appointed commandant of the artillery in the French Army of Italy. Robespierre fell from power in Paris on 9 Thermidor (July 27, 1794). When the news reached Nice, Bonaparte, regarded as a protégé of Robespierre, was arrested on a charge of conspiracy and treason. He was freed in September but was not restored to his command. The following March he refused an offer to command the artillery in the Army of the West, which was fighting the counter-revolution in the Vendée. The post seemed to hold no future for him, and he went to Paris to justify himself. Life was difficult on half pay, especially as he was carrying on an affair with Désirée Clary, daughter of a rich Marseille businessman and sister of Julie, the bride of his elder brother, Joseph. Despite his efforts in Paris, Napoleon was unable to obtain a satisfactory command because he was feared for his intense ambition and for his relations with the "Montagnards," the more radical members of the National Convention. He then considered offering his services to the sultan of Turkey.

The Directory. Bonaparte was still in Paris in May 1795 when the National Convention, on the eve of its dispersal, submitted the new constitution of the year III of the First Republic to a referendum, together with decrees according to which two-thirds of the members of the National Convention were to be reelected to the new legislative assemblies. The royalists, hoping that they would soon be able to restore the monarchy, instigated a revolt in Paris to prevent these measures from being put into effect. Vicomte Paul de Barras, who had been entrusted with dictatorial powers by the National Convention, was unwilling to rely on the commander of the troops of the interior; instead, knowing of Bonaparte's services at Toulon, he appointed him second in command. Thus, it was Napoleon who shot down the columns of rebels marching against the National Convention (13 Vendémiaire, year IV; October 5, 1795), thereby saving the National Convention and the republic.

Bonaparte became commander of the army of the interior and, consequently, was henceforth aware of every political development in France. He also became the respected adviser on military matters to the new government, the Directory. Lastly, he came to know an attractive Creole, Joséphine Tascher de La Pagerie, the widow of Gen. Alexandre de Beauharnais (guillotined during the Reign of Terror), the mother of two children, and a woman of many love affairs.

From every point of view, a new life was opening for Bonaparte. Having proved his loyalty to the Directory by dissolving a communist group led by François Babeuf and an Italian, Filippo Buonarroti, whom Bonaparte had known in Corsica, he was appointed commander in chief of the Army of Italy in March 1796. He had been trying to obtain that post for several weeks so that he could personally conduct part of the plan of campaign adopted by the Directory on his advice. He married Joséphine on March 9 and left for the army two days later.

Commander in chief of Army of Italy

Arriving at his headquarters in Nice, Bonaparte found that his army, which on paper consisted of 43,000 men, numbered scarcely 30,000 ill-fed, ill-paid, and ill-equipped men. On March 28, 1796, he made his first proclamation to his troops:

> Soldiers, you are naked, badly fed. . . . Rich provinces and great towns will be in your power, and in them you will find honour, glory, wealth. Soldiers of Italy, will you be wanting in courage and steadfastness?

He took the offensive on April 12 and successively defeated and separated the Austrian and the Sardinian armies and then marched on Turin. King Victor Amadeus III of Sardinia asked for an armistice; and, at the peace treaty in Paris on May 15, Nice and Savoy, occupied by the French since 1792, were annexed to France. Bonaparte continued the war against the Austrians and occupied Milan but was held up at Mantua. While his army was besieging this great fortress, he signed armistices with the duke of Parma, the duke of Modena, and finally with Pope Pius VI.

At the same time, he took an interest in the political organization of Italy. A plan for its "republicanization" by a group of Italian "patriots" led by Buonarroti had to be shelved when Buonarroti was arrested for complicity in Babeuf's conspiracy against the Directory. Thereafter, Bonaparte, without discarding the Italian patriots altogether, restricted their freedom of action. He set up a republican regime in Lombardy but kept a close watch on its leaders, and in October 1796 he created the Cisalpine Republic by merging Modena and Reggio nell'Emilia with the papal states of Bologna and Ferrara occupied by the French Army. Finally he sent an expedition to recover Corsica, which the British had evacuated.

Austrian armies advanced four times from the Alps to relieve Mantua but were defeated each time by Bonaparte. After the last Austrian defeat, at Rivoli in January 1797, Mantua capitulated. Next, he marched on Vienna. He was about 60 miles (100 kilometres) from that capital when the Austrians sued for an armistice. By the preliminaries of peace, Austria ceded the southern Netherlands to France and recognized the Lombard republic but received in exchange some territory belonging to the old Republic of Venice, which was partitioned between Austria, France, and Lombardy. Bonaparte then consolidated and reorganized the north Italian republics and encouraged Jacobin—radical republican—propaganda in Venetia. Some Italian patriots hoped that these developments would soon lead to the formation of a single and indivisible "Italian Republic" modeled on the French.

Defeat of the Austrians and peace terms

Meanwhile, Bonaparte grew uneasy at the successes of the royalists in the French elections in the spring of 1797 and advised the Directory to oppose them, if necessary, by force. In July it attempted a coup d'état against the royalists and failed; thereupon Bonaparte sent Gen. Pierre Augereau to Paris, along with several officers and men. Augereau's successful coup d'état of 18 Fructidor (September 4, 1797) eliminated the royalists' friends from the government and legislative councils and also enhanced Bonaparte's prestige. Thus, Bonaparte could conclude the Treaty of Campo Formio with Austria as he thought best. The Directory was displeased, however, because the Treaty had ceded Venice to the Austrians and did not secure the left bank of the Rhine for France. On the other hand, it raised Bonaparte's popularity to its peak, for he had gained victory for France after five years of war on the Continent.

Only the war at sea, against the British, continued. The directors, who wanted to launch an invasion of the British Isles, appointed Bonaparte to command the army assembled for this purpose along the English Channel. After a rapid inspection in February 1798, he announced that the operation could not be undertaken until France had command of the sea. Instead, he suggested that France strike at the sources of Great Britain's wealth by occupying Egypt and threatening the route to India. This proposal, seconded by Talleyrand, the foreign minister, was accepted by the directors, who were glad to get rid of their ambitious young general.

The expedition, thanks to some fortunate coincidences, was at first a great success: Malta, the great fortress of the Knights Hospitallers of St. John of Jerusalem, was occupied on June 10, 1798, Alexandria taken by storm on July 1, and all the delta of the Nile rapidly overrun. On August 1, however, the French squadron at anchor in Abū Qīr Bay was completely destroyed by Adm. Horatio Nelson's fleet in the Battle of the Nile, so that Napoleon found himself confined to the land that he had conquered. He proceeded to introduce Western political institutions, administration, and technical skills in Egypt; but Turkey, nominally suzerain over Egypt, declared war on France in September. To prevent a Turkish invasion of Egypt and also perhaps to attempt a return to France by way of Anatolia, Bonaparte marched into Syria in February 1799. His progress northward was halted at Acre, where

Failures in Egypt

the British withstood a siege, and in May Bonaparte began a disastrous retreat to Egypt.

The Battle of the Nile showed Europe that Bonaparte was not invincible, and Great Britain, Austria, Russia, and Turkey formed a new coalition against France. The French armies in Italy were defeated in the spring of 1799 and had to abandon the greater part of the peninsula. These defeats led to disturbances in France itself. The coup d'etat of 30 Prairial (June 18, 1799) expelled the men of moderate views from the Directory and brought into it men who were considered Jacobins. Yet the situation remained confused, and one of the new directors, Emmanuel Sieyès, was convinced that only military dictatorship could prevent a restoration of the monarchy: "I am looking for a sabre," he said. Bonaparte did not take long to make up his mind. He would leave his army and return to France—in order to save the republic, of course, but also to take advantage of the new circumstances and to seize power. The Directory had, in fact, ordered his return, but he had not received the order, so that it was actually in disregard of his instructions that he left Egypt with a few companions on August 22, 1799. Their two frigates surprisingly escaped interception by the British, and Bonaparte arrived in Paris on October 14.

By this time French victories in Switzerland and Holland had averted the danger of invasion, and the counter-revolutionary risings within France had more or less failed. A coup d'etat could therefore no longer be justified by any need to save the republic. Sieyès, however, had not given up his project, and now he had his "sabre." From the end of October he and Bonaparte were in league together planning the coup, and on 18–19 Brumaire, Year VIII (November 9–10, 1799), it was carried out: the directors were forced to resign, the members of the legislative councils were dispersed, and a new government, the Consulate, was set up. The three consuls were Bonaparte and two of the directors who had resigned, Sieyès and Pierre-Roger Ducos. But it was Bonaparte who was henceforth the master of France.

The coup of 18–19 Brumaire

THE CONSULATE

Consolidation of power. Bonaparte, now 30 years old, was thin and short and wore his hair cut close—*le petit tondu,* the "little crop-head," as he was called. Not much was known about his personality, but people had confidence in a man who had always been victorious (the Nile and Acre were forgotten) and who had managed to negotiate the brilliant Treaty of Campo Formio. He was expected to bring back peace, to end disorder, and to consolidate the political and social "conquests" of the Revolution. He was indeed exceptionally intelligent, prompt to make decisions, and indefatigably hardworking, but also insatiably ambitious. He seemed to be the man of the Revolution because it was due to the Revolution that he had climbed at so early an age to the highest place in the state. He was not to forget it: but more than a man of the Revolution, he was a man of the 18th century, the most enlightened of the enlightened despots, a true son of Voltaire. He did not believe in the sovereignty of the people, in the popular will, or in parliamentary debate. Yet he put his confidence more in reasoning than in reason and may be said to have preferred "men of talent"—mathematicians, jurists, and statesmen, for instance, however cynical or mercenary they might be—to "technicians" in the true sense of the word. He believed that an enlightened and firm will could do anything if it had the support of bayonets; he despised and feared the masses; and, as for public opinion, he considered that he could mold and direct it as he pleased. He has been called the most "civilian" of generals, but essentially he never ceased to be a soldier.

The military dictatorship

Bonaparte imposed a military dictatorship on France, but its true character was at first disguised by the Constitution of the Year VIII (4 Nivôse; December 25, 1799), drawn up by Sieyès. This constitution did not guarantee the "rights of man" or make any mention of "liberty, equality, and fraternity," but it did reassure the partisans of the Revolution by proclaiming the irrevocability of the sale of national property and by upholding the legislation against the émigrés. It gave immense powers to the first consul, leaving only a nominal role to his two colleagues. The first consul—namely, Bonaparte—was to appoint ministers, generals, civil servants, magistrates, and the members of the Council of State and even was to have an overwhelming influence in the choice of members for the three legislative assemblies, though their members were theoretically to be chosen by universal suffrage. Submitted to a plebiscite, the constitution won by an overwhelming majority in February 1800.

Program of reforms. The Consulate's work of administrative reform, undertaken at Bonaparte's instigation, was to be more lasting than the constitution and so more important for France. At the head of the government was the Council of State, created by the first consul and often effectively presided over by him; it was to play an important part both as the source of the new legislation and as an administrative tribunal. At the head of the administration of the *départements* were the prefects, who carried on the tradition of the intendants of the *ancien régime,* supervising the application of the laws and acting as the instruments of centralization. The judicial system was profoundly changed: whereas from the beginning of the Revolution judges had been elected, henceforth they were to be nominated by the government, their independence assured by their irremovability from office. The police organization was greatly strengthened. The financial administration was considerably improved: instead of the municipalities, special officials were entrusted with the collecting of direct taxes; the franc was stabilized; and the Banque de France, owned partly by shareholders and partly by the state, was created. Education was transformed into a major public service; secondary education was given a semi-military organization, and the university faculties were re-established. Primary education, however, was still neglected.

Bonaparte shared Voltaire's belief that the people needed a religion. Personally, he was indifferent to religion: in Egypt he had said that he wanted to become a Muslim. Yet he considered that religious peace had to be restored to France. As early as 1796, when he was concluding the armistice in Italy with Pope Pius VI, he had tried to persuade the Pope to retract his briefs against the French priests who had accepted the Civil Constitution of the Clergy, which in practice nationalized the church. Pius VII, who succeeded Pius VI in March 1800, was more accommodating than his predecessor, and ten months after negotiations were opened with him a concordat was signed reconciling the church and the Revolution. The Pope recognized the French Republic and called for the resignation of all former bishops; new prelates were to be designated by the First Consul and instituted by the Pope; and the sale of the property of the clergy was officially recognized by Rome. The concordat, in fact, admitted freedom of worship and the lay character of the state.

Religious peace and concordat with Rome

The codification of the civil law, first undertaken in 1790, was at last completed under the Consulate. The code promulgated on March 21, 1804, and later known as the Code Napoléon, gave permanent form to the great gains of the Revolution: individual liberty, freedom of work, freedom of conscience, the lay character of the state, and equality before the law; but, at the same time, it protected landed property, gave greater liberty to employers, and showed little concern for employees. It maintained divorce but granted only limited legal rights to women.

The army received the most careful attention. The First Consul retained in outline the system instituted by the Revolution: recruitment by forced conscription but with the possibility of replacement by substitutes; the mixing of the conscripts with old soldiers; and the eligibility of all for promotion to the highest ranks. Nevertheless, the creation of the Academy of Saint-Cyr to produce infantry officers made it easier for the sons of bourgeois families to pursue a military career. Moreover, the École Polytechnique, founded by the National Convention, was militarized in order to provide officers for the artillery and engineers. Yet Bonaparte was not concerned about introducing new technical inventions into his army. He put his trust in the "legs of his soldiers": his basic strategic idea was a fast-moving army.

Military campaigns and uneasy peace. The First Consul spent the winter and spring of 1799–1800 reorganizing the army and preparing for an attack on Austria alone, Russia having withdrawn from the anti-French coalition. With his usual quick assessment of the situation, he saw the strategic importance of the Swiss Confederation, from which he would be free to outflank the Austrian armies either in Germany or in Italy as he might see fit. His past successes made him choose Italy. Taking his army across the Great St. Bernard Pass before the snow had melted, he appeared unexpectedly behind the Austrian army besieging Genoa. The Battle of Marengo in June gave the French command of the Po Valley as far as the Adige; and in December another French army defeated the Austrians in Germany. Austria was forced to sign the Treaty of Lunéville of February 1801, whereby France's right to the natural frontiers that Julius Caesar had given to Gaul, namely, the Rhine, the Alps, and the Pyrenees, was recognized.

Great Britain alone remained at war with France, but it soon tired of the struggle. Preliminaries of peace, concluded in London in October 1801, put an end to hostilities, and peace was signed at Amiens on March 27, 1802.

General peace was re-established in Europe. The first Consul's prestige increased still more; and his friends—at his suggestion—proposed that a "token of national gratitude" should be offered to him. In May 1802 it was decided that the French people should vote in referendum on the following question: "Shall Napoleon Bonaparte be consul for life?" In August an overwhelming vote granted him the prolongation of his consulate as well as the right to designate his successor.

Consul for life

Bonaparte's conception of international peace differed from that of the British, for whom the Treaty of Amiens represented an absolute limit beyond which they were under no circumstances prepared to go. The British even hoped to take back some of the concessions they had been forced to make. For Bonaparte, on the other hand, the Treaty of Amiens marked the starting point for a new French ascendancy. He was, first of all, intent on reserving half of Europe as a market for France without lowering customs duties—to the indignation of British merchants. To revive France's expansion overseas, he also intended to recover San Domingo (now Hispaniola, which had rebelled), to occupy Louisiana (ceded to France by Spain in 1800), perhaps to reconquer Egypt, and at any rate to extend French influence in the Mediterranean and in the Indian Ocean. Finally, on the Continent of Europe, he advanced beyond France's natural frontiers: incorporating Piedmont into France; imposing a more democratic, decentralized government on the Swiss Confederation; and in Germany compensating the princes dispossessed of territory on the Rhine under the Treaty of Lunéville with shares of the secularized ecclesiastical states.

Great Britain was alarmed by this expansion of France in peacetime and found it scarcely tolerable that one state should command the coastline of the Continent from Genoa to Antwerp. The immediate occasion of Franco-British rupture, however, was the problem of Malta. According to the Treaty of Amiens, the British, who had taken the island on the collapse of the French occupation, should have restored it to the Knights Hospitallers; but the British, on the pretext that the French had not yet evacuated certain Neapolitan ports, refused to leave the island. Franco-British relations became strained, and in May 1803 the British declared war.

THE EMPIRE

The peace settlement had brought about the life consulate; the return of war was to stimulate the formation of the empire. The British government, which would have been glad to see Bonaparte deposed or removed by assassination, renewed its subsidies to the French royalists, who resumed their agitation and plotting. When a British-financed assassination plot was uncovered in 1804, Bonaparte decided to react vigorously enough to deter his opponents from any more such attempts. The police believed that the real head of the conspiracy was the young Duc d'Enghien, a scion of the royal house of Bourbon, who was residing in Germany, a few miles across the frontier. Accordingly, with the agreement of Talleyrand and the police chief Joseph Fouché, the Duc was kidnapped on neutral soil and brought to Vincennes, where he was tried and shot (March 21). This action provoked a resurgence of opposition among the old aristocracy but enhanced the influence of Fouché.

British-financed assassination plot

Founding the empire. In the hope of consolidating his own position, Fouché now suggested to Bonaparte that the best way to discourage conspiracy would be to transform the life consulate into a hereditary empire, which, because of the fact that there would be an heir, would remove all hope of changing the regime by assassination. Bonaparte readily accepted the suggestion, and on May 28, 1804, the empire was proclaimed.

Though there was little change in the organization of the government of France, Napoleon as emperor revived a number of institutions similar to those of the *ancien régime*. In the first place, he wanted to be consecrated by the pope himself, so that his coronation should be even more impressive than that of the kings of France. Pius VII agreed to come to Paris, and the ceremony, which seemed equally outrageous to royalists and to the old soldiers of the Revolution, took place in Notre-Dame on December 2, 1804. At the last moment, the Emperor took the crown from the Pope and set it on his own head himself.

The imperial regime also instituted its symbols and titles. Princely titles were brought back for the members of Napoleon's family in 1804, and an imperial nobility was created in 1808. As opposition was still lively, Napoleon intensified his propaganda and imposed an increasingly strict censorship on the press. A dictatorial regime allowed him to carry on his wars for years without worrying about French public opinion. Having been president of the Italian Republic (as the Cisalpine Republic was renamed) since January 1802, Napoleon in March 1805 was proclaimed king of Italy and crowned in Milan in May.

War with Britain. From 1803 to 1805 Napoleon had only the British to fight; and again France could hope for victory only by landing an army in the British Isles, whereas the British could defeat Napoleon only by forming a continental coalition against him. Napoleon began to prepare an invasion again, this time with greater conviction and on a larger scale. He gathered nearly 2,000 ships between Brest and Antwerp and concentrated his Grande Armée in the camp at Boulogne (1803). Even so, the problem was the same as in 1798: to cross the Channel, the French had to have control of the sea.

Still far inferior to the British Navy, the French fleet needed the help of the Spanish; and even then the two fleets together could not hope to defeat more than one of the British squadrons. Spain was induced to declare war on Great Britain in December 1804, and it was decided that French and Spanish squadrons massed in the Antilles should lure a British squadron into these waters and defeat it, thus making the balance roughly equal between the Franco-Spanish navy and the British. A battle in the entrance to the Channel could then be fought with some chance of success.

Franco-Spanish naval strategy

The plan failed. The French squadron from the Mediterranean, under Adm. Pierre de Villeneuve, found itself alone at the appointed meeting place in the Antilles. Pursued by Nelson and not daring to attack him, it turned back toward Europe and took refuge in Cádiz in July 1805; there the British blockaded it. Accused of cowardice by the angry Napoleon, Villeneuve resolved to run the blockade, with the support of a Spanish squadron; but on October 21, 1805, he was attacked by Nelson off Cape Trafalgar. Nelson was killed in the battle, but the Franco-Spanish fleet was totally destroyed. The British had won a decisive victory, which eliminated the danger of invasion and gave them freedom of movement at sea.

They had also succeeded in organizing a new anti-French coalition consisting of Austria, Russia, Sweden, and Naples. On July 24, 1805, three months before Trafalgar, Napoleon had ordered the Grande Armée from Boulogne to the Danube (thus ruling out an invasion of England even if the French had won at Trafalgar). In the week preceding Trafalgar, the Grande Armée won an outstanding

victory over the Austrians at Ulm, and on November 13 Napoleon entered Vienna. On December 2, 1805, in his greatest victory he defeated the combined Austrian and Russian armies in the Battle of Austerlitz. By the Treaty of Pressburg, Austria renounced all influence in Italy and ceded Venetia and Dalmatia to Napoleon, as well as extensive territory in Germany to his protégés Bavaria, Württemberg, and Baden. The French then proceeded to dethrone the Bourbons in the kingdom of Naples, which was bestowed on Napoleon's brother Joseph. In July 1806 the Confederation of the Rhine was founded—soon to embrace all western Germany in a union under French protection.

Victories in Europe

In September 1806 Prussia entered the war against France, and on October 14 the Prussian armies were defeated at Jena and at Auerstädt. The Russians put up a better resistance at Eylau in February 1807 but were routed at Friedland in June. In Warsaw Napoleon fell in love with Countess Marie Walewska, a Polish patriot who hoped that Napoleon would resurrect her country. Napoleon had a son by her.

The Russian emperor Alexander I could have continued the struggle, but he was tired of the alliance with the British. He met Napoleon at Tilsit, in northern Prussia near the Russian frontier. There, on a raft anchored in the middle of the Niemen River, they signed treaties that created the Grand Duchy of Warsaw from the Polish provinces detached from Prussia and, in effect, divided control of Europe between the emperors, Napoleon taking the west and Alexander the east. Alexander even made a vague promise of a land attack against the British possessions in India.

Blockade and the peninsular campaign. As Napoleon could no longer think of invading England, he tried to induce capitulation by stifling the British economy. By closing all of Europe to British merchandise, he hoped to bring about a revolt of the British unemployed that could force the government to sue for peace. He forbade all trade with the British Isles, ordered the confiscation of all goods coming from English factories or from the British colonies, and condemned as fair prize not only every British ship but also every ship that had touched the coasts of England or its colonies.

For the blockade to succeed, it had to be enforced rigorously throughout Europe. But from the beginning, England's old ally Portugal showed itself reluctant to comply, for the blockade would mean its commercial ruin. Napoleon decided to break down Portuguese opposition by force. Charles IV of Spain let the French troops cross his kingdom, and they occupied Lisbon; but the prolonged presence of Napoleon's soldiers in the north of Spain led to insurrection. When Charles IV abdicated in favour of his son Ferdinand VII, Napoleon, seeing the opportunity to rid Europe of its last Bourbon rulers, summoned the Spanish royal family to Bayonne in April 1808 and obtained the abdication of both Charles and Ferdinand; they were interned in Talleyrand's château. After the bloody suppression of an uprising in Madrid, insurrection spread across the whole country, for the Spaniards would not accept Joseph Bonaparte, king of Naples, as their new king.

Defeats in Spain and Portugal

The subsequent defeat of his forces in Spain and Portugal were sensational blows to Napoleon's prestige. Soon the Iberian Peninsula, up in arms, became a bridgehead on the Continent for the British. Under the energetic Arthur Wellesley (later 1st duke of Wellington), in command from 1809, the Anglo-Spanish-Portuguese forces were to achieve decisive successes.

At the Congress of Erfurt (September–October 1808), a conference with Alexander I, Napoleon assembled a great concourse of princes to impress the Russian emperor in an attempt to extract promises of help. Whether impressed or not, Alexander would make no definite commitment. Alexander's refusal, furthermore, was partly prompted by Talleyrand, who had become dismayed by Napoleon's policies and was already negotiating with the Russian emperor behind his master's back.

By early 1809, however, with most of the Grande Armée thrown into Spain, Napoleon seemed on the point of overcoming the revolt. Then, in April, Austria launched an attack in Bavaria in the hope of rousing all Germany against the French. Napoleon once again defeated the Habsburgs (July 6) and by the Treaty of Schönbrunn (October 14, 1809) obtained the Illyrian Provinces, thus rounding out the continental system.

Consolidation of empire. In 1810 Napoleon's fortunes were at their zenith, despite some failures in Spain and Portugal. He considered himself Charlemagne's heir. He repudiated Joséphine, who had not given him a child, so that he could marry Marie-Louise, daughter of the Austrian emperor Francis I. The birth of a son, the king of Rome, in March 1811 seemed to assure the future of his empire—now at its greatest extent, including not only the Illyrian Provinces but also Etruria (Tuscany), some of the Papal States, Holland, and the German states bordering the North Sea. The empire was surrounded by a ring of vassal states ruled over by the Emperor's relatives: the kingdom of Westphalia (Jérôme Bonaparte); the Kingdom of Spain (Joseph Bonaparte); the Kingdom of Italy (with Eugène de Beauharnais, Joséphine's son, as viceroy); the Kingdom of Naples (Joachim Murat, Napoleon's brother-in-law); and the Principality of Lucca and Piombino (Félix Bacciochi, another brother-in-law). Finally, other territories were closely bound to the empire by treaties: the Swiss Confederation (of which Napoleon was the mediator), the Confederation of the Rhine, and the Grand Duchy of Warsaw. Even Austria seemed bound to France by Napoleon's marriage to Marie-Louise.

The political map of Europe, which had been so complicated before 1796, was now greatly simplified. Yet the frontiers did not coincide either with geographical features or with "nationalities." Whatever he may later have said, Napoleon, while he was in power, was not interested in realizing either German or Italian unity. Yet by reducing the number of states, by pushing the frontiers about, by amalgamating populations, and by propagating institutions like those that the Revolution and nationalism had created in France, he prepared the ground for German and Italian unification. National feeling in Europe, stirred by French ideas and by contact with Frenchmen, in turn gave rise to the first resistance against French domination. From 1809 onward Spanish guerrillas, supported by British troops, were harassing the French, and the national Cortes, convened at Cádiz by the insurrectionaries, in 1812, promulgated a constitution inspired by the ideas of the French Revolution of 1789 and by British institutions.

European unity and the roots of new nationalisms

Disaster in Russia and its aftermath. Since the Congress of Erfurt, the Russian emperor had shown himself less and less inclined to deal with Napoleon as a trusted partner. In the spring of 1812, therefore, Napoleon massed his forces in Poland to intimidate Alexander. After some last attempts at agreement, in late June his Grande Armée—about 453,000 men, including contingents extorted from Prussia and from Austria—began to cross the Niemen River. The Russians retreated, adopting a "scorched earth" policy. Napoleon's army did not reach the approaches to Moscow until the beginning of September. The Russian commander in chief, Mikhail I. Kutuzov, engaged it at Borodino on September 7. The fight was savage, bloody, and indecisive, but a week later Napoleon entered Moscow, which the Russians had abandoned. On that same day, a huge fire broke out, destroying the greater part of the town. Moreover, Alexander unexpectedly refused to treat with Napoleon. Withdrawal was necessary, and the premature onset of winter made it disastrous. After the difficult crossing of the Berezina River in November, fewer than 10,000 men fit for combat remained with Napoleon's main force.

This catastrophe heartened all the peoples of Europe to defy Napoleon. In Germany the news unleashed an outbreak of anti-French demonstrations. The Prussian contingents deserted the Grande Armée in December and turned against the French. The Austrians also withdrew their troops and adopted an increasingly hostile attitude, and in Italy the people began to turn their backs on Napoleon.

Even in France, signs of discontent with the regime were becoming more frequent. In Paris a malcontent general nearly succeeded in carrying out a coup d'etat after announcing, on October 23, 1812, that Napoleon had died in Russia. This incident was a major factor in Napoleon's

Attempted coup d'etat in Paris

decision to hasten back to France ahead of the Grande Armée. Arriving in Paris on December 18, he proceeded to stiffen the dictatorship, to raise money by various expedients, and to levy new troops.

Thus, in 1813 the forces arrayed against France were no longer armies of mercenaries but were those of nations fighting for their freedom as the French had fought for theirs in 1792 and 1793; and the French themselves, for all their courage, had lost their former enthusiasm. The Emperor's ideal of conquest was no longer that of the nation.

In May 1813 Napoleon won some successes against the Russians and Prussians at the battles of Lützen and Bautzen, but his decimated army needed reinforcements. The armed mediation of Austria induced Napoleon to agree to an armistice, during which a congress was held at Prague. There, Austria proposed very favourable conditions: the French Empire was to return to its natural limits; the Grand Duchy of Warsaw and the Confederation of the Rhine were to be dissolved; and Prussia was to return to its frontiers of 1805. Napoleon made the mistake of hesitating too long. The congress closed on August 10 before his reply arrived, and Austria declared war.

The French were even worse off than in the spring. The allies were gaining new troops every day, as one German contingent after another left Napoleon to go over to the other side. The greatest debacle since Napoleon came to power was the Battle of Leipzig, or "Battle of the Nations" (October 16–19, 1813), in which the Grande Armée was torn to shreds. That defeat degenerated fast into collapse. The French armies in Spain, forced to retreat, had been defeated in June; and by October the British were attacking their defenses north of the Pyrenees. In Italy the Austrians took the offensive, crossed the Adige River, and occupied Romagna. Murat, now openly a traitor to the Emperor who had made him king of Naples, entered into negotiations with the Viennese court. The Dutch and the Belgians demonstrated against Napoleon.

Downfall and abdication. In January 1814 France was being attacked on all its frontiers. The allies cleverly announced that they were fighting not against the French people but against Napoleon alone, since in November 1813 he had rejected the terms offered by the Austrian foreign minister Metternich, which would have preserved the natural frontiers of France. The extraordinary strategic feats achieved by the Emperor during the first three months of 1814 with the army of young conscripts were not enough; he could neither defeat the allies, with their overwhelming numerical superiority, nor arouse the majority of French people from their resentful torpor. The Legislative Assembly and the Senate, formerly so docile, were now asking for peace and for civil and political liberties.

Four-nation pact against Napoleon

By the Treaty of Chaumont of March 1814, Austria, Russia, Prussia, and Great Britain bound themselves together for 20 years, undertook not to negotiate separately, and promised to continue the struggle until Napoleon was overthrown. When the allied armies arrived before Paris on March 30, Napoleon had moved east to attack their rear guard. The Parisian authorities, no longer overawed by the Emperor, lost no time in treating with the allies. As president of the provisional government, Talleyrand proclaimed the deposition of the Emperor and, without consulting the French people, began to negotiate with Louis XVIII, the brother of the executed Louis XVI. Napoleon had only reached Fontainebleau when he heard that Paris had capitulated. Persuaded that further resistance was useless, he finally abdicated on April 6.

By the Treaty of Fontainebleau, the allies granted him the island of Elba as a sovereign principality with an annual income of 2,000,000 francs to be provided by France and a guard of 400 volunteers; also, he retained the title of emperor. After unsuccessfully trying to poison himself, Napoleon spoke his farewell to his "Old Guard," and after a hazardous journey, during which he narrowly escaped assassination, he arrived at Elba on May 4.

ELBA AND THE HUNDRED DAYS

"I want from now on to live like a justice of the peace," Napoleon declared on his little island. But a man of such energy and imagination could hardly be expected to resign himself to defeat at the age of 45.

In France, moreover, the Bourbon Restoration was soon exposed to criticism. Though in 1814 the majority of the French people were tired of the Emperor, they had expressed no wish for the return of the Bourbons. They were strongly attached to the essential achievements of the Revolution, and Louis XVIII had come back "in the baggage train of the foreigners" with the last surviving émigrés who had "learnt nothing and forgotten nothing" and whose influence seemed to threaten most of the Revolution's achievements. The apathy of April 1814 quickly gave way to mistrust. Old hatreds were revived, resistance organized, and conspiracies formed.

From Elba, Napoleon kept a close watch on the Continent. He knew that some of the diplomats at Vienna, where a congress was deciding the fate of Europe, considered Elba, between Corsica and Italy, too close to France and to Italy and wanted to banish him to a distant island in the Atlantic. Also, he accused Austria of preventing Marie Louise and his son from coming to join him (in fact, she had taken a lover and had no intention of going to live with her husband). Finally, the French government refused to pay Napoleon's allowance so that he was in danger of being reduced to penury.

Napoleon's return to France

All these considerations drove Napoleon to action. Decisive as ever, he returned to France like a thunderbolt. On March 1, 1815, he landed at Cannes with a detachment of his guard. As he crossed the Alps, the republican peasants rallied round him, and near Grenoble he won over the soldiers dispatched to arrest him. On March 20 he was in Paris.

Napoleon was brought back to power as the embodiment of the spirit of the Revolution rather than as the emperor who had fallen a year before. To rally the mass of Frenchmen to his cause he should have allied himself with the Jacobins; but this he dared not do. Unable to escape from the bourgeoisie whose predominance he himself had assured and who feared above all else a revival of the socialist experiments of 1793 and 1794, he could only set up a political regime scarcely distinguishable from that of Louis XVIII. Enthusiasm ebbed fast, and the Napoleonic adventure seemed a dead end.

To oppose the allied troops massing on the frontiers, Napoleon mustered an army with which he marched into Belgium and defeated the Prussians at Ligny on June 16, 1815. Two days later, at Waterloo, he met the British under Wellington, the victor of the Peninsular War. A savage battle followed. Napoleon was in sight of victory when the Prussians under Gebhard Blücher arrived to reinforce the British, and soon, despite the heroism of the Old Guard, Napoleon was overthrown.

Back in Paris, Parliament forced Napoleon to abdicate; he did so, in favour of his son, on June 22, 1815. On July 3 he was at Rochefort, intending to take ship for the United States, but a British squadron prevented any French vessel from leaving the port. Napoleon then decided to appeal to the British government for protection. His request granted, he boarded the "Bellerophon" on July 15. The allies were agreed on one point: Napoleon was not to go back to Elba. Nor did they like the idea of his going off to America. It would have suited them if he had fallen a victim to the "White Terror" of the returned counter-revolutionaries or if Louis XVIII had had him summarily tried and executed. Great Britain had no choice but to send him to detention in a far-off island. The British government announced that the island of Saint Helena in the southern Atlantic had been chosen for his residence; because of its remote position Napoleon would enjoy much greater freedom than would be possible elsewhere. Napoleon protested eloquently: "I appeal to history!"

EXILE ON SAINT HELENA

On October 15, 1815, Napoleon disembarked in Saint Helena with those followers who were voluntarily accompanying him into exile: Gen. Henri-Gratien Bertrand, grand marshal of the palace, and his wife; the comte Charles de Montholon, aide-de-camp, and his wife; Gen. Gaspard Gourgaud; Emmanuel Las Cases, the former chamberlain;

and several servants. After a short stay at the house of a wealthy English merchant, they moved to Longwood, originally built for the lieutenant governor.

Daily life at St. Helena

Napoleon settled down to a life of routine. He got up late, breakfasting about 10 PM, but seldom went out. He was free to go anywhere on the island so long as he was accompanied by an English officer, but he soon refused to comply with this condition and so shut himself up in the grounds of Longwood. He wrote and talked much. At first Las Cases acted as his secretary, compiling what was later to be the *Mémorial de Sainte-Hélène* (first published in 1823). From 7 to 8 PM Napoleon had dinner, after which a part of the evening was spent in reading aloud—Napoleon liked to hear the classics. Then they played cards. About midnight Napoleon went to bed. Some of his time was devoted to learning English, and he eventually began reading English newspapers; but he also had a large number of French books sent from Europe, which he read attentively and annotated.

Saint Helena has a healthful climate, and Napoleon's food was good, carefully prepared, and plentiful. His inactivity undoubtedly contributed to the deterioration of his health. The man who for 20 years had played so great a role in the world and who had marched north, south, east, and west across Europe could hardly be expected to endure the monotony of existence on a little island, aggravated by a self-imposed life of a recluse. He had also more intimate reasons for unhappiness: Marie-Louise sent no word to him, and he may have learned of her liaison with the Austrian officer appointed to watch over her, Graf Adam von Neipperg (whom she eventually married in secret without waiting for Napoleon's death); nor did he have any news of his son, the former king of Rome, who was now living in Vienna with the title of duke of Reichstadt. Finally, though the severity of Sir Hudson Lowe has been much exaggerated, it is certain that this "jailer," who arrived as governor of Saint Helena in April 1816, did nothing to make Napoleon's life easier. Napoleon from the start disliked him as the former commander of the Corsican rangers, a band of volunteers largely composed of enemies of the Bonaparte family. Always anxious to carry out his instructions exactly, Lowe came into conflict with Las Cases. He saw Las Cases as Napoleon's confidant and had him arrested and expelled. Thenceforward, relations between the governor and Napoleon were limited strictly to those stipulated by the regulations.

First signs of illness

Napoleon showed the first signs of illness at the end of 1817; he seems to have had an ulcer or a cancer of the stomach. The Irish doctor Barry O'Meara, having asked in vain for a change in the conditions under which Napoleon lived, was dismissed; so also was his successor John Stokoe, who was likewise thought to be well-disposed toward Napoleon. The undistinguished Corsican doctor who took their place, Francesco Antommarchi, prescribed a treatment that could do nothing to cure his patient. It is uncertain, however, whether Napoleon's disease was curable at all, even by 20th-century methods.

From the beginning of 1821, the illness became rapidly worse. From March, Napoleon was confined to bed. In April he dictated his last will:

> I wish my ashes to rest on the banks of the Seine, in the midst of that French people which I have loved so much. . . . I die before my time, killed by the English oligarchy and its hired assassins.

On May 5 he spoke a few coherent phrases: "My God . . . The French nation . . . my son . . . head of the army . . . ." He died at 5:49 PM on that day, not yet 52 years old. His body was dressed in his favourite uniform, that of the Chasseurs de la Garde, covered by the gray overcoat that he had worn at Marengo. The funeral was conducted simply, in the Rupert Valley where Napoleon had sometimes walked, beside a stream in which two willows were reflected. The stone covering his tomb bore no name, only the words "Ci-Gît" ("Here Lies").

THE NAPOLEONIC LEGEND

Napoleon's fall had set loose a torrent of hostile books designed to sully his reputation. One of the least violent of these was the pamphlet *De Buonaparte, des Bourbons, et de la nécessité de se rallier à nos princes légitimes* (1814; *On Buonaparte and the Bourbons, and the Necessity of Rallying Around Our Legitimate Princes, for the Safety of France and of Europe*) by François de Chateaubriand, a well-known writer of royalist sympathies. But this anti-Napoleonic literature soon died down, while the task of defending Napoleon was taken up. Lord Byron had published his "Ode to Napoleon Buonaparte" as early as 1814; the German poet Heinrich Heine wrote his ballad "Die Grenadiere"; and in 1817 the French novelist Stendhal began his biography *Vie de Napoléon.* At the same time, the Emperor's most faithful supporters were working toward his rehabilitation, talking about him, and distributing reminders of him, including engravings. They idealized his life ("What a novel my life is!" he himself had said) and began to create the Napoleonic legend.

Early memoirs and chronicles

As soon as the Emperor was dead, the legend grew rapidly. Memoirs, notes, and narratives by those who had followed him into exile contributed substantially to it. In 1822 Dr. O'Meara, in London, had his *Napoleon in Exile, or a Voice from Saint Helena* published; in 1823 the publication of the *Mémoires pour servir à l'histoire de France sous Napoléon, écrits à Sainte-Hélène sous sa dictée* (*Memoirs of the History of France during the Reign of Napoleon, Dictated by the Emperor at St. Helena*) by Montholon and Gourgaud, began; Las Cases, in his famous *Mémorial,* presented the Emperor as a republican opposed to war who had fought only when Europe forced him to fight in defense of freedom; and in 1825 Antommarchi published his *Derniers moments de Napoléon.* Thereafter the number of works in Napoleon's honour increased continually; among them were Victor Hugo's "Ode à la Colonne," the 28 volumes of the *Victoires et conquêtes des Français,* and Sir Walter Scott's *Life of Napoleon Buonaparte, Emperor of the French.* Neither police action nor prosecutions could prevent books, pictures, and objects evoking the imperial saga from multiplying in France.

After the July Revolution of 1830, which created the bourgeois monarchy under Louis-Philippe, thousands of tricolour flags appeared in windows, and the government had not only to tolerate the growth of the legend but even to promote it. In 1833 the statue of Napoleon was put back on the top of the column in the Place Vendôme in Paris; and in 1840 the King's son François, prince de Joinville, was sent in a warship to fetch the Emperor's remains from Saint Helena to the banks of the Seine in accordance with his last wishes. A magnificent funeral was held in Paris in December 1840, and Napoleon's body was conveyed through the Arc de Triomphe in the Place de l'Étoile to entombment under the dome of the Invalides.

Napoleon's nephew Louis-Napoleon exploited the legend in order to seize power in France. Though his attempts at Strasbourg in 1836 and at Boulogne in 1840 were failures, it was chiefly because of the growth of the legend that he won election to the presidency of the Second Republic with an overwhelming majority in 1848 and was able to carry out the coup d'etat of December 1851 and make himself emperor in 1852.

The disastrous end of the Second Empire in 1870 damaged the Napoleonic legend and gave rise to a new anti-Napoleonic literature, best represented by Hippolyte Taine's *Origines de la France contemporaine* (1876–94). World Wars I and II, however, together with the experience of the 20th-century dictatorships, made it possible to judge Napoleon more fairly. Any comparison with Stalin or Hitler, for instance, can only be to Napoleon's advantage. He was tolerant, he released the Jews from the ghettos, and he showed respect for human life. Brought up on the rationalist *Encyclopédie* and on the writings of the Philosophes of the Enlightenment, he remained above all a man of the 18th century, the last of the "enlightened despots." One of the gravest accusations made against Napoleon is that he was the "Corsican ogre" who sacrificed millions of men to his ambition. Estimates indicate that the Napoleonic Wars of 1800–15, notwithstanding the many foreigners conscripted to fight for France, resulted in the loss of about 1,000,000 French troops—about half of whom were killed or wounded. The loss of these men did not greatly affect the growth of the population, however.

Assessment and legacy

The social structure of France changed little under the First Empire. It remained roughly what the Revolution had made it: a great mass of peasants comprising three-quarters of the population—about half of them working owners of their farms or sharecroppers and the other half with too little land for their own subsistence and hiring themselves out as labourers. Industry, stimulated by the war and the blockade of English goods, made remarkable progress in northern and eastern France, whence exports could be sent to central Europe; but it declined in the south and west because of the closing of the Mediterranean and the Atlantic. The great migrations from rural areas toward industry in the towns began only after 1815. The nobility would probably have declined more swiftly if Napoleon had not restored it; but it could never recover its former privileges.

Above all, Napoleon left durable institutions, the "granite masses" on which modern France has been built up: the administrative system of the prefects, the Code Napoléon, the judicial system, the Banque de France and the country's financial organization, the universities, and the military academies. Napoleon changed the history of France and of the world. (J.Go.)

BIBLIOGRAPHY

Sources. An enormous mass of documents is dispersed throughout the archives of Europe, but the essential sources are *Correspondance de Napoléon Ier*, 32 vol. (1858–69, reprinted 1974), published on command of Napoleon III; *Oeuvres de Napoléon Ier à Sainte-Hélène*, 4 vol. (1870); and *Oeuvres littéraires et écrits militaires*, 3 vol. (1967). In English are *The Bonaparte Letters and Despatches, Secret, Confidential, and Official*, 2 vol. (1846); *The Confidential Correspondence of Napoleon Bonaparte with His Brother Joseph*, 2 vol. (1855); and *Unpublished Correspondence of Napoleon I, Preserved in the War Archives*, 3 vol. (1913). The principal ideas of Napoleon may be found in the following works: R.M. JOHNSTON (comp.), *The Corsican: A Diary of Napoleon's Life in His Own Words*, new ed. (1921); J.M. THOMPSON (trans. and ed.), *Napoleon Self-Revealed* (1934); J. CHRISTOPHER HEROLD (ed. and trans.), *The Mind of Napoleon* (1955); ANDRÉ PALLUEL (ed.), *Dictionnaire de l'empereur* (1969); and ADRIEN DANSETTE (ed.), *Pensées politiques et sociales de Napoléon* (1969). Napoleon's itinerary is available in ALBERT SCHUERMANS, *Itinéraire général de Napoléon Ier*, 2nd ed. (1911); and LOUIS GARROS, *Itinéraire de Napoléon Bonaparte* (1947).

Biographies. General studies of his life and career include PIERRE LANFREY, *The History of Napoleon the First*, 2nd ed., 4 vol. (1886, reprinted 1973; originally published in French, 1867–75), a hostile work written at the end of the Second Empire; AUGUST FOURNIER, *Napoleon I* (1911, reissued 1930; originally published in German, 1886), an impartial study written by an Austrian historian; FRÉDÉRIC MASSON, *Napoléon et sa famille*, 13 vol. (1897–1919), which furnishes numerous details on the everyday life of Napoleon and his relationships with his relatives; JOHN HOLLAND ROSE, *The Life of Napoleon I*, 11th ed., 2 vol. in 1 (1935), an apologetic work; J.M. THOMPSON, *Napoleon Bonaparte: His Rise and Fall* (1952, reissued 1969), an excellent rectification; EUGENE TARLÉ, *Bonaparte*, trans. from Russian (1937), the point of view of a Soviet historian; FELIX MAURICE HIPPISLEY MARKHAM, *Napoleon* (1963), an objective study; JEAN MISTLER, *Napoléon et l'empire*, 2 vol. (1968, reissued 1979), a magnificently illustrated work, each chapter written by a specialist; ANDRÉ CASTELOT, *Napoléon* (1971; originally published in French, 1968), a vulgarized book that realized great success in France; and JACQUES GODECHOT, *Napoléon* (1969), an essay and an empirical study (in French).

The following focus on specific aspects of Napoleon's personal life. ARTHUR CHUQUET, *La Jeunesse de Napoléon*, 3 vol. (1897–99), is a basic work on his youth. A revisionist history by DOROTHY CARRINGTON, *Napoleon and His Parents* (1988), explores Napoleon's first 16 years. The more intimate life of Napoleon is detailed in ARTHUR LÉVY, *Napoléon intime*, 7th ed. (1932); and FRÉDÉRIC MASSON, *Napoleon at Home*, 2 vol. (1894; originally published in French, 1894). THEO ARONSON, *Napoleon and Josephine* (1990), is a general account of their life together. JAMES KEMBLE, *Napoleon Immortal* (1959), surveys Napoleon's health. The theory that Napoleon died of arsenic poisoning is explored in BEN WEIDER and DAVID HAPGOOD, *The Murder of Napoleon* (1982).

Specialized studies. There are many studies of Napoleon's career. DONALD D. HORWARD (ed.), *Napoleonic Military History: A Bibliography* (1986), contains more than 7,000 entries in 14 languages on military, social, political, economic, and other topics. DAVID G. CHANDLER, *The Illustrated Napoleon* (1990); and OWEN CONNELLY, *Blundering to Glory: Napoleon's Military Campaigns* (1987), focus on Napoleon's military career. Accounts of specific military maneuvers are JAMES R. ARNOLD, *Crisis on the Danube: Napoleon's Austrian Campaign of 1809* (1990); CURTIS CATE, *The War of the Two Emperors: The Duel Between Napoleon and Alexander—Russia, 1812* (1985); and RICHARD K. RIEHN, *1812: Napoleon's Russian Campaign* (1990). R.S. ALEXANDER, *Bonapartism and Revolutionary Tradition in France: The Fédérés of 1815* (1992), discusses the politico-military organizations that supported Napoleon during the Hundred Days. PAUL FREGOSI, *Dreams of Empire: Napoleon and the First World War, 1792–1815* (1989), recounts how close Napoleon came to world domination. STUART WOOLF, *Napoleon's Integration of Europe* (1991), studies the modernization of Napoleonic Europe.

Other works of interest include MABEL EMMERTON BROOKES, *St. Helena Story* (1960); NORMAN MACKENZIE, *The Escape from Elba: The Fall and Flight of Napoleon, 1814–1815* (1982), a popular account of his 10 months on Elba; JULIA BLACKBURN, *The Emperor's Last Island: A Journey to St. Helena* (1991), an examination of Napoleon's last years in exile along with information on the island itself; JEAN LUCAS-DUBRETON, *Le Culte de Napoléon, 1815–1848* (1960), a definitive study of the Napoleonic legend; HUGH RAGSDALE, *Détente in the Napoleonic Era: Bonaparte and the Russians* (1980); and EDWARD A. WHITCOMB, *Napoleon's Diplomatic Service* (1979).

Navigation

Navigation, a word derived from the Latin *navis,* "ship," and *agere,* "to drive," originally denoted the art of ship driving, including steering and setting the sails. The skill itself is even more ancient than the word, and it has evolved over the course of many centuries into a science and a technology that encompasses the planning and execution of safe, timely, and economical operation of watercraft, aircraft, and spacecraft.

Many animals can find their way home from considerable distances by remembering what they saw or smelled along the way. For example, a honeybee returning to its hive with food performs a dance to communicate to its fellows the direction (relative to the Sun) and distance (as far as six miles [10 kilometres]) they should fly to reach the source of the food. Many species of birds migrate thousands of miles with great precision, orienting themselves by the Sun and stars. Such pathfinding feats have undoubtedly been performed since long before human sailors first ventured out of sight of land, but detailed investigation of these activities has made no direct contribution to the analogous skills that have been developed and refined by human navigators.

Early mariners who embarked on voyages of exploration gradually developed systematic methods of observing and recording their position, the distances and directions they traveled, the currents of wind and water, and the hazards and havens they encountered. The facts accumulated in their journals made it possible for them to find their way home and for them or their successors to repeat and extend their exploits. Each new landfall became a signpost along a route that could be retraced and integrated into a growing body of reliable information.

For these pathfinders, the danger of running into another vessel was of negligible concern, but as heavy traffic developed along established routes, collision avoidance became a serious matter. In all fields of navigation, emphasis shifted from finding the way to maintaining an appropriate distance between craft moving in various directions at different speeds. The larger a ship is, the easier it is to see, but, by the same token, the larger a ship is, the more time it requires to change its speed or direction. When many ships are in a small area, an action taken by one to avoid colliding with another may endanger a third. This problem has been alleviated near busy seaports by confining incoming and outgoing ships to separate lanes, which are clearly marked and divided by the greatest practical distance. Airplanes travel so fast that even though two pilots may see one another in time to initiate evasive action, their maneuvers may be nullified if either one incorrectly predicts the other's move. Ground-based air traffic controllers are charged with the responsibility for assigning aircraft to selected paths that minimize the likelihood of collision. Civil air navigation is profoundly influenced by the requirements of following the instructions of these controllers.

The advent of steam-powered ships during the first half of the 19th century added the problem of fuel consumption to the navigator's duties. In the air as well as at sea, the need to carry large amounts of fuel for long trips reduces the cargo capacity; even if plenty of fuel is on board, economy requires that its consumption be kept to a minimum. In spaceflight, fuel is a major navigational consideration. The route to be followed and even the moment for lift-off must be chosen to keep the fuel requirements as small as possible.

Adherence to a predetermined schedule, a matter of vital importance in space navigation in connection with fuel consumption, has become important in sea and air navigation for a different reason. Today each voyage or flight is a single link in a coordinated network of transport that carries people and goods from any starting place to any chosen destination. The efficient operation of the whole system depends upon assurance that each journey will begin and end at the specified times.

Modern navigation, in short, has to do with the whole of a preconceived passage, from start to finish, and is concerned with four basic objectives: selecting the course (and staying on it); avoiding collision with other moving ships and crashing into fixed obstacles; minimizing fuel consumption; and conforming to an established timetable.

(E.W.A./Ed.)

This article deals with the methods and devices integral to the science of navigation. It also provides a brief historical survey of their development.

DEVELOPMENT OF MARINE NAVIGATION

Ancient sea voyages

The earliest navigators probably learned to steer their ships between distant ports by familiarizing themselves with the sequences of intervening landmarks. Keeping these reference points in view required them to stay quite close to shore, but they made the transition to ocean voyages well out of sight of land thousands of years ago in various parts of the world. Regular trade was carried on between the island of Crete and Egypt, a distance of approximately 300 miles (500 kilometres), more than 25 centuries before the Christian era. A passage in the *Odyssey* describes such a voyage from Crete: running before a north wind, sailing ships reached the mouth of the Nile in five days. Longer and longer routes became established by later sailors. By 600 BC the Phoenicians were routinely importing tin from Cornwall. Well before the 10th century AD, Irish seafarers successively reached the Shetland Islands, the Faeroe Islands, and Iceland, crossing 200 to 300 miles of the North Atlantic at each stage. The Vikings repeated those passages and ventured even farther, settling Greenland and visiting North America. In about AD 400, Polynesian navigators had reached Hawaii from the Marquesas Islands, 2,300 miles (3,700 kilometres) across the open Pacific.

Direction finding. The details of how these voyagers found their way are not known, but the use of the Sun and stars as guides is mentioned in many sources, including

the works of Homer and Herodotus, the Bible, and the Norse sagas.

East and west are traditionally synonymous with the directions of sunrise and sunset; north and south are determined by the directions of shadows cast by the noonday Sun. By night the stars rise in the east and set in the west, and in the Northern Hemisphere their apparent rotation around the Pole Star has long been a fact of the navigator's life.

For many centuries practical navigators oriented themselves by relying just as strongly on meteorological clues (the directions from which steady winds blew) as on astronomical ones (the positions and apparent motions of the Sun and stars). The Mediterranean sailor could confidently distinguish the cold north wind from the warm south wind. Names were assigned to eight principal winds, and the directions of these winds became the eight equally spaced points of the wind rose (*rosa ventorum*) of the classical mariner. The wind rose may have been devised by the Etruscans, whose power reached its peak around the 6th century BC; it certainly antedates the octagonal Tower of the Winds built in Athens by Andronicus of Cyrrhus in about 100 BC. From Roman times through the Middle Ages, an alternative 12-point wind rose was used by some navigators, but it was discarded in the 15th century when the Portuguese, at the opening of the great age of discovery, subdivided the eight points of the ancients and introduced a 16-point system.

Wind rose

Sailing instructions. The first written aid to coastal navigation was the pilot book, or periplus, in which the courses to be steered between ports were set forth in terms of wind directions. These books, of which examples survive from the 4th century BC, described routes, headlands, landmarks, anchorages, currents, and port entrances. No doubt the same information had formerly been passed along by word of mouth, as it still is in some parts of the world. It seems improbable that any sort of sea chart was used with these sailing guides, even though Herodotus' map of the known world, drawn in the 5th century BC, delineated the Mediterranean shoreline quite accurately. Reliable sea charts were not introduced until the advent of the magnetic compass (see below) and of methods for determining latitude and longitude.

Distance and speed measurements. Distances were cited in the early pilot books in units of a day's sail. Later, distances were deduced from estimates of the ship's speed and the lengths of time over which these speeds were maintained. Probably the oldest method of determining the speed is the so-called Dutchman's log, in which a floating object, the log, was dropped overboard from the bow of the ship; the time elapsing before it passed the stern was counted off by the navigator, who kept it in sight while walking the length of the vessel. This technique was eventually replaced by that in which the log, attached to a reel of light line, was dropped from the stern; as the ship moved away from the log, the length of line paid out during the emptying of a sandglass was the measure of the speed. In 1637 the English navigator Richard Norwood recommended the use of a line knotted at intervals of 47¼ feet (14.3 metres) and a 28-second sandglass; if the first knot appeared as the sand ran out, the ship's speed was 6,076 feet (1,852 metres [one nautical mile]) per hour, or one knot. As early as 1688 an English instrument maker, Humphry Cole, invented the so-called patent log, in which a vaned rotor was towed from the stern, and its revolutions were counted on a register. Logs of this kind did not become common until the mid-19th century, when the register was mounted on the taffrail, where it could be read at any time; another Englishman, Thomas Walker, introduced successive refinements of the patent log beginning in 1861. This form of log is still in use. (M.W.Ri.)

Maritime logs

The magnetic compass. *Development.* It is not known where or when it was discovered that the lodestone (a mineral composed of an iron oxide) aligns itself in a north–south direction, as will a piece of iron that has been magnetized by contact with a lodestone. Neither is it known where or when marine navigators first availed themselves of these discoveries. Plausible records indicate that the Chinese were using the magnetic compass around AD 1100, western Europeans by 1187, Arabs by 1220, and Scandinavians by 1300. The device could have originated in each of these groups, or it could have been passed from one to the others. All of them had been making long voyages, relying on steady winds to guide them and sightings of the Sun or a familiar star to inform them of any change. When the magnetic compass was introduced, it probably was used merely to check the direction of the wind when clouds obscured the sky.

The first mariner's compass may have consisted of a magnetized needle attached to a wooden splinter or a reed floating on water in a bowl. In a later version the needle was pivoted on a pin fixed to the bottom of the bowl. By the 13th century a card bearing a painted wind rose was mounted on the needle; the navigator could then simply read his heading from the card. So familiar has this combination become that it is called the compass, although that word originally signified the division of the horizon. The suspension of the compass bowl in gimbals (originally used to keep lamps upright on tossing ships) was first mentioned in 1537.

On early compass cards the north point was emphasized by a broad spearhead and the letter *T* for tramontana, the name given to the north wind. About 1490 a combination of these evolved into the fleur-de-lis, still almost universally used. The east point, pointing toward the Holy Land, was marked with a cross; the ornament into which this cross developed continued on British compass cards well into the 19th century (see Figure 1). The use of 32 points by sailors of northern Europe, usually attributed to Flemish compass makers, is mentioned by Geoffrey Chaucer in his *Treatise on the Astrolabe* (written in 1391). It also has been said that the navigators of Amalfi, Italy, first expanded the number of compass points to 32, and they may have been the first to attach the card to the needle.

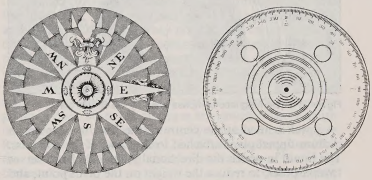

Figure 1: *Compass cards.*
(A) Eighteenth-century compass card divided into points and having ornamentation at the east point. (B) U.S. Navy compass card made of metal with graduations perforated through it.

During the 15th century it became apparent that the compass needle did not point true north from all locations but made an angle with the local meridian. This phenomenon was originally called by seamen the northeasting of the needle but is now called the variation or declination. For a time, compass makers in northern countries mounted the needle askew on the card so that when the needle pointed to magnetic north the fleur-de-lis indicated true north. This practice died out about 1700 because it succeeded only for short voyages near the place where the compass was made; it caused confusion and difficulty on longer trips, especially in crossing the Atlantic to the American coast, where the declination was west instead of east as in Europe. The declination in a given location varies over time. For example, in northern Europe in the 16th century the magnetic north pole was east of true geographic north; in subsequent centuries it has drifted to the west.

Compass variation

Despite its acknowledged value, the magnetic compass long remained a fragile, troublesome, and unreliable instrument, subject to mysterious disturbances. The introduction of iron and then steel for hulls and engines in the 19th century caused further concern because it was well known that nearby ironwork would deflect the compass needle. In 1837 the British Admiralty set up a commit-

tee to seek rational methods of ensuring the accuracy of compasses installed on iron ships. In 1840 the committee introduced a new design that proved so successful that it was promptly adopted by all of the principal navies of the world. Further refinements, aimed at reducing the effects of engine vibration and the shock of gunfire, continued throughout the century.

The modern magnetic compass. The liquid magnetic compass (see Figure 2), now almost universally used, is commonly accompanied by an azimuth instrument for taking bearings of distant objects. The compass consists of a set of steel needles with a compass card, attached to a float, in a bowl of water and alcohol. In modern instruments, the magnetic element is often in the form of a ring magnet, fitted within the float. The card is usually of mica or plastic with photographically printed graduations; metal cards with perforated graduations also are used. Cards are usually graduated clockwise from 0° at north to 359°, with the eight principal points indicated.

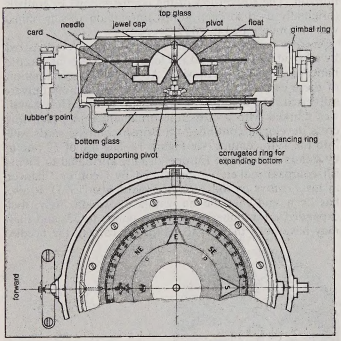

Figure 2: Liquid magnetic compass used by the British Navy.

A jewel is fitted at the centre of the float to bear on an iridium-tipped pivot attached to the bowl of the compass. The liquid in which the directional system is placed serves two purposes: to reduce the weight on the pivot point, and thereby to minimize friction; and to damp out oscillations from the ship's motion. The bowl is closed on the top and bottom by glass, the bottom glass permitting illumination from below, and is mounted in gimbals. A flexible diaphragm or bellows attached to the bowl accommodates the change in volume of the liquid caused by temperature changes. The ship's heading is read with the aid of the lubber's point, at the forward part of the compass, which indicates the direction of the ship's centre line.

When the ship alters course, liquid at the side of the bowl tends to displace slightly, deflecting the card and causing what is known as swirl error. To minimize swirl error the card is often made considerably smaller in diameter than the bowl. The directional system is made sufficiently bottom-heavy (pendulous) to counteract the downward pull of the vertical component of the Earth's magnetic field, which would otherwise cause the system to tilt.

The simplest, and probably earliest, azimuth instrument consisted of two sights on opposite sides of the compass bowl connected by a thread. The assembly could be rotated to permit sighting on the distant object. Because it was impossible to sight through the instrument and look at the compass card simultaneously, a prism (mirror) was positioned to reflect an image of the card, which was given a second set of graduations with reversed figures. Modern azimuth instruments embody a number of refinements, but the principle remains unchanged.

The binnacle

The binnacle, formerly called the bittacle, is the receptacle in which the compass is mounted. Originally constructed in the form of a cupboard, it is now usually a cylindrical pedestal with provision for illuminating the compass card, usually from below. It contains various correctors to reduce the deviations of the compass caused by the magnetism of the ship. These usually consist of properly placed magnets, a pair of soft iron spheres (or small strips close to the compass), and a vertical soft iron bar called the Flinders bar, which originated in recommendations made by the English navigator Matthew Flinders.

Binnacles are sometimes constructed so that an image of part of the compass card can be projected or reflected through a tube onto a viewing screen on the deck below. This arrangement can make it unnecessary to provide a second compass for the helmsman and may allow the binnacle to be placed in a position less susceptible to magnetic disturbances. (W.E.M./J.L.H./Ed.)

Marine charts. *The portolano.* During the course of 15 centuries or more the coastal pilot book of classical times evolved into the portolano, the harbour-finding manual of the Middle Ages. An early portolano for the whole Mediterranean Sea, *Lo Compasso da Navigare* (1296), gives directions in terms of half points, that is, halves of the angles defined by the 32-point compass. From such works, accumulated over generations and collected during the 13th century into a single volume for the entire Mediterranean, the first marine charts were drawn. On these charts, most of which were compiled in Genoa, Venice, and Majorca, north was at the top, rather than east, as was the practice on most land maps of the time. They carried a scale of distances and a pattern of rhumb lines (each of constant bearing) in different colours. To set a course between two ports, the pilot would join the corresponding points on the chart with a straight line, find the rhumb line most nearly parallel to it, and trace the rhumb line back to its parent wind rose, from which he obtained the required heading. As long as the ship's location was to be found by dead reckoning (keeping a running record of the distances and directions traveled), the Mediterranean chart was entirely adequate. Questions of latitude, longitude, compass variation, and curvature of the Earth's surface could be safely ignored.

Rhumb lines

The Mercator chart. When the Portuguese, under the leadership of Prince Henry the Navigator, ventured farther south along the west coast of Africa, they encountered navigational difficulties by assuming that the charts used in the Mediterranean could simply be extended. Over long distances the rhumb lines could not be taken as straight, and the charts bore no relation to the new methods of checking the dead reckoning that Portuguese astronomers and mathematicians had devised. These methods required a chart on which positions were expressed as latitudes and longitudes rather than bearings and distances. Such a chart had to embody a practical method of representing the curved meridians and parallels on a flat surface. Even for an area as large as the Mediterranean, this can be done without grossly falsifying either distances or directions, but for larger regions some distortions are inevitable, and a choice has to be made between alternative mapping techniques. On certain types of charts, distances can be shown accurately, but directions cannot; on other types, directions are reliably presented, but the scale of distance varies greatly between different parts of the chart. The navigator accepts the second type because the risk of lengthening the voyage is preferable to that of missing the target.

Map distortions

In 1569 the Flemish cartographer Gerardus Mercator published a world map that he had composed using a "projection suitable for navigation," the details of which he did not disclose. (The Mercator and other projections are treated in the article MAPPING AND SURVEYING.) On a Mercator chart the meridians of longitude are represented by equally spaced vertical lines, and the parallels of latitude are represented by horizontal lines that are closer together near the Equator than near the poles. The uneven spacing of the parallels compensates for the increasing exaggeration of the east–west distance between adjacent meridians at higher latitudes; this distance decreases on the Earth but remains the same on the chart. In 1599 the English mathematician Edward Wright supplied a rational explanation of Mercator's projection and provided tables by which the distorted distances could be corrected.

Latitude measurements. Portuguese seamen determined latitude by observing the altitude of the Pole Star, that is, the angle between its direction and the horizontal. They knew from astronomical studies that the star does not lie exactly on the extension of the Earth's axis, so that it appears to move daily in a small circle around the celestial pole, but the necessary correction (as much as 3½° in the 15th century) could be applied by noting the position of the nearby star Kochab. When the navigators got close to the Equator, these stars fell below the horizon; there it became necessary to rely on observing the altitude of the noonday Sun and calculating latitude with the aid of an almanac.

The first instruments used at sea for altitude measurements seem to have been the quadrant and the astrolabe, long known to astronomers. For both devices the reference direction was the vertical, rather than the horizontal, but conversion of the readings was an elementary matter.

The cross-staff

The mariner's astrolabe, however, was less widely used than its 16th-century successor, the cross-staff, a simple device consisting of a staff about three feet long fitted with a sliding crosspiece. The navigator, holding the staff to one eye, would move the crosspiece until its lower end coincided with the horizon and its upper end with the Pole Star (see Figure 3). The desired altitude could then

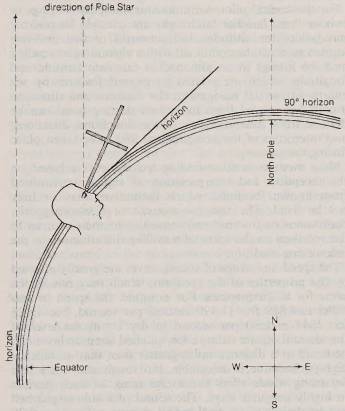

Figure 3: Altitude of Pole Star and latitude.

be read from the intersection of the crosspiece with the staff, on which a scale was marked in degrees. The cross-staff remained in use until the 18th century despite several drawbacks, the most serious being that it required the observer to look directly into the Sun. Coloured shades were fitted to the crosspiece, but the decisive improvement was made in 1594 by the English navigator John Davis. His instrument, called the backstaff because it was used with the observer's back to the Sun, remained common even after 1731 when the octant (an early form of the modern sextant) was demonstrated independently by John Hadley of England and Thomas Godfrey of Philadelphia. In the octant and the sextant, two mirrors—one fixed, the other movable—bring the image of the Sun into coincidence with the horizon. In the hands of the practiced observer, the modern sextant can be used to measure altitudes with an accuracy of 10 seconds of arc, that is, closely enough to determine a ship's north–south position within a few hundred metres.

Longitude measurements. *Almanacs and tables.* One of the earliest tabulations of the day-to-day positions of the heavenly bodies was *Ephemerides,* compiled by the German astronomer Regiomontanus and published by him in Nürnberg in 1474. This work also set forth the principle of determining longitude by the method of lunar distances, that is, the angular displacement of the Moon from other celestial objects. This method, which was destined to become the standard for a time during the 19th century, remained impracticable for more than three centuries because of the inaccuracy of the existing lunar tables, and because special knowledge and tedious computations were necessary in its use. Meanwhile, during the 16th and 17th centuries, working from translations of Portuguese and Spanish manuals, a flourishing school of instrument makers, chart makers, and teachers grew in England. This group rapidly improved the theory of navigation and compiled tables of increasing accuracy. In 1675 the Royal Observatory was established at Greenwich with the specific object of providing the sailor with astronomical data of the required precision. At Paris the *Connaissance des temps,* the first national almanac, was founded in 1679; it contained tables for the crude determination of longitude from observations of the eclipses of Jupiter's satellites, first seen by Galileo in 1610. (Galileo himself had advocated the preparation of such tables for this purpose, but the method, though sound in principle, could not be made practical.) In 1755 Johann Tobias Mayer, a German astronomer, published remarkably accurate tables of the motion of the Moon. To make them useful to navigators, however, it was necessary to prepare from them an ephemeris of the Moon for every noon and midnight. The English astronomer royal, Nevil Maskelyne, supervised this task; the results were published in the annual *Nautical Almanac,* which was inaugurated in 1766.

Mayer's lunar tables

The marine chronometer. Latitude could be determined by measuring the altitude of the Sun at noon or the altitude of any tabulated star when it crossed the local meridian, but the determination of longitude at sea remained a serious problem. By the Middle Ages, astronomers knew that the local time of an eclipse depended on the longitude, and in the 16th century they pointed out the principle of determining longitude by comparing the local time with the reading of a clock that reliably kept the time of a known meridian. No such clock was then available, but in 1714 the British Parliament offered a prize of £20,000 to anyone who could discover a method of finding the longitude within 30 miles during a sea voyage. The English inventor John Harrison eventually was awarded the prize for a chronometer tested in 1761–62. His success heralded the practice of making timed observations of heavenly bodies at sea. (M.W.Ri./Ed.)

Other aids to navigation. An Egyptian temple decoration dating from about 1600 BC shows a ship on which a member of the crew is measuring the depth of the water with a long pole. The Viking sailor took soundings with a lead weight on a line, hauling in the line and measuring it by the span of his arms. Depths are still cited in six-foot (1.8-metre) intervals called fathoms from the Old Norse word *fathmr* ("outstretched arms"). The weight was commonly given a hollow bottom filled with tallow to pick up a sample of the seabed for comparison with the composition indicated on the chart. Distance from a cliff could be estimated by timing the echoes of shouts or drumbeats.

Running lights

To reduce the risk of collision, a ship under way at night displayed running lights by which sailors on nearby vessels could judge its course and speed. The traditional coloured lights, red to port and green to starboard, were augmented on steamships with a white light at the head of the foremast. In foggy weather, gongs, bells, or explosives were used to produce loud warning sounds; eventually these devices were replaced by foghorns. Rules that specified what lights must be shown, what signals must be given, and how ships must navigate in respect of each other were formulated for British mariners in 1862. These rules formed the basis of the International Regulations for Preventing Collisions at Sea, which were adopted by nearly all maritime nations after a conference held in 1889. Collision avoidance also was fostered by general acceptance of the recommendation—separate lanes for eastbound and westbound steamers in the heavily traveled North Atlantic—appearing in *Sailing Directions* (1855), prepared by the

U.S. naval officer Matthew F. Maury. The danger of running aground was lessened by a worldwide system of lighthouses, lightships, buoys, bells, and channel markers; the development of these aids to navigation is treated in the article PUBLIC WORKS: *Lighthouses*.

20TH-CENTURY NAVIGATION

Navigation, in sharp distinction from aimless sailing or flying, presupposes a specific objective and may be subdivided into three stages. The first stage is the selection of the route along which the craft is to move and, ordinarily, a schedule that specifies the times at which the craft leaves its starting point, passes intermediate points, and reaches its destination. The route consists of a continuous succession of points, either on the surface of the sea or below it, in the air, on land, or in space. The second stage is the execution of the planned movement of the craft by driving it in the directions defined by the course at the speeds necessary to conform to the schedule. The third stage is the application of various accelerations at appropriate times and places. These accelerations are changes in velocity; they include increases and decreases in speed as required by the timetable or as dictated by external conditions along with alteration of direction as required to stay on the chosen course.

As the craft proceeds, the navigator regularly finds its position, comparing the progress with the predetermined route. If a deviation is detected, the navigator amends the route, adjusting speed and direction as needed to restore the craft to the proper path. Progress along the amended route is checked again by finding further positions, and further corrections are undertaken as required. The repetitive process of assessing progress and taking appropriate action is known as a closed loop.

Closed-loop navigation

Closed loops are seldom simple but consist of a series of loops one inside the other like the skins of an onion. Inside the outer position-finding loop there is an inner course and speed loop. In this loop, the course to be steered and the speed to be maintained are checked by compass and speedometer or log. Within the inner course and speed loop, there is also an innermost driving loop that relies on instruments to measure accelerations or, alternatively, on the judgment of the navigator. Finding the way thus involves three loops. Of these, the outer position-finding loop is used only at intervals, the course and speed loop is corrected more frequently, and the innermost driving loop is continually in action. A motor vehicle driver, by analogy, looks only occasionally at signposts, more frequently at the speedometer, but always keeps one or both hands on the steering wheel.

The aids that are employed in the outer position-finding loop cannot effectively be adapted to measure course and speed. For example, in the case of an aid that tells the distance to the destination, a minor irregularity, which momentarily diminishes this distance, would be translated as a complete reversal of speed, giving a completely false picture.

The reverse process is, however, quite possible. It has already been shown how, by dead reckoning, course, speed, and time can be used to find position. Similarly, devices used for driving may be adapted to give useful course and speed information and even position. To avoid collision, an outer position loop is used that relies on separation; for example, by one-way traffic lanes. There is also an inner course and speed loop that enables vehicles to avoid more imminent collision with each other by changing course or speed. (E.W.A./Ed.)

By the end of the 19th century, marine navigation had evolved into a fully systematic technique, combining the simplicity and reliability required by its practitioners with the rigour and accuracy founded in the skills and knowledge of astronomers, mathematicians, cartographers, and instrument makers. Accurate and detailed sea charts and books of sailing directions were available for the planning of any proposed voyage. At any stage during the voyage, dependable almanacs, sextants, and chronometers made it possible to ascertain the ship's position with great precision through observation of the altitudes and azimuths of a few familiar stars. Routine trigonometric procedures for making the needed computations had been introduced by Thomas H. Sumner of the United States in 1837 and Marcq St. Hilaire of France in 1875. These astronomical determinations were supplemented by dead reckoning, which had been made more trustworthy by the continued development of compasses and logs.

The navigational principles, techniques, and devices in use around 1900 formed a secure foundation upon which to superimpose the changes brought about during the 20th century. The advent of air travel and then space travel made it necessary to modify some of the concepts that had been developed for the period in which voyages had been restricted to the surface of the Earth. Many of the new problems, however, were solved by the application of technological innovations, notably radio communication and electronic instrumentation and computation. (Ed.)

Position finding. To find the position of a craft on the surface of the Earth, it is necessary to measure or estimate distances or directions, or both, in relation to one or more ground features at known locations. For vessels that travel above or below the surface, information about their altitude or depth also is needed; for those that move beyond the Earth's gravitational field, the reference points may be transferred to features of the Moon or to the predictable positions of the planets in relation to each other and to the Sun.

For the coastal pilot, simultaneous compass bearings of two or three familiar landmarks are enough. In celestial navigation, the altitudes and azimuths of two or three known stars can be combined with a chronometer reading and the listings in an almanac to calculate latitude and longitude, which are related to ground features by sea charts. In inertial navigation, the distance and direction a craft has moved from its known starting point can be derived from measurements of the directions, durations, and intensities of the accelerations that have taken place during the journey.

Transmission of signals

Most modern position-finding techniques are based on the reception and interpretation of signals transmitted from known locations, which themselves may or may not be fixed. The signals—acoustic or electromagnetic, continuous or intermittent—travel from their sources to the receivers in the form of wavelike disturbances in the intervening medium.

The speed and range of sound waves are greatly affected by the properties of the medium, which may not be the same for all frequencies. For example, the speed in seawater is 4,889 feet (1,490 metres) per second, but 1,128 feet (344 metres) per second in dry air at sea level. If the sea and air are calm, a low-pitched siren or horn can be heard at a distance miles greater than that at which a high-pitched one is detectable, but rough and noisy seas or strong winds affect the useful range of such devices in highly irregular ways. The sound of a submerged bell can be detected in a steel-hulled ship at a distance of 20 miles or more.

Electromagnetic radiation, including light and radio waves, travels very fast: about 186,000 statute miles (162,000 nautical miles; 300,000 kilometres) per second through empty space. This speed varies somewhat, depending on whether the waves are passing through space, air, water, the ground, or a telegraph wire; the wavelengths are inversely proportional to the speeds, but the frequencies remain unchanged. Frequency intervals, therefore, ordinarily are used to designate the bands into which the broad electromagnetic spectrum is divided for various purposes. In many microwave radar systems, for example, the frequencies of the waves lie in the so-called superhigh frequency band, between three and 30 gigahertz; the corresponding wavelengths are between one and 10 centimetres. The classification of these bands and their applications are treated in the article BROADCASTING: *Radio systems and equipment*.

At altitudes of tens to hundreds of kilometres above the Earth's surface, ionizing radiation from the Sun produces high concentrations of electrically charged particles in certain layers of the upper atmosphere. In the lower layers of this region, which is called the ionosphere, the charged particles revert to their neutral forms during the night.

Low-frequency waves reaching the ionized layers bounce back toward the Earth; such waves also are transmitted long distances through the ground and the oceans. High-frequency waves that strike the ionosphere at glancing angles also are reflected, but those incident at large angles (perpendicular or nearly so) pass through into outer space. High-frequency ground waves do not travel very far, so there is a gap, or dead space, between the range at which the ground wave dies out and that at which the waves reflected from the ionosphere (called sky waves) are first detectable.

Electromagnetic waves with frequencies greater than 30 gigahertz have wavelengths less than one centimetre. They are strongly scattered or reflected by raindrops, mist, fog, and snowflakes; for this reason, they are of no value for long-distance communication.

Speed measurement. The classical methods of measuring speed through the water have already been described. In the mid-18th century the French hydraulic engineer Henri Pitot, studying the flow of water in rivers and canals, invented a device—now called the Pitot tube—for measuring the speed of the flow past a given point. The Pitot tube has been applied to the measurement of wind speed, and it is equally useful as a log for ships or aircraft. A typical Pitot marine log consists of a pair of thin-walled tubes projecting through the bottom of the ship and bent so as to face the direction of motion. One tube is open at the forward end; the opening is referred to as the dynamic-pressure orifice. The second tube is closed at the end but has openings at right angles to its length; these openings are the static-pressure orifices. When the ship is dead in the water, the pressure is the same in the dynamic and static connections, but, when the vessel moves ahead, the dynamic pressure exceeds the static pressure by an amount that varies as the square of the ship's speed. Another part of the log consists of a centrifugal water pump driven by a variable-speed electric motor. The dynamic pressure that is produced by such a pump varies as the square of the speed of the motor. The pressure produced by the motion of the ship is exerted against one face of a diaphragm; that produced by the pump is exerted against the other. Movement of the diaphragm operates the speed control of the motor so as to equalize the two pressures and thereby make the speed of the motor directly proportional to the speed of the ship. A magneto attached to the shaft of the motor generates a voltage proportional to the speed, and on the ship's bridge a voltmeter calibrated in knots provides a continuous indication of the progress of the vessel. Analogous Pitot logs, with less bulky attachments for translating air pressure differentials to speed readings, are almost universally installed in aircraft. (M.R.Da./Ed.)

Pitot tube

Electro-acoustic log

In ships, a modern form of log incorporates a pair of electroacoustic transducers. One of these launches a sound wave from a point close to the keel; the second, a few metres ahead or astern, detects this wave and measures the time required for it to traverse the known distance. Motion of the ship relative to the water changes this interval in a way directly related to the speed of the ship. The speed of sound through water is slightly affected by temperature and salinity; even so, the electroacoustic log is much more accurate than its mechanical forerunners, and it is much less susceptible to malfunction caused by fouling by barnacles or weeds.

The Doppler effect—the familiar shift in the pitch of the sound of an automobile engine as it passes a stationary listener—also can be exploited to measure the speed of a vessel or an aircraft. Such an effect can be accurately measured in either sound waves or electromagnetic waves emitted from a moving craft and reflected from a fixed object. (S.S.D.J.)

Dead reckoning. *Correction for drift.* Starting from a known point, the mariner with a compass could draw a line on the chart to represent a vessel's course, then mark off the distance given by the log. The calculation of a new position was known as dead reckoning. In addition to errors in the compass and in the log, dead reckoning suffered from errors due to the drift of the water. When ocean currents were first marked on charts of the open sea, and tidal streams appeared on coastal charts, navigators could make allowance for drift. Fortunately, the currents were seldom fast and, on long voyages, often tended to cancel each other out. The situation in the air, however, was quite different. Early airplanes flew at around 100 knots, and the air that supported them was blown over the ground by the wind at speeds of up to 40 knots. It was therefore necessary to determine the velocity of the aircraft through the air and the velocity of the air over the ground in order to find the true velocity of the aircraft with respect to the ground. This was achieved by the triangle of velocities as shown in Figure 4. A line was drawn to show the direction in which the aircraft was heading, the length of the line representing the distance that the aircraft would travel through still air in one hour—in other words, the true air speed. Such a line represents a vector; that is, a quantity that embodies both magnitude and direction. From the end of this line, a second line or vector was drawn in the direction toward which the wind was blowing, the length of this second line being determined by the wind speed. Finally, a third line drawn from the starting point of the first line to the end of the second line showed the path that the aircraft was following over the ground, the length of this line representing the true ground speed. Stated mathematically, the true ground speed was the vector sum of the craft's air velocity and the wind velocity.

Calculating aircraft velocity

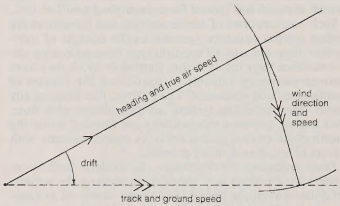

Figure 4: Triangle of velocities.

The angle between the heading of the aircraft and its track along the ground was known as the drift because it resulted from the drifting effect of the wind. Early aircraft were fitted with drift sights through which the aviator visually aligned a grid with the moving ground below and so determined the drift. The plotting of triangles of velocity was simplified by using graphic instruments called computers before that term was appropriated for much more complex devices.

Paradoxically, higher aircraft speeds failed to eliminate the problem of wind drift because jet aircraft fly higher as well as faster, and, above 20,000 feet (6,100 metres), very narrow belts of wind—known as jet streams, which travel at speeds of 100 or 200 knots—occur under certain meteorological conditions.

Sea navigators did not follow the practice of air navigators and allow for ocean currents and tidal drifts in their initial calculations. Dead reckoning, long established as a navigational technique, continued to be used; an estimate for ocean current or tidal drift was added afterward. This practice continues today.

By dead reckoning, the navigator can quickly find a position that can often be checked by a landmark. On the other hand, the errors that are inherent in dead reckoning accumulate; when a position has been checked, the reckoning is therefore generally restarted from that position.

Importance of dead reckoning

Dead reckoning enables the navigator to plot not only where the craft is but also where it will be at any given time, provided the planned course and speed are maintained. It also makes it possible for the navigator to plan the journey in its entirety, including the time of arrival at the destination. Planning is a part of all navigation; the preparation of a complete flight plan is mandatory before taking off in a civil aircraft. Space navigation is based even more completely on flight planning, and the time of splashdown is calculated to within minutes many weeks before lift-off.

Inertial guidance systems. By established principles of mathematical physics, the velocity of an object is defined as the rate of change of its position, and the acceleration is defined as the rate of change of the velocity. These relations can be applied to the navigational problem of position finding if an instrument can be devised to measure acceleration and then to convert it successively to velocity and to position. In the terminology of the calculus, velocity is the first derivative of distance (hence, position) with respect to time, and acceleration is the first derivative of velocity (the second derivative of distance). The process of evaluating a variable quantity (in this case, the distance) when its derivatives (velocity and acceleration) are known is called integration.

Accelerometers

In one form of accelerometer, a reference mass is suspended on springs within a housing firmly attached to the craft. The inertia of the mass causes it to tend to remain stationary, but any acceleration of the craft tends to displace the housing relative to the mass. The forces required to nullify relative motion of the mass and the housing—in three directions fixed by gyroscopes—can be measured electrically. The electrical signals are directly related to the forces and, by Newton's second law of motion, to the accelerations. Standard electronic circuitry performs the necessary integrations of the accelerations to provide the distances and directions, in three dimensions, through which the craft has moved from its original position.

Such combinations of accelerometers and integrators are called inertial guidance systems; in the context of navigation they amount to sophisticated dead-reckoning devices. Since their introduction, starting in 1950, they have proved extremely valuable in controlling the courses of submarines and spacecraft. Their errors, like those of any other dead-reckoning system, are cumulative with time, but nuclear-powered submarines have traveled under the north polar ice cap, guided solely by inertial systems, with errors of less than a mile per week.

Dead reckoning by computer. In modern craft, computers have proved well suited to processing the streams of data—directions, speeds, and times—involved in keeping track of position. In military land vehicles, computers are fed by compasses and signals taken from the wheels. Navigators aboard ships depend on the gyrocompass and the log; those in aircraft rely on the gyromagnetic compass and Doppler-effect speed measurements. The computers can be programmed to print periodically updated positional information. Generally, inertial guidance systems provide dead-reckoning information only, though compass and Doppler data can be included with inertial outputs. Information from radio fixing systems can be added to the dead reckoning; each item of information can be automatically compared with the others.

Radio fixing systems that can provide continuous indication of position are eliminating the distinction between position fixing and dead reckoning. Navigation is effected by supplying both the classical dead-reckoning data (speed and direction) and the continuously updated position to a computer, which determines the speed, heading, and rate of climb or descent that must be maintained to execute the flight plan. Many computers apply the technique called Kalman filtering, which weights each of the several supplied data according to its expected quality.

Instead of being mapped on a chart, position may be continuously displayed on a moving map. If the route is known beforehand, the map may be prepared in the form of a strip driven by rollers with a pointer moving to and fro to indicate exact position. When greater flexibility of route is essential, a series of maps covering a very wide area may be printed on film and projected on a ground glass screen on the bridge or in the cockpit.

Dead reckoning plays an important role in air traffic control. Not only does every air navigator have to file a complete flight plan showing courses and timings, but, during the flight, air traffic controllers keep what is virtually a dead-reckoning check on each aircraft. The flight plans are split into sections, and flight strips are prepared showing height, speed, and timings of each aircraft in a section. The air traffic controller responsible for that section can thus see which aircraft will be arriving and in what sequence. These flight strips are continually updated by reports sent by radio from the aircraft and also by changes in height and course ordered by the air traffic controller to maintain adequate separation. In modern systems, automatic flight strips are displayed on cathode-ray tubes.

Flight strips

Radio navigation. *Direction finders.* To avoid the hazards marked on the charts, a mariner needs to know the vessel's exact position. By means of a sight fitted to the compass, the direction of any visible landmark or buoy can be measured. This direction, called a bearing, can be marked on the chart as a line passing through the identified reference point. A similar line corresponding to a second bearing will intersect the first and fix the position of the vessel, as shown in Figure 5.

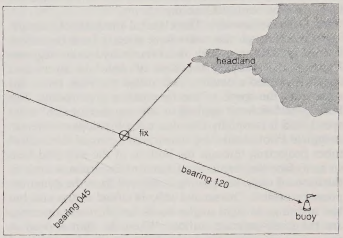

Figure 5: Determining position by intersection of compass bearings to known points.

The invention of radio transmission and reception led to an improvement in this navigational technique, making it possible to obtain bearings from reference points obscured by fog or darkness. The signals picked up by a loop antenna are weakest when the plane of the loop is perpendicular to the direction in which the radio waves are traveling. If the receiver is tuned to the frequency of a particular transmitter and the loop is rotated for minimum signal pickup, the direction to the transmitter can be found and plotted. A second position line then fixes the navigator's position, as before.

Loop antennas

Soon after ships were first equipped with radio, direction-finding stations were placed on shore at strategic points along navigational routes and near harbour approaches. Upon receiving a request by radio from a ship, two or more shore stations determined the directions from which the ship's signal arrived and transmitted this information to the vessel. The navigator then could fix his position. The limitation of this service to one vessel at a time, however, was a serious drawback in bad weather, when demands were heavy. Beginning in 1921, continuously operating transmitters were placed ashore and the direction finder on the ship to eliminate the possibility of overloading the system and to give the navigator two further advantages: that of taking continuous or frequent bearings on any shore beacon and that of taking bearings of any receivable signal, such as transmissions from commercial broadcasting stations and from other vessels. This change in the system was roughly coincident with the initial growth of aviation, and the airborne direction finder immediately became a valuable aid to air navigation.

Under ideal conditions a well-designed direction finder will provide bearings within 1° or 2° of the true value. The uncertainty can be considerably increased, however, if the direction of the radio waves is altered by reflection from the ionosphere or refraction in the atmosphere.

The loop-antenna radio direction finder, almost as old as radio itself, developed into a device in which a motor turned the loop, and electronic circuitry identified the direction of the source of the signals. This instrument, originally called a radio compass, could guide the navigator toward any detectable transmitter. It was often linked to a compass so as to display not merely the direction of the radio station compared to the heading of the craft but the actual direction as plotted on a chart.

Radio-beam systems. The directional selectivity of loop antennas when they are used as receivers is duplicated when they are used as transmitters. Such an antenna can be oriented so that it radiates strong signals to the north and south but practically none to the east or west. Pathway-defining ground stations for aircraft were developed during the 1920s and '30s. They were equipped with loop antennas in pairs at right angles, arranged so that one antenna broadcast the International Morse Code character *A* (dot–dash), and the other broadcast the character *N* (dash–dot). Midway between the directions in which only *A* or only *N* could be heard, the characters interleaved to produce a steady tone; these four intermediate directions were the preferred courses, called beams. Only a slight deviation of the receiver from a beam disrupted the steady tone, and the direction in which the craft was off the beam was indicated by the predominance of one Morse character or the other. The pilot flew in one of the four directions toward or away from the transmitting beacon, which was called a four-course beacon or a radio range.

The distance at which the signals could be detected was limited, and the four-course beacons were replaced by VOR (very-high-frequency omnidirectional radio range), the beacons of which operated on an entirely different principle. At each beacon, one antenna sent out waves that had the same intensity in all directions. A second antenna rotated and sent out a narrow beam of waves that, when directed north, coincided in phase with those of the first antenna; that is, the peaks of the waves from the two antennas reached the receiver at the same instant. When the rotating beam pointed east, the two sets of waves were out of phase by 90° (one quarter of a wavelength); when the beam pointed south, the phase difference was 180°; and so on. A receiver in the aircraft measured the phase difference and displayed the bearing of the VOR beacon along with the heading of the aircraft.

VOR beacons

From the radio range, with its so-called beams, true beam systems have developed. In these the loops are replaced by improved antennas that concentrate the radio waves into narrow beams a few degrees wide; the dots and dashes are replaced by more sophisticated patterns or modulations. In the instrument landing system (ILS), used to help aircraft approach and land on an airfield, the two antennas transmit waves about three metres long. This wavelength, though shorter than those employed in earlier systems, necessitates antenna structures about 100 feet (30 metres) long on the ground. Such installations make it possible for suitably equipped aircraft to land in conditions of practically zero visibility. The beams point in almost the same direction, and, once the aircraft has entered the beams, a receiver can measure the angular displacement from the centre line and display this displacement on an instrument or use it to guide the aircraft along a line toward the point of landing. In addition to the steering beams, which make up the localizer element of the ILS, there are two similar but even narrower beams transmitted in the vertical plane that guide the aircraft down the correct slope toward the point of touchdown.

Instrument landing systems have been made highly reliable, but further development with wavelengths of a metre or more is limited by the interference resulting from reflections of these waves from hills, buildings, and other aircraft. Systems based on microwaves (about one centimetre in length) are less susceptible to such interference.

Distance measurement. The echo sounder, already mentioned, measures the time that elapses between the transmission of a sharp acoustic "ping" from the keel of a ship and the return of the echo from the sea bottom. A radar altimeter similarly measures the distance between an aircraft and the ground by timing the reflection of short pulses of radio waves. A more common form of radio altimeter, better suited for measuring rate of change of altitude, transmits waves continuously and derives the height from the phase difference between the transmitted signal and that reflected from the ground. An observed phase difference is, in fact, consistent with a large set of discrete altitudes, but in practice such radio altimeters are used in connection with instrument landing systems for measuring altitude and rate of descent during the last few seconds before touchdown. At this stage, the lowest altitude consistent with the observed phase difference is the correct one. When the aircraft reaches a height of about 65 feet (20 metres) the landing system initiates a programmed reduction in rate of descent to ensure a firm but safe touchdown.

In the usage of navigation, distance-measuring equipment (DME) denotes a specific system, defined by internationally accepted standards. Aircraft fitted with DME transmit radio pulses at one of 126 designated frequencies; arrival of these pulses at a DME beacon on the ground causes the beacon—after a 50-microsecond delay—to transmit responding pulses at another frequency. The time elapsing between the aircraft's transmission and its reception of the response is measured by a clock accurate to a few nanoseconds and converted into the distance, which is displayed in digital form. The position of the aircraft can be determined by combining the distance indicated by the DME with the direction from a VOR beacon at the same site as the DME beacon. Alternatively, position can be established by triangulation, using the distances between the aircraft and two well-separated DME beacons.

Position hyperbolas. If a gun at position M in Figure 6 were fired, a listener 1,100 feet (340 metres) away in any direction—that is, anywhere on the smallest circle centred at M—would hear the sound one second later; a listener 2,200 feet away, on the second circle, two seconds later;

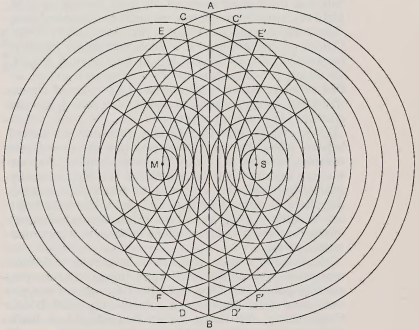

Figure 6: Hyperbolic position lines (see text).

and so on. If guns at M and S were fired simultaneously, a listener anywhere on AB, equidistant from M and S, would hear them at the same time. On a craft closer to one gun than the other, the sound of the nearer gun would be detected first. If gun M were heard one second before gun S, the craft would lie on CD, one of the two branches of a hyperbola; at a craft on *C′D′*, the other branch of the same hyperbola, gun S would be heard one second earlier than gun M. At a craft 2,200 feet closer to gun M, that gun would be heard two seconds before gun S, and the craft would lie on EF. Hence, by timing the interval to the nearest second, it is possible to find nearest which hyperbola the observer is located; knowledge of which gun was fired first makes it possible to choose between the two branches.

Signals from two sources

For navigation, the firing of guns is replaced by radio transmissions. A family of hyperbolas as shown in Figure 6 may be printed on a chart. A second family of hyperbolas, referring to a second pair of stations, can be printed on the same chart; the position of a craft is determined by the unique intersection of two curves. In radio systems, one of the two stations in a pair (the master) controls the other (the slave) to ensure accurate synchronization of the signals. In some systems, two or three slaves are distributed around a single master, and two or three families of hyperbolas are printed on the appropriate chart.

Loran

Systems of this kind are called loran, an acronym for long-range navigation.

Loran in its original form (now called loran A) was introduced during World War II; it operated at frequencies near two megahertz, but interference with and by other services and unreliable performance at night and over land led to its replacement by loran C. Loran C transmitters operate at the frequency of 100 kilohertz, and the signals are useful at distances of 1,800 nautical miles or more.

Decca, named for the British company that introduced it in 1946, is a hyperbolic system related to loran. Its master and slave transmitters broadcast different harmonics of a common frequency as continuous waves, rather than pulses. The hyperbolic position lines for any pair of transmitters are determined by the phase difference between the signals received, rather than the difference in arrival times of pulses. This arrangement provides a remarkably accurate and reliable system covering a range of 100–300 miles (160–480 kilometres) from the master station. Decca equipment is widely installed on ships and enjoys particular favour among fishermen, who can use it to return to specific shoals with great precision. Aircraft installations are less common than those of VOR/DME, the internationally accepted system for position finding. Decca is very well suited to navigation of helicopters, however, which usually operate at altitudes well below those at which VOR/DME is most effective.

Omega is a very-long-wave hyperbolic system that probably has the longest range of all radio navigation aids. Eight permanent transmitters, mutually synchronized, provide worldwide service. There is little redundancy in the Omega system, however; if a single transmitter becomes inoperative, a considerable gap in the coverage results. Its signals penetrate seawater to a substantial extent, so that submarines can receive them. Like those of Decca, transmissions are continuous, rather than pulsed, and are encoded to prevent ambiguities.

During World War II, Germany produced the Sonne beacon, which has been developed into the consol and consolan systems, in which the masters and slaves are so close together that the hyperbolas become practically straight lines radiating out from the centre. By changing the phase of transmissions of the slaves, the hyperbolas can be made to swing to and fro. Morse signals are superimposed so that a craft can tell its location in a particular lane or sector.

Decca covers a wide area and is inherently a flexible navigation system. Before Decca's invention, however, aviation policy had been committed to signpost navigation using VOR beacons and subsequently VOR/DME. Consequently, the Decca system was adapted to work with a computer that would make the area system work as if there were beacons placed anywhere the navigator wished. Thus Decca could work as a signpost or point navigation system.

The point navigation philosophy has since run into difficulties. As air traffic builds up, more and more routes are needed; thus more and more signposts must be set up. VOR/DME computers, however, have been developed so an aircraft can follow any track irrespective of the position of the VOR/DME. Thus the computer has restored to the point navigation system the flexibility originally possessed only by the area navigation system, a flexibility increasingly needed to ensure adequate separation between aircraft.

The computer has already become part of the inertial navigator; it is used also in automatic dead reckoning. Originally, analog computers were used in navigation systems, and calculations of a relatively simple nature involving inputs from various electrical sources were continuously performed. Today, digital computers are employed for performing the necessary calculations.

Use of the digital computer

The digital computer works so fast that for navigational purposes it can be considered virtually instantaneous and can therefore provide continuous information for control purposes. It has a memory to store information for use when needed. It is built from electronic modules that are mass-produced at low cost. It has only one disadvantage. Conversion of analog information into digital form is costly. Hence, although far superior to the analog computer, it is less economical whenever a large number of electrical signals must be combined in relatively simple ways without any need for memory. Such situations still apply to control systems in many craft.

(E.W.A./S.S.D.J./Ed.)

Satellites as navigation aids. Artificial satellites can be equipped to transmit electromagnetic radiation at precisely controlled times and frequencies. The frequencies are chosen to avoid interference with other services, to minimize attenuation or delay as the signals penetrate the ionosphere, and to minimize the power needed by the satellite for broadcasting the signals. The practical range of frequencies corresponds to wavelengths between 10 and 100 centimetres.

Transit satellites

During the early 1960s a series of satellites named Transit was launched by the U.S. Navy to provide a worldwide navigation system. These satellites circled the Earth about every 90 minutes, moving in polar orbits about 600 miles (1,000 kilometres) above the Earth's surface. They radiated continuous signals modulated to indicate departures from the nominal frequencies and orbits. A receiver on the surface or in a submarine could compare the frequency received with that known to be transmitted and identify its own location by measuring both the magnitude and the rate of change of the Doppler shift. The calculations, which were performed by a small digital computer, were accurate to about 180 yards (160 metres).

Movement of the user modifies the Doppler shift and introduces an error unless it is taken into account. An uncertainty of one metre per second (two knots) in the velocity of the user causes an uncertainty of one kilometre in the deduced position. Such an error is of no great consequence in the case of ships, but it disqualifies the Transit system for the navigation of aircraft.

A global position system suitable for aircraft navigation was initiated by the U.S. Air Force in 1978, when the first two of the series of NavStar satellites were launched. These move in circular orbits inclined at 63° to the equatorial plane at an altitude of about 12,500 miles (20,200 kilometres); their period is 12 hours. Eighteen of these satellites can provide continuous worldwide coverage adequate for determining latitude and longitude within about 10 metres and, in many places, altitude with the same accuracy. A system of 24 NavStar satellites would give worldwide three-dimensional coverage.

NavStar

The NavStar system does not depend on the Doppler effect. The satellites transmit their signals on a time schedule precisely controlled by atomic clocks. The receivers automatically select the three (or four, if possible) satellites most favourably located and relay their signals into a computer, which calculates the position of the receiver by solving three or four simultaneous algebraic equations. The variables in these equations are the desired two or three position coordinates and a time-dependent quantity. The system is related to the hyperbolic systems loran and Decca, but the hyperbolas (two-dimensional figures) are replaced by hyperboloids of revolution (three-dimensional) that are moving rapidly in relation to the Earth. The complexity of the calculations makes the use of a fast digital computer essential.

(S.S.D.J./Ed.)

Improved compasses. In the early days of aviation, it was soon learned that a liquid-filled mariner's compass could not operate satisfactorily in a rapidly accelerating and sharply turning aircraft. Spring-mounted bowls and cards of extremely small diameter alleviated the problem, but tilting still occurred, bringing the system frequently under the influence of the vertical component of the Earth's magnetic field and causing erroneous readings. The most important of such effects, called northerly turning error, caused the compass to indicate a greater or smaller angle than was actually being turned through. Other problems were the difficulty of obtaining stable magnetic conditions in the cockpit, with its array of metal and electrical equipment, and the need for the compass reading to be fed to other navigational aids. In the end, the direct-reading magnetic compass was reduced to a secondary role, its place being taken for most purposes by the gyromagnetic compass (see below).

Saturable-inductor compasses

The inductor compass. Whereas the pivoted-needle magnetic compass indicates direction by aligning itself with the horizontal component of the Earth's magnetic field, the inductor compass measures, in effect, the strength of this horizontal component and indicates the direction in which the strength is greatest. One such instrument, the saturable-inductor compass, makes use of magnetic materials that are easily saturated—that is, materials in which it is easy to build up the maximum number of lines of magnetic flow, or flux. The amount of flux through such a material depends on its orientation in the Earth's field, being greatest when it is aligned in the magnetic north–south direction. By means of suitable electronic circuitry, it is possible to determine the exact orientation of a bar of such material and thus indicate precisely the direction of magnetic north. Compasses of this type require no rotating parts. Several can be installed at various points aboard a craft and their outputs combined electronically.

The gyromagnetic compass. The errors that occur in aircraft and small, fast vessels during alterations of course or speed can be avoided by mounting the compass on a platform kept horizontal by a gyroscope. The directive element must be nonpendulous. The vertical pin supporting the compass needle can be pivoted at both ends, or an inductor element can be employed. In one such arrangement, a saturable inductor is mounted on a gyroscope, but this is not always convenient from the point of view of size and weight. (W.E.M./J.L.H.)

Complementary compasses

Another system has a means of comparison between the gyroscope heading and that of the magnetic element. The gyroscope maintains a specific directional line in space with a possible error caused by drift of two or three degrees in each half hour that the gyroscope is left free. The utility of this instrument may appear to be very limited, but it happens to complement the magnetic compass very well. By itself, neither is satisfactory as a directional reference, but a combination of the directional gyroscope with a magnetic compass gives the pilot complete and stable directional information. The magnetic compass is useful in an airplane only so long as the airplane continues on a straight course in smooth air. While the airplane is making banked turns, the magnetic compass may err by 90° or more. Therefore, if the pilot desires to change course by a definite number of degrees, the magnetic compass will be of little use. On the other hand, the directional gyroscope is not affected by banked turns or rough air. It accordingly gives a reliable and stable indication of the exact number of degrees of turn that the airplane makes. The relatively slow drift of the directional gyroscope from its heading may be corrected manually from time to time when the airplane is in level and straight flight.

(R.E.Gi./A.L.Ra./R.J.S./Ed.)

The gyrocompass. The gyrocompass is independent of the magnetic field of the Earth and depends upon the properties of the gyroscope and upon the rotation of the Earth.

The axis of a free gyroscope will describe a circle around the pole of the heavens. To convert it into a gyrocompass, a control must be introduced that, when the axis tilts, will operate to precess (turn) it toward the meridian. The case of the gyroscope is made pendulous, or a liquid is arranged to flow from side to side. Either will convert the path traced by the axis into an ellipse. By delaying the flow of the liquid or by making eccentric the point of action of the control, a damping factor is introduced that converts the ellipse into a spiral so that the gyrocompass finally settles pointing true north (see Figure 7).

(W.E.M./J.L.H.)

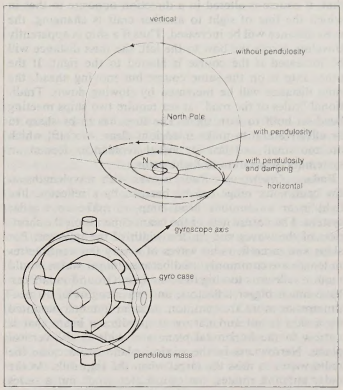

Figure 7: *Gyrocompass operation.*
Circular line shows the apparent motion of the axis of a gyroscope around the Pole Star in the absence of a pendulous mass. The addition of the pendulous mass (lower drawing) converts the circular motion into an ellipse; the ellipse can then be damped out and the gyroscope becomes a gyrocompass pointing to true north.

Instruments. The tactical management of a craft demands, for steering, continuous indication of heading and speed through the water or air and, for the propulsion system, information—either continuous or on demand—on engine speed, temperatures at critical regions, fuel flow, and fuel supply. In a modern aircraft, continuous monitoring by the crew of the numerous variables is impractical; instead, each instrument that indicates the value of a critical variable is designed so that any departure beyond specified limits is brought to the attention of the crew by warning lights, audible signals, or in the particular case of airspeed, "stick shake"; that is, artificially induced vibration of the control column in the event that indicated airspeed falls close to stalling speed.

Alarm systems

Rate of climb and, particularly, rate of descent must be indicated continuously because of their vital safety connotations. Rate of turn also is important in aircraft, and it is sometimes indicated in ships.

Airspeed is correctly indicated by the Pitot apparatus only if the air has the density typical at sea level at 15° C. Altitude has a major effect on air density, and temperature a minor one; in modern aircraft, indicated airspeed, altitude, and temperature are combined by a computer that indicates true airspeed and Mach number. Similarly, the independently operating compass, artificial horizon (an instrument that shows the degree of pitch and roll), and other instruments have been integrated into a so-called attitude and heading reference system.

The combination of daylight-visible optical displays with systems for storage and retrieval of digital data simplifies the design of aircraft cockpits and ship bridges by allowing the presentation of essential information on demand, relieving the navigator of the task of interpreting the readings of numerous separate indicators. (S.S.D.J./Ed.)

Collision avoidance. Figure 4 illustrates the calculation of an airplane's true ground velocity. A similar procedure can be used to calculate the course an airplane must avoid to prevent collision with another aircraft. In Figure 4 the wind is replaced by the course and speed of the other craft drawn in the opposite direction. What was track and ground speed in Figure 4 becomes the line of sight to the craft to be intercepted and the speed at which the two planes are approaching each other. If both planes maintain the speeds and directions indicated in Figure 4, a collision will occur.

Interception theory is based on a development of the way in which one animal hunts another. The predator runs toward its prey, and, as the prey tries to escape, the pursuer changes direction so that it is always running straight toward its target. Thus the hunter changes course at the same rate as its line of sight to its prey changes direction. Missiles that have to intercept ships or aircraft do a little better than this; they alter course faster than the direction of the line of sight changes, moving toward a predicted position rather than the present one.

Modern collision-avoidance theory depends on the fact

that, if course is altered in a direction opposite to that in which the line of sight to another craft is changing, the miss distance will be increased. Thus if a ship is apparently traveling across the bow to the left, the miss distance will be increased if the course is altered to the right. If the other ship is on the same course but moving ahead, the miss distance will be increased by slowing down. Traditional "rules of the road" at sea require two ships meeting head-on both to turn right. The turn has to be sharp to be effective and to make intentions clear. Aircraft, which are too small and fast for visual avoidance, depend on systematic separation of flight paths.
